Viewer Guide

Navigation Tips:

- Use the outline/bookmarks pane (left side in most PDF viewers) to jump between sections.
- Click links at the bottom of each question to switch between Part A (questions) and Part B (answers).
- Master Index links take you to topic parts.

Viewer Settings:

- Adobe Reader: View > Show/Hide > Navigation Panes > Bookmarks
- Chrome: Install PDF viewer extension if needed.
- Mobile: Use apps like Adobe Acrobat or Xodo for outline support.

■ *For queries & support: Message @Neet_pg_bot on Telegram*

[01_Cell Injury] 001 Cell Injury Free Radical Injury And Er Stress Related — Quick Jump

Q1 (p. 30)	*Q2 (p. 30)*	*Q3 (p. 31)*	*Q4 (p. 31)*	*Q5 (p. 31)*	*Q6 (p. 32)*
Q7 (p. 32)	*Q8 (p. 32)*	*Q9 (p. 33)*	*Q10 (p. 33)*	*Q11 (p. 34)*	*Q12 (p. 34)*
Q13 (p. 34)	*Q14 (p. 35)*	*Q15 (p. 35)*	*Q16 (p. 36)*		

Q1: Which of the following are pathological factors that contribute to the development of thrombosis? (Q879510)

A. Endothelial injury, abnormal blood flow, hypercoagulability

B. Increased vascular compliance, reduced platelet activity, and fibrinolysis

C. Decreased vascular tone, enhanced anticoagulant proteins, and vasodilation

D. Smooth muscle hypertrophy, hypocoagulability, and increased tissue perfusion

See Answer in Part B → Q1

@Neet_pg_bot

Q2: What is the most common cause of cell injury? (Q845267)

A. Hypoxia

B. Immunologic reactions

C. Drug-induced

D. Nutritional imbalance

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Identify the correct combination of most and least sensitive cells to hypoxia. (Q845270)

A. Most sensitive - hepatocytes and least sensitive - Lymphocytes

B. Most sensitive - bone marrow cells and least sensitive - nerve cells

C. Most sensitive - retina and least sensitive - adipose tissue

D. Most sensitive - neurons and least sensitive - fibroblasts

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which among the following is not a feature of reversible cell injury? (Q845271)

A. Large amorphous densities in the mitochondria

B. Decrease in ATP generation

C. Swelling of the endoplasmic reticulum

D. Detachment of ribosomes from granular ER

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following are features of irreversible cell injury? Increased eosinophilia Pyknosis Decrease in ATP production Small amorphous densities in mitochondria (Q845275)

A. 1, 2

B. 1, 2, 3, 4

C. 1, 2, 4

D. 2, 3

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Match the following descriptions of the nuclear changes in irreversible cell injury. I. Pyknosis a. Nuclear fragmentation II. Karyorrhexis b. Dissolution of nucleus III. Karyolysis c. Shrinking of the nucleus and clumping of nuclear chromatin (Q845280)

A. I-a, II-b, III-c

B. I-b, II-c, III-a

C. I-c, II-a, III-b

D. I-c, II-b, III-a

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is the most important electron microscopic finding in irreversible cell injury? (Q845288)

A. Small amorphous densities in the mitochondria

B. Swelling of the endoplasmic reticulum

C. Large amorphous densities in the mitochondria

D. Detachment of ribosomes from the granular endoplasmic reticulum

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding free radical injury is true? (Q845289)

A. Free radicals are highly stable molecules with unpaired electrons that contribute positively to cellular functions.

B. Free radical injury can lead to cell damage through lipid peroxidation, protein oxidation, and DNA strand breaks.

C. Antioxidants play a minor role in protecting cells from free radical damage.

D. Free radicals primarily cause cell death through apoptosis and do not contribute to necrosis.

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following ultrastructural findings given below can be seen in irreversible cell injury? (Q845292)

A. Swelling of endoplasmic reticulum

B. Formation of myelin figures

C. Disaggregation of granular and fibrillar elements

D. Nuclear fragmentation

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A sample of tissue preparation is subjected to oxidative stress under experimental conditions. Different types of free radicals are generated in the process. However, the researcher wants to work on the most potent and reactive free radicals among the ones generated. Which of the following will he be working on? (Q845294)

A. Hydroxyl radical (OH•)

B. Nitric oxide radical (NO•)

C. Superoxide anion radical (O2•-)

D. Peroxyl radical (ROO•)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is a telltale sign of free radical injury in cells? (Q845295)

A. Increased antioxidant levels in the cell

B. Decreased lipid peroxidation products

C. Generation of Lipofuscin and stress markers such as malondialdehyde (MDA)

D. Enhanced cellular energy production.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the primary function of superoxide dismutase (SOD) in cells? (Q845298)

A. Activation of inflammatory responses.

B. Generation of reactive oxygen species (ROS)

C. Neutralization of superoxide anion radicals (O2•-) into hydrogen peroxide (H2O2)

D. Promotion of lipid peroxidation.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 50-year-old male presents with progressive weakness and muscle atrophy, primarily affecting his arms and legs. He reports difficulty with tasks such as buttoning shirts and lifting objects. On examination, you note fasciculations in his upper extremities and decreased muscle strength. His reflexes are brisk, and there is no sensory deficit. Nerve conduction studies show signs of denervation. Genetic testing reveals a mutation in the SOD1 gene. Based on this clinical scenario, what is the most likely diagnosis for this patient? (Q845300)

A. Multiple sclerosis

B. Myasthenia gravis

C. Amyotrophic lateral sclerosis

D. Guillain-Barré syndrome

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following best describes the primary function of chaperones within the cellular environment? (Q845304)

A. Facilitating the degradation of misfolded proteins

B. Promoting protein folding and preventing misfolding

C. Catalyzing enzymatic reactions by providing a scaffold

D. Transporting proteins across cellular membranes

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 60-year-old man has been complaining of fatigue, unintentional weight loss, and swelling in his ankles and legs over the past few months. On physical examination, you notice hepatomegaly and proteinuria. Laboratory tests reveal elevated serum creatinine levels and microscopic hematuria. Which of the following types of amyloid is most likely responsible for this patient's presentation? (Q845308)

A. AA amyloidosis

B. AB amyloidosis

C. AL amyloidosis

D. ATTR amyloidosis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which cellular pathway is primarily involved in the pathogenesis of Amyotrophic Lateral Sclerosis (ALS)?Which of the following pathways are responsible for the pathogenesis of ALS? (Q845311)

A. Autophagy-lysosome pathway

B. Ubiquitin-proteasome pathway

C. Endocytic pathway

D. Apoptotic pathway

See Answer in Part B → Q16

[01_Cell Injury] 002 Cell Death — Quick Jump

Q1 (p. 37)	*Q2 (p. 37)*	*Q3 (p. 38)*	*Q4 (p. 38)*	*Q5 (p. 38)*	*Q6 (p. 39)*
Q7 (p. 39)	*Q8 (p. 39)*	*Q9 (p. 40)*	*Q10 (p. 40)*	*Q11 (p. 40)*	*Q12 (p. 41)*
Q13 (p. 41)	*Q14 (p. 41)*	*Q15 (p. 42)*	*Q16 (p. 43)*	*Q17 (p. 43)*	*Q18 (p. 43)*
Q19 (p. 44)	*Q20 (p. 44)*	*Q21 (p. 44)*	*Q22 (p. 45)*	*Q23 (p. 46)*	*Q24 (p. 46)*

Q1: A construction worker involved in bridge building reports widespread bone pain. Imaging reveals ischemic necrosis affecting both femoral heads, the left tibia, and the right humerus. Which of the following factors is most likely responsible for this condition? (Q879491)

A. Alterations in ambient pressure

B. Changes in blood viscosity

C. Impaired blood flow

D. Increased coagulability

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following diseases is primarily attributed to protein misfolding, resulting in cellular dysfunction or apoptosis? (Q879402)

A. Cystic fibrosis

B. Familial hypercholesterolemia

C. Tay-Sachs disease

D. All of the above

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 65-year-old patient with a neurodegenerative disorder is found to have neuronal death associated with iron accumulation and lipid peroxidation. Which form of cell death is most likely involved? (Q879401)

A. Apoptosis

B. Necrosis

C. Ferroptosis

D. Pyroptosis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 30-year-old individual has cells that resist Fas-mediated apoptosis despite Fas ligand binding. Which of the following proteins is most likely responsible for blocking caspase-8 activation in this scenario? (Q879400)

A. Bcl-2

B. FLIP

C. BID

D. FADD

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements about caspases is true? (Q879392)

A. Caspases function independently of apoptotic signaling pathways

B. Caspases cleave at cysteine residues

C. Caspases act on asparagine residues

D. Caspases are cysteine proteases

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following represents pathological apoptosis rather than physiological apoptosis? (Q879391)

A. Regression of the lactating breast after weaning

B. Elimination of autoreactive T-lymphocytes in the thymus

C. Death of hepatocytes during viral hepatitis

D. Removal of neutrophils after resolution of acute appendicitis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A pathology slide shows necrotic cells with intense eosinophilic cytoplasm on H&E staining. Which of the following best explains this increased eosinophilia? (Q879390)

A. Loss of glycogen and lipid droplets

B. Accumulation of denatured cytoplasmic proteins that bind eosin

C. Swelling of mitochondria with amorphous densities

D. Presence of intracytoplasmic myelin figures

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is true about apoptosis? (Q879389)

A. It is an irreversible type of cell injury

B. It is associated with inflammation

C. It results in nuclear changes such as pyknosis, karyorrhexis, and karyolysis

D. It is an active process

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A pathology student is reviewing the sequence of nuclear and cellular changes that occur during necrosis. Which of the following correctly represents the order of events? 1. Cell swelling 2. Karyolysis 3. Karyorrhexis 4. Pyknosis (Q879387)

A. 1 → 2 → 3 → 4

B. 1 → 4 → 3 → 2

C. 2 → 3 → 4 → 1

D. 4 → 3 → 2 → 1

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following are involved in the pathogenesis of pyroptosis? (Q845353)

A. Caspase 8 and FADD

B. RIPK3 and MLKL

C. Caspase 1 and inflammasome

D. Iron and glutathione antioxidants

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which type of cell death prevents metastasis? (Q845357)

A. Necroptosis

B. Pyroptosis

C. Anoikis

D. Necrosis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is true about programmed necroptosis? (Q845354)

A. Caspase-independent programmed cell death.

B. It is non-inflammatory.

C. It is only pathological.

D. It helps kill the Herpes simplex virus.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is true about coagulative necrosis? (Q845314)

A. It is the least common type of necrosis

B. Brain is most likely to undergo coagulative necrosis

C. It causes a wedge-shaped necrosis in the affected organs

D. The tissue architecture is lost

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following cell deaths is most likely to show pattern B? (Q845352)

A. Apoptosis

B. Necrosis

C. Both

D. None of the above

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following substances is not a component of ‘eat-me signals’ of efferocytosis? (Q845351)

A. C1q

B. Thrombospondin

C. Phosphatidyl serine

D. Fas Ligand

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following forms the apoptosome complex? (Q845350)

A. SMAC, DIABLO

B. Cyt C and Apaf

C. Procaspase 9 and Caspase 9

D. Caspase 3, 6, 7

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Arrange the steps of the extrinsic pathway of apoptosis in the correct order. i. Binding of Fas ligand of T cells to Fas ii. Trimerization of Fas iii. Activation of caspase 8, 10. iv. Formation of FADD (Q845349)

A. i>ii>iii>iv

B. iii>i>ii>iv

C. i>ii>iv>iii

D. iv>i>ii>iii

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Match the following apoptotic genes with their functions: 1. BCL2 , MCL1 a. Allows cytochrome c leakage 2. BAX, BAK b. Initiates apoptosis when upregulated 3. BAD, BID, NOXA c. Prevents leakage of cytochrome C from the cytosol (Q845346)

A. 1-b , 2-c , 3-a

B. 1-c , 2-a , 3-b

C. 1-a , 2-b , 3-c

D. 1-b , 2-a , 3-c

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following statements about apoptosis is false? (Q845342)

A. Characterized by the activation of caspases leading to DNA fragmentation by endonuclease

B. Inflammatory response and release of damage-associated molecular patterns (DAMPs).

C. Chromatin condensation and formation of cytoplasmic blebs.

D. Eliminates cells that are injured beyond repair without eliciting a host reaction.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Identify the correctly matched pair among the following (Q845340)

A. Coagulative necrosis- Leucocytic enzymes- Brain

B. Liquefactive necrosis- Lysosomal enzymes - Heart

C. Fat necrosis- Pancreatic lipase- Omentum

D. Fibrinoid necrosis- Bacterial enzymes- Leg

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Based on the provided image, which features are indicative of the type of gangrene depicted? {{caption_text}} (Q845334)

A. Presence of gas bubbles in the affected tissue

B. Formation of bullae filled with fluid

C. Dry, shrunken, and mummified appearance with a clear demarcation

D. Presence of foul-smelling discharge and crepitus on palpation

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following conditions does not involve fibrinoid necrosis? (Q845330)

A. Systemic Lupus Erythematosus.

B. Malignant hypertension

C. Atherosclerosis

D. Polyarteritis Nodosa (PAN)

See Answer in Part B → Q22

@Neet_pg_bot

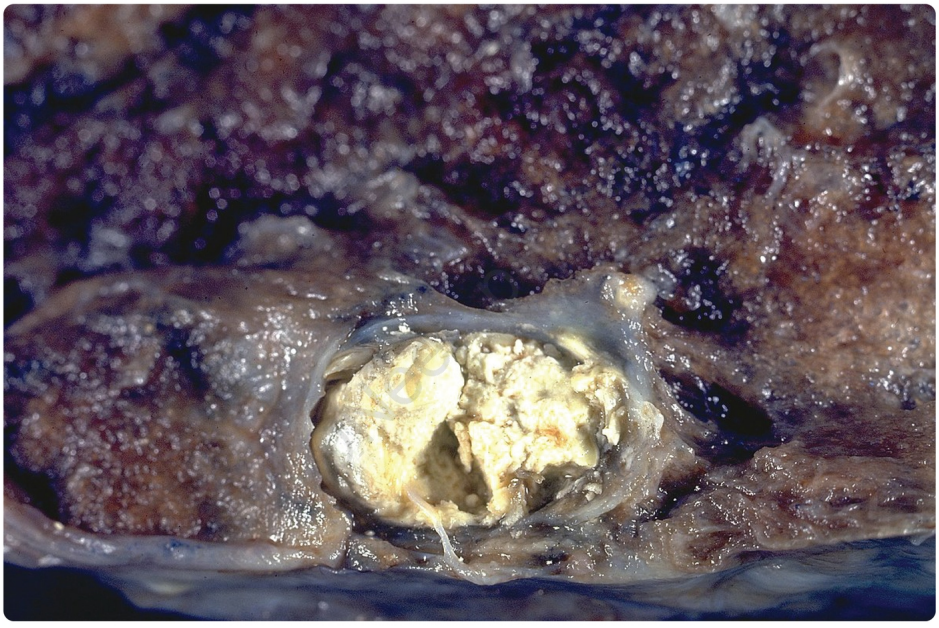
Q23: A 45-year-old man presents to the clinic with a persistent cough, weight loss, and night sweats. A chest X-ray shows cavitary lesions in the upper lobes of the lungs. Sputum analysis is positive for acid-fast bacilli. A biopsy is taken, and a cut section of the lung is shown below.What type of necrosis is most likely present in this patient's lung tissue? (Q845324)

A. Coagulative necrosis

B. Caseous necrosis

C. Fatty necrosis

D. Liquefactive necrosis



@Neet_pg_bot

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 65 year male presents with weakness on the right half of his body. He is a known case of atrial fibrillation, not on any treatment. CT angiography shows a complete occlusion of a small branch of the middle cerebral artery. What is the most likely change seen in this pathology? (Q845318)

A. Coagulative necrosis

B. Liquefactive necrosis

C. Apoptosis

D. Fibrinoid necrosis

See Answer in Part B → Q24

Q1: Which option best characterizes the cellular phenomenon known as anaplasia? (Q879557)

A. Abnormal increase in cell size

B. Loss of cellular differentiation

C. Replacement of one mature cell type with another

D. Physiological increase in cell number

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Bronchial biopsy in a middle-aged chronic smoker shows replacement of columnar epithelium by squamous epithelium. Deficiency of which vitamin can contribute to this metaplastic change? (Q879553)

A. Vitamin K

B. Vitamin E

C. Vitamin D

D. Vitamin A

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following conditions is associated with metaplastic transformation into connective tissue? (Q879547)

A. Myositis ossificans

B. Squamous metaplasia of bronchi

C. Barrett’s esophagus

D. Chronic gastric reflux

See Answer in Part B → Q3

@Neet_pg_bot

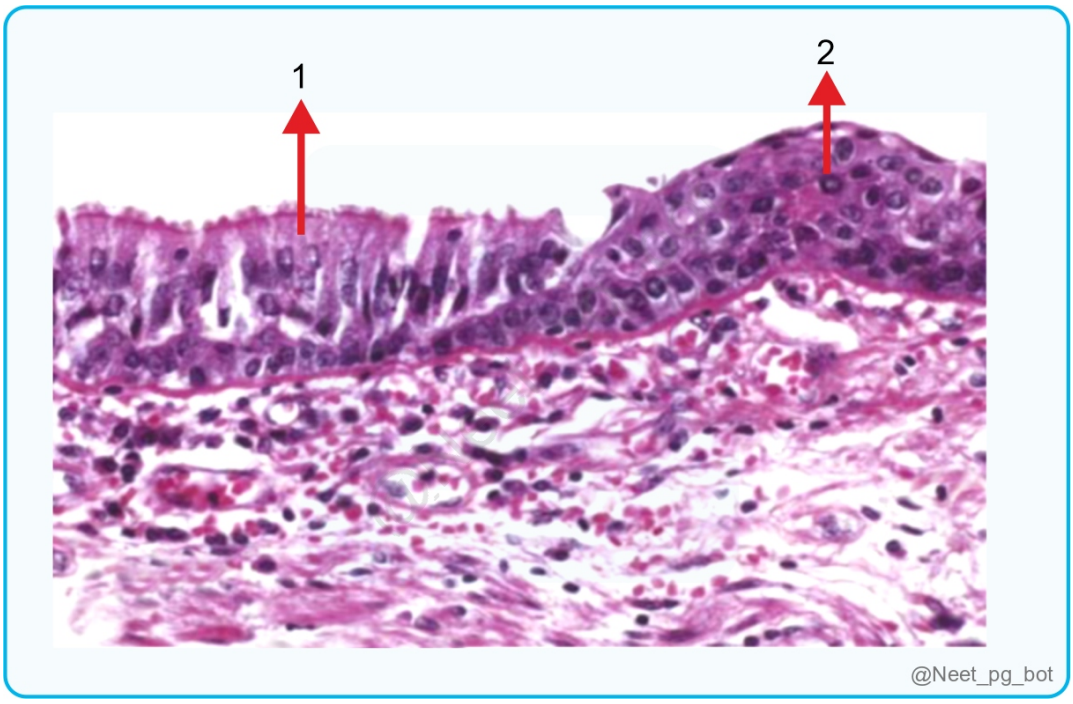
Q4: The image below is the lining epithelium of a middle-aged man who is a chronic smoker. Which of the following is the correct marking? (Q879540)

A. 1. Normal columnar epithelium 2. Squamous metaplasia

B. 1. Columnar metaplasia 2. Normal squamous epithelium

C. 1. Normal squamous epithelium 2. Columnar metaplasia

D. 1. Normal columnar epithelium 2. Normal squamous epithelium



See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which epithelial transformation is encountered most frequently as an example of metaplasia? (Q879538)

A. Replacement of squamous epithelium by columnar epithelium

B. Replacement of squamous epithelium by transitional epithelium

C. Replacement of columnar epithelium by transitional epithelium

D. Replacement of columnar epithelium by squamous epithelium

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Below is the image of a 79-year-old male with a history of long-standing atherosclerosis who presented with progressive cognitive decline and neurological deficits. What type of atrophy is noticed in the image? (Q879536)

A. Nutritional atrophy

B. Neurogenic atrophy

C. Pressure atrophy

D. Ischemic atrophy

See Answer in Part B → Q6

@Neet_pg_bot

Q7: In which of the following scenarios do both physiological hypertrophy and hyperplasia occur? (Q879535)

A. Enlargement of skeletal muscle with exercise

B. Left ventricular thickening in hypertension

C. Uterine growth during pregnancy

D. Enlargement of breast tissue at puberty

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following organs undergoes only hypertrophy? (Q879516)

A. Breast

B. Heart

C. Liver

D. Uterus

See Answer in Part B → Q8

@Neet_pg_bot

Q9: By which of the following mechanisms does muscle hypertrophy occur? (Q879514)

A. ■-myosin heavy chain is replaced by the ■ form of the myosin heavy chain

B. ■-myosin heavy chain is replaced by the ■ form of the myosin light chain

C. ■-myosin light chain is replaced by the ■ form of the myosin heavy chain

D. ■ form of the myosin light chain is replaced by the ■-myosin heavy chain

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements accurately describes cellular adaptations in response to environmental changes? (Q879512)

A. Hypertrophy refers to an increase in cell number without a change in cell size

B. Hyperplasia is an increase in cell size without an increase in cell number

C. Metaplasia is a reversible change of one differentiated cell type to another

D. Atrophy results from a combination of increased protein synthesis and decreased protein degradation

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A pathology resident is reviewing special stains for detecting tissue deposits. Which of the following stains is not used for demonstrating calcium in histological sections? (Q879411)

A. Congo red

B. Von Kossa stain

C. Alizarin Red S

D. Azan stain

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 55-year-old man with long-standing hyperlipidemia presents with multiple yellowish nodules over his Achilles tendon and extensor tendons of the hands. Biopsy of one lesion shows foam cells packed with cholesterol and cholesterol esters. Which of the following conditions does this represent? (Q879407)

A. Fabry's disease

B. Xanthoma

C. Niemann-Pick disease type C

D. Strawberry gallbladder

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements regarding metaplasia is true? (Q845260)

A. Metaplasia refers to the abnormal growth of cells, often leading to cancer.

B. It is a reversible change in which one adult cell type is replaced by another adult cell type.

C. Metaplasia is always a pathological process and never occurs in response to normal physiological stimuli.

D. Metaplasia is characterized by the replacement of differentiated cells with undifferentiated stem cells.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following statements best describes the role of telomerase in cellular ageing? (Q845194)

A. Telomerase accelerates ageing by reducing the length of telomeres with each cell division

B. Telomerase maintains the constant telomere length in somatic cells throughout their lifespan.

C. Telomerase prevents the shortening of telomeres by adding DNA sequences to the ends of chromosomes, thus potentially extending cell's lifespan.

D. Telomerase is a Ribozyme delaying cell aging.

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which type of metaplasia characterizes the histological changes observed in Barrett's oesophagus? (Q845257)

A. Transformation of columnar epithelium to squamous epithelium

B. Replacement of squamous epithelium with columnar epithelium containing goblet cells

C. Conversion of glandular epithelium to squamous epithelium

D. Substitution of mesenchymal cells with epithelial cells

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which type of atrophy is observed in a patient with smaller and weaker muscles who is bedridden for several weeks? (Q845255)

A. Disuse atrophy

B. Neurogenic atrophy

C. Endocrine atrophy

D. Senile atrophy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following is an example of physiological atrophy? (Q845254)

A. Testicular atrophy due to hypogonadism

B. Intestinal villi atrophy in malabsorption syndromes

C. Reduction in thymus gland size during ageing

D. Brain atrophy in neurodegenerative diseases

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements about the mechanism of hypertrophy is inaccurate? (Q845250)

A. Activation of G-protein-coupled receptor-initiated pathways

B. Stimulation of growth factor production such as TGF-β and IGF1

C. Inhibition of transcription factors like GATA4, MEF2, NFAT

D. Activation of downstream pathways including the PI3K/AKT pathway

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old female presents with irregular and heavy menstrual bleeding for the past six months. She reports experiencing prolonged periods lasting more than ten days with excessive bleeding, abdominal discomfort, and pelvic pain during her menstrual cycle. On further evaluation, transvaginal ultrasound reveals thickening of the endometrial lining. Endometrial biopsy confirms the presence of abnormal glandular proliferation without cytologic atypia. Which of the following best describes the cellular adaptation observed in this clinical scenario? (Q845248)

A. Physiological hypertrophy

B. Pathological hypertrophy

C. Physiological hyperplasia

D. Pathological hyperplasia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which statement accurately distinguishes between hypertrophy and hyperplasia? (Q845245)

A. Hypertrophy involves an increase in cell number, while hyperplasia involves an increase in cell size.

B. Hypertrophy increases tissue mass, while hyperplasia maintains tissue mass.

C. Hypertrophy is irreversible, while hyperplasia is reversible.

D. Hypertrophy results from increased cellular protein production, while hyperplasia involves growth factor-driven proliferation of mature cells.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following biomarkers is associated with autophagy? (Q845243)

A. Annexin A1

B. Annexin V

C. Beclin 1

D. LC3

See Answer in Part B → Q21

@Neet_pg_bot

Q22: What is the mechanism by which chaperone-mediated autophagy (CMA) targets misfolded proteins for degradation? (Q845240)

A. Direct uptake by lysosomes via endocytosis

B. Activation of mTOR leading to inhibition of ULK1 complex

C. Selective degradation of damaged or dysfunctional mitochondria

D. Binding of chaperones to misfolded proteins, followed by lysosomal entry via LAMP2A for autophagy

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which cellular process is primarily responsible for the degradation and recycling of unnecessary or dysfunctional cellular components? (Q845237)

A. Autophagy

B. Necrosis

C. Apoptosis

D. Pyroptosis

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 36-year-old male presents to the clinic with complaints of bilateral cataracts, short stature, premature greying and loss of hair, and skin changes. He also reports joint stiffness and pain, as well as type 2 diabetes mellitus. On examination, the patient appears older than his stated age, with characteristic "bird-like" facies and a high-pitched voice. Which of the following conditions is most likely to be associated with his presentation? (Q845202)

A. Hutchinson-Gilford Syndrome

B. Werner syndrome

C. Wermer syndrome

D. Cockayne Syndrome

See Answer in Part B → Q24

@Neet_pg_bot

Q25: How do “Sirtuins” contribute to cellular ageing? (Q845198)

A. By accelerating telomere shortening.

B. By enhancing cell repair mechanisms and exerting anti-ageing effects.

C. By functioning as histone acetyltransferases, promoting chromatin condensation.

D. By decreasing insulin sensitivity

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which of the following statements is correct about the concept of the Hayflick Limit? (Q845196)

A. The ageing of cells is not determined by telomere length.

B. It refers to the age at which cells cease all metabolic activities and undergo apoptosis.

C. A cell typically undergoes 20-40 cell divisions before reaching senescence.

D. It represents the average number of times a cell can divide before experiencing replicative senescence.

See Answer in Part B → Q26

Q1: Which of the following pathological conditions involves the accumulation of pigments through exogenous sources? (Q845361)

A. Chronic venous insufficiency

B. Vitiligo

C. Obstructive jaundice

D. Coal worker’s pneumoconiosis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 83-year-old man presents to his gastroenterologist with complaints of fatigue and discomfort in the upper abdomen. He has a history of hypertension and type 2 diabetes mellitus, for which he takes medications regularly. On physical examination, the liver edge is palpable below the right costal margin, indicating hepatomegaly. Laboratory investigations reveal mildly elevated liver enzymes. Which of the following pigments is most likely responsible for the brown discolouration of the liver observed in this patient? (Q845363)

A. Melanin

B. Glycogen

C. Lipofuscin

D. Bilirubin

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old woman presents with a painless, slow-growing, pigmented lesion on her back with irregular borders and varying shades of brown and black. Excisional biopsy of the lesion is performed, and histopathological examination reveals nests of melanocytes within the dermis, with prominent melanin pigment deposition. Which of the following staining techniques would be most suitable for visualization of the melanin pigment within the melanocytes in this patient's biopsy specimen? (Q845365)

A. Massaon Fontana stain

B. Masson Trichome stain

C. Periodic-Acid-Schiff (PAS) stain

D. Immunohistochemical staining for Melan- A

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old man presents with complaints of fatigue, joint pain, and abdominal discomfort. On examination, he exhibits bronze-coloured skin pigmentation mainly on the face and hands. Laboratory tests reveal elevated serum ferritin levels and transferrin saturation. Which of the following staining techniques would be most appropriate to visualize hemosiderin deposition in tissues in this patient? (Q845368)

A. Perl’s stain

B. Lillie's stain

C. Rhodanine stain

D. Supravital stains

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following pathological conditions is associated with the 'Tabby cat' effect? (Q845369)

A. Diphtheria myocarditis

B. Xanthomas

C. Cholesterolosis

D. Fatty liver

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following stains is not typically employed for the detection of lipid accumulation in histological samples? (Q845371)

A. Sudan Black

B. Sudan IV

C. Oil red O

D. Toluidine blue

See Answer in Part B → Q6

@Neet_pg_bot

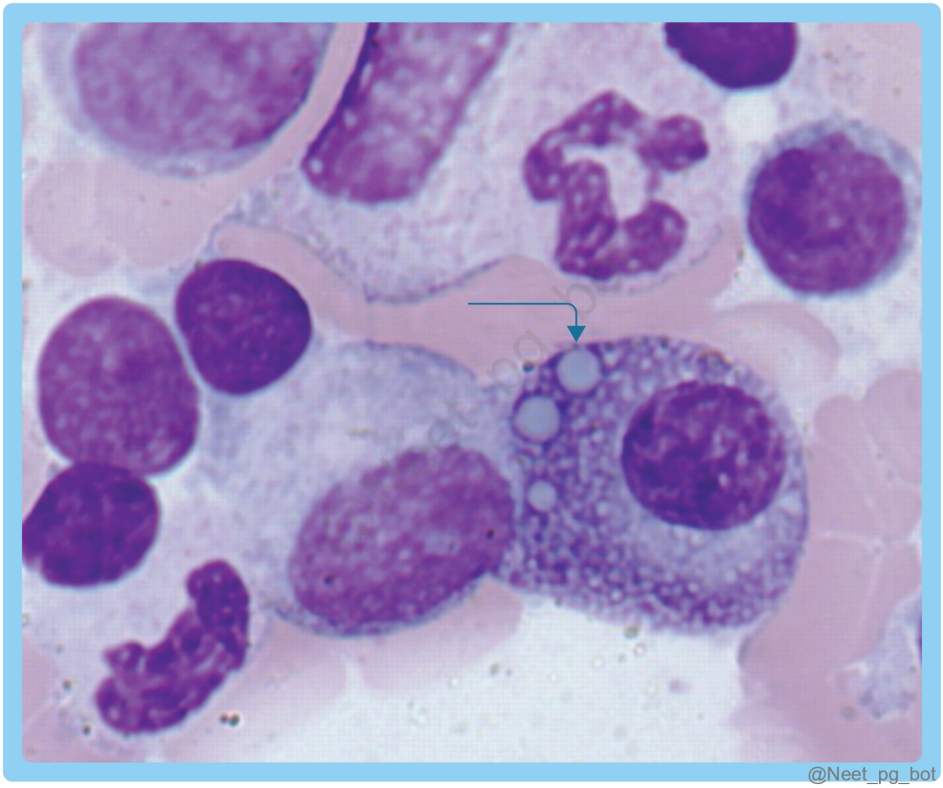
Q7: A 60-year-old woman presents with bone pain and tenderness over her lower back. Imaging reveals multiple lytic lesions in the vertebral column. Laboratory tests indicate anaemia, elevated serum calcium levels, and monoclonal gammopathy. A bone marrow biopsy confirms plasma cell proliferation. Microscopic examination of the biopsy reveals intracellular inclusions, as shown in the image. What is the composition of the intracellular inclusions marked in the image? {{caption_text}} (Q845373)

A. Aggregates of misfolded proteins

B. Clusters of ribosomes

C. Accumulations of immunoglobulins

D. Vacuoles containing lipids



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Following the resection of the pituitary adenoma in a patient with Cushing's disease, which intracellular change is most likely in residual adenoma cells? (Q845374)

A. Mallory-Denk bodies

B. Lewy bodies

C. Crooke hyaline change

D. Civatte bodies

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following stains would be most appropriate for visualizing glycogen deposits? (Q845375)

A. Hematoxylin and eosin (H&E) stain

B. Periodic acid-Schiff (PAS) stain

C. Masson's trichrome stain

D. Oil Red O stain

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements is incorrect about dystrophic calcification? (Q845376)

A. It occurs in damaged or necrotic tissues.

B. It is characterized by the deposition of calcium salts in normal tissues.

C. It is often seen in areas of chronic inflammation.

D. Serum calcium levels are normal

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following case scenarios is not indicative of metastatic calcification? (Q845378)

A. A 60-year-old male with a history of chronic renal failure presented with shortness of breath and bilateral lung opacities on chest X-ray.

B. A 45-year-old female with spinal tuberculosis complained of back pain.

C. A 30-year-old male with a long-standing history of heavy milk and calcium carbonate intake now experiencing recurrent kidney stones.

D. A 55-year-old female with sarcoidosis demonstrated elevated levels of serum vitamin D and calcium.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which staining technique is commonly used to visualize calcium deposits in tissues and is particularly useful for detecting minute amounts of calcium? (Q845380)

A. Masson's trichrome stain

B. Prussian blue stain

C. Alizarin Red S stain

D. Wright-Giemsa stain

See Answer in Part B → Q12

Q1: Identify the correct statements regarding amyloidosis. Amyloidosis is called so because it looks like the deposition of starch. Beta-pleated sheets are seen. AL is a type of secondary amyloidosis. It is an extracellular protein. (Q857424)

A. 1, 2 and 3

B. 1, 4

C. 2, 3 and 4

D. 1, 2 and 4

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A diabetic male presented with seizures. Radiological examination shows a lesion. Histopathological examination shows liquefactive necrosis. What is the most important mechanism responsible for this? (Q866754)

A. Enzymatic degradation

B. Mechanical

C. Ischemic

D. Pressure

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is pro-apoptotic? (Q866665)

A. Bcl-2

B. Bcl-xL

C. Mcl-1

D. Bax

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following types of cell death involves activation of caspase enzymes? (Q866340)

A. Necrosis and Apoptosis

B. Apoptosis and Pyroptosis

C. Apoptosis and necroptosis

D. Apoptosis only

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Caspase-1 is primarily involved in which type of programmed cell death? (Q865391)

A. Apoptosis

B. Pyroptosis

C. Necroptosis

D. Necrosis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Apoptotic bodies comprise of? (Q860513)

A. Include cytoplasm + intranuclear material + organelle

B. Cytoplasm + organelle

C. Organelle + intranuclear material

D. Only organelle

See Answer in Part B → Q6

@Neet_pg_bot

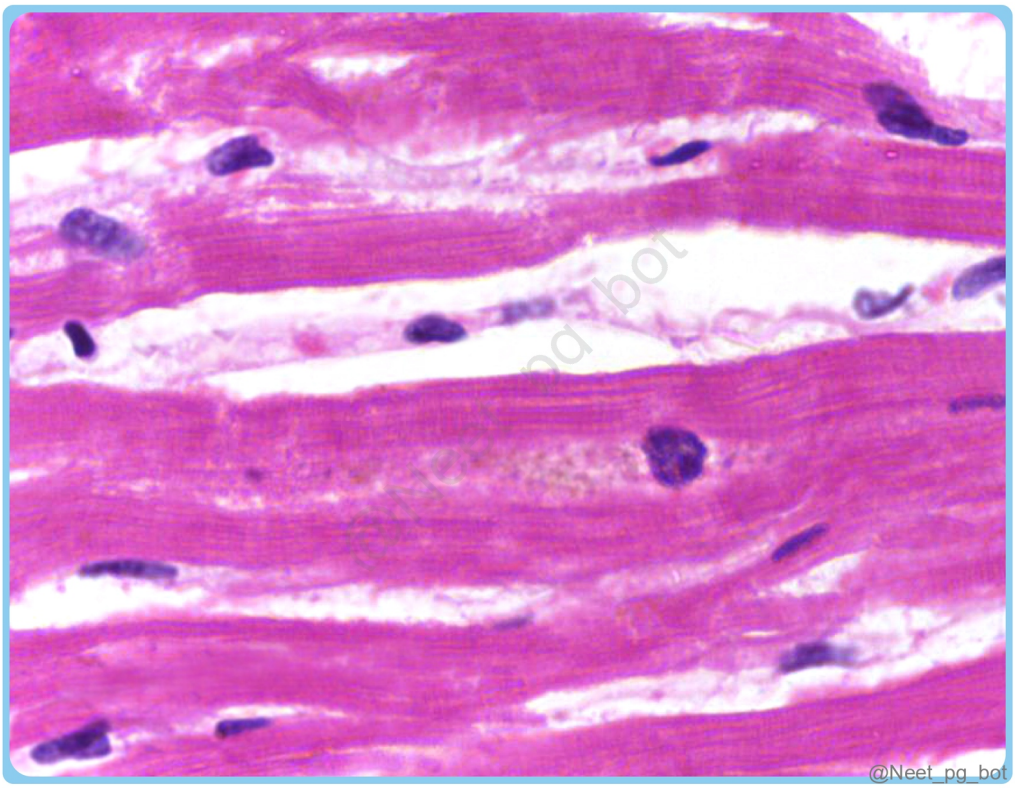
Q7: The body of an 82-year-old man has been seen for a post-mortem to determine the cause of death. You are examining a histopathological slide containing a section of his cardiac tissue where you notice some pigmentation. Which is the substance that is seen in the image given below? (Q859859)

A. Melanin

B. Lipofuscin

C. Hemosiderin

D. Iron



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Among the following, which molecule is required for the presentation of the antigens by the APCs to TH2 cells? (Q859298)

A. NK cells

B. G-protein coupled receptor

C. MHC

D. Lectin receptor

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Supravital stains are used in the identification of all except? (Q857588)

A. Reticulocytes

B. Copper in tissue

C. Heinz bodies

D. Ribosomal RNA

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is an anti-apoptotic gene? (Q857450)

A. BAK

B. MCL1

C. PUMA

D. BAD

@Neet_pg_bot

Q15: Which of the following caspases binds to Cyt c and the APAF-1 complex? (Q856488)

A. Caspase 1

B. Caspase 8

C. Caspase 9

D. Caspase 4

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A chronic alcoholic patient presented with increasing abdominal girth. On examination, shifting dullness was present, and the liver span was less than 7cm.

Histopathological examination revealed the presence of intracytoplasmic eosinophilic inclusions in hepatocytes. What is the content of these inclusions? (Q856152)

A. Intermediate filaments

B. Actin

C. Microtubules

D. Fibronectin

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 70-year-old patient presented with cough, fatigue, and weight loss. He was diagnosed with squamous cell carcinoma on bronchoscopy. The resected specimen had a hilar lymph node that was 1 cm in size and showed a black pigment. What is the black pigment likely to be? (Q856097)

A. Anthracotic pigment

B. Melanin

C. Lipochrome

D. Hemosiderin

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Senile atrophy occurs due to which of the following? (Q856024)

A. Denervation

B. Decreased nutrition

C. Decreased workload

D. Reduced blood supply

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following measures is associated with an increased life span? (Q855961)

A. Regular moderate exercise for 30 min

B. Decrease stress

C. Decreasing calorie intake by 30%

D. Pharmacological intervention with proton pump inhibitors

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Choose the correct statement regarding the telomerase theory of ageing: (Q855914)

A. Telomere stability is associated with ageing

B. Abnormal telomerase activation is associated with ageing

C. Decreased telomere length is associated with ageing

D. Increased telomere length is associated with ageing

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following is true regarding sirtuins? Increases insulin sensitivity and glucose metabolism Promotes genes that increase longevity They are of 7 types They are one of the types of histone deacetylases (Q855087)

A. 1, 2, 3

B. 1, 2, 3, 4

C. 2, 3

D. 2, 4

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Cell-in-cell appearance is seen in which of the following? (Q855076)

A. Necrosis

B. Apoptosis

C. Necroptosis

D. Entosis

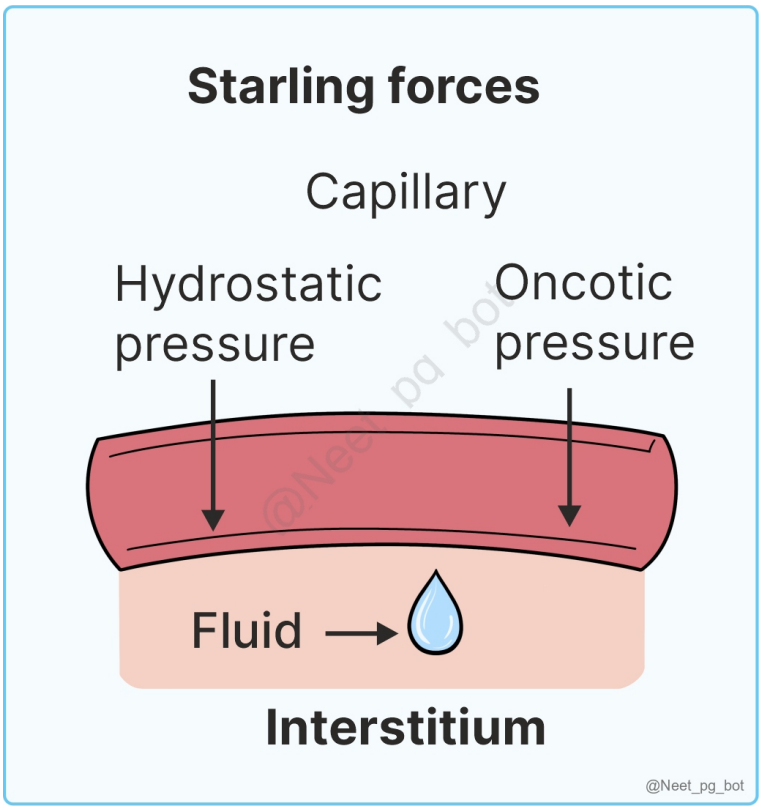
Q1: A 42-year-old man comes with swelling of both ankles. On examination, pitting oedema is noted. Which of the following alterations in Starling forces could contribute to the development of this condition? Increased capillary hydrostatic pressure Decreased capillary hydrostatic pressure Increased plasma oncotic pressure Decreased plasma oncotic pressure (Q879471)

A. 1 and 3

B. 2 and 3

C. 1 and 4

D. 2 and 4



See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following inflammatory cells contains granules rich in major basic protein, toxic to helminths? (Q879443)

A. Neutrophils

B. Eosinophils

C. Basophils

D. Macrophages

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A child presents with recurrent pyogenic infections, partial oculocutaneous albinism, and peripheral neuropathy. Which immunodeficiency is most likely due to defective phagolysosome fusion? (Q879442)

A. Chronic granulomatous disease

B. Chediak-Higashi syndrome

C. Mannose-binding lectin deficiency

D. Glanzmann-Rinicker syndrome

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following enzymes/proteins is not involved in neutralizing reactive oxygen species? (Q879440)

A. Myeloperoxidase

B. Ceruloplasmin

C. Catalase

D. Glutathione peroxidase

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which infection is characteristically associated with prolonged neutrophilic infiltration at the site of inflammation, even after 2–3 days? (Q879436)

A. Pseudomonas

B. Staphylococcus

C. Fungal infection

D. Viral infection

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 40-year-old woman develops acute pyelonephritis. Within the first 2 days of infection, she experiences high fever, flank pain, and dysuria. Urine microscopy reveals abundant pus cells. Which cell type is the main mediator of tissue damage in this stage of inflammation? (Q879435)

A. Neutrophils

B. Eosinophils

C. Macrophages

D. Plasma cells

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following adhesion molecules does not serve as a ligand for integrins during leukocyte adhesion? (Q879419)

A. CD54 (ICAM-1)

B. CD102 (ICAM-2)

C. CD106 (VCAM-1)

D. CD34

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding selectins are correct? They mediate the initial rolling of leukocytes on the endothelium There are three main types: L-selectin, E-selectin, and P-selectin P-selectin is expressed on endothelial cells and

platelets Selectins mediate firm, high-affinity adhesion of leukocytes (Q879417)

A. 1 and 2 only

B. 1, 2 and 3

C. 2, 3 and 4

D. 1 and 4 only

See Answer in Part B → Q8

@Neet_pg_bot

Q9: During normal laminar blood flow in venules, the phenomenon of axial streaming determines the distribution of blood cells. Which cells predominantly occupy the central axial column? (Q879414)

A. Red blood cells

B. Neutrophils

C. Platelets

D. Lymphocytes

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old female presents to the clinic with complaints of abdominal discomfort and bloating. Upon further evaluation, an abdominal ultrasound reveals a heterogeneous mass within the right ovary. Subsequent histopathological examination of the ovarian mass demonstrates the presence of entotic cells. Which of the following best describes the process observed in the histopathological findings? (Q845364)

A. Phagocytosis of apoptotic cells by neighboring cells

B. Engulfment of live cells by neighboring cells

C. Fusion of lysosomes within a cell leading to autophagy

D. Exocytosis of cellular debris from a damaged cell

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 6-month-old male infant presents with recurrent bacterial infections, including otitis media and pneumonia. Laboratory investigations reveal markedly reduced levels of all immunoglobulin classes (IgG, IgA, and IgM). Flow cytometry analysis shows a complete absence of mature B cells in peripheral blood. Which of the following gene mutations is most likely responsible for this condition? (Q845372)

A. BTK gene

B. LYST gene

C. WASP gene

D. ADA gene

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following defects is most likely associated with Leukocyte Adhesion Deficiency Type 1 (LAD)-1? (Q845370)

A. Defective synthesis of β2 integrin

B. Defective synthesis of Sialyl Lewis X modified glycoprotein

C. Defective FERMT3 gene

D. Myeloperoxidase deficiency

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which condition is characterized by recurrent catalase positive bacterial, and fungal infections, defective nitroblue tetrazolium (NBT) test results, and deficient reactive oxygen species production by phagocytes? (Q845366)

A. Leukocyte Adhesion Deficiency

B. Hyper-IgM Syndrome

C. X-linked Agammaglobulinemia

D. Chronic Granulomatous Disease

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which among the following is a cardinal sign of inflammation? (Q845313)

A. Prolonged fever

B. Tissue scarring

C. Abrasions

D. Redness

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements is incorrect regarding Emperipolesis and Phagocytosis? (Q845362)

A. Emperipolesis involves engulfment by any cell depending on disease; Phagocytosis involves engulfment by macrophages, neutrophils, and dendritic cells.

B. Emperipolesis doesn’t involve the killing of the cell; phagocytosis results in the degradation of engulfed cells.

C. Emperipolesis maintains internalized cell membrane integrity; Phagocytosis involves the fusion of engulfed material with lysosomes.

D. Emperipolesis is physiological; phagocytosis is pathological.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45-year-old male complains of painless bilateral cervical lymphadenopathy for the past six months. Biopsy of a lymph node reveals sheets of large histiocytes with emperipolesis, surrounded by lymphocytes and plasma cells. What is the most likely diagnosis? (Q845360)

A. Hodgkin lymphoma

B. Sarcoidosis

C. Infectious mononucleosis

D. Rosai-Dorfman disease

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following statements regarding neutrophil extracellular traps (NETs) is incorrect? (Q845359)

A. NETs are formed in response to infectious pathogens and inflammatory mediators.

B. NETs consist of nuclear chromatin and granule proteins like antimicrobial peptides and enzymes.

C. NET formation is initiated by the release of histones from activated neutrophils.

D. NETs directly phagocytose the invading pathogens.

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 40-year-old male presents with recurrent bacterial infections. Laboratory tests reveal reduced opsonization activity in his serum. Which of the following processes is primarily affected in this patient? (Q845356)

A. Complement activation

B. Diapedesis

C. Microbial engulfment

D. Leucocyte rolling.

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old man with a history of poorly controlled diabetes presents to the hospital with complaints of fever, productive cough, and chest pain. Chest imaging reveals the presence of multiple cavitary lesions in the lung parenchyma. Microscopic examination of lung tissue obtained via biopsy demonstrates numerous neutrophils and macrophages surrounding fungal hyphae. Which of the following phenomena is most likely associated with the formation of these cavitary lesions? (Q845347)

A. Activation of complement proteins

B. Release of lysozymes from neutrophils

C. Impaired phagocytosis

D. Formation of neutrophil extracellular traps (NETs)

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following plays a crucial role in mediating firm adhesion of leukocytes during acute inflammation? (Q845345)

A. CD11a/CD18

B. PECAM 1

C. CD31

D. CD44

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A patient presents with fluid accumulation in the pleural cavity. Which of the following characteristics would be consistent with a diagnosis of exudate rather than a transudate? (Q845336)

A. High LDH

B. Low protein concentration

C. Presence of mainly albumin

D. Low specific gravity

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is considered the hallmark event of acute inflammation? (Q845332)

A. Vasodilation

B. Increased vascular permeability

C. Stasis

D. Leukocyte extravasation

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following mechanisms primarily contributed to the increased vascular permeability in this patient's with a right knee injury after fall from stairs? (Q845326)

A. Contraction of endothelial cells resulting in the opening of interendothelial gaps

B. Direct damage to endothelial cells

C. Neutrophil-mediated injury to the endothelium

D. Proliferation of lymphatic vessels

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 30-year-old male presents to the emergency department with sudden onset right lower abdominal pain, accompanied by nausea and fever. On examination, there is tenderness over McBurney's point, and rebound tenderness is noted. Laboratory investigations reveal leukocytosis. Which type of inflammation is most likely to be associated with the following clinical scenario? (Q845322)

A. Serous inflammation

B. Fibrinous inflammation

C. Purulent inflammation

D. Ulcerative inflammation

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following features is a characteristic of acute inflammation? (Q845319)

A. Presence of granulomas

B. Proliferation of fibroblasts and angiogenesis

C. The predominance of lymphocytes in the inflammatory infiltrate

D. Accumulation of neutrophils at the site of injury

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 30-year-old female presents with a history of recent major surgery, deep vein thrombosis (DVT) in the lower extremities, and a family history of thrombotic events. Which of the following components constitute Virchow's triad, predisposing individuals to thrombosis? (Q845316)

A. Endothelial injury, hypercoagulability, and venous stasis

B. Endothelial dysfunction, leukocytosis, and platelet activation

C. Arterial dilation, decreased platelet count, and fibrinolysis

D. Hypothermia, acidosis, and coagulopathy

See Answer in Part B → Q26

Q1 (p. 89)	*Q2 (p. 89)*	*Q3 (p. 90)*	*Q4 (p. 90)*	*Q5 (p. 90)*	*Q6 (p. 91)*
Q7 (p. 92)	*Q8 (p. 92)*	*Q9 (p. 92)*	*Q10 (p. 93)*	*Q11 (p. 93)*	*Q12 (p. 94)*
Q13 (p. 94)	*Q14 (p. 95)*	*Q15 (p. 96)*	*Q16 (p. 97)*	*Q17 (p. 97)*	

Q1: A 50-year-old man developed a small purulent abscess on his shoulder. After appropriate drainage and infection control measures, the wound healed well, leaving a healthy scar. During the early stages of tissue repair, which type of collagen predominates in the provisional matrix? (Q879470)

A. Type I

B. Type II

C. Type III

D. Type IV

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old woman undergoes excision of a sebaceous cyst with primary closure of the wound. During the healing process, angiogenesis is initiated early but reaches its maximum on which postoperative day? (Q879468)

A. Day 4

B. Day 3

C. Day 5

D. Day 7

See Answer in Part B → Q2

@Neet_pg_bot

Q3: During healing by primary intention, the initial acute inflammatory response is dominated by neutrophils. On which postoperative day do macrophages typically replace neutrophils as the predominant inflammatory cells at the wound site? (Q879467)

A. Day 1

B. Day 2

C. Day 3

D. Day 7

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is NOT true regarding the actions of Transforming Growth Factor Beta (TGF-β)? (Q879464)

A. TGF-β promotes collagen synthesis by fibroblasts

B. TGF-β enhances the breakdown of extracellular matrix proteins

C. TGF-β contributes to tissue fibrosis in organs

D. TGF-β has anti-inflammatory properties

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following diseases are typically associated with non-caseating granulomas? (Q879462)

A. Leprosy, Sarcoidosis, and Crohn’s disease

B. Tuberculosis and Syphilis

C. Cat-scratch disease only

D. All of the above

See Answer in Part B → Q5

@Neet_pg_bot

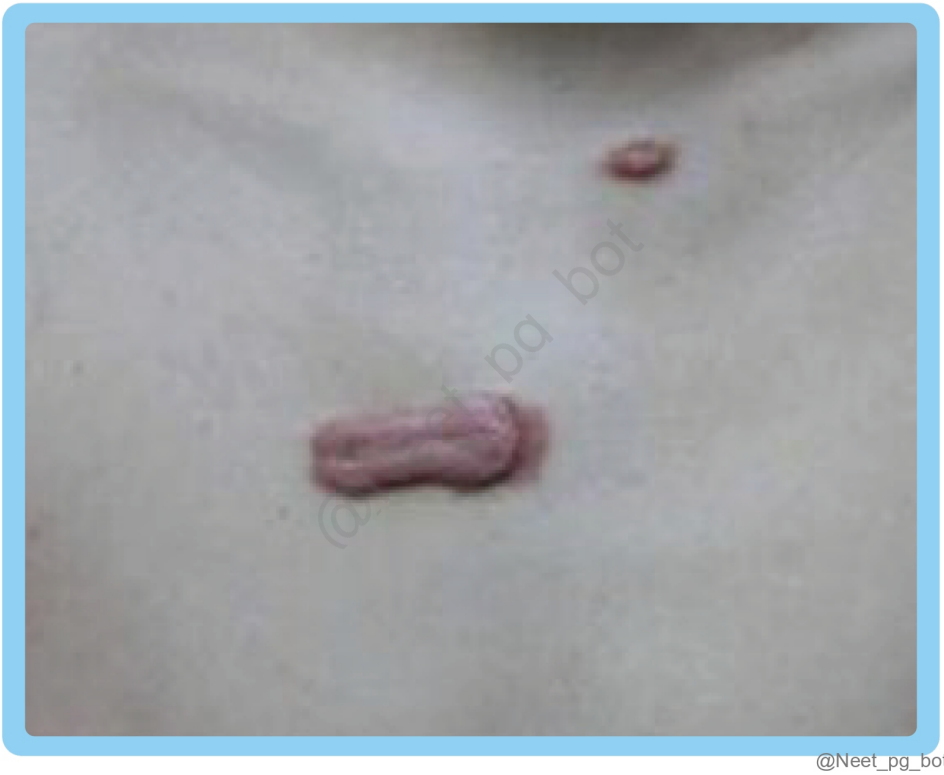
Q6: A 30-year-old man presents to the clinic with a raised scar on his chest. He reports that the scar has been gradually increasing in size since he had a minor injury in that area about a year ago. On examination, the scar extends beyond the original wound margins and appears firm and raised. Which of the following is the most likely diagnosis for the scar on the patient's chest? {{caption_text}} (Q845432)

A. Hypertrophic scar

B. Keloid

C. Exuberant granulation tissue

D. Contracture



@Neet_pg_bot

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following statements regarding wound healing is true? (Q847861)

A. The wound regains 20% of its normal strength by 1 week.

B. The wound regains 70-80% of its normal strength by 12 weeks.

C. The wound regains its original strength eventually.

D. The initial collagen formed in the process of wound healing is Type-1 collagen.

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old man undergoes a minor surgical procedure to remove a small skin lesion from his forearm, and the wound is meticulously closed with sutures. Three days after the surgery, he comes to the OPD for review. Which event of the wound healing process is typically observed in this patient? (Q845437)

A. Platelet and fibrin clot formation

B. Neutrophils start to accumulate

C. Replacement of neutrophils by macrophages

D. Collagen bridging initiation

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following cell types is classified as stable cells in terms of their proliferative capacity and turnover rate? (Q845435)

A. Neurons in the brain

B. Hematopoietic cells in bone marrow

C. Stratified squamous epithelia of the skin

D. Endothelial cells in blood vessels

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Match the following tissue macrophages with respective organs: 1. Kupffer cells a) liver 2. Dust cells b) spleen 3. Hofbauer cells c) lung 4. Littoral cells d) placenta 5. Mesangial cells e) kidney (Q845403)

A. 1-b, 2-a, 3-d, 4-e, 5-c

B. 1-a, 2-c, 3-d, 4-b, 5-e

C. 1-a, 2-d, 3-e, 4-b, 5-c

D. 1-c, 2-e, 3-b, 4-d, 5-a

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old woman undergoes a routine elective surgery for the removal of a benign skin lesion on her forearm. The procedure involves making a small incision, excising the lesion, and closing the wound with sutures. Which of the following statements accurately describes wound healing by primary intention in this scenario? (Q845430)

A. Myofibroblasts play a significant role in wound contraction.

B. The wound is associated with large tissue deficits.

C. Granulation tissue formation is extensive.

D. The wound is expected to heal with minimal inflammatory response.

See Answer in Part B → Q11

@Neet_pg_bot

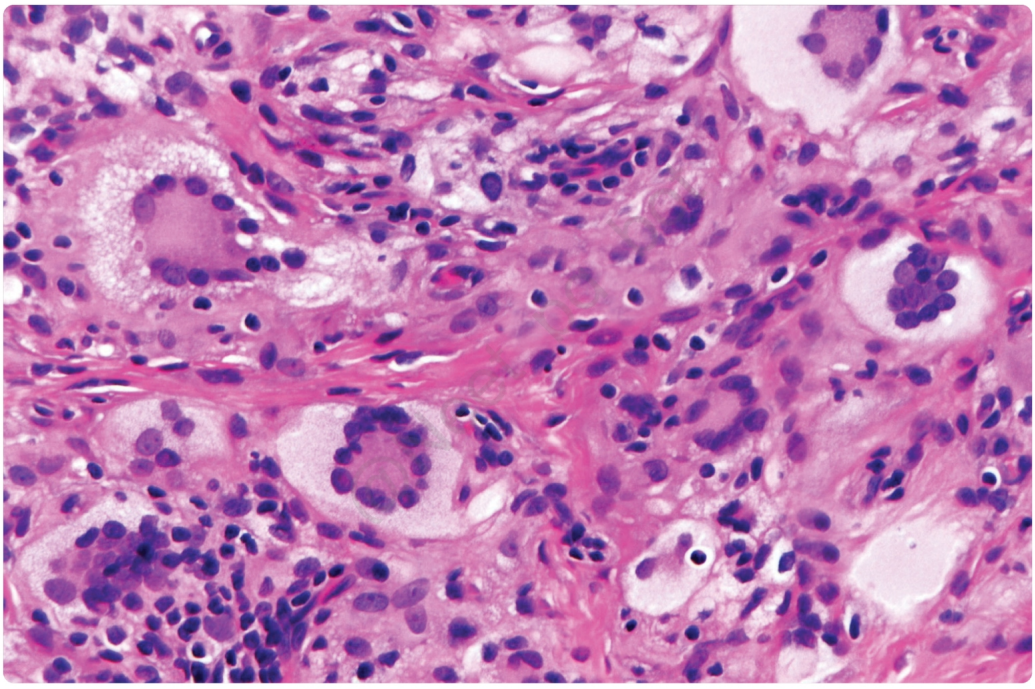
Q12: A 45-year-old male presents with a persistent subcutaneous nodule on his forearm. Biopsy reveals the presence of multinucleated giant cells within the lesion, as shown in the accompanying HPE image. Further analysis indicates a central zone of lipid-laden macrophages surrounded by a wreath-like arrangement of nuclei. Which type of giant cell is most likely to be observed in this scenario? {{caption_text}} (Q845424)

A. Touton giant cells

B. Reed-Sternberg Cells

C. Warthin-Finkeldey giant cells

D. Foreign body giant cells



@Neet_pg_bot

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is not a physiological giant cell? (Q845413)

A. Osteoclast

B. Syncytiotrophoblast

C. Megakaryocytes

D. Langhans cells

See Answer in Part B → Q13

@Neet_pg_bot

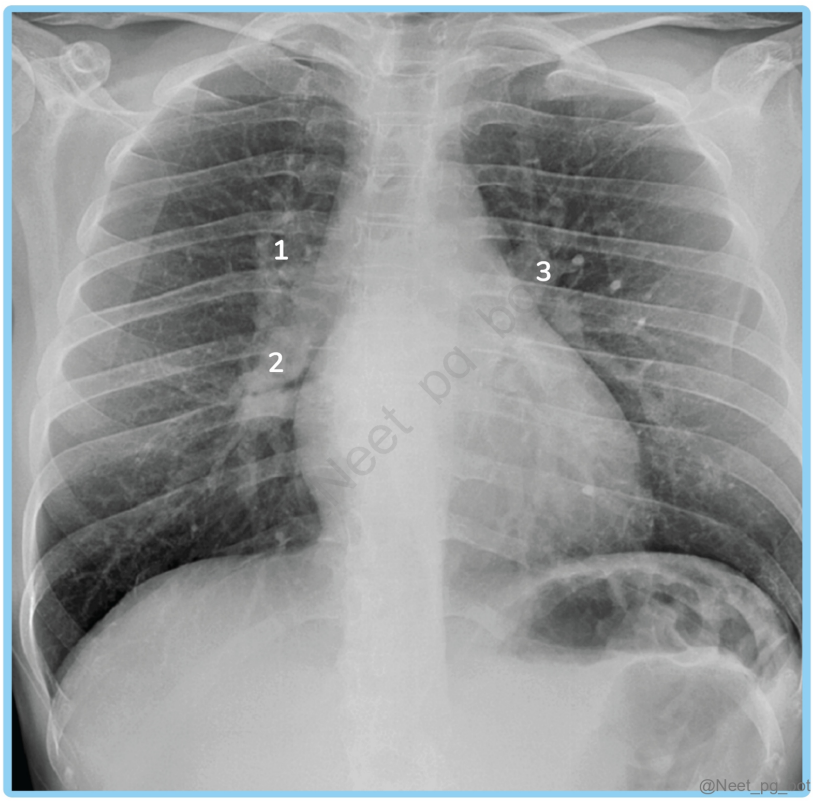
Q14: A 40-year-old woman presents with a persistent dry cough, shortness of breath, and bilateral enlargement of the lymph nodes in her chest, incidentally detected on a routine chest X-ray given below. Physical examination reveals fine crackles in her lung bases. Pulmonary function tests show reduced lung volumes and a decreased diffusion capacity for carbon monoxide. Which type of granuloma is commonly associated with the histopathological findings in this patient? {{caption_text}} (Q845412)

A. Naked granuloma

B. Stellate granuloma

C. Eosinophilic granuloma

D. Durck granuloma



See Answer in Part B → Q14

@Neet_pg_bot

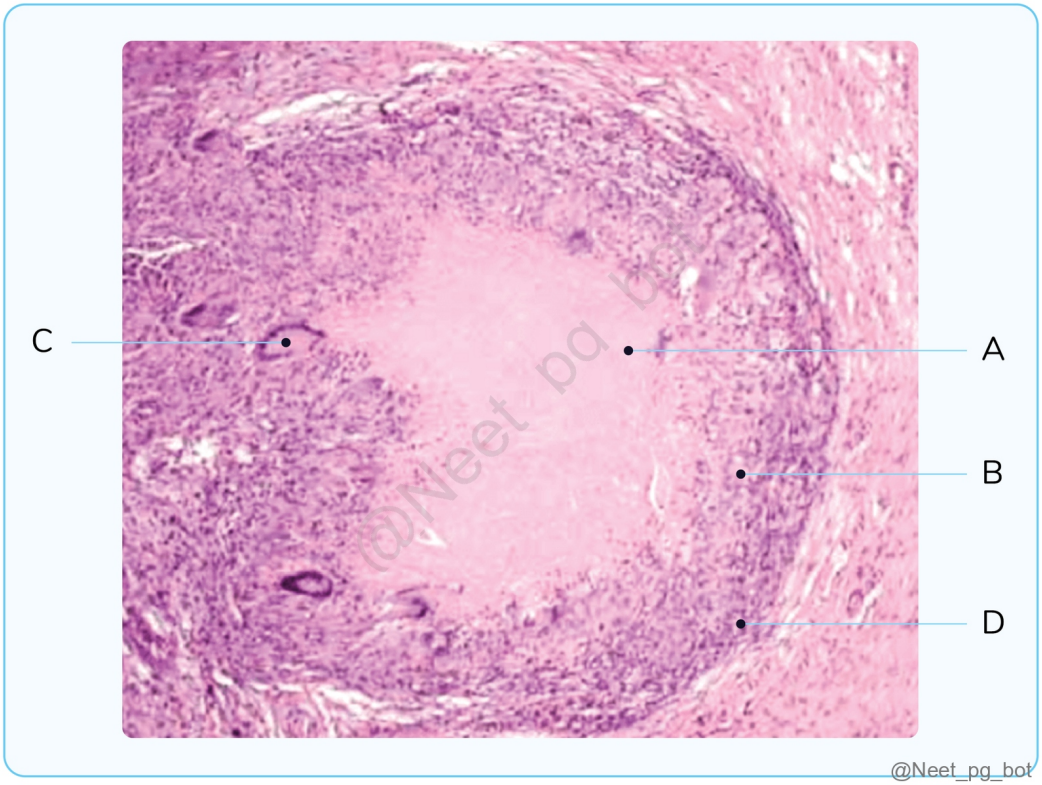
Q15: Which sequence accurately identifies lymphocytes, epithelioid cells, Langhans giant cells, and caseous necrosis in the image given below? (Q845410)

A. b, d, a, c

B. d, b, a, c

C. d, b, c, a

D. b, d, c, a



See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following statements about granulomas is incorrect? (Q845408)

A. Granuloma formation is a Type IV hypersensitivity reaction

B. IFN-gamma is an important cytokine involved in this process

C. CD8+ is the type of T lymphocytes involved in this process

D. Epitheloid cells in granuloma are modified macrophages

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which type of macrophages predominantly contributes to tissue repair and resolution of inflammation in patients with chronic obstructive pulmonary disease

complicated by pneumonia? (Q845406)

A. M1 macrophages

B. M2 macrophages

C. Both M1 and M2 macrophages

D. Resting macrophages

See Answer in Part B → Q17

Q25 (p. 108)	*Q26 (p. 109)*				

Q1: In some chronic inflammatory reactions, organized lymphoid follicles resembling lymph nodes may form. These are called tertiary lymphoid structures. Which of the following conditions may show these structures? (Q879461)

A. Synovium in long-standing rheumatoid arthritis

B. Thyroid in Hashimoto thyroiditis

C. Infiltrates around some tumors

D. All of the above

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following mediators is not primarily involved in producing fever during inflammation? (Q879460)

A. IL-1

B. Prostaglandins

C. TNF

D. Histamine

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following inflammatory mediators are correctly matched with their primary actions? 1. Histamine – arteriolar dilation and ↑ vascular permeability causing hypotension in anaphylaxis 2. Bradykinin – major mediator of pain in inflammation 3. Platelet-activating factor (PAF) – bronchoconstriction via activation of platelets and leukocytes with mediator release 4. Neutrophil lysosomal enzymes – cleavage of C3 and C5 to generate active complement fragments 5. Interleukin-1 (IL-1) mediates vasodilation and bronchoconstriction in asthma (Q879459)

A. 1, 2, 3

B. 1, 3, 5

C. 1, 2, 3, 4

D. 2, 4, 5

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 39-year-old woman with long-standing rheumatoid arthritis presents with fatigue and pallor. Lab tests reveal anemia of chronic disease. Elevated levels of which of the following acute-phase reactants are primarily responsible for this anemia? (Q879458)

A. Fibrinogen

B. C-reactive protein (CRP)

C. Serum amyloid A (SAA)

D. Hepcidin

See Answer in Part B → Q4

@Neet_pg_bot

Q5: During the acute-phase response in inflammation, which of the following acts as a negative acute-phase reactant by decreasing in serum concentration? (Q879456)

A. Albumin

B. Serum amyloid A (SAA)

C. C-reactive protein (CRP)

D. Fibrinogen

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Fractalkine, a unique chemokine with both membrane-bound and soluble forms, belongs to which chemokine family? (Q879453)

A. C

B. CX3C

C. CXC

D. CC

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following cytokines primarily exhibits anti-inflammatory activity? (Q879452)

A. IL-1

B. IL-4

C. TNF

D. IFN-γ

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding prostaglandins and related eicosanoids is INCORRECT? (Q879451)

A. Thromboxane A2 (TxA2) is the predominant product of platelets

B. Prostacyclin (PGI2) acts as a vasodilator and inhibits platelet aggregation

C. PGD2 is one of the major prostaglandins released from mast cells

D. Vascular endothelium lacks prostacyclin synthase

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Release of arachidonic acid, the precursor of prostaglandins and leukotrienes, is mainly mediated by which of the following enzymes? (Q879449)

A. Phospholipase A1 and C

B. Phospholipase A2 and C

C. Phospholipase B and C

D. Phospholipase A1 and B

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following mediators is released immediately during the earliest phase of acute inflammation? (Q879446)

A. Serotonin

B. Interleukins

C. Prostaglandins

D. Bradykinin

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 25-year-old female presents to the emergency department with sudden-onset swelling of her face, lips, and tongue. She reports a history of similar episodes occurring intermittently since childhood, often triggered by stress or trauma. On examination, she appears anxious and has marked swelling of her lips and tongue, with difficulty speaking and swallowing. There are no signs of urticaria or pruritus. Her vital signs are stable. Which of the following deficiencies is seen in this condition? (Q845600)

A. Deficiency of properdin

B. Deficiency of C1, C2, C3, C4

C. Deficiency of C1 esterase inhibitor

D. Deficiency of C5-C9

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Pain during inflammation is mediated by? (Q845603)

A. Serotonin

B. Leukotrienes

C. Interleukin-1

D. Bradykinin

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following deficiencies is seen in paroxysmal nocturnal hemoglobinuria? (Q845602)

A. C5-C9

B. CD59

C. C1

D. Factor H

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 25-year-old female presents to the emergency department with severe allergic reaction symptoms, including urticaria and hypotension, after ingesting a shrimp. How does the vasoactive mediator involved primarily cause hypotension? (Q845563)

A. Vasodilation and increased vascular permeability

B. Enhancing nitric oxide production and vasodilation

C. Inducing the release of other pro-inflammatory cytokines

D. Inhibiting platelet aggregation and causing clotting

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is false regarding the alternate complement pathway? (Q845599)

A. Teichoic acid is an initiator of the alternate complement pathway.

B. The first complement protein to be activated is C1.

C. The C3 convertase of the alternate pathway is C3bBb.

D. Properdin is the stabilizer of the alternate pathway.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the following with their correct answers. 1 C3a i Decay accelerating factor 2 C3b ii EBV receptor 3 CR2 iii Anaphylatoxin 4 CD55 iv Opsonin (Q845597)

A. 1-iii, 2-iv, 3-ii, 4-i

B. 1-iii, 2-iv, 3-i, 4-ii

C. 1-iv, 2-iii, 3-i, 4-ii

D. 1-iv, 2-iii, 3-ii, 4-i

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 45-year-old male presents to the clinic with a high fever, chills, and malaise. He reports feeling unwell for the past few days and has noticed redness and swelling around a cut on his forearm. On examination, the healthcare provider observes a localized area of erythema and induration at the site of the wound. Which of the following events is a crucial step in the activation of the complement system in response to the patient's initial condition? (Q845594)

A. Binding of C1q to antigen-antibody complexes

B. Formation of membrane attack complex

C. Cleavage of C3 into C3a and C3b

D. Cleavage of C5 by C5 convertase

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Select the correct statements about the complement system. 1) The complement system primarily functions by adaptive immunity. 2) Complement proteins are solely produced in the liver. 3) All complement proteins are synthesized in inactive forms and are activated by proteolysis. 4) Complement activation occurs through three pathways. 5) Complements have two equal fragments. (Q845573)

A. 1,2,3

B. 2,4

C. 2,3,5

D. 3,4

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 20-year-old male is prescribed naproxen for a musculoskeletal injury. What is naproxen's mechanism of action? (Q845572)

A. Lipoxygenase inhibition

B. COX-2 inhibition

C. Cycloxygenase (COX) 1 and COX-2 inhibition

D. Prostaglandin (PG) F2 inhibition

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following mediators is responsible for cancer cachexia? (Q845571)

A. TNF-alpha

B. IFN-gamma

C. IL-8

D. TGF-beta

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old male presents with a history of chronic obstructive pulmonary disease (COPD) exacerbation. Which of the following chemokines is primarily responsible for recruiting neutrophils to the airways in COPD exacerbations? (Q845570)

A. IL-8

B. MCP-1

C. SDF-1

D. RANTES

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 30-year-old male presents with symptoms of flu-like illness, including fever, sore throat, and fatigue. Further investigation reveals a positive HIV serology. Which of the following chemokine receptors primarily facilitates the entry of HIV into CD4+ T cells? (Q845569)

A. CX3CL1

B. CCR5 , CXCR4

C. CCL11 , MCP-1

D. CXCL8

See Answer in Part B → Q22

@Neet_pg_bot

Q23: All are chemoattractants among the following except : (Q845568)

A. IL-8

B. C5a

C. LTB4

D. C3b

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following best describes the mechanism of action of PAF in inducing bronchoconstriction? (Q845567)

A. By binding to seven transmembrane G protein–coupled receptors.

B. Causing smooth muscle constriction by directly stimulating muscarinic receptors

C. Induction of smooth muscle relaxation and bronchodilation

D. Activation of platelets and leukocytes leading to release of inflammatory mediators

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following is the role of neutrophil lysosomal enzymes in acute inflammation? (Q845566)

A. Cleavage of C3 and C5

B. Inhibition of complement proteins

C. Activation of macrophages

D. Degradation of prostaglandins

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which type of nitric oxide synthase (NOS) is involved in microbial killing and is induced in macrophages by cytokines or microbial products? (Q845565)

A. Endothelial NOS (eNOS)

B. Neuronal NOS (nNOS)

C. Inducible NOS (iNOS)

D. None of the above

See Answer in Part B → Q26

@Neet_pg_bot

Q1: Which of the following cytokines does not cause the Jarisch-Herxheimer reaction? (Q855911)

A. TNF alpha

B. IL-6

C. IL-8

D. INF-γ

See Answer in Part B → Q1

@Neet_pg_bot

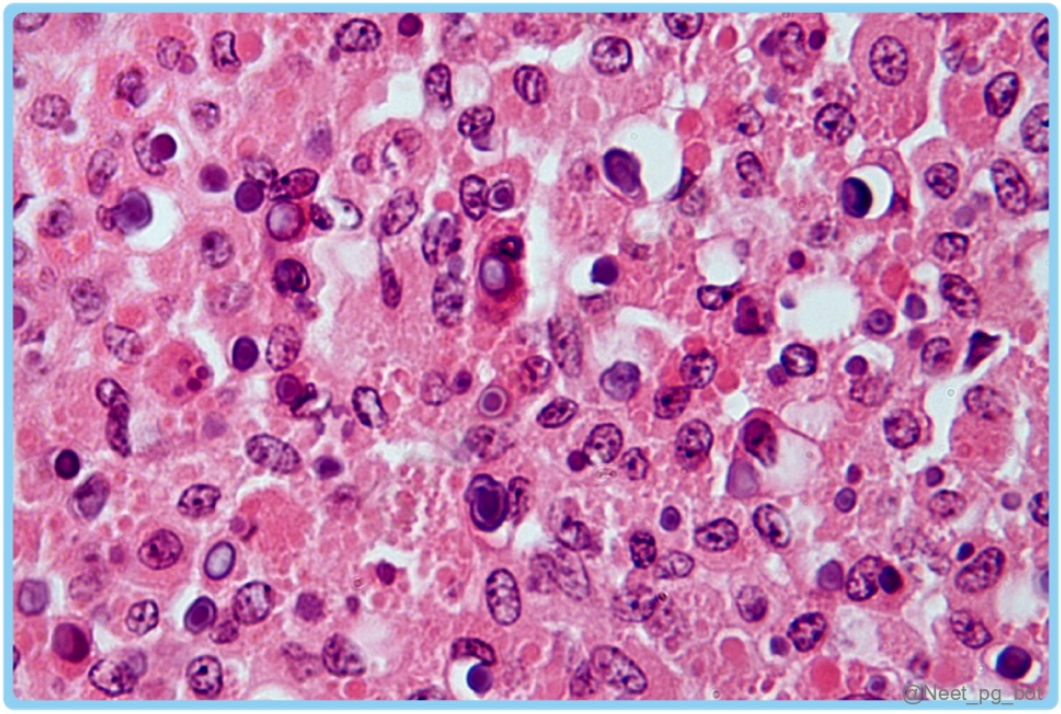
Q2: A patient underwent a cystoscopy, which showed multiple yellow-white plaques in the trigone of the bladder. The histopathology image is given below. What is the diagnosis? (Q855952)

A. Interstitial cystitis

B. Malakoplakia

C. Polypoid cystitis

D. Acute cystitis



See Answer in Part B → Q2

@Neet_pg_bot

Q3: All of the following statements regarding neutrophil extracellular trapping (NET) are true, except? (Q855938)

A. It is detected in blood during sepsis

B. It is produced in response to bacterial infection

C. Mitochondrial DNA is seen

D. It is chromatin with antibacterial enzymes

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 12-year-old child presented with 15 days of cough. On examination, cervical lymphadenopathy was noted, and the lymph node biopsy showed caseating granulomas. What is the most probable diagnosis? (Q854881)

A. Tuberculosis

B. Leprosy

C. Sarcoidosis

D. Syphilis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: During acute inflammation, leukocytes exit the bloodstream and migrate toward the site of tissue injury through several coordinated steps. Arrange the following events in the correct chronological order: Chemotaxis Adhesion Opsonization Rolling Phagocytosis Margination Cytokine-mediated integrin activation Transmigration (Q856703)

A. 1, 2, 3, 4, 5, 6, 7, 8

B. 6, 4, 7, 2, 8, 1, 3, 5

C. 4, 6, 2, 1, 3, 7, 8, 5

D. 2, 1, 4, 3, 5, 6, 7, 8

See Answer in Part B → Q5

@Neet_pg_bot

Q6: During wound healing, the cells that appear first, due to chemotaxis, at the site of the wound are: (Q857608)

A. Neutrophils

B. Monocytes

C. Macrophages

D. Lymphocytes

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following molecules helps in the firm adhesion of the leukocyte to the endothelium during inflammation? (Q857101)

A. P-selectin

B. Platelet-activating factor

C. VCAM-1

D. Complements

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Cyclooxygenase plays a role in which of the following pathways? (Q855125)

A. Kreb’s cycle

B. Prostaglandin

C. Leukotriene

D. Vitamin K

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Match the following cells with their locations: Cells Locations 1. Kupffer cells a. Stomach 2. Parietal cells b. Liver 3. Dust cells c. Alveoli 4. Clara cells d. Bronchioles (Q855088)

A. 1-a, 2-b, 3-c, 4-d

B. 1-c, 2-d, 3-a, 4-b

C. 1-d, 2-a, 3-d, 4-c

D. 1-b, 2-a, 3-c, 4-d

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Match the cytokines with the effector cells 1. IL-4 a. Eosinophils 2. IL-5 b. Mast cells 3. IL-9 c. B cells 4. IL-13 d. Dendritic cells (Q856029)

A. 1-c, 2-a, 3-b, 4-d

B. 1-a, 2-c, 3-d, 4-b

C. 1-b, 2-d, 3-c, 4-a

D. 1-d, 2-b, 3-a, 4-c

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following molecules helps leukocytes roll over endothelial cells in vessels? (Q856001)

A. Cadherins

B. PECAM-1

C. E-selectin

D. CD11a

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Match the following: 1. IL-5 A. Regulates acute phase reactants 2. IL-6 B. T cell maturation 3. IL-7 C. Neutrophil recruitment 4. IL-8 D. Eosinophils activation (Q860495)

A. 1-B, 2-C, 3-D, 4-A

B. 1-D, 2-A, 3-B, 4-C

C. 1-C, 2-D, 3-B, 4-A

D. 1-D, 2-C, 3-B, 4-A

See Answer in Part B → Q12

@Neet_pg_bot

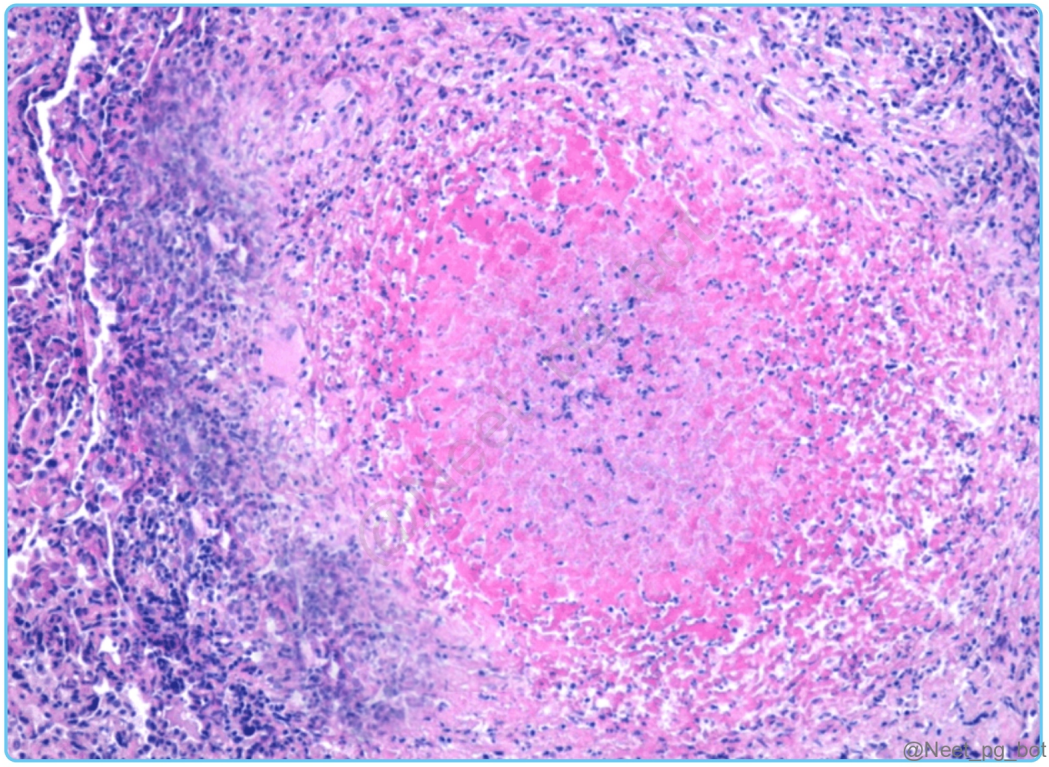
Q13: A patient presents with complaints of cough, night sweats, and fever. A lung biopsy demonstrates the following histological findings. What is the most likely cytokine involved? (Q854700)

A. Interferon-γ

B. Complement C5a

C. Histamine

D. Bradykinin



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which substance plays a role as a mediator in chronic inflammation? (Q830804)

A. IL-1

B. TNF-α

C. TGF-β

D. None

See Answer in Part B → Q14

@Neet_pg_bot

Q15: All of the following are correct about 'Neutrophil extracellular traps' except? (Q860299)

A. May result in SLE

B. Phagocytosis

C. Sepsis

D. Arginine needed

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the following: 1. IL-5 A. Regulates acute phase reactants 2. IL-6 B. T cell maturation 3. IL-7 C. Neutrophil recruitment 4. IL-8 D. Eosinophils activation (Q860293)

A. 1-B, 2-C, 3-D, 4-A

B. 1-D, 2-A, 3-B, 4-C

C. 1-C, 2-D, 3-B, 4-A

D. 1-D, 2-C, 3-B, 4-A

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 50-year-old female presents with cervical lymphadenopathy. A biopsy has revealed granulomatous necrotising inflammation. Which of the following options is correct? (Q860203)

A. Metastatic calcification with normal serum calcium level

B. Dystrophic calcification with normal serum calcium level

C. Metastatic calcification with increased serum calcium level

D. Dystrophic calcification with increased serum calcium level

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is the most effective enzyme in Acute inflammation? (Q860193)

A. NADPH oxidase

B. Defensin

C. Catalase

D. MPO

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following parameters decreases in acute inflammation? (Q860161)

A. CRP

B. Hepcidin

C. Fibrinogen

D. Albumin

See Answer in Part B → Q19

@Neet_pg_bot

Q20: All of the following are growth-promoting proto-oncogenes, except? (Q840061)

A. FGF

B. PDGF

C. TGF-α

D. TGF-β

See Answer in Part B → Q20

@Neet_pg_bot

Q21: All of the following are correct about NETs except? (Q860511)

A. May result in SLE

B. Phagocytosis

C. Sepsis

D. Arginine needed

See Answer in Part B → Q21

Q13 (p. 124)

Q1: Match the following with their correct terms. 1 Exon i Non-coding region 2 Intron ii One of the alternate forms of a single gene occupying a given position in a chromosome 3 Locus iii Coding region 4 Allele iv Location of a gene on the chromosome (Q845099)

A. 1-iii, 2-i, 3-iv, 4-ii

B. 1-iii, 2-i, 3-ii, 4-iv

C. 1-i, 2-iii, 3-iv, 4-ii

D. 1-i, 2-iii, 3-ii, 4-iv

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 25-year-old male from a tribal area of Madhya Pradesh presents to the clinic with complaints of fatigue and shortness of breath. On examination, he appears pale, and jaundice is noted. Laboratory investigations reveal low hemoglobin levels and increased reticulocyte count. The peripheral blood smear shows numerous sickle-shaped erythrocytes. What is the most likely molecular mechanism underlying the pathogenesis of this patient's condition? (Q845100)

A. Chromosomal translocation

B. Missense mutation

C. Frameshift mutation

D. Nonsense mutation

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A couple visits a genetics counselor due to concerns about their baby's blood type. The father has blood type A (genotype I A I A), and the mother has blood type B (genotype I B I B). The counselor explains that blood type is determined by codominant alleles, where both alleles contribute equally to the phenotype in the heterozygous condition. Which of the following best describes codominance? (Q845101)

A. One allele completely masks the expression of the other allele

B. The phenotype of the heterozygote is intermediate between the phenotypes of the homozygotes

C. Only one allele is expressed, while the other remains silent

D. Both alleles contribute to the phenotype equally in the heterozygous condition

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 30-year-old man presents to the clinic with a history of tall stature, long limbs, and joint hypermobility. Upon further examination, he also exhibits features such as a high-arched palate, arachnodactyly (long, slender fingers), and aortic root dilation. His father has a similar appearance. Which of the following statements is true regarding the inheritance pattern seen in this condition? (Q845103)

A. Males are more commonly affected than females.

B. Most mutations lead to reduced production of a gene product or give rise to a dysfunctional or inactive protein.

C. Complete penetrance can be seen

D. The least common mode of inheritance

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 6-month-old male infant presents to the pediatric clinic with failure to thrive, recurrent respiratory infections, and hepatosplenomegaly. Upon further examination, the infant also displays signs of skeletal abnormalities including bowed legs and frontal bossing. Lab investigations reveal pancytopenia with markedly decreased platelet count. Genetic testing confirms a diagnosis of Gaucher disease. What is the pattern of inheritance and underlying genetic defect leading to this disorder? (Q845104)

A. Autosomal Dominant Inheritance, Mutation in the CFTR Gene

B. X-linked Recessive Inheritance, Mutation in the GBA Gene

C. Autosomal Dominant Inheritance, Mutation in the HEXA Gene

D. Autosomal Recessive Inheritance, Mutation in the GBA Gene

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 6-month-old infant presents with hepatosplenomegaly, failure to thrive, and hypotonia. The infant has a cherry-red spot on the macula and exhibits poor startle reflexes on physical examination. Further evaluation reveals foam cells in the bone marrow. What is the diagnosis and associated enzyme deficiency? (Q845105)

A. Diagnosis: Niemann-Pick disease type A, Enzyme Deficiency: Acid sphingomyelinase

B. Diagnosis: Tay-Sachs disease, Enzyme Deficiency: Hexosaminidase A

C. Diagnosis: Gaucher disease, Enzyme Deficiency: Glucocerebrosidase

D. Diagnosis: Metachromatic leukodystrophy, Enzyme Deficiency: Arylsulfatase A

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Sarah is a 3-year-old girl who is brought to her pediatrician by her parents due to concerns about her development. Her parents report that Sarah has been experiencing a loss of previously acquired skills, such as hand skills and language, stereotypic hand movements and seizure episodes . What is the mode of inheritance? (Q845106)

A. X-linked dominant

B. X-linked recessive

C. Autosomal recessive

D. Autosomal dominant

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 25-year-old male presents with severe hypotonia at birth, joint hypermobility, scoliosis, fragile skin, and ocular fragility. Genetic testing reveals mutations in the gene encoding Lysyl Hydroxylase. Which subtype of Ehlers-Danlos Syndrome (EDS) is most likely present in this patient and its mode of inheritance? (Q845107)

A. Classical EDS - Autosomal Dominant

B. Hypermobility EDS - Autosomal Dominant

C. Kyphoscoliotic EDS - Autosomal Dominant

D. Kyphoscoliotic EDS - Autosomal Recessive

See Answer in Part B → Q8

@Neet_pg_bot

Q9: What type of inheritance pattern is associated with hypertrichosis pinnae? (Q845108)

A. Autosomal Dominant

B. Autosomal Recessive

C. X-Linked Dominant

D. Holandric

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 5-year-old boy is brought to the emergency department due to excessive bleeding after a minor injury. His mother reports that his grandfather also had similar bleeding episodes. Laboratory tests reveal a deficiency in factor IX. What is the mode of inheritance for this condition? (Q845109)

A. Autosomal dominant

B. Autosomal recessive

C. X-linked recessive

D. X-linked dominant

See Answer in Part B → Q10

@Neet_pg_bot

Q11: If the mother and father have the β-thalassemia trait, what percentage of their children are expected to have β-thalassemia major? (Q845110)

A. 25%

B. 50%

C. 75%

D. 100%

See Answer in Part B → Q11

@Neet_pg_bot

Q12: If a mother has sickle cell trait and the father has sickle cell disease , what percentage of their children are expected to have sickle cell disease? (Q845111)

A. 25%

B. 50%

C. 75%

D. 100%

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 10-year-old boy presents to the clinic with a complaint of bone pain. He does not sustain any trauma. He denies a history of fever. On examination, hepatosplenomegaly and bone tenderness are noted. Biopsy specimen from the spleen shows a crumpled tissue paper appearance. Keeping in view the most likely diagnosis, which of the following substance would most likely accumulate in this disorder? (Q882175)

A. Glucocerebroside

B. SphingomyelinSulfatide

C. Sulfatide

D. Ganglioside

See Answer in Part B → Q13

@Neet_pg_bot

Q1: Fabry disease is an X-linked lysosomal storage disorder caused by a deficiency of which enzyme? (Q879663)

A. Alpha-galactosidase A

B. Beta-glucocerebrosidase

C. Acid alpha-glucosidase

D. Sphingomyelinase

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following correctly describes the genetic basis of Myotonic Dystrophy type 1? (Q879658)

A. Autosomal recessive disorder caused by CAG expansion in the HTT gene on chromosome 4

B. Autosomal dominant disorder caused by CTG trinucleotide expansion in the DMPK gene on chromosome 19q13.3

C. X-linked disorder caused by CGG repeat expansion in the FMR1 gene

D. Autosomal dominant disorder caused by GAA trinucleotide expansion in the FXN gene

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A one-month-old infant presents with developmental delays and physical features such as a prominent occiput, low-set ears, clenched hands with overlapping fingers, and a small mouth with a protruding tongue. Heart murmurs and rocker-bottom foot deformity are also noted. Which syndrome is the most likely cause of these features? (Q845124)

A. Noonan syndrome

B. Down syndrome

C. Patau syndrome

D. Edward syndrome

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 15-year-old boy presents to the clinic with tall stature and long limbs, along with a history of frequent joint dislocations. Upon physical examination, he exhibits long fingers ,sunken chest, and an echocardiogram shows a dilated aortic root. Considering these clinical features, which of the following genes are commonly mutated in this condition? (Q845130)

A. FBN 1

B. FBN 2

C. FBN 3

D. FBN 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 3-year-old boy presents with developmental delay, short stature, a heart murmur, and characteristic facial features, as shown in the image below. What is the most likely diagnosis for this patient? (Q845129)

A. Noonan syndrome

B. Down syndrome

C. Williams syndrome

D. Turner syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: An 18-year-old girl presents to the clinic due to the concern that she hasn't started menstruating yet. The girl has a short stature and a webbed neck. Physical examination reveals a broad chest with widely spaced nipples. What is the most likely diagnosis for this patient? (Q845128)

A. Turner syndrome

B. Mullerian agenesis

C. Congenital adrenal hyperplasia

D. 47, XXX syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 30-year-old tall male patient presents to the clinic for fertility treatment. He undergoes testing and is found to have low sperm counts. He has a history of diabetes, and a physical examination reveals gynecomastia, small testes, and minimal facial and body hair. What chromosomal abnormality is most likely causing this condition in the patient? (Q845127)

A. 45,X

B. 47,XXY

C. 47,XXX

D. 47,XYY

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 6-month-old child has recently passed away after a long ICU stay. Examination reveals microphthalmia and microcephaly. Other known diagnoses included ventricular septal defect, polycystic kidney disease, and omphalocele at birth. What is the chromosome involved? (Q845126)

A. Chromosome 21

B. Chromosome 18

C. Chromosome 13

D. Chromosome Y

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 2-year-old boy is brought to the pediatrician by his parents for delayed milestones. Upon examination, the pediatrician notices several physical features, including upward-slanting eyes, a flat facial profile, a protruding tongue, and a single palmar crease. Which type of inheritance is definitely not present in this child? (Q845125)

A. Meiotic nondisjunction of chromosome 21.

B. Robertsonian translocation

C. Mitotic non-disjunction

D. Autosomal recessive inheritance

See Answer in Part B → Q9

@Neet_pg_bot

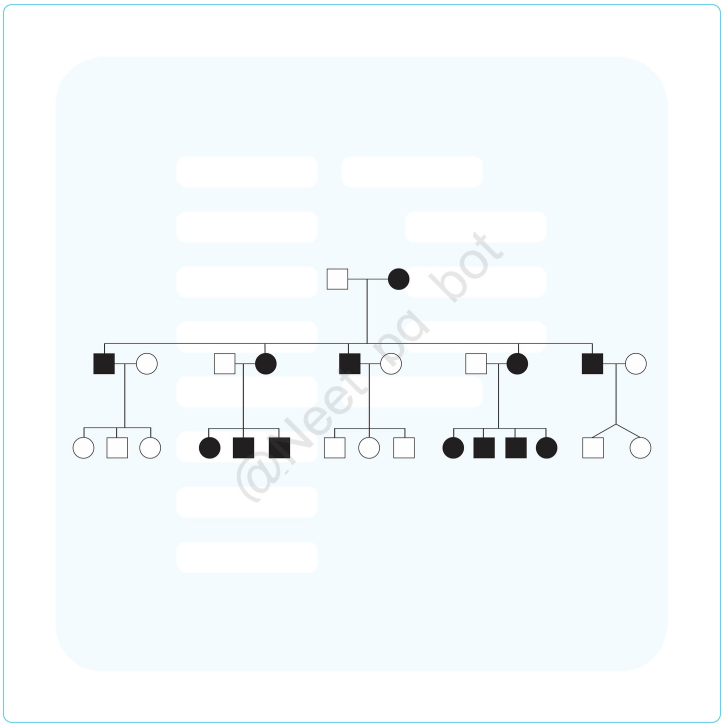
Q10: A young male patient presented with recurrent episodes of acute neurologic dysfunction, cognitive changes, muscle weakness, and lactic acidosis. There is a family history of similar conditions depicted in the pedigree chart below. What is the most likely diagnosis? (Q845115)

A. MELAS

B. MERRF

C. Metachromatic leukodystrophy

D. Adrenoleukodystrophy



@Neet_pg_bot

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 50-year-old man presents with intentional tremors, cerebellar ataxia, and intellectual disability. His father had similar symptoms at 60 and died due to aortic dissection. The patient's son started showing tremors and has an intellectual disability and aggressive behavior. Additionally males of the family have large ears and mandibles. What condition is most likely affecting him? (Q845123)

A. Fragile X syndrome

B. Huntington's disease

C. Parkinson's disease

D. Alzheimer's disease

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A group of researchers studying genetic material noticed the presence of both wild-type and mutated mitochondrial genomes in different mitochondria of the same cells. What does this finding indicate? (Q845122)

A. Copy number variation

B. Heteroplasmy

C. Trinucleotide expansion

D. Imprinting

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following explains a single mutant gene leading to different end effects in sickle cell anemia? (Q845121)

A. Variable expressivity

B. Variable penetrance

C. Pleiotropy

D. Genetic heterogeneity

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 4-year-old girl is brought to the pediatrician's office for evaluation of developmental delay and seizures. She is very jovial, has microcephaly and is diagnosed with happy puppet syndrome. What is the genetic basis for this child's diagnosis? (Q845120)

A. Imprinting

B. Robertsonian translocation

C. Trinucleotide repeats

D. Monosomy

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 25-year-old male presents with brief, abrupt, involuntary movements of his arms and face for the last 2 months. A history of Huntington's disease in his father, who was diagnosed at 40 years of age and passed away at the age of 50, is found. What is the mechanism behind this patient's earlier presentation? (Q845119)

A. Anticipation

B. Mosaicism

C. Imprinting

D. Non-penetrance

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the following Disease Trinucleotide repeats a. Fragile X syndrome 1. CAG b. Friedreich ataxia 2. CTG c. Myotonic dystrophy 3. GAA d. Huntington disease 4. CGG (Q845118)

A. a-2, b-1, c-4, d-3

B. a-4, b-3, c-2, d-1

C. a-3, b-2, c-1, d-4

D. a-4, b-1, c-3, d-2

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following does not show the same pattern of inheritance as Leber hereditary optic neuropathy? (Q845117)

A. MERRF

B. MELAS

C. Fragile-X syndrome

D. NARP

See Answer in Part B → Q17

@Neet_pg_bot

Q18: What is the most likely diagnosis of a 5-year-old child with hyperphagia, delayed milestones, and growth retardation? (Q845116)

A. Angelman syndrome

B. Prader-Willi syndrome

C. Fragile X syndrome

D. Patau syndrome

See Answer in Part B → Q18

Q1: Which of the following chromosomal aberrations results in a change in the amount of genetic material? (Q879652)

A. Balanced reciprocal translocation

B. Inversion

C. Deletion

D. Paracentric inversion

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following chromosomal aberrations and mechanisms is correctly matched? (Q879646)

A. Trisomy – caused by deletion of a chromosome segment.

B. Balanced reciprocal translocation – inversion of a chromosome segment without change in gene copy number.

C. Isochromosome formation – fusion of chromosome ends after breaks.

D. Ring chromosome – breaks at both ends of a chromosome with fusion of the damaged ends.

See Answer in Part B → Q2

@Neet_pg_bot

Q3: In cytogenetic notation, what does Xp21.2 represent? (Q879644)

A. Long arm of the X chromosome, region 21, band 1, sub-band 2

B. Short arm of the X chromosome, region 2, band 1, sub-band 2

C. Short arm of the X chromosome, region 21, band 2, sub-band 1

D. Long arm of the X chromosome, region 1, band 2, sub-band 1

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old pregnant woman presents for prenatal screening due to advanced maternal age. She undergoes amniocentesis, and chromosome analysis is performed on the fetal cells to assess for chromosomal abnormalities . The results indicate Down syndrome. From the below chromosomal analysis, which of the following results is most likely associated with this case? (Q845185)

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Arrange the following steps of karyotyping in the correct sequence: Staining/Banding Sample collection Fixative Arrangement of chromosomes Arrest Interpretation (Q847860)

A. 2, 5, 3, 1, 4, 6

B. 2, 3, 5, 1, 4, 6

C. 1, 2, 3, 5, 4, 6

D. 3, 5, 2, 4, 1, 6

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A researcher wants to analyze gene expression levels in a sample using a PCR technique that quantifies the amount of DNA produced after each amplification cycle. Which type of PCR is most suitable for this purpose? (Q845190)

A. Real-time PCR

B. Nested PCR

C. Reverse Transcription PCR (RT-PCR)

D. Multiplex PCR

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 35-year-old female undergoes genetic testing due to a family history of Cystic Fibrosis. The test reveals a suspected deletion in the CFTR gene. Which technique is most suitable for confirming large deletions or duplications in the CFTR gene? (Q845189)

A. Polymerase Chain Reaction (PCR)

B. Comparative Genomic Hybridization (CGH)

C. Multiplex Ligation Dependent Probe Amplification (MLPA)

D. Sanger sequencing

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which technique is specifically designed to detect copy number variations (CNVs) in the genome by comparing patient DNA with a reference DNA sample? (Q845188)

A. PCR

B. Comparative Genomic Hybridization (CGH)

C. DNA sequencing

D. Southern blotting

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which steps are NOT involved in the Polymerase Chain Reaction (PCR) process? (Q845187)

A. Denaturation

B. Annealing

C. Amplification

D. Ligation

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In a cytogenetics laboratory, a technician is tasked with preparing chromosomes obtained from a patient's blood sample for analysis under a light microscope. The patient has been experiencing unexplained developmental delays, and the physician suspects a potential chromosomal abnormality. To aid in the identification and analysis of individual chromosomes, which technique will the technician employ to produce distinct banding patterns? (Q845186)

A. G-banding

B. C-banding

C. Q-banding

D. R-banding

See Answer in Part B → Q10

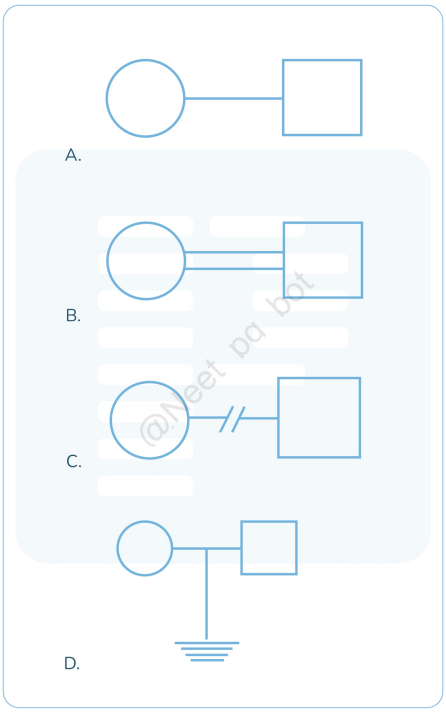
Q11: In a community where consanguineous marriages are prevalent, a distant relative couple decide to get married. They later have a child who presents with symptoms of anaemia and requires regular blood transfusions. Further investigation reveals that the child has beta-thalassemia, a genetic disorder prevalent in the region. Which of the following symbols can be anticipated in this couple, which is a risk factor for this disease? (Q845176)

A. A

B. B

C. C

D. D



See Answer in Part B → Q11

Q12: A 45-year-old woman has been newly diagnosed with breast cancer. Histopathological analysis of the tumour reveals invasive ductal carcinoma. Given the aggressive nature of her tumour, the oncologist wants to determine if the patient's cancer is HER2-positive. Which diagnostic method is most appropriate for detecting HER2/neu amplification in this patient? (Q845184)

A. Immunohistochemistry (IHC)

B. Fluorescence In Situ Hybridization (FISH)

C. Polymerase Chain Reaction (PCR)

D. Western Blotting

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements regarding gonadal mosaicism is true? (Q845183)

A. It is associated with autosomal recessive disorders.

B. It occurs due to a pre-zygotic mutation during early embryonic development.

C. It can be associated with osteogenesis imperfecta.

D. It follows the laws of Mendelian inheritance.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 25-year-old male has been complaining of painless, progressive central vision loss in both eyes over the past few months. He reports a family history of similar visual problems, with his maternal grandfather and maternal uncle experiencing sudden vision loss in their 20s. On examination, the ophthalmologist notes bilateral optic disc pallor and central scotomas on visual field testing. The patient denies any systemic symptoms or significant medical history. What is the inheritance pattern seen in this

condition? (Q845182)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Hairy pinna is associated with which type of Mendelian inheritance? (Q845181)

A. Autosomal dominant

B. X-linked recessive

C. Mitochondrial inheritance

D. Y-linked inheritance

See Answer in Part B → Q15

@Neet_pg_bot

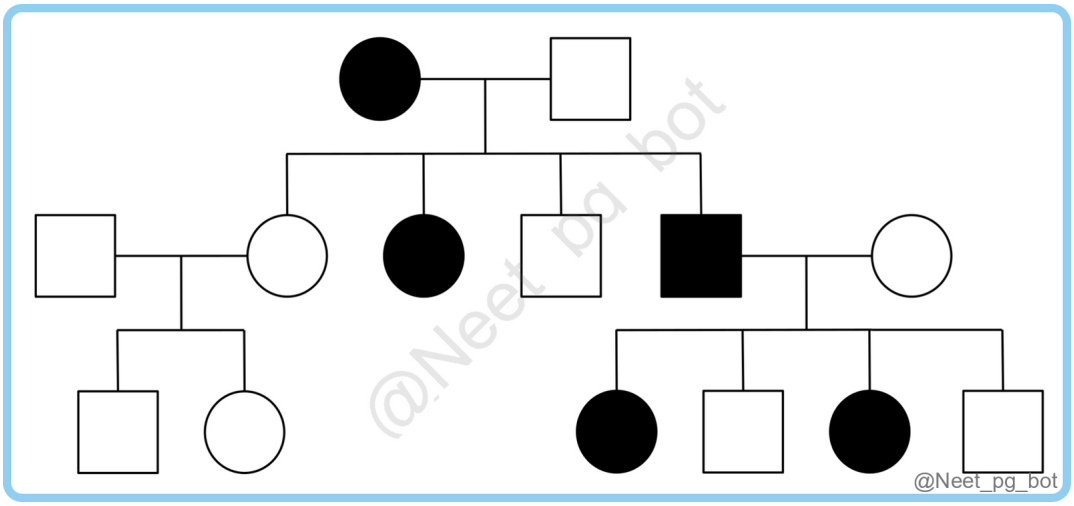
Q16: In which of the following conditions can you see this pedigree chart? (Q845180)

A. Fabry disease

B. Albinism

C. Reye syndrome

D. Alport syndrome



See Answer in Part B → Q16

@Neet_pg_bot

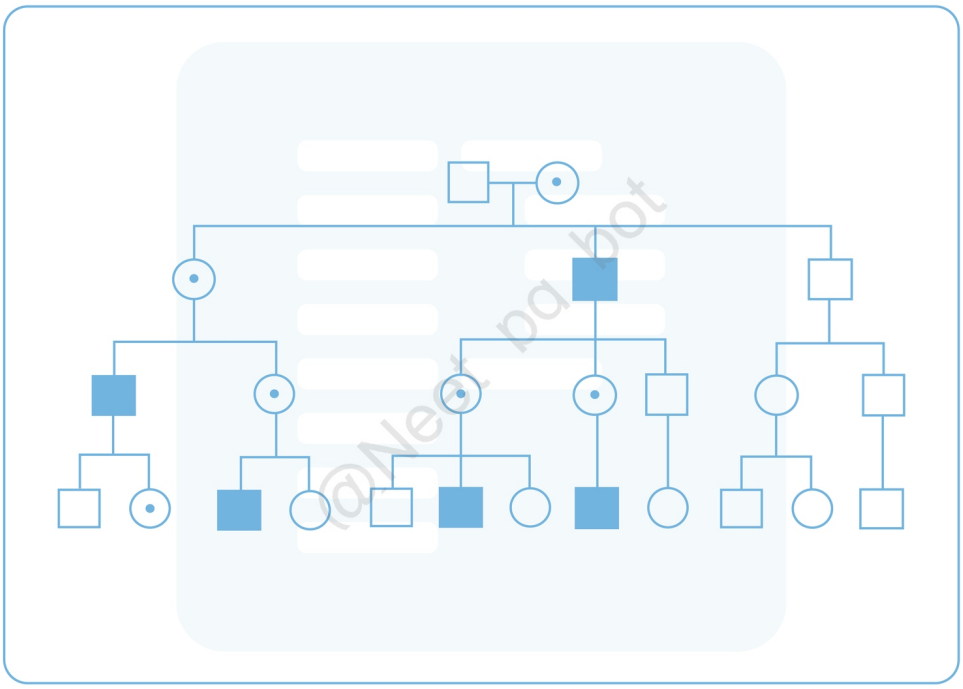
Q17: A 6-year-old boy presents to the clinic with complaints of muscle weakness and difficulty walking. His parents report a family history of similar symptoms. A detailed history was obtained, and a pedigree analysis was done, which is shown below. What is the most likely diagnosis and the inheritance pattern seen in this condition? (Q845179)

A. Dystonia myotonica, autosomal dominant

B. Dystonia myotonica, X-linked recessive

C. Duchenne muscular dystrophy, autosomal recessive

D. Duchenne muscular dystrophy, X-linked recessive



@Neet_pg_bot

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 10-year-old boy presents to the clinic with complaints of unsteady gait and frequent falls. Upon further inquiry, it is revealed that he has experienced progressive difficulty with coordination and balance over the past few years. His parents report a similar history in his older sister, who is now 15 years old. Interestingly, the parents are both asymptomatic, but the boy's maternal uncle was diagnosed with a similar condition in his late 20s. What is the most likely inheritance pattern seen in this condition? (Q845178)

A. Autosomal Dominant

B. X linked dominant

C. X linked recessive

D. Autosomal Recessive

See Answer in Part B → Q18

@Neet_pg_bot

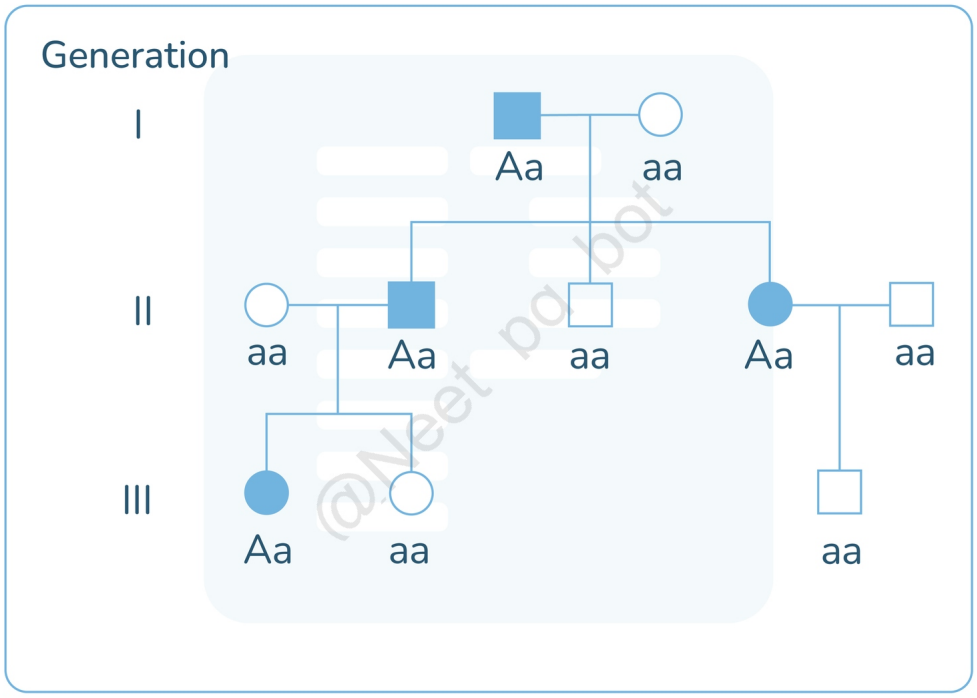
Q19: A couple seeks medical advice after their daughter presents with frequent nosebleeds and easy bruising. Lab investigations reveal prolonged bleeding time, prolonged aPTT, and a normal PT. A detailed history and a pedigree analysis were obtained, suspecting a genetic disorder. Based on the pedigree chart, what is this condition's most likely inheritance pattern? (Q845177)

A. Autosomal recessive

B. Autosomal dominant

C. X linked recessive

D. X linked dominant



@Neet_pg_bot

See Answer in Part B → Q19

@Neet_pg_bot

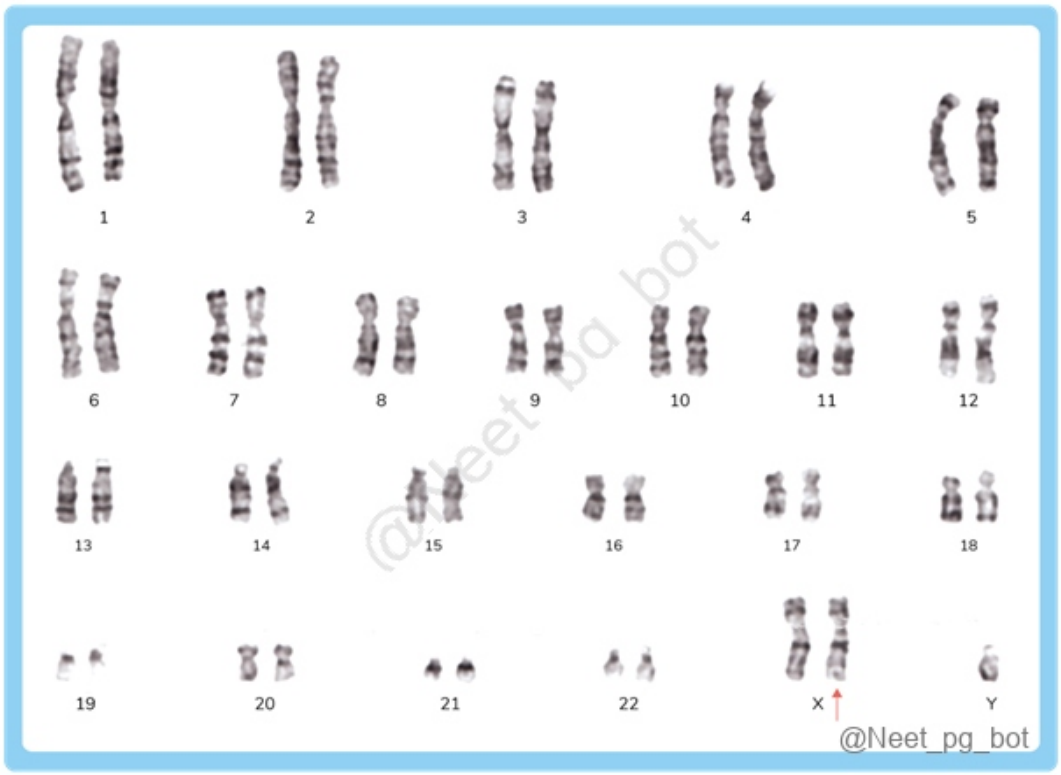
Q1: A karyotyping image is given below. What are the clinical features most likely to be expected in such patients? (Q856714)

A. Gynecomastia and long limbs

B. Flat occiput

C. Webbing of neck and lymphedema

D. Cleft lip and polydactyly



See Answer in Part B → Q1

@Neet_pg_bot

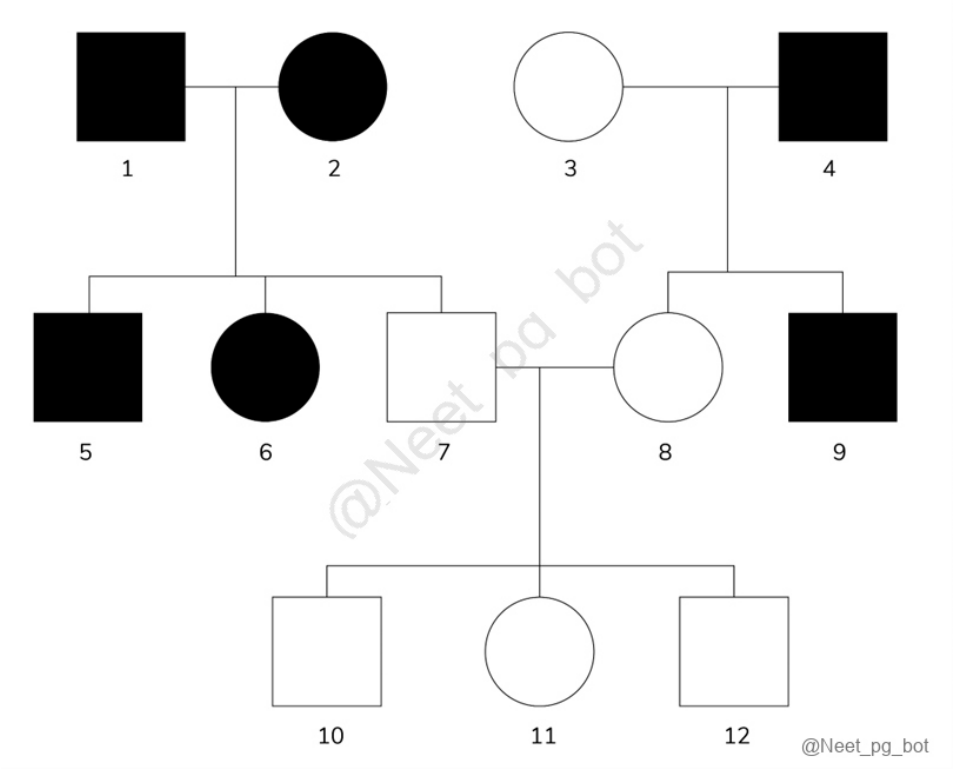
Q2: Identify the type of inheritance? (Q820500)

A. Autosomal Dominant

B. Autosomal Recessive

C. X-linked dominant

D. X-linked recessive



See Answer in Part B → Q2

@Neet_pg_bot

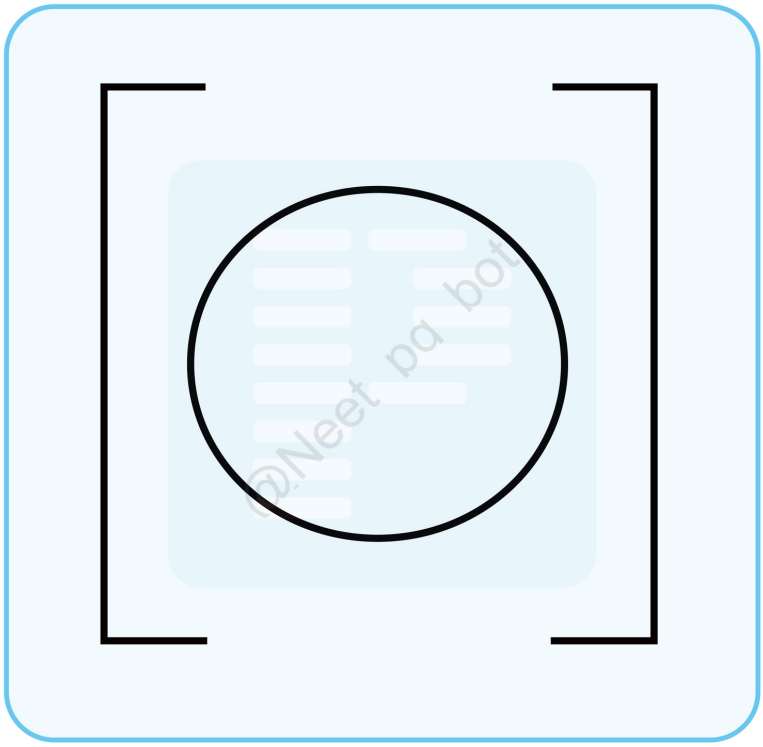
Q3: What is the status of the marked individual? (Q866668)

A. Adopted from another family

B. Has a disease of chronic origin

C. Curable disease

D. Twin



See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following statements regarding Mendelian (single-gene) disorders is correct? (Q855359)

A. X-linked dominant disorders are the most common type of Mendelian disorders.

B. Autosomal recessive disorders always appear in every generation of a family.

C. Y-linked disorders are extremely rare because few genes are present on the Y-chromosome.

D. In autosomal dominant disorders, two defective alleles are required for the disease to manifest.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 30-year-old pregnant woman who has the thalassemia trait visits the clinic for genetic counselling. Her husband is also confirmed to have the thalassemia trait. Considering their genetic background, what is the likelihood of their next offspring having thalassemia? (Q858074)

A. 100%

B. 50%

C. 75%

D. 25%

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following correctly represents the effect of the mutation causing sickle cell anaemia? (Q858078)

A. Glutamate by valine at the 6th position

B. Valine by glutamate at the 6th position

C. Glutamate by valine at the 5th position

D. Valine by glutamate at the 5th position

See Answer in Part B → Q6

@Neet_pg_bot

Q7: B cells express IgM and IgD antibodies at the same time. Which phenomenon is it due to? (Q856008)

A. Somatic hypermutation

B. Alternative RNA splicing

C. Affinity maturation

D. Allelic exclusion

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Differential expression of a gene depending upon the parent of origin is a feature of: (Q855071)

A. Gonadal mosaicism

B. Genomic imprinting

C. Anticipation

D. Incomplete penetrance

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following disorders is inherited in an X-linked dominant pattern? (Q855075)

A. Rett syndrome

B. Duchenne muscular dystrophy

C. Huntington’s disease

D. Tuberous sclerosis

See Answer in Part B → Q9

@Neet_pg_bot

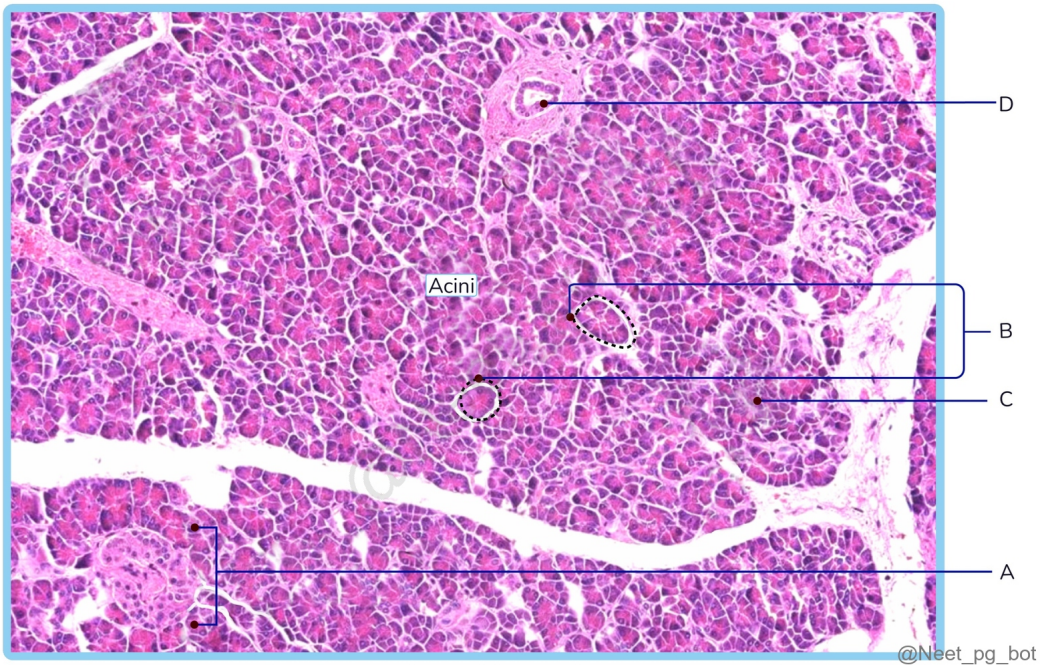
Q10: In cystic fibrosis, which of the following structures is affected in the pancreas? (Q855391)

A. A

B. B

C. C

D. D



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 30-year-old pregnant woman who has the thalassemia trait visits the clinic for genetic counseling. Her husband is also confirmed to have the thalassemia trait. Considering their genetic background, what is the likelihood of their next offspring having thalassemia? (Q820511)

A. 100%

B. 50%

C. 75%

D. 25%

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A girl presents with short stature, a webbed neck, thick calves, a shield-shaped chest, swelling of the ankle, and an increased carrying angle. What is the likely diagnosis? (Q856105)

A. Turner syndrome

B. Down syndrome

C. Patau syndrome

D. Edward syndrome

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements is correct about Huntington's chorea? (Q854894)

A. It is a trinucleotide repeat disorder

B. There is a loss of function type of mutation

C. There are abnormal length repeats of CUG

D. Abnormality is seen due to a defect in chromosome 6

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Premature ageing in Werner syndrome is due to: (Q858514)

A. Increased telomerase activity

B. Defects in DNA helicase

C. Increase in length of telomere due to decrease in telomerase activity

D. Decreased telomerase activity

See Answer in Part B → Q14

@Neet_pg_bot

Q15: What is the mode of inheritance in a patient suffering from colour blindness? (Q859300)

A. AD

B. AR

C. XLR

D. XLD

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A female is heterozygous for an autosomal recessive mitochondrial disorder. What does this involve? (Q879194)

A. Skeletal muscle and immune system

B. Skeletal muscle and cardiac muscle

C. Skeletal muscle and neural tissue

D. Gastric and respiratory tissue

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 3-year-old child presents with unilateral proptosis and leukocoria. Histopathology demonstrates Flexner–Wintersteiner rosettes. Regarding this condition, which of the following statements is false? It is always unilateral Called the guardian of the genome The RB protein is hypophosphorylated in the inactive state Oncogenesis is due to a loss-of-function mutation (Q879199)

A. 1,2,3

B. 1,2,3,4

C. 3,4

D. 2,3

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements regarding Gaucher disease are correct? Enzyme defect: Sphingomyelinase Enzyme defect: β-glucocerebrosidase Presence of foamy macrophages Macrophages exhibit a “crumpled tissue paper” appearance (Q879204)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 2, 4

D. 1, 3, 4

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What are the steps involved in the polymerase chain reaction (PCR)? (Q879217)

A. Denaturation - Annealing - Extension

B. Denaturation - Annealing - Extension - Hybridization

C. Annealing - Extension - Denaturation

D. Extension - Denaturation - Annealing

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A boy with karyotype 46,XY del(15)(q11–13) presents with obesity and elevated ghrelin levels. What is the most likely diagnosis? (Q879225)

A. Prader-Willi syndrome

B. Angelman syndrome

C. Cri du chat syndrome

D. Fragile X syndrome

See Answer in Part B → Q20

@Neet_pg_bot

Q21: An adult tall male presents with subluxation of the lens, long arm span, pectus excavatum, and cardiac abnormalities. What is the most likely protein found to be defective? (Q844234)

A. Elastin

B. Collagen

C. Fibrillin

D. Laminin

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 25-year-old man presents with headaches, visual disturbances, and hypertension. MRI brain shows a cerebellar hemangioblastoma, and abdominal imaging reveals multiple cysts in the kidneys along with a solid renal mass suggestive of renal cell carcinoma. His father had similar findings and died from a brain tumor in his 40s.Which of the following chromosomal abnormalities is most likely associated with his condition? (Q866733)

A. Deletion on chromosome 13q

B. Deletion on chromosome 17p

C. Deletion on chromosome 3p

D. Trisomy of chromosome 12

See Answer in Part B → Q22

@Neet_pg_bot

Q23: FBN1 gene mutation is seen in which of the following genetic disorders? (Q866750)

A. Ehlers-Danlos syndrome

B. Marfan syndrome

C. Homocystinuria

D. von Hippel-Lindau syndrome

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is not an aneuploidy? (Q865426)

A. Bloom syndrome

B. Trisomy 13

C. Trisomy 21

D. Klinefelter syndrome

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A lymphoma characterised by the presence of centrocytes and centroblasts, along with BCL2 positivity and CD10 expression, is most commonly associated with

which chromosomal translocation? (Q866357)

A. t(2;5)

B. t(8;14)

C. t(14;18)

D. t(11;14)

See Answer in Part B → Q25

@Neet_pg_bot

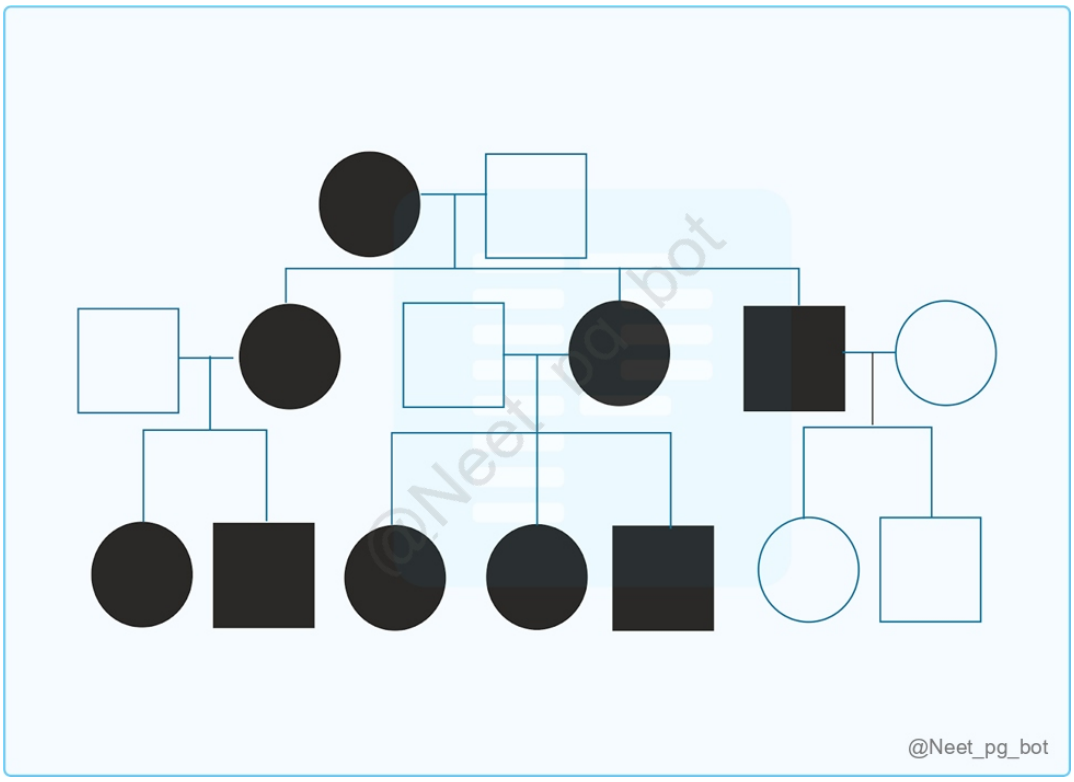
Q26: Which of the following diseases exhibits the inheritance pattern shown? (Q866378)

A. Kearns-Sayre syndrome

B. Williams syndrome

C. Achondroplasia

D. Cystic fibrosis



See Answer in Part B → Q26

@Neet_pg_bot

Q27: Match the following with the appropriate disorder. A. Autosomal recessive Kennedy disease B. Mitochondrial 2. Duchenne's muscular dystrophy C. X-linked recessive 3. Leber's disease D. Trinucleotide repeats 4. Cystic fibrosis (Q853376)

A. A-4, B-3, C-1, D-2

B. A-4, B-3, C-2, D-1

C. A-2, B-1, C-3, D-4

D. A-1, B-2, C-4, D-3

See Answer in Part B → Q27

@Neet_pg_bot

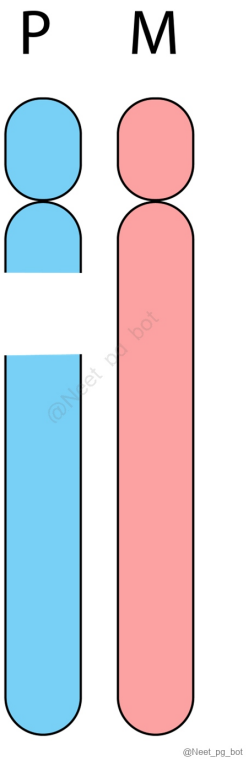
Q28: Identify the syndrome associated with the following chromosomal pattern on chromosome number 15 : (Q843980)

A. Angelman syndrome

B. Prader-Willi syndrome

C. Rett syndrome

D. Cri-du-chat syndrome



See Answer in Part B → Q28

@Neet_pg_bot

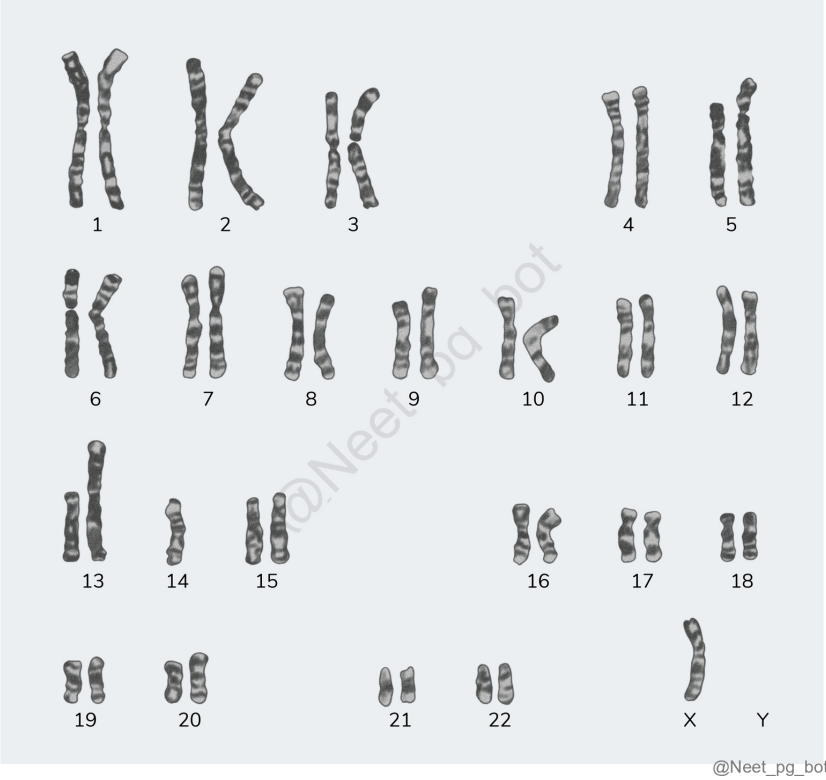
Q29: A 23-year-old female with a height of 4 feet has a karyotype, as shown in the image below. Which of the following conditions is the most likely etiology? (Q844074)

A. Turner syndrome

B. Klinefelter syndrome

C. Mayer-Rokitansky-Küster-Hauser syndrome (MRKHS)

D. Edwards syndrome



See Answer in Part B → Q29

@Neet_pg_bot

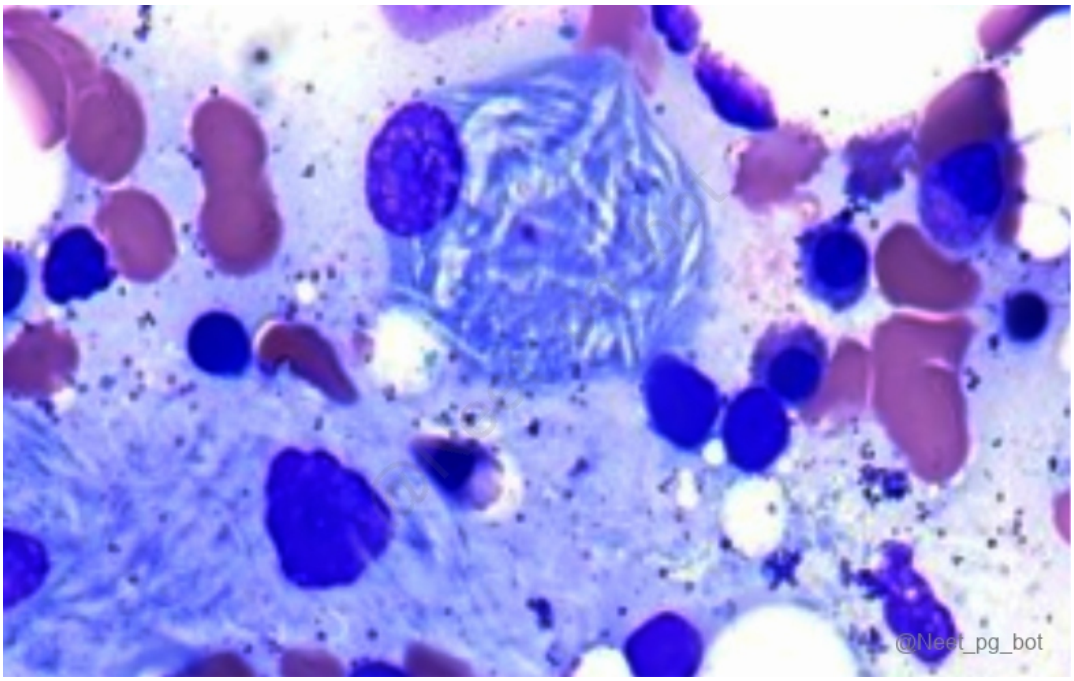
Q30: Identify the disease associated with the image provided: (Q844143)

A. Gaucher's disease

B. Tay-Sachs disease

C. Sandhoff's disease

D. Fabry's disease



See Answer in Part B → Q30

@Neet_pg_bot

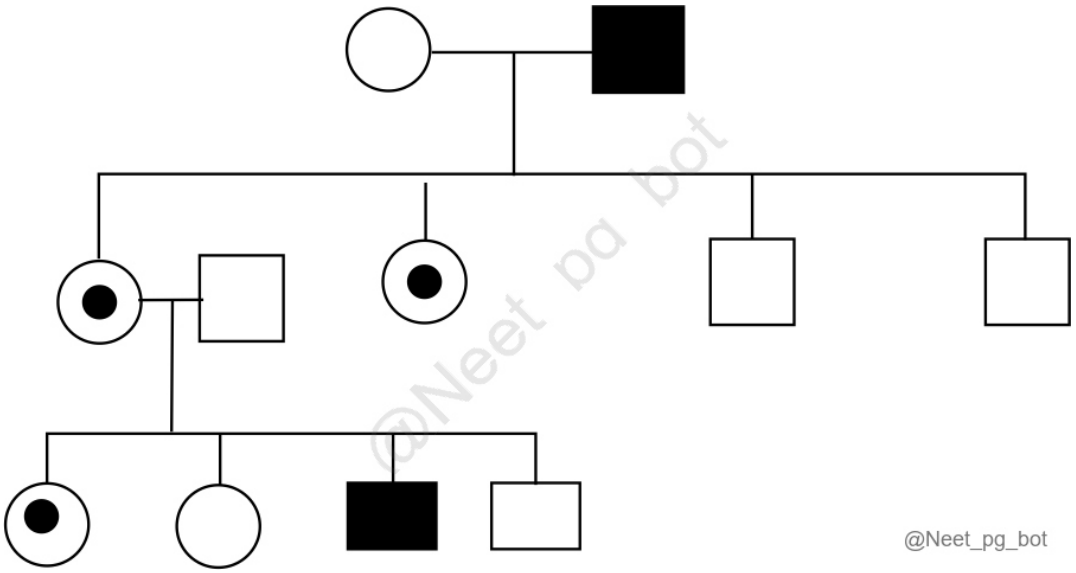
Q31: Which of the following diseases follows the mode of inheritance shown in the image provided? (Q844173)

A. Wiskott-Aldrich syndrome

B. Wilson's disease

C. Prader-Willi syndrome

D. Achondroplasia



See Answer in Part B → Q31

@Neet_pg_bot

Q32: The SRY gene is present on: (Q857449)

A. Y-chromosome short arm

B. Y-chromosome long arm

C. X-chromosome short arm

D. X-chromosome long arm

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which mutation is linked to the Philadelphia chromosome? (Q860544)

A. Inversion

B. Deletion

C. Reciprocal translocation

D. Insertion

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A teenager was brought to the OPD with complaints of delayed fertility and primary amenorrhea. Physical examination reveals a webbed neck and widely spaced nipples. Which karyotype is associated with a given condition? (Q860555)

A. 45, X

B. 47, XXY

C. 47, XXX

D. 47, XYY

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which of the following is not a feature of G6PD deficiency? (Q840016)

A. Males and females are equally affected

B. Oxidative stress

C. Absence of NADPH

D. Presence of Heinz's bodies

See Answer in Part B → Q35

@Neet_pg_bot

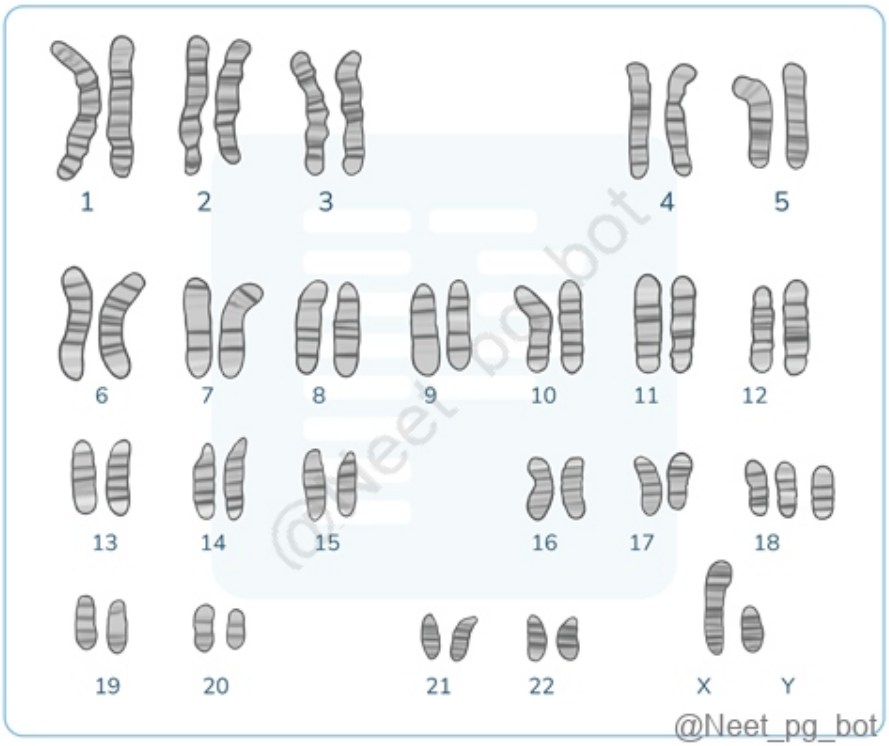
Q36: A child with a strawberry skull, mental retardation, and the given karyotype suggests which diagnosis? (Q860199)

A. Patau syndrome

B. Edward syndrome

C. Prader-Willi syndrome

D. Angelman syndrome



See Answer in Part B → Q36

@Neet_pg_bot

Q37: All of the following are used to detect abnormal gene sequences, except? (Q857421)

A. FISH

B. RFLP analysis

C. Pyrosequencing

D. Flow cytometry

See Answer in Part B → Q37

@Neet_pg_bot

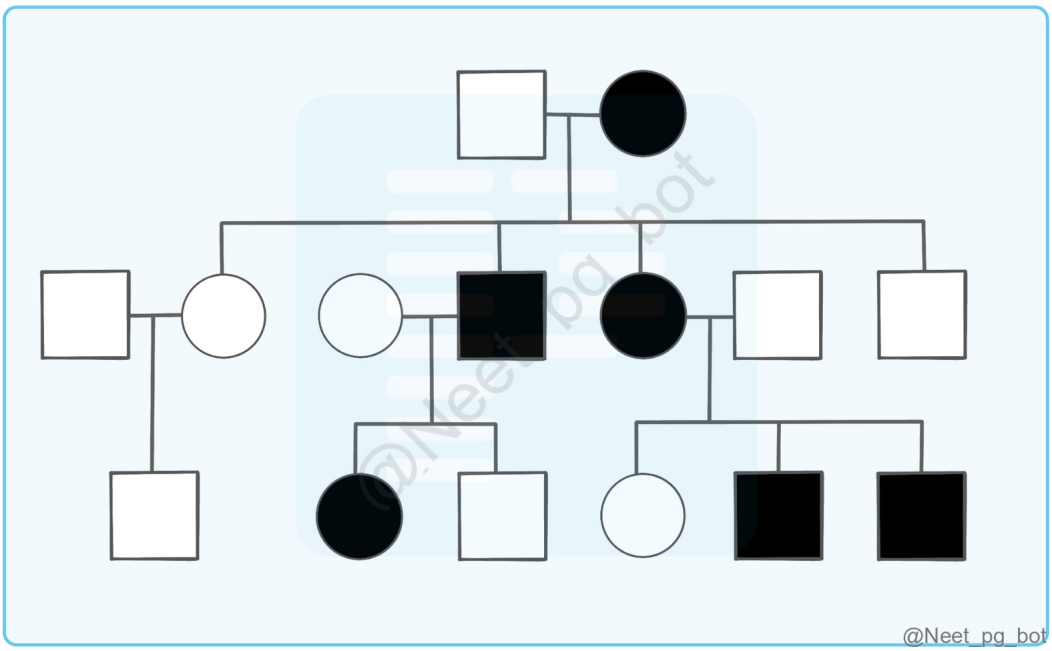
Q38: What is the interpretation of the given pedigree chart? (Q857425)

A. Incomplete penetrance

B. Autosomal dominant

C. Autosomal recessive

D. Pseudo-dominance



See Answer in Part B → Q38

@Neet_pg_bot

Q39: Match the following genetic abnormalities with their disorders. A. Trinucleotide repeat Patau syndrome B. Trisomy 18 2. Huntington C. Trisomy 13 3. Sickle cell anemia D. Hb beta chain Glu 4. Edward syndrome (Q857437)

A. A-1, B-3, D-4, D-2

B. A-1, B-2, C-3, D-4

C. A-2, B-4, C-1, D-3

D. A-2, B-1, C-4, D-3

See Answer in Part B → Q39

@Neet_pg_bot

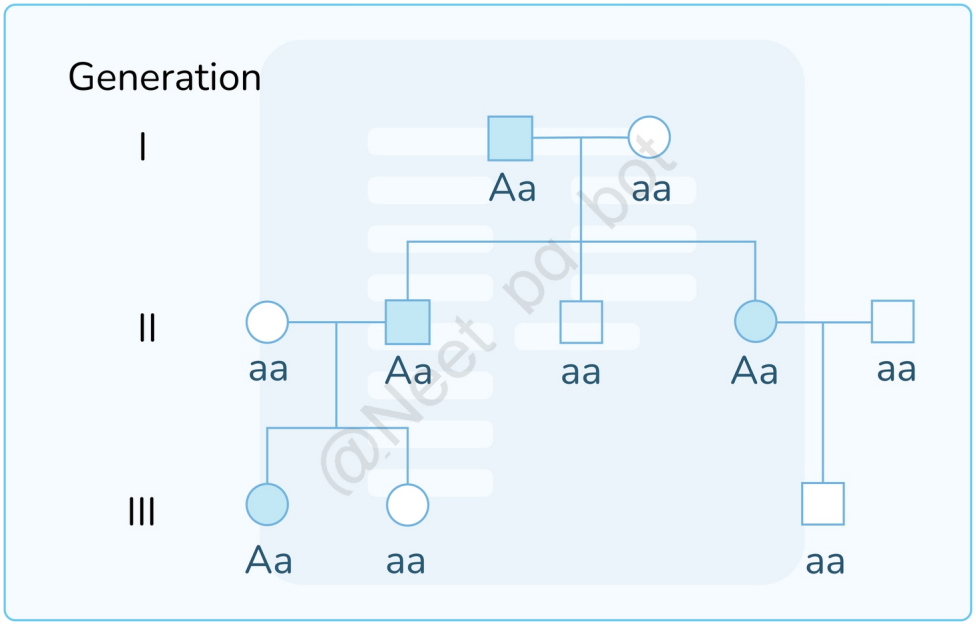
Q40: The family pedigree chart is given below. Identify the mode of inheritance of this condition. (Q854889)

A. Autosomal dominant

B. Autosomal recessive

C. X-linked dominant

D. X-linked recessive



@Neet_pg_bot

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A boy was diagnosed with a medical condition that is believed to have been passed down from his grandmother to his father, and now to him. What is the pattern of inheritance in this case ? (Q793641)

A. X-linked dominant

B. X-linked recessive

C. Autosomal dominant

D. Autosomal recessive

See Answer in Part B → Q41

@Neet_pg_bot

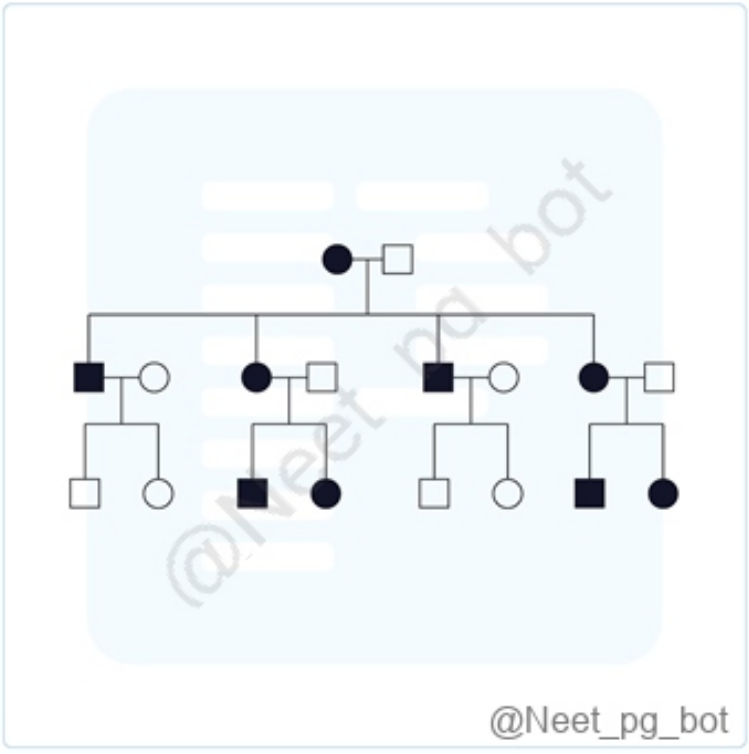
Q42: What does the given pedigree chart indicate? (Q860176)

A. Autosomal Dominant (AD)

B. Autosomal Recessive (AR)

C. Mitochondrial Disorder

D. X-linked Recessive (XLR)



See Answer in Part B → Q42

@Neet_pg_bot

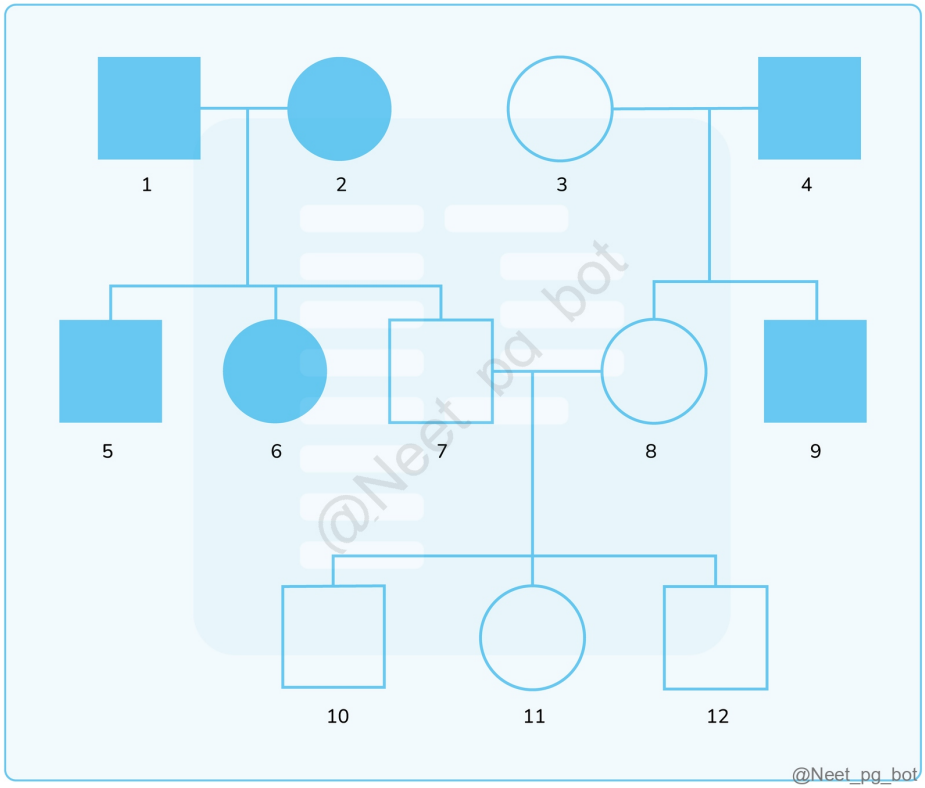
Q43: What is the interpretation of the given pedigree chart? (Q858065)

A. Autosomal dominant

B. Autosomal recessive

C. X-linked recessive

D. X-linked dominant



See Answer in Part B → Q43

@Neet_pg_bot

Q44: Match the columns A. Autosomal dominant 1. Duchenne muscular dystrophy B. X-linked recessive 2. Leber hereditary optic neuropathy C. Autosomal recessive 3. Cystic fibrosis D. Mitochondrial 4. Myotonic dystrophy (Q854706)

A. A-1, B-4, C-2, D-3

B. A-2, B-3, C-4, D-1

C. A-1, B-3, C-2, D-4

D. A-4, B-1, C-3, D-2

See Answer in Part B → Q44

Q1: A biopsy from a rapidly enlarging thigh mass in a 35-year-old man reveals a malignant tumor composed of spindle-shaped cells arising from mesenchymal tissue. Which of the following is the most appropriate designation for this neoplasm? (Q879697)

A. Adenocarcinoma

B. Lymphoma

C. Sarcoma

D. Papilloma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following statements best characterizes a hamartoma? (Q879693)

A. Malignant neoplasm composed of immature, non-native cells

B. Disorganized but benign proliferation of mature, native cells within an organ

C. Developmental cyst always present from birth and never clonal

D. Metastatic lesion that reproduces the normal architecture of the tissue

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 4-year-old child presents with an abdominal mass. Biopsy shows a poorly differentiated neoplasm composed of uniform, undifferentiated cells with scant cytoplasm and hyperchromatic nuclei, giving a "small round blue cell" appearance. Which of the following tumors is not typically classified under the group of small round blue cell tumors of childhood?' (Q879691)

A. Neuroblastoma

B. Wilms tumor

C. Medulloblastoma

D. Hepatoblastoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following statements about adenomas is correct? (Q879679)

A. Adenoma refers only to benign epithelial tumors that form true glandular structures.

B. Adenoma can refer to benign epithelial tumors of glandular origin, even if they do not form glands

C. Adenoma is a term used for malignant tumors of glandular epithelium

D. Adenoma refers exclusively to tumors of the adrenal cortex

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 55-year-old patient is diagnosed with a tumor. Histopathology shows uncontrolled proliferation, invasion into adjacent structures, and the presence of cells with variable differentiation. Which of the following features is the most definitive indicator of malignancy in this tumor? (Q879673)

A. Presence of mitotic figures

B. Tissue of origin identifiable as epithelial

C. Ability to invade surrounding tissues

D. Formation of glandular patterns in some areas

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following types of cancer is least likely to exhibit distant metastasis? (Q845142)

A. Renal cell carcinoma

B. Melanoma

C. Basal cell carcinoma

D. Prostatic carcinoma

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is true regarding the Sentinel lymph node? (Q845146)

A. The first lymph node to receive metastasis from a secondary tumour.

B. Also helpful in identifying metastasis in Melanoma.

C. Commonly involved in skip metastasis

D. The presence of cancer cells indicates a good prognosis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following tumors do not follow lymphatic route of spread? (Q845145)

A. Rhabdomyosarcoma

B. Krukenberg tumor

C. Follicular thyroid carcinoma

D. Synovial sarcoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following tumours do not typically exhibit direct seeding of body cavities? (Q845144)

A. Pseudomyxoma peritonei

B. Gastric carcinoma

C. Hepatocellular carcinoma

D. Medulloblastoma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old female presents with a palpable lump in her left breast which is freely mobile and painless. A biopsy of the lump was performed, and a histopathological examination was done. Which feature from the biopsy report is most likely to differentiate between benign and malignant breast lesions? (Q845134)

A. Presence of well-defined glandular structures

B. Evidence of invasion into surrounding tissues

C. Low mitotic rate

D. Presence of fibrous stroma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following characteristics distinguishes hemangiomas from other benign tumors? (Q845141)

A. Rapid growth rate

B. Presence of extracellular matrix (ECM) deposited by stromal cells

C. Easily resected by excision

D. Unencapsulated

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following statements is/are True? The basement membrane remains intact in dysplasia. Dysplasia is always irreversible. Pleomorphism is observed in metaplasia. Myositis ossificans is an example of dysplasia. (Q845140)

A. 1, 3 and 4

B. 1 only

C. 2 and 4

D. 1, 2 and 3

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following features is not a characteristic of anaplasia? (Q845139)

A. Pleomorphism

B. Loss of polarity

C. Increased nuclear-to-cytoplasmic ratio

D. Intact basement membrane

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 55-year-old man presents with chronic heartburn and difficulty swallowing. Upon examination, the physician suspects gastroesophageal reflux disease (GERD) and orders an upper GI endoscopic biopsy, which reveals the presence of columnar epithelium in the lower oesophagus, replacing the normal squamous epithelium. Which of the following terms describes the observed cellular change? (Q845138)

A. Metaplasia

B. Dysplasia

C. Anaplasia

D. Desmoplasia

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 30-year-old female presents with pelvic pain and irregular menstrual cycles. She undergoes surgical resection of the mass, and histopathological examination reveals a tumour composed of mature tissues derived from multiple germ layers, including hair, teeth, and sebaceous material. Based on the histopathological findings described, which of the following tumours is the most likely diagnosis? (Q845137)

A. Teratoma

B. Serous cystadenoma

C. Mucinous cystadenoma

D. Granulosa cell tumour

See Answer in Part B → Q15

@Neet_pg_bot

Q16: What is the most likely diagnosis of a patient with a painless, slowly enlarging mass in the right parotid gland region that is well-defined and heterogeneous, with both epithelial and mesenchymal components present in the biopsy? (Q845136)

A. Pleomorphic adenoma

B. Mucoepidermoid carcinoma

C. Acinic cell carcinoma

D. Warthin tumour

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following tumour is of mesenchymal origin? (Q845135)

A. Adenoma

B. Papilloma

C. Seminoma

D. Leiomyoma

See Answer in Part B → Q17

Q1: Which of the following conditions is most likely associated with vinyl chloride exposure? (Q845149)

A. Hepatocellular carcinoma

B. Hepatic angiosarcoma

C. Cholangiocarcinoma

D. Focal nodular hyperplasia

See Answer in Part B → Q1

@Neet_pg_bot

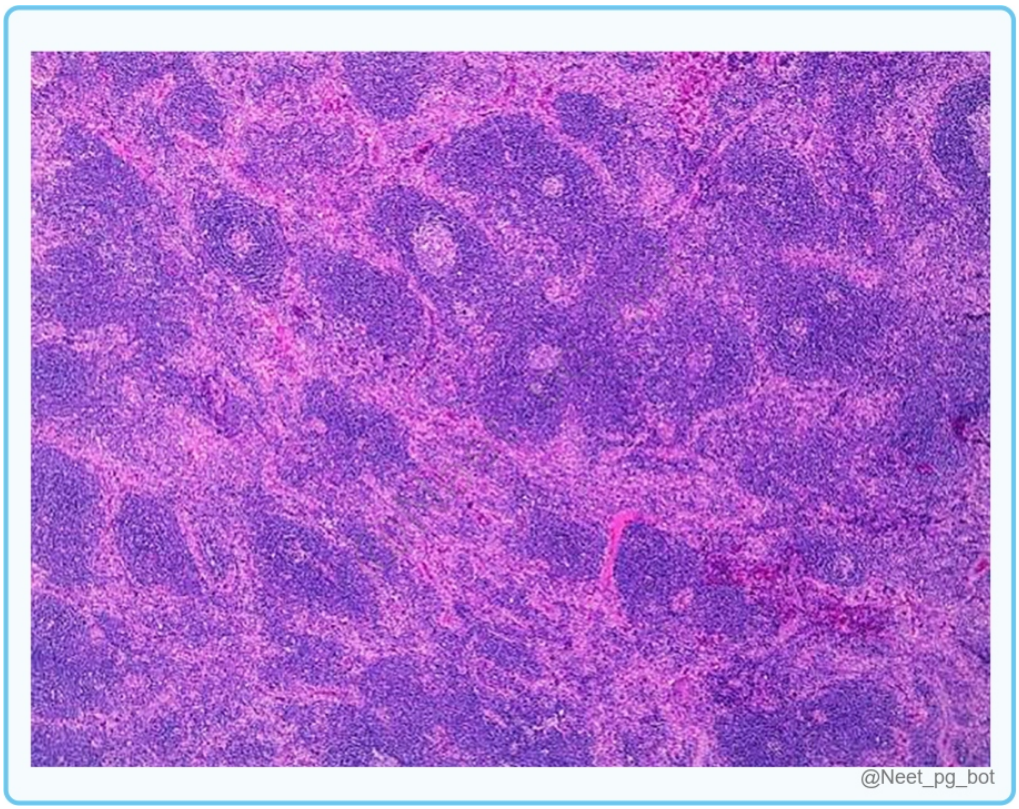
Q2: A 35-year-old man presents with painless enlarged lymph nodes in the neck and intermittent low-grade fever. Laboratory studies show normal peripheral blood counts. A biopsy of the lymph node reveals enlarged follicles with prominent vascular proliferation and increased plasma cells. Which of the following is the most likely diagnosis? (Q879869)

A. Angiolymphoma

B. Hodgkin’s lymphoma

C. IgG4-related disease

D. Castleman disease



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A teenager is diagnosed with infectious mononucleosis, confirmed by a positive Monospot (heterophile antibody) test. The virus responsible for this condition is also linked to several malignancies. Which of the following cancers is least likely to be associated with this viral infection? (Q879867)

A. Burkitt lymphoma

B. Hodgkin’s lymphoma

C. Nasopharyngeal carcinoma

D. Follicular lymphoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Infection with Human T-lymphotropic virus type 1 (HTLV-1) is most strongly associated with which of the following hematologic malignancies? (Q879844)

A. Adult T-cell leukemia/lymphoma

B. Enteropathy-associated T-cell lymphoma

C. Diffuse large B-cell lymphoma

D. B-cell lymphomas

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following cancers is least likely to be linked to an infectious etiology? (Q879840)

A. Burkitt lymphoma

B. Castleman’s disease

C. Adenocarcinoma of the lung

D. Primary effusion lymphoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 52-year-old construction worker with a history of chronic sun exposure presents for a routine skin examination. Which of the following skin conditions are considered UV-induced premalignant or malignant lesions? 1. Squamous cell carcinoma 2. Basal cell carcinoma 3. Seborrheic keratosis 4. Actinic keratosis (Q879835)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 3, 4

D. 1, 2, 4

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following compounds acts as a direct-acting carcinogen, meaning it does not require metabolic conversion to become carcinogenic? (Q879831)

A. Cyclophosphamide

B. Benzidine

C. 3-Methylcholanthrene

D. Dimethylaminoazobenzene

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following neoplasms is considered the prototype for studying the multi-step process of carcinogenesis? (Q879825)

A. Colon carcinoma

B. Melanoma

C. Thyroid carcinoma

D. Breast carcinoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following immune checkpoint interactions is correctly matched with its inhibitory effect on T-cell activation? (Q879809)

A. CTLA-4 binding to B7 molecules on APCs – prevents costimulatory signaling via CD28

B. PD-1 binding to PD-L1/PD-L2 on tumor cells – enhances T-cell cytotoxic activity

C. CD28 binding to B7 molecules on APCs – induces long-lived unresponsiveness of T cells

D. PD-1 blockade – reduces T-cell function in the tumor microenvironment

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Deletion of which microRNAs is most commonly associated with increased BCL2 expression in chronic lymphocytic leukemia? (Q879806)

A. miR-15 and miR-16

B. miR-155 and miR-21

C. miR-34a and miR-200

D. miR-17 and miR-92

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following genes is most frequently mutated in malignant rhabdoid tumors? (Q879801)

A. SNF5

B. ARID1A

C. PBRM1

D. DNMT3A

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which type of circulating blood cell shows the greatest resistance to radiation damage? (Q879733)

A. Lymphocytes

B. Granulocytes

C. Platelets

D. Erythrocytes

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following cancers is most strongly associated with excessive alcohol use? (Q879729)

A. Carcinoma of lip

B. Carcinoma of larynx

C. Carcinoma of pancreas

D. Carcinoma of stomach

See Answer in Part B → Q13

@Neet_pg_bot

Q14: The Notch signaling pathway in angiogenesis is mainly involved in? (Q879725)

A. ECM degradation

B. Vasodilation

C. Regulating sprouting and branching of new vessels

D. Endothelial cell proliferation

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 60-year-old man who has worked in the zinc mines presents to his urologist with urinary symptoms, including increased frequency, hesitancy, and nocturia. During a digital rectal examination, he is found to have an enlarged prostate with a palpable nodule. Which environmental exposure is most likely associated with his prostate cancer risk? (Q845148)

A. Zinc

B. Benzopyrene

C. Arsenic

D. Cadmium

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 16-year-old girl presents with a clear-cell vaginal tumour. Upon further inquiry, it was revealed that her mother has a history of taking medication during pregnancy to prevent premature labour. Which medication is most likely associated with the development of this tumour in the daughter? (Q845150)

A. DES (Diethylstilbestrol)

B. Thalidomide

C. Tamoxifen

D. Medroxyprogesterone acetate

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following is not an indirect-acting carcinogen? (Q845151)

A. Griseofulvin

B. Azo dyes

C. Nitrosoureas

D. Betel nuts

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following radiations is the most common cause of skin cancer? (Q845152)

A. UV-A radiation

B. UV-B radiation

C. UV-C radiation

D. UV-D radiation

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 55-year-old female radiology technician with 25 years of occupational exposure to diagnostic X-rays and fluoroscopy presents with a three-month history of increasing fatigue, unintentional weight loss, and frequent infections. Which cancer type is most likely associated with her occupational history? (Q845153)

A. Acute Myeloid Leukemia

B. Pancreatic cancer

C. Medullary thyroid cancer

D. Chronic Lymphocytic Leukemia

See Answer in Part B → Q19

@Neet_pg_bot

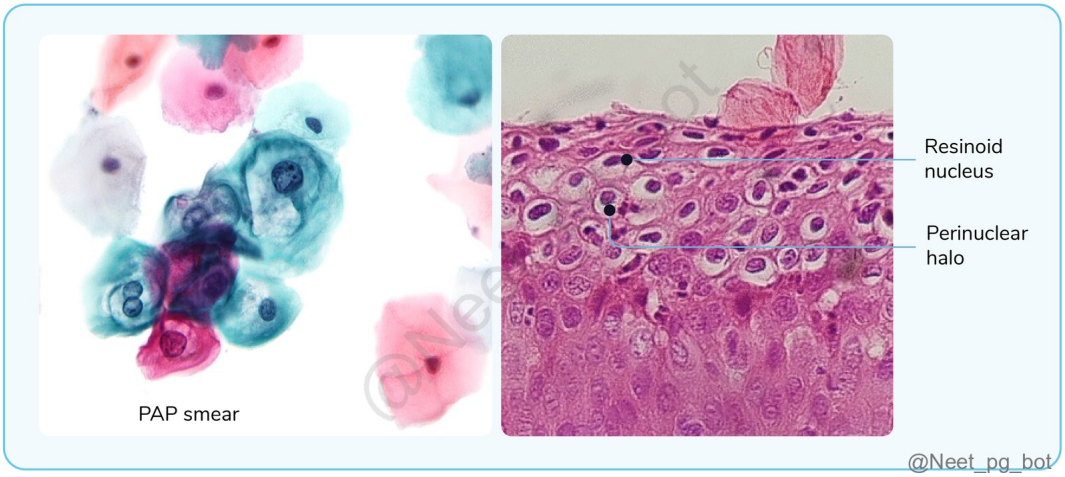
Q20: A 35-year-old woman presents for a routine gynaecological examination. Her Pap smear and biopsy reveals abnormal cells suggestive of cervical dysplasia. Further, HPV testing indicates the presence of specific HPV types associated with cervical cancer. Which HPV types are most commonly linked to an increased risk of cervical cancer in this patient? (Q845154)

A. Low-risk 6, 11

B. High-risk 6, 11

C. Low-risk 16, 18

D. High-risk 16, 18



See Answer in Part B → Q20

@Neet_pg_bot

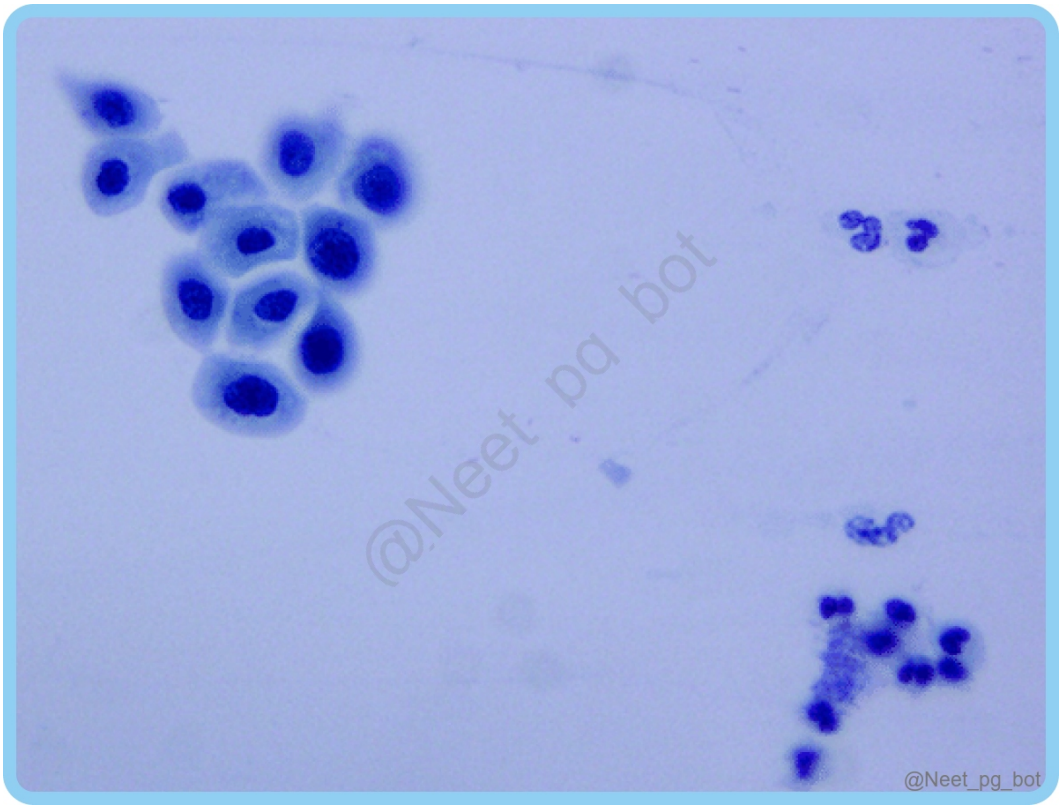
Q21: A 35-year-old woman with regular menstrual cycles undergoes routine Pap smear screening, which reveals a high-grade squamous intraepithelial lesion (HSIL) of the cervix. Further testing confirms infection with high-risk HPV type 16. Which of the following mechanisms regarding the oncogenic activity of E6 and E7 of HPV is correct? (Q845155)

A. E6 protein inhibits the degradation of p53.

B. E6 stimulates the expression of TERT.

C. E7 activates CDK inhibitors.

D. E7 can inactivate cyclins A and E



See Answer in Part B → Q21

@Neet_pg_bot

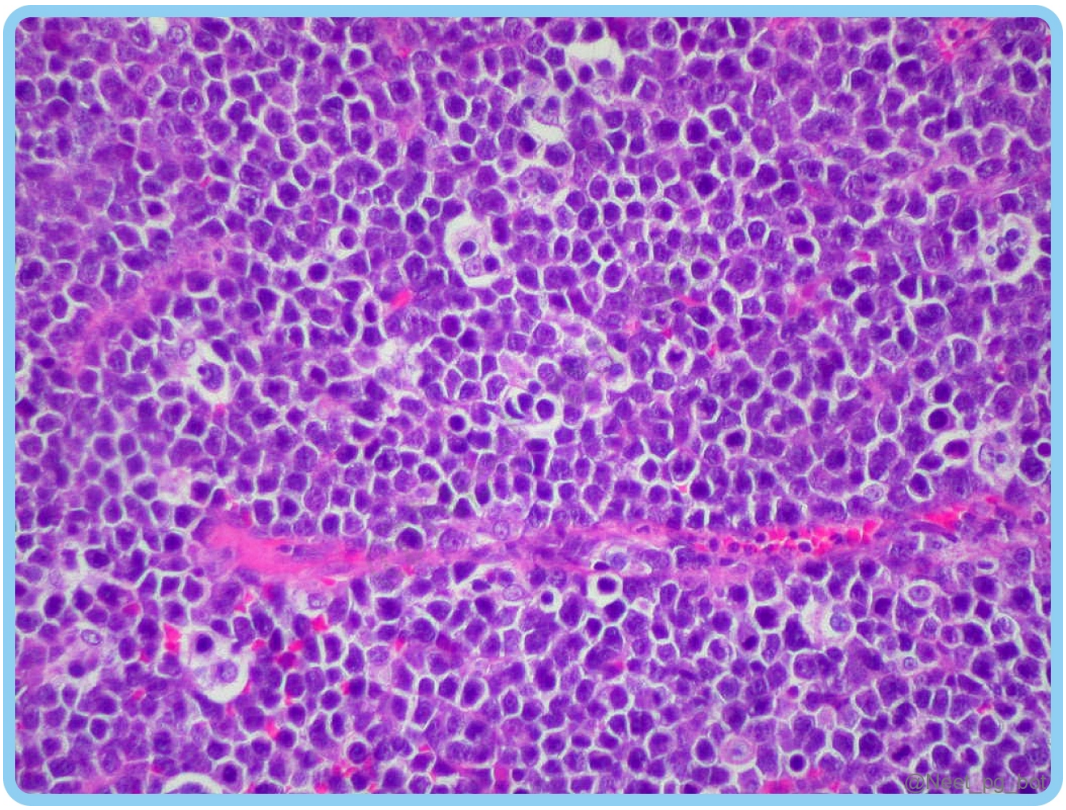
Q22: A 10-year-old girl presents with rapidly growing jaw swelling and pain. Further examination reveals bilateral enlargement of the mandible and maxilla. Biopsy suggests the presence of a starry-sky appearance as shown in the image. Which of the following infectious agents is most commonly associated with the pathogenesis of this malignancy? (Q845156)

A. EBV

B. HTLV-1

C. HHV-8

D. Aspergillus flavus



See Answer in Part B → Q22

@Neet_pg_bot

Q23: Infection with Helicobacter pylori is linked to the development of several gastrointestinal diseases. Which of the following conditions is least likely to be associated with H. pylori infection? (Q845158)

A. Peptic ulcer disease

B. Barrett’s esophagus

C. Gastric adenocarcinoma

D. Mucosa-associated lymphoid tissue (MALT) lymphoma

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Match the following carcinogens with the respective cancer risk 1. Azodyes a) Urothelial carcinoma of the bladder 2. Schistosoma haematobium b) AML & ALL 3. Radon c) Squamous cell carcinoma of the bladder 4. Benzene d) Squamous cell carcinoma of the lung (Q845159)

A. 1-a, 2-c, 3- d, 4-b

B. 1-a, 2-c, 3- b, 4-d

C. 1-c, 2-a, 3- d, 4-b

D. 1-c, 2-a, 3- b, 4-d

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 60-year-old man who has worked in the zinc mines presents to his urologist with urinary symptoms, including increased frequency, hesitancy, and nocturia. During a digital rectal examination, he is found to have an enlarged prostate with a palpable nodule. Which environmental exposure is most likely associated with his prostate cancer risk? (Q845484)

A. Benzene

B. Benzopyrene

C. Arsenic

D. Cadmium

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which of the following is not an indirect-acting carcinogen? (Q845487)

A. Griseofulvin

B. Azo dyes

C. Nitrosoureas

D. Betel nuts

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following conditions is most likely associated with vinyl chloride exposure? (Q845485)

A. Hepatocellular carcinoma

B. Hepatic angiosarcoma

C. Cholangiocarcinoma

D. Focal nodular hyperplasia

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 16-year-old girl presents with a clear-cell vaginal tumour. Upon further inquiry, it was revealed that her mother has a history of taking medication during pregnancy to prevent premature labour. Which medication is most likely associated with the development of this tumour in the daughter? (Q845486)

A. DES (Diethylstilbestrol)

B. Thalidomide

C. Tamoxifen

D. Medroxyprogesterone acetate

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Match the following carcinogens with the respective cancer risk: 1. Azodyes a) Urothelial carcinoma of the bladder 2. Schistosoma haematobium b) Adenocarcinoma of the lung 3. Radon c) Squamous cell carcinoma of the bladder 4. Asbestos d) Squamous cell carcinoma of the lung (Q845494)

A. 1-a, 2-c, 3- d, 4-b

B. 1-a, 2-c, 3- b, 4-d

C. 1-c, 2-a, 3- d, 4-b

D. 1-c, 2-a, 3- b, 4-d

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Which of the following statements regarding H. pylori infection and its association with malignancies is correct ? (Q845493)

A. Gastric lymphomas associated with H. pylori infection are primarily of B-cell origin.

B. H. pylori strains associated with gastric adenocarcinomas contain the cytotoxin-associated B gene.

C. VacA, a toxin from H. pylori, causes gastric cell apoptosis, reducing cancer risk.

D. MALT lymphomas associated with t(11;18) translocation respond to anti-H.Pylori therapy.

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 10-year-old girl presents with rapidly growing jaw swelling and pain. Further examination reveals bilateral enlargement of the mandible and maxilla. Biopsy suggests the presence of a starry-sky appearance. What is the characteristic chromosomal translocation associated with this tumor? (Q845492)

A. t(8;14)

B. t(15;17)

C. t(9;22)

D. t(11;14)

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 35-year-old woman with regular menstrual cycles undergoes routine Pap smear screening, which reveals a high-grade squamous intraepithelial lesion (HSIL) of the cervix. Further testing confirms infection with high-risk HPV type 16. Which of the following mechanisms regarding the oncogenic activity of E6 and E7 of HPV is correct? (Q845491)

A. E6 protein inhibits the degradation of p53.

B. E6 stimulates the expression of TERT.

C. E7 activates CDK inhibitors.

D. E7 can inactivate cyclins A and E.

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 35-year-old woman presents for a routine gynaecological examination. Her Pap smear and biopsy reveals abnormal cells suggestive of cervical dysplasia. Further, HPV testing indicates the presence of specific HPV types associated with cervical cancer. Which HPV types are most commonly linked to an increased risk of cervical cancer in this patient? (Q845490)

A. Low-risk 6, 11

B. High-risk 6, 11

C. Low-risk 16, 18

D. High-risk 16, 18

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 55-year-old female radiology technician with 25 years of occupational exposure to diagnostic X-rays and fluoroscopy presents with a three-month history of increasing fatigue, unintentional weight loss, and frequent infections. Which cancer type is most likely associated with her occupational history? (Q845489)

A. Acute Myeloid Leukemia

B. Pancreatic cancer

C. Medullary thyroid cancer

D. Chronic Lymphocytic Leukemia

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which of the following radiations is the most common cause of skin cancer? (Q845488)

A. UV-A radiation

B. UV-B radiation

C. UV-C radiation

D. UV-D radiation

See Answer in Part B → Q35

Q1: Which of the following best describes the change in the nuclear-to-cytoplasmic ratio seen in malignant cells compared to normal cells? (Q879702)

A. Decreased ratio due to abundant cytoplasm

B. Increased ratio due to larger nuclei and scant cytoplasm

C. No change; ratio remains constant across benign and malignant cells

D. Decreased ratio due to nuclear shrinkage (pyknosis)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following markers is not used to identify gastrointestinal stromal tumors (GISTs)? (Q879908)

A. KIT

B. SDH

C. PDGFRA

D. NRG-1

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is not classified as an oncofetal tumor marker? (Q879907)

A. Alpha-fetoprotein

B. Carcinoembryonic antigen

C. Prostate-specific antigen

D. Both A and B

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following tumor markers is most useful for diagnosing pheochromocytoma? (Q879906)

A. Calcitonin

B. Catecholamine

C. Alpha-fetoprotein

D. Carcinoembryonic antigen

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 48-year-old man develops recurrent, painful, red, tender nodules that appear and disappear on his arms and legs over several weeks. This clinical picture suggests migratory thrombophlebitis. Which of the following cancers is not commonly associated with this condition? (Q879904)

A. Uterine carcinoma

B. Pancreatic carcinoma

C. Bronchogenic carcinoma

D. Bladder carcinoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old man presents with headache, dizziness, and blurred vision. He has a ruddy complexion and mild hypertension. Labs show hemoglobin 19.2 g/dL and hematocrit 60%. Secondary polycythemia from ectopic erythropoietin is suspected. Which tumor is least likely to be responsible? (Q879901)

A. Melanoma

B. Renal cell carcinoma

C. Cerebellar hemangioma

D. Hepatocellular carcinoma

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Based on the image and clinical presentation of this 58-year-old obese female, which of the following tumors is not commonly associated with this dermatologic condition? (Q879896)

A. Gastric carcinoma

B. Bladder carcinoma

C. Uterine carcinoma

D. Thymoma

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old patient presents with generalized fatigue, muscle weakness, and bone pain. Laboratory tests reveal a serum calcium level of 14.2 mg/dL. Which type of lung cancer is most commonly associated with this hypercalcemia? (Q879874)

A. Squamous cell carcinoma

B. Small cell carcinoma

C. Adenocarcinoma

D. Large cell carcinoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which subtype of acute myeloid leukemia is characteristically linked to disseminated intravascular coagulation (DIC) as a paraneoplastic syndrome?

(Q879871)

A. AML minimally differentiated

B. Acute promyelocytic leukemia

C. Acute myelomonocytic leukemia

D. Acute megakaryoblastic leukemia

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Choose the correct option regarding tumor invasion and metastasis: Assertion (A): All tumors that show invasive properties eventually metastasize. Reason (R): The ability to invade allows tumor cells to penetrate blood vessels or lymphatics, facilitating spread to distant organs. (Q879708)

A. Both A and R are true, and R correctly explains A

B. Both A and R are true, but R does not explain A

C. A is false, but R is true

D. A is true, but R is false

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A biopsy from a liver mass in a 60-year-old man reveals clusters of malignant epithelial cells forming irregular glands. The surrounding liver architecture is compressed but not invaded by native hepatocytes. Which histological feature most strongly suggests that this mass represents a metastatic carcinoma rather than a primary liver tumor? (Q879705)

A. Presence of malignant epithelial cells with atypia

B. Lack of normal organ-specific architecture within the tumor

C. Presence of mitotic figures in tumor cells

D. Hyperchromatic nuclei with increased nuclear-to-cytoplasmic ratio

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is used in immunohistochemical (IHC) staining as a chromogen to diagnose tumours of unknown origin? (Q845495)

A. Diaminobenzidine

B. Congo Red

C. Masson's Trichrome

D. Mucicarmine

See Answer in Part B → Q12

@Neet_pg_bot

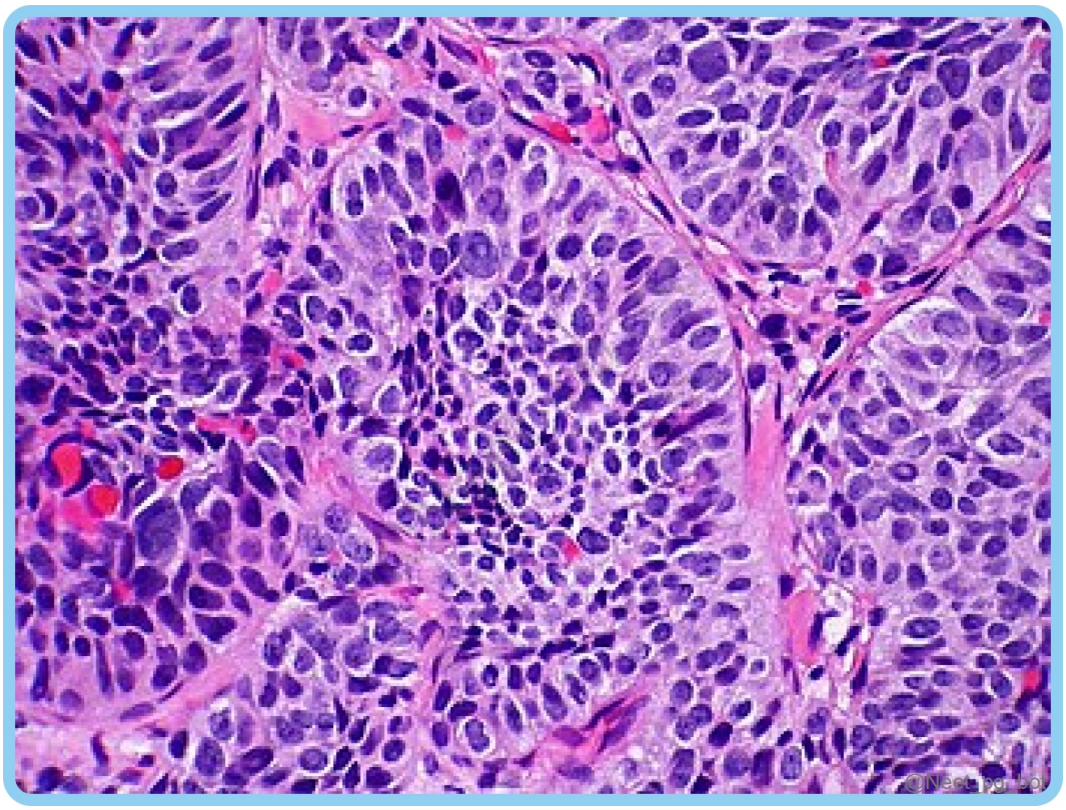
Q13: An appendix specimen, whose HPE is shown below, had a 2 cm submucosal nodule identified. Electron microscopy showed numerous neurosecretory granules in the cytoplasm. Twenty-four-hour urine analysis showed an elevation of 5-hydroxy indoleacetic acid (5-HIAA). Which of the following would not be seen in this condition? (Q845506)

A. Flushing

B. Diarrhea

C. Valvular heart disease

D. Bronchodilation



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following paraneoplastic syndrome is not associated with lung cancer? (Q845504)

A. Dermatomyositis

B. Acanthosis nigricans

C. Myasthenia

D. Red cell aplasia

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 60-year-old male was diagnosed with a lung malignancy two months ago. He now came with complaints of malaise, abdominal pain, bone pain, lethargy, and confusion. The intern suspects a condition related to lung cancer and decides to send a blood test. Which of the following would be the appropriate test? (Q845503)

A. Erythropoietin

B. Adrenocorticotrophic hormone

C. Parathyroid hormone-related protein

D. Antidiuretic hormone

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the given neoplasias with their respective immunohistochemistry markers. 1. Carcinoma A. S100 2. Sarcoma B. Leucocyte common antigen 3. Lymphoma C. Cytokeratin 4. Melanoma D. Vimentin (Q845502)

A. 1-C, 2-A, 3-B, 4-D

B. 1-A, 2-C, 3-B, 4-D

C. 1-C, 2-D, 3-B, 4-A

D. 1-A, 2-D, 3-B, 4-C

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 45-year-old female presents with a breast lump. On biopsy, the tissue shows anaplastic cells without any differentiation. Immunohistochemistry (IHC) staining is performed to characterise the tumour further. Which marker would be most appropriate to confirm the epithelial origin of the tumour cells in breast cancer? (Q845500)

A. CD20

B. p63

C. TTF-1

D. CK7

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following conditions is FNAC helpful in establishing diagnosis ? (Q845499)

A. Follicular adenoma of the thyroid

B. Testicular cancer

C. Hydatid cyst

D. Medullary thyroid carcinoma

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What needle size is typically employed for Fine Needle Aspiration Cytology (FNAC) procedures? (Q845498)

A. 18-gauge needle

B. 22-gauge needle

C. 25-gauge needle

D. 30-gauge needle

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is used to determine treatment response in patients with colorectal cancer? (Q845497)

A. Alpha-fetoprotein

B. Carcinoembryonic antigen

C. Human Chorionic Gonadotropin

D. Calcitonin

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following is a marker for breast cancer? (Q845496)

A. CA-19-9

B. CA-125

C. CA-15-3

D. β - HCG

See Answer in Part B → Q21

Q1: What is the consequence of the RB protein being in its hypophosphorylated (active) state? (Q879748)

A. Cell cycle is halted at the G2 phase

B. Cell cycle is arrested at the G1 phase

C. RB protein’s phosphorylation status does not impact the cell cycle

D. Cell cycle continues normally, leading to cell division

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following disorders is unrelated to defects in homologous recombination-mediated DNA repair pathways? (Q879792)

A. Bloom syndrome

B. Ataxia-telangiectasia

C. Fanconi anemia

D. Li-Fraumeni syndrome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following oncogenes, when mutated, can give rise to neoantigens recognized by the immune system? (Q879786)

A. KRAS

B. TP53

C. CDKN2A

D. PTEN

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following changes does not convert a proto-oncogene into an oncogene? (Q879784)

A. Gene amplification

B. Point mutation

C. Chromosomal translocation

D. Gene deletion

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is a receptor tyrosine kinase, rather than a nonreceptor tyrosine kinase? (Q879766)

A. ABL

B. BCR-ABL

C. JAK2

D. EGFR

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which gene plays a key role in promoting epithelial-mesenchymal transition (EMT) in carcinomas? (Q879764)

A. E-cadherin

B. SNAIL

C. Vimentin

D. Smooth muscle actin

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following mechanisms is commonly used by cancer cells to evade apoptosis? (Q879763)

A. Overexpression of pro-apoptotic BAX and BAK proteins

B. Loss of TP53 function and overexpression of anti-apoptotic BCL2 family proteins

C. Increased activation of caspase-9

D. Enhanced release of cytochrome c from mitochondria

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements about BRCA mutations is correct? (Q879762)

A. BRCA1 and BRCA2 are involved in DNA repair via homologous recombination

B. BRCA proteins primarily use nonhomologous end-joining (NHEJ) for DNA repair

C. BRCA1 mutations are not associated with ovarian cancer

D. BRCA2 mutations cause only breast cancer

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old man presents with progressive abdominal discomfort and weight loss. Endoscopy reveals a gastric mass, and biopsy confirms diffuse gastric carcinoma. Which protein responsible for maintaining cell-to-cell adhesion and inhibiting cell motility is most likely mutated in this condition? (Q879760)

A. p63

B. p53

C. E-cadherin

D. Integrin

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 19-year-old woman presents with recurrent episodes of abdominal pain and melena. On physical examination, she has dark-blue to brown macules on her lips and buccal mucosa. Genetic testing reveals germline loss-of-function mutations in the STK11 gene. What is the most likely diagnosis? (Q879758)

A. HNPCC

B. Gorlin syndrome

C. von Hippel-Lindau syndrome

D. Peutz-Jeghers syndrome

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is the etiology of Gorlin syndrome? (Q879757)

A. Germline loss-of-function mutation in STK11

B. Germline missense mutation in SDHB

C. Germline loss-of-function mutation in WT1

D. Germline loss-of-function mutation in PTCH1

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 25-year-old woman experiences progressive balance issues and bilateral sensorineural hearing loss. Imaging reveals tumors affecting both vestibular nerves. This clinical picture is characteristic of a hereditary condition involving a mutation in which protein that plays a role in linking the cytoskeleton to the cell membrane? (Q879756)

A. Neurofibromin

B. Merlin

C. PATCHED

D. RB protein

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 35-year-old woman presents with multiple trichilemmomas on her face, a history of breast cancer, and the recent discovery of endometrial hyperplasia. She also reports that her father had colon polyps. Germline loss-of-function mutations of which gene are most likely responsible for her condition? (Q879753)

A. CDKN2A

B. SMAD2

C. APC

D. PTEN

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following statements about p53 is true? (Q879752)

A. p53 is rarely altered in cancers

B. p53 is induced by DNA damage

C. p53 promotes cell cycle progression by downregulating p21

D. p53 inhibits apoptosis by suppressing BAX

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements about Knudson's two-hit hypothesis for retinoblastoma is true? (Q879746)

A. Both familial and sporadic cases require two somatic mutations in the same retinoblast

B. In familial cases, one defective RB allele is inherited in the germline, and the second hit occurs somatically

C. Sporadic cases are caused by inheritance of one defective RB allele and a spontaneous second hit

D. Only one mutation is sufficient to cause retinoblastoma in any case

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following cancers is typically associated with a translocation involving cyclin D1? (Q879744)

A. Chronic myeloid leukemia

B. Non-Hodgkin's lymphoma

C. Acute lymphoblastic leukemia

D. Mantle cell lymphoma

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which type of proteins are produced as a result of MYC gene expression? (Q879741)

A. Proteins that control the cell division cycle

B. Proteins that regulate gene activity within the nucleus

C. Proteins involved in transmitting signals inside the cell

D. Proteins that act as receptors for growth-promoting signals

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which gene mutation is associated with the development of astrocytoma? (Q845511)

A. PDGFB

B. HST1

C. FGF3

D. HGF

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following genetic events best describes the carcinogenesis mechanism in a patient with retinoblastoma? (Q876253)

A. Balanced translocation

B. Expansion of trinucleotide repeat

C. Gene amplification

D. Loss of heterozygosity

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following mechanisms is not employed by tumour cells to evade the host immune system? (Q845522)

A. Selective outgrowth of the antigen-negative variants

B. Reduced expression of MHC molecules

C. Secretion of immunosuppressive factors

D. Enhanced antigen presentation to promote T cell activation

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following is true regarding the Warburg effect? (Q845521)

A. Cancer cells primarily rely on oxidative phosphorylation for ATP production.

B. It involves a shift from glycolysis to oxidative phosphorylation in cancer cells.

C. Cancer cells exhibit increased glucose uptake and preferentially metabolise glucose via glycolysis, even in the presence of oxygen.

D. It is characterised by decreased glucose uptake and utilisation by cancer cells.

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following statements are true regarding Lynch syndrome? (Q845519)

A. It is autosomal recessive in inheritance.

B. It is also known as hereditary breast and ovarian cancer syndrome.

C. It is caused by mutations in genes involved in nonhomologous end-joining repair.

D. Amsterdam II criteria are used for diagnosis.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following diseases is associated with a defect in homologous DNA repair? (Q845517)

A. Trichothiodystrophy

B. Fanconi anemia

C. Endometrial carcinoma

D. Wermer syndrome

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 9-year-old child presents with multiple freckle-like dark spots on sun-exposed areas such as the face and arms. The child complains of discomfort and pain upon exposure to sunlight, and there is evidence of sunburn even after brief periods outdoors. Upon further questioning, they reveal a family history of skin cancer in relatives who also experienced similar skin issues from a young age. What is the most likely diagnosis and the genetic defect in this condition? (Q845516)

A. Xeroderma pigmentosum, defective homologous repair

B. Cockyane syndrome, nucleotide excision repair

C. Xeroderma pigmentosum, nucleotide excision repair

D. Bloom syndrome, defective homologous repair

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following cyclin-CDK combinations is incorrectly matched? (Q845515)

A. Cyclin A- CDK 2

B. Cyclin B- CDK 6

C. Cyclin D- CDK 4

D. Cyclin E- CDK 2

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Match the following protooncogenes with their malignancies. Proto-oncogene Malignancy 1. JAK-2 a. Hairy cell leukemia 2. BRAF b. Neuroblastoma 3. N Myc c. Burkitt's lymphoma 4. C Myc d. Polycythemia vera (Q845514)

A. 1-b, 2-a, 3-d, 4-c

B. 1-d, 2-a, 3-b, 4-c

C. 1-c, 2-a, 3-b, 4-d

D. 1-d, 2-b, 3-c, 4-a

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Identify the correctly matched pair of RAS mutation and its associated malignancy. (Q845513)

A. KRAS- Bladder cancer

B. HRAS- Lung cancer

C. KRAS- Kidney cancer

D. NRAS- Melanoma

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 70-year-old male presented with a persistent cough, weight loss, and shortness of breath. A CT scan of the chest revealed a lesion consistent with adenocarcinoma of the lung. Which of the following growth factor receptor mutations can lead to adenocarcinoma of the lungs? (Q845512)

A. FLT3 and RET

B. ALK and ERBB1

C. RET and KIT

D. KIT and FLT3

See Answer in Part B → Q28

@Neet_pg_bot

Q1: Match the malignancies in Column A with the genes in Column B: Column A Column B 1. Pleomorphic adenoma a. Rb 2. Burkitt lymphoma b. N-MYC 3. Neuroblastoma c.C-MYC 4. Retinoblastoma d. PLAG1 (Q855077)

A. 1-c, 2-b, 3-d, 4-a

B. 1-b, 2-c, 3-d, 4-a

C. 1-d, 2-c, 3-b, 4-a

D. 1-b, 2-d, 3-c, 4-a

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following best describes the mechanism by which mutations in the Ras/MAP kinase gene cause oncogenicity? (Q879232)

A. Constitutive activation of a GTP-binding protein leading to continuous MAP kinase signalling

B. Enhanced DNA repair leading to genomic instability

C. Inactivation of a tumour suppressor gene resulting in loss of cell cycle checkpoint control

D. Increased activity of tyrosine kinase receptors through gene amplification

See Answer in Part B → Q2

@Neet_pg_bot

Q3: All of the following are correct about neuroendocrine tumours except? It has a salt and pepper appearance of chromatin Tumours arising from different organs have different microscopic features Light microscopy reveals secretory granules On microscopic examination, small, round, blue cells forming a rosette pattern are visible (Q879192)

A. 1, 2, and 3

B. Only 3

C. 2, 3, and 4

D. 1, 3, and 4

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Why do neoplastic cells utilise Warburg metabolism? (Q855927)

A. It decreases glucose utilization by neoplastic cells

B. It forms metabolic intermediates which are needed for cell growth and multiplication

C. It provides more energy in the form of increased ATP production

D. It prevents apoptosis and makes the cancer immortal

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 3-year-old boy was brought by his parents with concerns about being increasingly clumsy for the past 6 months. On examination, there is leukocoria with an absence of the red reflex in the left eye. As further workup reveals a tumour, the eye is enucleated, and the microscopic appearance is as shown in the image. Molecular analysis of the tumour indicates a loss of cell cycle control in the tumour cells. What is

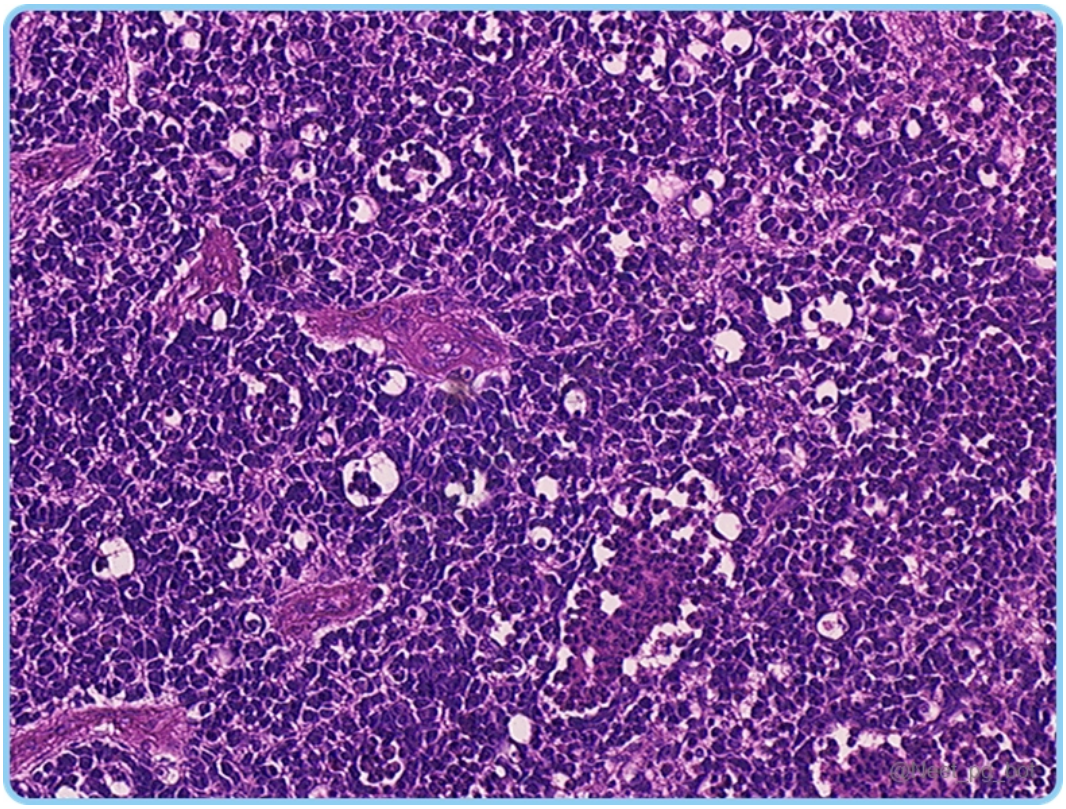
the most likely diagnosis? (Q859874)

A. Wilms tumor

B. Retinoblastoma

C. Ependymoma

D. Neuroblastoma



See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following enzymes is responsible for the immortality of cancer cells? (Q859238)

A. Telomerase

B. Topoisomerase

C. Helicase

D. RNA polymerase

See Answer in Part B → Q6

@Neet_pg_bot

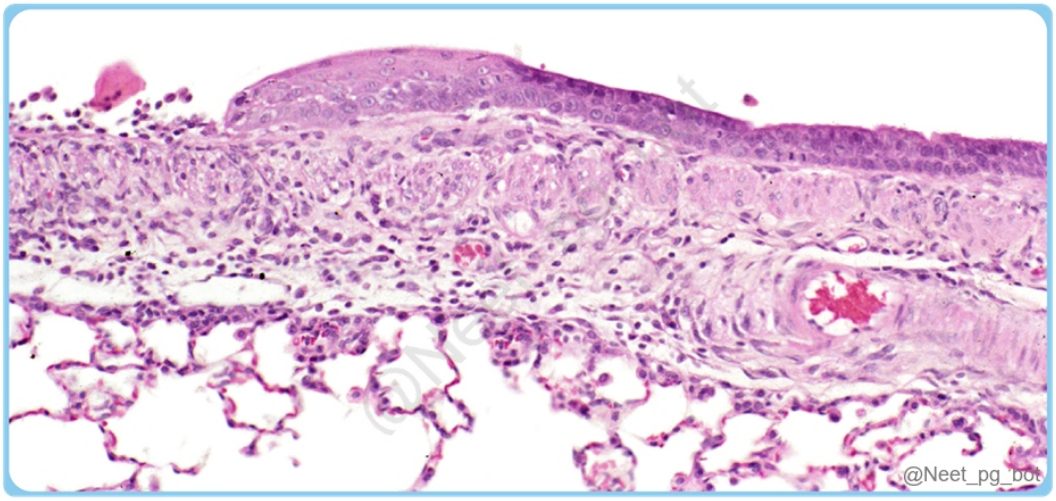
Q7: The lining epithelium of the respiratory tract of a middle-aged man who is a chronic smoker shows a change from columnar to stratified squamous epithelium, as depicted in the image below. The change is called what? {{caption_text}} (Q858510)

A. Dysplasia

B. Hypertrophy

C. Atrophy

D. Metaplasia



See Answer in Part B → Q7

@Neet_pg_bot

Q8: What is the fixation technique employed to examine fat in histopathology? (Q856484)

A. IHC

B. Frozen section

C. Liquid paraffin

D. Formalin-fixed

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A woman was diagnosed with metastatic liver adenocarcinoma with CK7-, CK20+, and CDX1+ immunohistochemistry (IHC) markers. Which of the following is the most likely primary site of origin for this metastasis? (Q856914)

A. Colon carcinoma

B. Breast carcinoma

C. Pancreatic carcinoma

D. Ovarian carcinoma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A pap smear taken from a patient revealed hyperchromatic nuclei, irregular nuclear borders, and a low maturation index involving the whole thickness but did not breach the basement membrane. What is the diagnosis? (Q856160)

A. Dysplasia

B. Carcinoma

C. Metaplasia

D. Hyperplasia

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65-year-old female patient is diagnosed with pure red cell aplasia and a mediastinal mass. Which of the following is a likely cause? (Q856155)

A. Thymoma

B. Non-Hodgkin lymphoma

C. Bronchogenic carcinoma

D. Germ cell tumour

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient with occupational exposure to benzene presents with repeated infections, easy fatigability, weight loss, and an evening rise in temperature. This occupational exposure will predispose him to which of the following cancers? (Q856108)

A. Leukemia

B. Lung cancer

C. Bladder cancer

D. Skin cancer

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is true? BRCA1 is an oncogene HER2neu is amplified only in a fraction of breast cancer EGFR+ is seen in non-small cell lung cancer N-MYC is a tumor suppressor gene (Q856708)

A. 1, 2

B. 1, 3

C. 2, 3

D. All of these

See Answer in Part B → Q13

@Neet_pg_bot

Q14: The human papillomavirus inactivates the Rb gene by which of the following proteins? (Q855392)

A. E6

B. E7

C. L1

D. L2

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is true about anaplasia? (Q857175)

A. Loss of cohesion between cells

B. Loss of differentiation

C. Change of epithelium type

D. Benign and fully reversible

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following statements is true about proto-oncogenes? KIT has decreased expression via the tyrosine kinase signalling pathway in GIST. KRAS mutation is more commonly associated with small-cell lung cancer. ERBB2 is overexpressed in association with breast carcinomas. PDGFR-β has suppressed expression in colorectal cancer. (Q855121)

A. 2 only

B. 3 only

C. 1 and 4

D. 2 and 3

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 25-year-old woman presents with lower abdominal discomfort. The surgical image is given below. What is the most likely diagnosis? (Q866741)

A. Serous cystadenoma

B. Immature teratoma

C. Mature cystic teratoma

D. Endometrioma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Neurosecretory bodies are seen in all of the following, except: (Q855069)

A. Medullary thyroid carcinoma

B. Pituitary adenoma

C. Paraganglioma

D. Adrenal cortical tumour

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Match the following microscopic appearance and the respective tumour in which they are seen Microscopic appearance Tumor 1. Schiller Duval bodies a. Krukenberg tumor 2. Presence of teeth, hair, etc B. Granulosa cell tumor 3. Signet ring cells C. Yolk sac tumour 4. Call-Exner bodies d. Teratoma (Q855924)

A. 1-c, 2-a, 3-d, 4-b

B. 1-b, 2-c, 3-a, 4-d

C. 1-d, 2-b, 3-c, 4-a

D. 1-c, 2-d, 3-a, 4-b

See Answer in Part B → Q19

@Neet_pg_bot

Q20: The type of cancer that rarely spreads through the lymphatic system is: (Q855915)

A. Squamous cell carcinoma

B. Merkel cell carcinoma

C. Basal cell carcinoma

D. Malignant melanoma

See Answer in Part B → Q20

@Neet_pg_bot

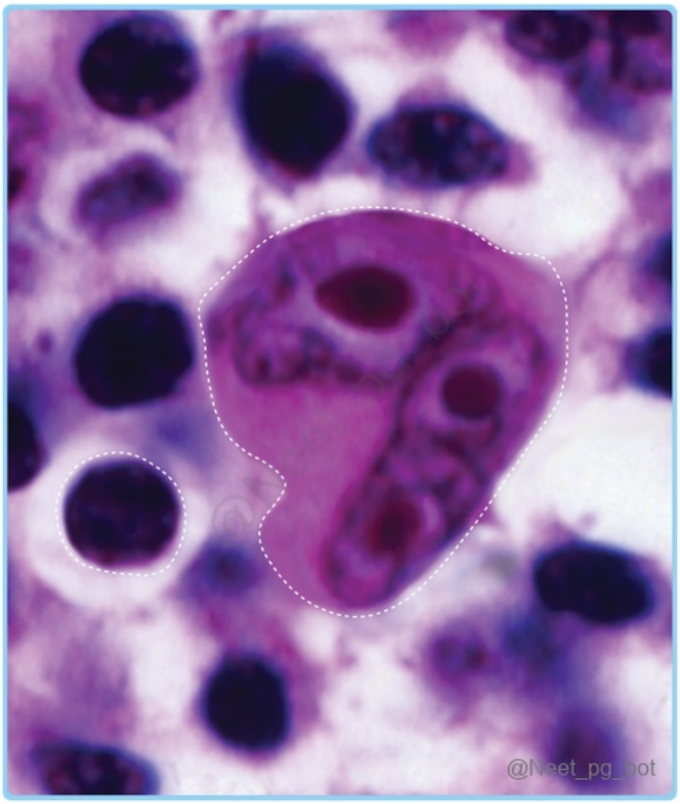
Q21: The following picture shows a lymph node biopsy of a 30-year-old male with cervical lymphadenopathy. The diagnosis is: (Q858133)

A. Acute myeloid leukemia (AML)

B. Hodgkin disease

C. Human papillomavirus (HPV)

D. Chronic lymphocytic leukemia (CLL)



See Answer in Part B → Q21

@Neet_pg_bot

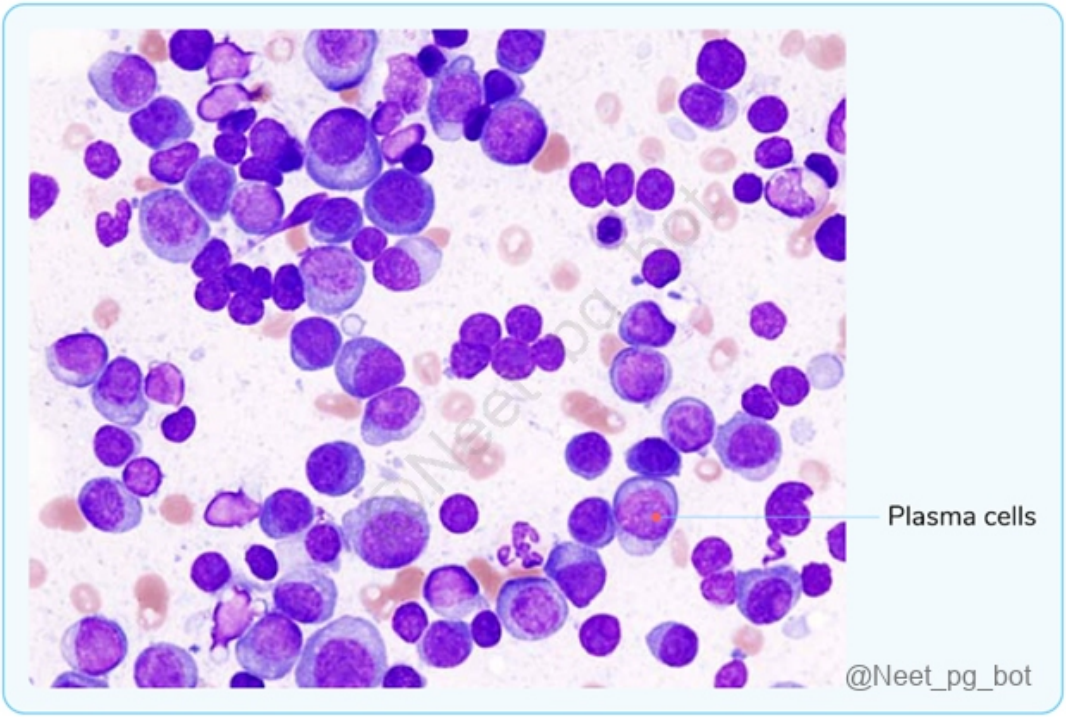
Q22: A 70-year-old male comes with complaints of hip pain. An X-ray of the hip shows lytic lesions and elevated serum calcium levels. Bone marrow plasma cells are 42%, and the cells seen are given in the image below. What is the most likely diagnosis? (Q858126)

A. Multiple myeloma

B. CLL

C. ALL

D. CML



See Answer in Part B → Q22

@Neet_pg_bot

Q23: Asbestos exposure may be associated with which of the following malignancies? (Q858108)

A. Mesothelioma

B. Acute myeloid leukemia

C. Hepatic angiosarcoma

D. Skin carcinoma

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Match the given mutations with the respective cancers: A. K-RAS Myeloproliferative neoplasm B. KIT 2. Adenocarcinoma C. JAK 2 3. Pancreatic cancer D. ALK 4. GIST (Q854690)

A. A-3, B-4, C-1, D-2

B. A-2, B-3, C-4, D-1

C. A-1, B-3, C-2, D-4

D. A-2, B-4, C-3, D-1

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following features does not distinguish between necrosis and apoptosis? (Q840014)

A. Enzymatic degradation

B. Association with underlying pathology

C. Lipid change

D. Intact membrane

See Answer in Part B → Q25

@Neet_pg_bot

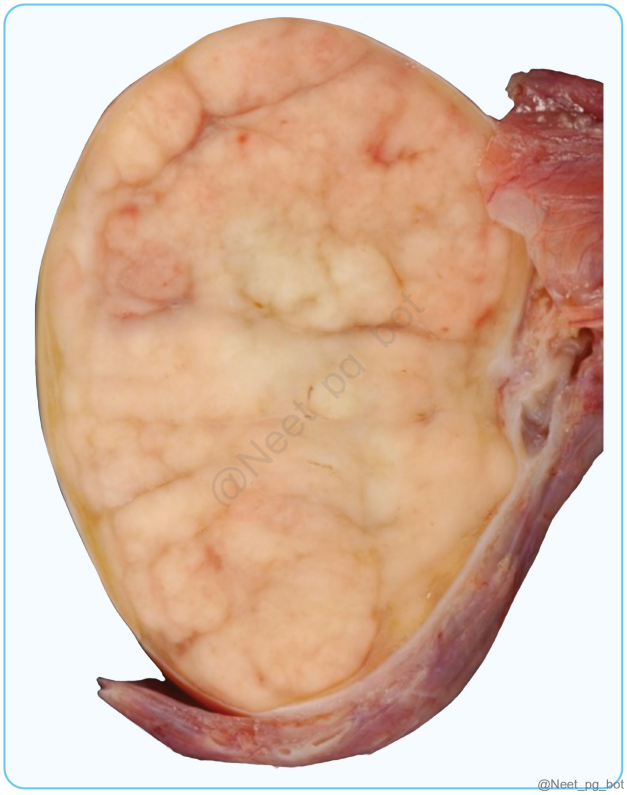
Q26: A 35-year-old male presents with a testicular mass, and a gross image of the mass is provided. What is the most likely diagnosis? (Q860552)

A. Teratoma

B. Seminoma

C. Yolk sac tumour

D. Choriocarcinoma



See Answer in Part B → Q26

@Neet_pg_bot

Q27: What is the tumour marker for a carcinoid tumour? (Q860551)

A. Beta-HCG

B. Calcitonin

C. 5-HIAA

D. Alpha-fetoprotein

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Epithelial-mesenchymal transition induced by which pair of transcription factors? (Q853375)

A. TF IIA & TF IIB

B. Cathepsin & MMP 8

C. SNAIL & TWIST

D. STAT-5 & HIF-1 alpha

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Match the following: A. Medullary thyroid cancer i. Catecholamine B. Hepatoblastoma ii. AFP C. Choriocarcinoma iii. Calcitonin D. Pheochromocytoma iv. Beta HCG (Q853373)

A. A-i, B-ii, C-iii, D-iv

B. A-iii, B-ii, C-iv, D-i

C. A-iv, B-iii, C-ii, D-i

D. A-ii, B-i, C-iii, D-iv

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Which of the following is not correct? (Q853368)

A. C- MYC - Burkitts lymphoma

B. Least radiosensitive phase is S phase of cell cycle

C. Least radiosensitive cell is platelet

D. Cyclin E triggers cells to move from G0 to G1 and G1 to S phase

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which of the following is an incorrect gene-disease association? (Q865377)

A. STK11 - Breast Cancer

B. PTEN - Thyroid Carcinoma

C. TP53 - Mucosal Neuroma

D. BRCA2 - Prostate Carcinoma

See Answer in Part B → Q31

@Neet_pg_bot

[05_Immunity] 019 Types Of Immunity — Quick Jump

Q1 (p. 228) *Q2 (p. 228)* *Q3 (p. 228)* *Q4 (p. 229)* *Q5 (p. 229)* *Q6 (p. 230)*
Q7 (p. 230) *Q8 (p. 230)* *Q9 (p. 231)* *Q10 (p. 231)* *Q11 (p. 232)* *Q12 (p. 232)*

Q1: Which of the following is not a feature of innate immunity? (Q845264)

A. Present since birth

B. Made of epithelial barriers, phagocytes, innate lymphoid cells (ILCs) and NK cells

C. Quick, non-specific response

D. Has a lag phase between exposure and response

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old male presents with a fever, sore throat, and swollen lymph nodes. He is diagnosed with a viral infection. Which of the following cells is most likely involved in the early defense against the offending agent in this patient? (Q845266)

A. NK cells

B. T cells

C. Macrophages

D. Histocytes

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 20-year-old medical student went for a screening health test and was injected with PPD intradermally. Identify the immune cell in the skin that picks up the PPD to present it to T cells. (Q845274)

A. Langhans cells

B. Follicular dendritic cells

C. Langerhans cells

D. Natural killer cells

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Match the following immune cells with their markers. Cells Markers 1. Natural killer cell a. CD 19 2. T lymphocyte b. CD 16 3. B lymphocyte c. CD 11 4. Monocyte d. CD 3 (Q845278)

A. 1-a; 2-d; 3-b; 4-c

B. 1-b; 2-a; 3-c; 4-d

C. 1-b; 2-d; 3-a; 4-c

D. 1-a; 2-c; 3-d; 4-b

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Toll-like receptors are predominantly expressed in which of the following cell types? (Q845386)

A. Macrophages

B. Endothelial cells

C. Natural killer cells

D. All of the above

See Answer in Part B → Q5

@Neet_pg_bot

Q6: An 8-year-old child is brought with complaints of fever and burning micturition. She was diagnosed to have UTI with toxin-producing strains of E.coli. Where are blood-borne antigens trapped in the immune response to these toxins? (Q845387)

A. Lymph nodes

B. Thymus

C. Bone marrow

D. Spleen

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following HLA gene regions encodes Class II MHC molecules? (Q845389)

A. HLA-A

B. HLA-B

C. HLA-C

D. HLA-D

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient presented with a fever and loose stool for one week. He was diagnosed with typhoid infection. Which of the following MHC class is responsible for antigen presentation in this patient? (Q845390)

A. Class I

B. Class II

C. Class III

D. Non-MHC-dependent antigen presentation

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which component functions as the antigen binding site in MHC complexes 1 and 2, respectively? (Q845404)

A. MHC 1 - beta microglobulin; MCH 2 - alpha 3 domain

B. MHC 1 - alpha 1 and 2; MHC 2 - alpha 1 and beta 1

C. MHC 1 - alpha 1 and beta 1; MHC 2 - alpha 1 and 2

D. MHC 1 - invariant chain; MHC 2 - beta microglobulin

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A newborn delivered by a mother who received no prenatal care is being evaluated. On examination, the baby has severe oedema, icterus, and organomegaly and is in respiratory distress. What immunoglobulin class was responsible for this child's presentation? (Q845407)

A. IgG

B. IgM

C. IgA

D. IgE

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65-year-old male presents to the emergency department with a fever, productive cough, and shortness of breath. He is diagnosed with pneumonia. Which of the following cytokines is most likely to be elevated in this patient due to the activation of classical macrophages in response to the infection? (Q845411)

A. Interleukin- 1

B. Interleukin- 2

C. Interleukin- 4

D. Interleukin- 10

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 10-year-old boy is brought with a history of eating sand. His stool examination showed Ascaris eggs. What type of T-cell is responsible for dealing with this infection? (Q845415)

A. TH1 cells

B. TH2 cells

C. TH17 cells

D. Treg cells

See Answer in Part B → Q12

« Back to Folder Directory

[05_Immunity] 020 Types Of Hypersensitivity Reactions — Quick Jump

Q1 (p. 233) *Q2 (p. 233)* *Q3 (p. 234)* *Q4 (p. 234)* *Q5 (p. 234)* *Q6 (p. 235)*
Q7 (p. 235) *Q8 (p. 236)* *Q9 (p. 236)* *Q10 (p. 236)* *Q11 (p. 237)* *Q12 (p. 237)*

Q1: A 35-year-old woman presents to the clinic with sudden hives, facial swelling, and difficulty breathing shortly after eating shrimp at a restaurant. She reports similar reactions in the past. She appears anxious, with pronounced facial swelling and wheezing. Which sequence correctly describes the immunological events in this type of reaction? (Q845417)

A. Allergen exposure → Mast cell activation → IgE production → Th2 cell activation → Release of inflammatory mediators

B. Th2 cell activation → Allergen exposure → IgE production → Mast cell activation → Release of inflammatory mediators

C. Allergen exposure → Th2 cell activation → IgE production → Mast cell activation → Release of inflammatory mediators

D. Allergen exposure → Th2 cell activation → Mast cell activation → IgE production → Release of inflammatory mediators

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following cytokines acts on B cells to stimulate class switching to IgE and promotes the development of additional Th2 cells in type I hypersensitivity reactions? (Q845419)

A. IL-4

B. IL-5

C. IL-13

D. IL-10

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old patient with a history of allergic asthma presents with worsening respiratory symptoms. The sputum sample shows the presence of Charcot-Leyden crystals. Which of the following is NOT typically associated with this phase of hypersensitivity reaction? (Q845420)

A. Recruitment of eosinophils to the site of inflammation by chemokines like eotaxin

B. Production of IL-5 by Th2 cells to activate eosinophils

C. Release of histamine and tryptase by eosinophils

D. Liberation of major basic protein and eosinophil cationic protein by activated eosinophils

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is not an example of a Type I hypersensitivity reaction? (Q845421)

A. Graft rejection

B. Vernal Keratoconjunctivitis

C. Casoni test

D. P-K reactions

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following diseases is not an example of a Type II hypersensitivity reaction? (Q845426)

A. Rheumatic fever

B. Multiple sclerosis

C. Immune thrombocytopenic purpura

D. Pernicious anaemia

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following statements regarding pernicious anaemia is incorrect? (Q845428)

A. Natural Killer (NK) cells participate in Antibody-dependent cellular cytotoxicity.

B. Opsonisation involves IgG antibodies coating cells, enhancing phagocytosis via Fc receptors.

C. When antibodies deposit in intracellular tissues, the injury is due to inflammation and not phagocytosis or cell lysis.

D. Myasthenia gravis is an example of antibody-mediated cell surface receptor dysfunction.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: An 11-year-old boy presents to the emergency department with swelling in his face and legs, decreased urine output, and dark-colored urine. His parents reported that he had a sore throat about three weeks ago, which resolved without treatment. Urinalysis shows proteinuria and hematuria. Which type of hypersensitivity reaction is associated with this condition? (Q845438)

A. Type I hypersensitivity

B. Type II hypersensitivity

C. Type III hypersensitivity

D. Type IV hypersensitivity

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is typically associated with localized immune-complex mediated hypersensitivity? (Q845440)

A. Serum sickness

B. Arthus reaction

C. Membranous glomerulonephritis

D. Reactive arthritis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 40-year-old man presents with jaundice and fatigue, recently diagnosed with hepatitis B infection. Further investigation reveals abnormal liver function tests, indicating hepatic injury. Which of the following statements regarding the mechanisms of hypersensitivity involved in this case is true? (Q845442)

A. CD8+ T cells differentiate into Th1 and Th17 cells upon antigen exposure

B. CD4+ T cells differentiate into Th2 cells upon exposure to antigen

C. Cytotoxic T-lymphocytes (CTLs) directly kill virus-infected cells via the Fas-Fas ligand pathway

D. Perforin-granzyme-dependent killing is a mechanism employed by CD4+ T cells

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old woman presents with a history of persistent cough and unintentional weight loss. The physician suspects a TB infection and performs a tuberculin skin test. Which of the following is not an example of the type of hypersensitivity reaction associated with this test? (Q845444)

A. Contact dermatitis from poison ivy exposure.

B. Rheumatoid arthritis.

C. Crohn's disease.

D. Reactive arthritis.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements accurately describes Type V hypersensitivity? (Q845446)

A. Antibodies bind to cell surface receptors, leading to altered cellular function

B. Immune complexes form and deposit in tissues, triggering localized inflammation and damage.

C. Antibodies target cell surface antigens, resulting in complement activation and cell destruction.

D. IgE antibodies mediate the release of histamine from mast cells, causing immediate allergic reactions.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following sequences correctly describes the phases of pathogenesis in Type III hypersensitivity? (Q845447)

A. Formation of immune complexes → Inflammation and tissue injury → Deposition in blood vessels.

B. Deposition of immune complexes → Formation of antibodies → Tissue injury and inflammation.

C. Formation of immune complexes → Deposition in tissues → Inflammation and tissue injury.

D. Antibody production → Immune complex formation → Activation of cytotoxic T cells.

See Answer in Part B → Q12

Q1: In healthy individuals, what is the typical ratio of CD4+ to CD8+ T lymphocytes? (Q890517)

A. 1:2

B. 2:1

C. 1:4

D. 4:1

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following conditions belongs to the spectrum of IgG4-related disorders? Mikulicz syndrome Riedel thyroiditis Idiopathic retroperitoneal fibrosis Autoimmune pancreatitis Sclerosing cholangitis (Q890556)

A. 1,2

B. 1,2,4

C. 1,4,5

D. All of the above

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following best describes the cell type that forms the characteristic lupus erythematosus (LE) cell? (Q890555)

A. Monocyte

B. Neutrophil

C. Basophil

D. Lymphocyte

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following autoantibodies is least likely to cause a homogeneous nuclear staining pattern on immunofluorescence? (Q890554)

A. Anti-histone antibodies

B. Anti-chromatin antibodies

C. Anti-double-stranded DNA antibodies

D. Anti-RNA antibodies

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which mechanism primarily contributes to the development of autoimmunity in Epstein-Barr virus infection? (Q890553)

A. Molecular mimicry

B. Polyclonal B-cell activation

C. Upregulation of co-stimulatory molecules

D. Cross-reactive antigen recognition

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following genes is a frequently implicated non-HLA susceptibility gene associated with multiple autoimmune diseases? (Q890552)

A. FOXP3

B. PTPN22

C. NOD2

D. AIRE

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following autoimmune diseases is predominantly driven by T cell-mediated inflammation, although autoantibodies and immune complexes also contribute to its pathogenesis? (Q890551)

A. Pemphigus vulgaris

B. Pernicious anemia

C. Rheumatoid arthritis

D. Goodpasture syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following proteins are encoded by genes in the MHC class III region? Complement component C4 Tumour necrosis factor (TNF) Heat shock proteins β2-microglobulin (Q890532)

A. 2,3

B. 1,3,4

C. 1,2,3

D. 4 only

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following cytokines is a potent activator of basophils? (Q890529)

A. IL-3

B. IL-2

C. IFN-γ

D. TNF-α

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements about γδ T-cells are correct? They kill extracellular bacteria using granulysin and perforin. They require antigen processing and presentation for recognition. They can directly kill infected macrophages. They protect against mycobacterial infections. (Q890528)

A. 2 only

B. 1,2

C. 2,3,4

D. 1,3,4

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following cell types shows recirculation? (Q890526)

A. Plasma cells

B. T lymphocytes

C. Plasma cells and T lymphocytes

D. B lymphocytes and plasma cells

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Papain digestion of an immunoglobulin molecule produces which of the following end products? (Q890525)

A. 2 Fc and 1 Fab fragments

B. 1 variable chain and 1 constant chain

C. 1 Fc and 2 Fab fragments

D. 2 Fc and 2 Fab fragments

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which class of antibodies is primarily produced in response to polysaccharide and lipid antigens? (Q890524)

A. IgG

B. IgM

C. IgD

D. IgA

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which cytokine primarily stimulates B cells to induce and produce IgE antibodies? (Q890523)

A. IL-1

B. IL-2

C. IL-4

D. IL-6

See Answer in Part B → Q14

@Neet_pg_bot

Q15: On antigen-presenting cells, which of the following molecules provide the necessary costimulatory signals to activate T cells? (Q890521)

A. CD28 and CD86

B. CD80 only

C. CD28 and CD80

D. CD80 and CD86

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which feature is shared by both natural killer (NK) cells and cytotoxic T lymphocytes (CTLs)? (Q890519)

A. They are restricted by MHC class I molecules

B. They need antibodies to mediate their effect

C. They can target virus-infected cells

D. Their activity is antigen-specific

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 5-year-old boy presents with severe, chronic diarrhoea, failure to thrive, and a rash. His medical history includes a diagnosis of type 1 diabetes mellitus and thyroiditis. Laboratory tests show elevated levels of anti-enterocyte antibodies. Based on these findings, which mechanism is most likely impaired in this patient's condition? (Q845501)

A. Central tolerance

B. Peripheral tolerance

C. Anergy

D. Hidden antigen

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Activation of NOD-like receptors by gain-of-function mutations is most likely to result in which of the following conditions? (Q890516)

A. Malignancy

B. Granulomatous disease

C. Autoinflammatory syndrome

D. Autoimmune disorders

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following immune cells are capable of mediating antibody-dependent cellular cytotoxicity (ADCC)? (Q890515)

A. Only macrophages

B. Only natural killer (NK) cells

C. Neutrophils and eosinophils

D. NK cells, neutrophils, and eosinophils

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is not a feature of dermatomyositis? (Q845621)

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 28-year-old female presents with fatigue, joint pain, and a rash. A blood test reveals positive anti-nuclear antibodies. Which of the following fluorescence patterns is most commonly associated with systemic lupus erythematosus (SLE)? (Q845616)

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 30-year-old woman is being evaluated for proximal muscle weakness. Which of the following is consistent with a diagnosis of polymyositis? (Q845529)

A. CD4+ T cell infiltration in affected tissue

B. Endomysial inflammation

C. Associated with underlying malignancies

D. Vascular injury involved in pathogenesis

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 32-year-old woman presents with fatigue, muscle weakness, and joint pain. On examination, she has a rash over her cheeks, along with Raynaud's phenomenon and swollen fingers. Laboratory tests reveal positive anti-U1 RNP antibodies. Which of the following conditions is this patient most likely suffering from? (Q845527)

A. Systemic lupus erythematosus

B. Scleroderma

C. Mixed connective tissue disease

D. Sjögren's syndrome

See Answer in Part B → Q23

@Neet_pg_bot

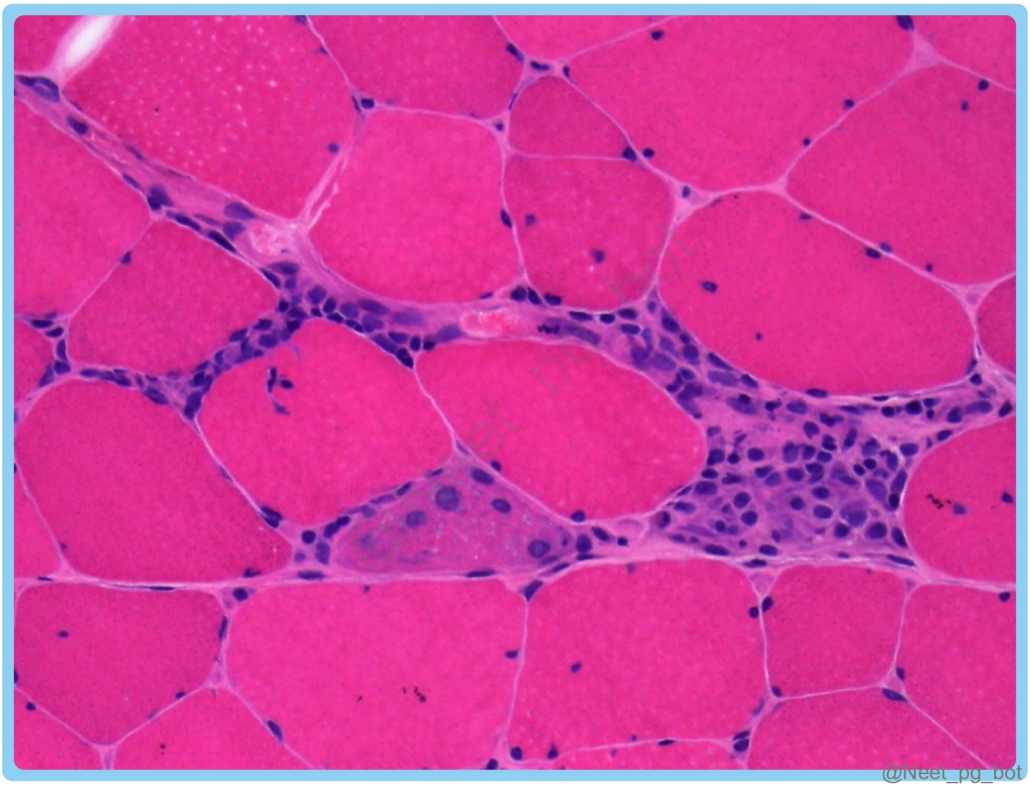
Q24: A 45-year-old woman presents with progressive proximal muscle weakness over the past 6 months. On examination, the hip and shoulder girdle muscles have symmetrical weakness. Laboratory investigations show elevated serum creatine kinase (CK) levels. A muscle biopsy reveals endomysial inflammation with CD8+ T lymphocytes and muscle fiber necrosis. Which of the following is the most likely diagnosis? (Q845525)

A. Dermatomyositis

B. Myasthenia gravis

C. Inclusion body myositis

D. Polymyositis



See Answer in Part B → Q24

@Neet_pg_bot

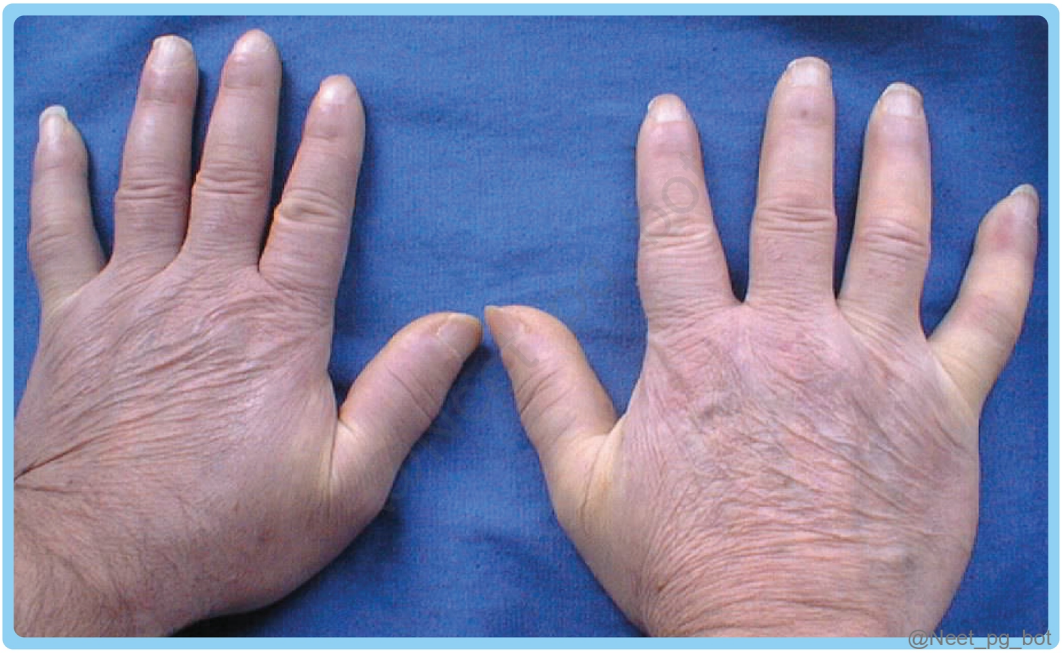
Q25: A 60-year-old woman complains of bilateral hand pain and stiffness, especially in the morning. On examination, you notice diffuse thickening and tightening of the skin all over her body. Echo showed pulmonary hypertension. Laboratory tests show positive Anti-SCL-70 antibodies What is the most likely diagnosis? (Q845523)

A. Rheumatoid arthritis

B. Osteoarthritis

C. CREST syndrome

D. Systemic sclerosis



See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 20-year-old female complains of recurrent episodes of her fingers turning symmetrically white, which are associated with pain and a tingling sensation. This is worse when exposed to cold water and is relieved when she dips her fingers in warm water. The autoimmune panel is negative. What is the likely diagnosis? (Q845520)

A. Primary Raynaud phenomenon

B. Dermatomyositis

C. Secondary Raynaud phenomenon

D. Calcinosis cutis

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 55-year-old woman has had persistent dry eyes and mouth for the past several months. She also reports difficulty in swallowing solid foods and occasional blurred

vision. On examination, she has bilateral parotid gland enlargement. She has a history of rheumatoid arthritis. Which antibodies are specific for this disease? (Q845518)

A. Anti-Sm

B. Anti La

C. Anti-Scl 70

D. Anti-U1 RNP

See Answer in Part B → Q27

@Neet_pg_bot

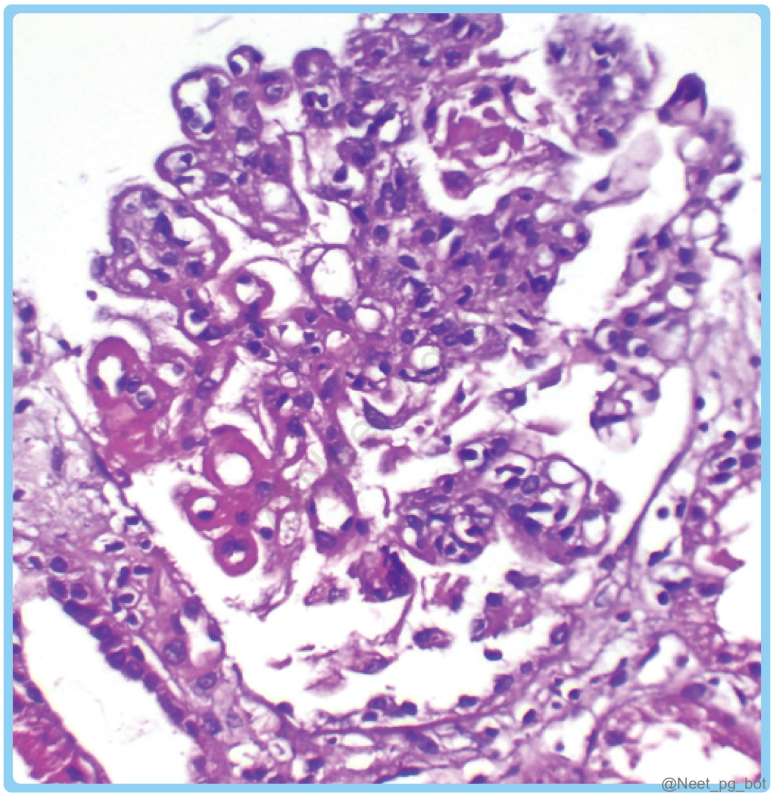
Q28: A 45-year-old woman with SLE complains of red, frothy urine for the past two months despite being on treatment. Urine analysis shows RBCs and proteins. An image of renal biopsy is given below. Which of the following accurately describes the histopathological findings? (Q845510)

A. Diffuse capillary wall thickening.

B. Wire loop lesions

C. Glomerular crescents

D. Kimmelstiel-Wilson lesion



See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 19-year-old woman presents with malaise, joint pain, and fever for the past 3 months. Physical examination shows a malar rash and mouth ulcers. She has significant proteinuria and decreased GFR. Which of the following antibodies are most specific and most sensitive, respectively? (Q845509)

A. ANA, Anti ds DNA

B. Anti-Sm, ANA

C. Anti- Ro, Anti- La

D. Anti-beta-2-glycoprotein, Anticardiolipin

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 30-year-old woman presents with a history of fatigue, fever, and weight loss. She also reports joint pain, swelling and a rash, as shown below. What is the most likely diagnosis? (Q845508)

A. Dermatomyositis

B. Systemic Lupus Erythematosus

C. Psoriatic Arthritis

D. Ankylosing Spondylitis

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which of the following is an immune-privileged site? (Q845507)

A. Heart

B. Lung

C. Kidney

D. Testis

See Answer in Part B → Q31

@Neet_pg_bot

Q32: Match the following processes in immune tolerance with their associated regulators. Process Regulators 1. Negative selection a. CD-28 2. Anergy b. FOXP3 3. Deletion by apoptosis c. AIRE 4. Suppression by regulatory T cells d. CD95 (Q845505)

A. 1-c, 2-a, 3-d, 4-b.

B. 1-a, 2-c, 3-d, 4-b.

C. 1-c, 2-b, 3-d, 4-a.

D. 1-a, 2-d, 3-c, 4-b.

See Answer in Part B → Q32

Q1: Assertion: Patients with Common Variable Immunodeficiency (CVID) commonly present with recurrent respiratory infections, gastrointestinal issues, and autoimmune disorders. Reason: Defects in the BTK gene lead to impaired B cell signaling, resulting in decreased maturation of B cells from pre-B-cells. (Q845677)

A. Both Assertion and Reason are true, and Reason is the correct explanation for Assertion

B. Both Assertion and Reason are true, but Reason is not the correct explanation for Assertion

C. Assertion is true, but Reason is false

D. Assertion is false, but Reason is true

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 52-year-old HIV-positive male presents with multiple raised, violaceous plaques and nodules over both legs. The lesions have gradually increased in number over the past few months. Skin biopsy shows a dermal lesion composed of irregular, slit-like vascular spaces lined and surrounded by plump, spindle-shaped cells. The stroma contains extravasated red blood cells, hemosiderin deposits, areas of haemorrhage, and a mixed mononuclear inflammatory infiltrate. Occasional mitotic figures are seen. Which of the following infectious agents is associated with this tumour? (Q890583)

A. Human herpesvirus type 8

B. Epstein-Barr virus

C. Cytomegalovirus

D. Human papillomavirus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 30-year-old HIV-positive patient presents with persistent, painless swelling of multiple lymph nodes. A lymph node biopsy is performed. Which of the following histopathological findings is least likely to be observed in this patient? (Q890582)

A. Florid follicular hyperplasia

B. Destruction of germinal centres

C. Hematoxylin bodies

D. Expansion of monocytoid B cells in the sinuses

See Answer in Part B → Q3

@Neet_pg_bot

Q4: In patients with HIV/AIDS, which of the following is the most frequently observed brain tumour? (Q890581)

A. Oligodendroglioma

B. Primary CNS lymphoma

C. Ependymoma

D. Pilocytic astrocytoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following immune cells is least likely to be directly infected by HIV during the course of the disease? (Q890580)

A. Helper T cells (CD4+ cells)

B. Neutrophils

C. Dendritic cells

D. Macrophages

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 6-year-old boy presents with recurrent eczema, recurrent pneumonia and otitis media since infancy, and easy bruising. Laboratory investigations show thrombocytopenia with small platelets and abnormal immunoglobulin levels. Which of the following statements regarding his condition is correct? Serum IgE is elevated Serum IgA is elevated Serum IgM is normal Serum IgG is normal (Q890569)

A. 2, 3 and 4

B. 1, 2 and 4

C. 2 and 4 only

D. 1, 2 and 3

See Answer in Part B → Q6

@Neet_pg_bot

Q7: In patients diagnosed with common variable immunodeficiency (CVID), which of the following best describes the typical finding in peripheral B-cell numbers? (Q890567)

A. B-cell count is consistently reduced

B. B-cell count is markedly increased

C. B-cells are completely absent

D. B-cell count is usually within the normal range

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Mutation in which of the following is responsible for the development of X-linked lymphoproliferative disorder, characterised by an abnormal immune response to Epstein-Barr virus (EBV)? (Q890564)

A. SLAM-associated protein

B. WAS gene

C. LYST gene

D. FOXP3 gene

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Individuals with selective IgA deficiency most commonly show reduced levels of which IgG subclass? (Q890563)

A. IgG1

B. IgG2

C. IgG3

D. IgG4

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following genes is not typically associated with the development of severe combined immunodeficiency (SCID)? (Q890562)

A. IL-7Rα

B. RAG1 and RAG2

C. JAK3

D. BTK

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 7-month-old infant presents with persistent oral thrush and extensive diaper rash. History reveals multiple serious infections since birth, requiring repeated hospital admissions. Oral examination shows easily scrapable white patches. Thymic biopsy demonstrates underdeveloped Hassall's corpuscles. Which of the following statements about this condition is correct? The most common form of SCID is X-linked Adenosine deaminase (ADA) enzyme deficiency is the most common cause Hematopoietic stem cell transplantation is the preferred treatment It is due to defects in both humoral and cell-mediated immune responses (Q890561)

A. 1,2

B. 2,3,4

C. 1,3,4

D. All of the above

See Answer in Part B → Q11

@Neet_pg_bot

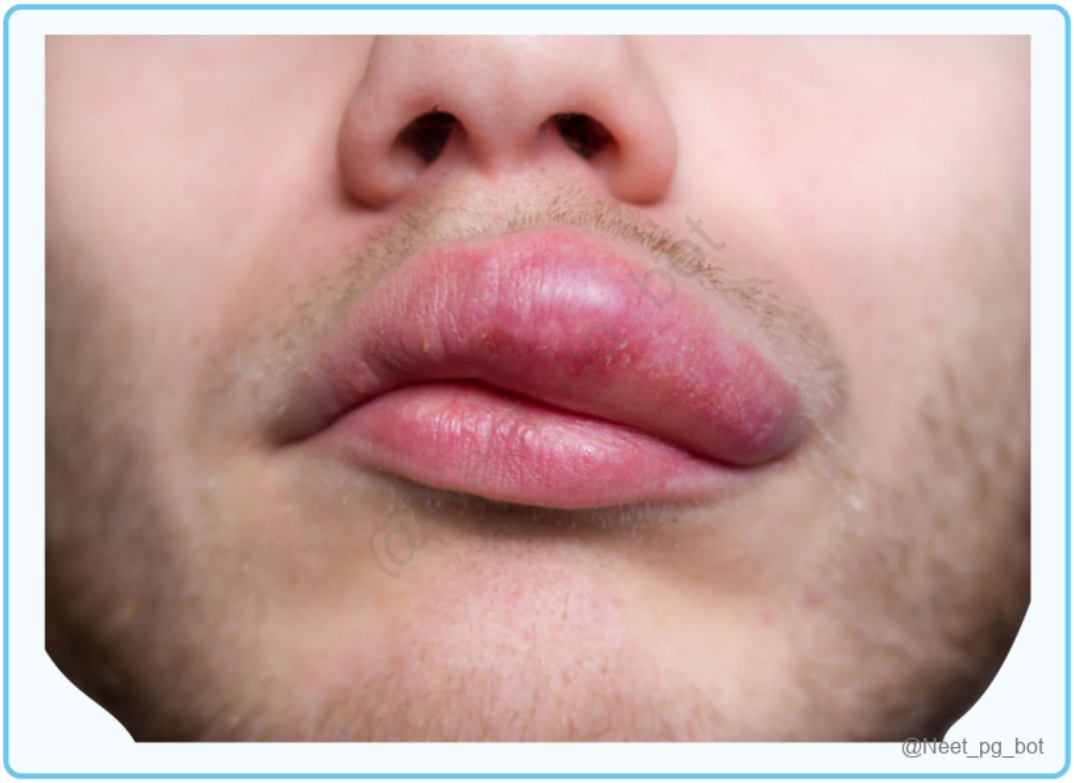
Q12: A young adult develops recurrent episodes of facial and lip swelling accompanied by abdominal pain and vomiting following minor stress or trauma. There is no associated urticaria. Which of the following complement deficiencies is most likely responsible? (Q890560)

A. C1 inhibitor

B. C2

C. C3

D. C5,C6, C7, C8, C9



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following complement deficiencies is correctly matched with its associated disorder? (Q890559)

A. C1 esterase inhibitor - Hereditary angioedema

B. C3 - Recurrent Neisseria infections

C. Factor H - Glomerulonephritis

D. C6-C9 - Hemolytic uremic syndrome

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 6-month-old infant presents with persistent fever and rapid breathing for 1 week. History reveals multiple previous infections. Blood culture grows Serratia marcescens. Nitroblue tetrazolium (NBT) test is negative. Which of the following statements about this condition is true? (Q890558)

A. It is inherited in an autosomal dominant manner

B. Due to lymphocytic inflammatory reaction

C. Primarily affects the adaptive immune system

D. It is due to defects in leukocytic superoxide production

See Answer in Part B → Q14

@Neet_pg_bot

Q15: In a pediatric clinic, a six-year-old male presents with a history of frequent respiratory and skin infections, eczema flare-ups, and microthrombocytopenia. Given these symptoms, which genetic evaluation method would be the most effective for confirming the suspected diagnosis? (Q845948)

A. WASP gene mutation analysis

B. ANA titer

C. FISH

D. B cell tyrosine kinase activity detection

See Answer in Part B → Q15

@Neet_pg_bot

Q16: In a pediatric clinic, a six-year-old male presents with a history of frequent respiratory and skin infections, eczema flare-ups, and thrombocytopenia. Given these symptoms, which genetic evaluation method would be the most effective for confirming the suspected diagnosis? (Q845648)

A. WASP gene mutation analysis

B. ANA titer

C. FISH

D. B cell tyrosine kinase activity detection

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 35-year-old male with a known history of selective IgA deficiency receives a blood transfusion during surgery. Shortly after the transfusion, he develops acute allergic reactions, including hives and difficulty breathing. Given his IgA deficiency, which blood products should have been considered to minimize the risk of such complications? (Q845676)

A. Standard red blood cells with no modification

B. Plasma products that are rich in IgA

C. Washed red blood cells

D. Fresh frozen plasma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 7-year-old child presents with recurrent skin abscesses and pneumonia. He also has a history of skeletal abnormalities, including scoliosis and delayed shedding of primary teeth. His lab work shows elevated serum IgE levels. What is the most likely diagnosis? (Q845675)

A. Job syndrome

B. Bruton’s Agammaglobulinemia

C. Wiskott-Aldrich syndrome

D. Ataxia-Telangiectasia

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 4-year-old boy presents with recurrent bacterial infections, including pneumonia and otitis media. He also has a history of chronic diarrhoea. Laboratory tests reveal elevated IgM levels with markedly reduced IgG, IgA, and IgE levels. Flow cytometry shows normal numbers of CD19+ B cells and CD3+ T cells. Genetic testing reveals a mutation in the CD40L gene. Which of the following pathogens is the patient most at risk for developing severe infections with? (Q845674)

A. Streptococcus pneumoniae

B. Haemophilus influenzae

C. Staphylococcus aureus

D. Pneumocystis jirovecii

See Answer in Part B → Q19

@Neet_pg_bot

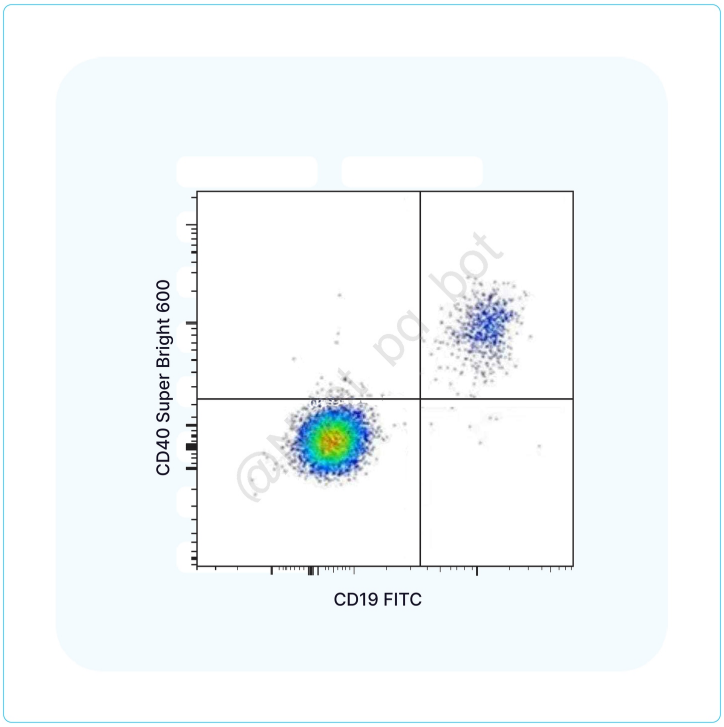
Q20: A patient presents with autoimmune hemolytic anemia, thrombocytopenia and neutropenia. Based on the flow cytometry findings, what is the most likely diagnosis? (Q845673)

A. Paroxysmal Nocturnal Hemoglobinuria

B. Hyper IgE syndrome

C. Hyper IgM syndrome

D. Glanzmann Thrombasthenia



@Neet_pg_bot

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 7-year-old boy is brought to the pediatric clinic due to recurrent infections, including pneumonia and abscesses. He has a history of photophobia and exhibits partial oculocutaneous albinism. On examination, he has notable nystagmus and ataxia. Genetic testing confirms a defect in the LYST gene. Which of the following laboratory findings would be most characteristic of this patient's condition? (Q845672)

A. Decreased immunoglobulin levels

B. Elevated eosinophil count

C. Presence of giant granules in leukocytes

D. Elevated platelet count

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Match the following. i) X-linked Agammaglobulinemia a) WAS ii) Job syndrome b) LYST iii) Wiskott-Aldrich syndrome c) STAT3 iv) Ataxia Telangiectasia d) BTK v) Chediak-Higashi syndrome e) ATM (Q845671)

A. i-d, ii-c, iii-b, iv-e, v-a

B. i-c, ii-d, iii-a, iv-e, v-b

C. i-d, ii-b, iii-a, iv-e, v-c

D. i-d, ii-c, iii-a, iv-e, v-b

See Answer in Part B → Q22

@Neet_pg_bot

Q23: An 8-month-old male infant presents with a history of severe, recurrent bacterial infections. On physical examination, the tonsils were found to be absent. Peripheral blood examination reveals an absence of B cells, while the T cell count is normal. Additionally, serum analysis reveals undetectable levels of immunoglobulins (IgG, IgA, and IgM). Which of the following most accurately explains the molecular mechanism responsible for this patient's immunodeficiency? (Q845670)

A. BTK gene mutation

B. RAG1/2 gene mutation

C. CD40L deficiency

D. BAFF receptor abnormality

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 30-year-old female patient presents with a history of recurrent respiratory infections, chronic diarrhoea, and autoimmune manifestations. Laboratory investigations reveal low levels of serum immunoglobulins (IgG, IgA, and IgM). BAFF

gene defect noted. Which of the following immunodeficiency disorders is most likely associated with these clinical findings? (Q845669)

A. X-linked agammaglobulinemia (XLA)

B. Common variable immunodeficiency (CVID)

C. Hyper IgM syndrome

D. Severe Combined Immunodeficiency (SCID)

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 6-year-old child presents with recurrent bacterial infections, delayed wound healing, and poor pus formation. Genetic testing reveals a mutation in the SLC35C1 gene, leading to a deficiency in Sialyl Lewis X (SLex) synthesis. Which of the following is the most likely consequence of this deficiency? (Q845668)

A. Leukocyte adhesion deficiency II

B. Defective opsonisation

C. Reduced chemokine production

D. Increased neutrophil apoptosis

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 2-year-old child presents with recurrent bacterial infections, delayed wound healing, and poor pus formation despite having a normal leukocyte count. Upon further investigation, a defect is identified in the integrin-mediated adhesion of leukocytes. Which of the following conditions is most likely responsible for this clinical presentation? (Q845667)

A. Chronic granulomatous disease (CGD)

B. Leukocyte Adhesion Deficiency Type 1 (LAD-1)

C. Hyper IgM syndrome

D. Severe Combined Immunodeficiency (SCID)

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following disorders is characterised by absent tonsils and lymph nodes, markedly decreased levels of serum immunoglobulins (particularly IgG, IgA, and IgM), and a lack of mature B cells in peripheral blood? (Q845666)

A. Common Variable Immunodeficiency (CVID)

B. Severe Combined Immunodeficiency (SCID)

C. X-linked Agammaglobulinemia (XLA)

D. Hyper-IgM Syndrome

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 5-year-old male presents with progressive difficulty in coordinating movements, slurred speech, and frequent infections. Physical examination reveals the findings shown in the image below and dysarthria. Laboratory investigations show decreased levels of serum IgA, IgG, and IgE. Which of the following is the most likely diagnosis? (Q845665)

A. Hereditary spastic paraplegia

B. Friedreich ataxia

C. Ataxia Telangiectasia

D. Spinocerebellar ataxia type 1

See Answer in Part B → Q28

@Neet_pg_bot

Q29: An 8-month-old infant is brought to the clinic with a history of persistent, severe respiratory infections since birth. Physical examination reveals failure to thrive and absent tonsils and lymph nodes. The child is diagnosed with adenosine deaminase deficiency; what is the most appropriate diagnosis? (Q845650)

A. DiGeorge Syndrome

B. X-linked Agammaglobulinemia (XLA)

C. Hyper-IgM Syndrome

D. Severe Combined Immunodeficiency (SCID)

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 4-year-old child presents with recurrent infections, congenital heart defects, and facial dysmorphisms, including a long face with a prominent nasal bridge. Genetic testing reveals a microdeletion on chromosome 22q11. What is the most likely diagnosis? (Q845649)

A. Down syndrome

B. Turner syndrome

C. DiGeorge syndrome

D. Cri-du-chat syndrome

See Answer in Part B → Q30

@Neet_pg_bot

« Back to Folder Directory

[05_Immunity] 023 Amyloidosis — Quick Jump

Q1 (p. 268) *Q2 (p. 268)* *Q3 (p. 269)* *Q4 (p. 269)* *Q5 (p. 269)* *Q6 (p. 270)*
Q7 (p. 270) *Q8 (p. 270)* *Q9 (p. 271)* *Q10 (p. 271)* *Q11 (p. 271)* *Q12 (p. 272)*
Q13 (p. 272)

Q1: Which of the following sites is most commonly affected in secondary (AA) amyloidosis? (Q879914)

A. Heart and brain

B. Kidneys and liver

C. Lungs and spleen

D. Skin and skeletal muscle

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 58-year-old man with end-stage renal disease has been receiving hemodialysis for 6 years. He now presents with joint pain, carpal tunnel syndrome, and shoulder stiffness. Laboratory tests show normal inflammatory markers and no evidence of plasma cell disorder. Which type of amyloid is most likely responsible for his symptoms? (Q879916)

A. AA amyloid

B. AL amyloid

C. Aβ2-m

D. ATTR

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which type of amyloid is commonly deposited in the pancreas of patients with type 2 diabetes mellitus? (Q879919)

A. AL amyloid

B. AA amyloid

C. Islet amyloid polypeptide (IAPP)

D. β2-microglobulin

See Answer in Part B → Q3

@Neet_pg_bot

Q4: In medullary thyroid carcinoma, amyloid deposits are primarily derived from which of the following? (Q879920)

A. Thyroglobulin

B. Calcitonin

C. Parathyroid hormone

D. Islet amyloid polypeptide

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following organs is most commonly affected in AL (primary) amyloidosis? (Q879921)

A. Kidneys

B. Liver

C. Heart

D. Pancreas

See Answer in Part B → Q5

@Neet_pg_bot

Q6: In primary (AL) amyloidosis, the typical bone marrow finding is? (Q879936)

A. Extensive osteolytic lesions with >30% plasma cells

B. Modest increase in plasma cells producing monoclonal light chains

C. Normal plasma cell count with no monoclonal proteins

D. Hypercellular marrow with granulocytic predominance

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is the preferred initial investigation for suspected systemic amyloidosis? (Q879937)

A. Kidney biopsy

B. Abdominal fat pad aspiration stained with Congo red

C. Bone marrow aspirate

D. Radiolabeled serum amyloid P scintigraphy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following stains is most commonly used to detect amyloid deposits in kidney biopsies? (Q879938)

A. Hematoxylin and eosin

B. Congo red

C. Masson’s trichrome

D. Periodic acid–Schiff

See Answer in Part B → Q8

@Neet_pg_bot

Q9: When stained with Congo red and viewed under polarized light, amyloid deposits in tissue typically show? (Q879939)

A. Bright red fluorescence

B. Apple-green birefringence

C. Blue-black metachromasia

D. Orange-red color under light microscope only

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Identify the false statements regarding the amyloid. 1) It is a proteoglycan. 2) It is a misfolded protein seen intracellularly. 3) They show cross-β-pleated sheet conformation in light microscopy. 4) 95% of amyloid consists of fibril proteins. 5) It appears as an amorphous, basophilic, hyaline, extracellular substance. (Q845450)

A. 1,2,3

B. 2,5

C. 3,4

D. 2,3,5

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Match the following. Condition Amyloid protein 1 Chronic inflammation i ATTR 2 Alzheimer's disease ii AA 3 Familial amyloid polyneuropathy iii AIAPP 4 Diabetes mellitus iv Aβ (Q845453)

A. 1-i, 2-ii, 3-iii, 4-iv

B. 1-ii, 2-iv, 3-iii, 4-i

C. 1-ii, 2-iv, 3-i, 4-iii

D. 1-iii, 2-ii, 3-i, 4-iv

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65-year-old male with a history of multiple myeloma in remission presents with fatigue, weight loss, and abdominal discomfort. He reports early satiety and a palpable firm mass in the left upper quadrant. Which finding is not associated with this condition? (Q845454)

A. Sago's spleen

B. Lardaceous spleen

C. Carpal tunnel syndrome

D. Nephritic syndrome

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 60-year-old man with poorly controlled hypertension and diabetes presents with fatigue, shortness of breath, ankle swelling, hepatomegaly, and bilateral lower extremity oedema. Labs show proteinuria and elevated serum creatinine. Which staining technique is most appropriate to confirm the diagnosis? (Q845458)

A. Periodic acid Schiff (PAS) stain

B. Masson trichome stain

C. Congo red stain

D. Oil red O

See Answer in Part B → Q13

@Neet_pg_bot

« Back to Folder Directory

[05_Immunity] 024 Transplant Immunity — Quick Jump

Q1 (p. 274) *Q2 (p. 274)* *Q3 (p. 275)* *Q4 (p. 275)* *Q5 (p. 275)* *Q6 (p. 276)*
Q7 (p. 276) *Q8 (p. 276)* *Q9 (p. 277)* *Q10 (p. 277)*

Q1: Which immune cells primarily mediate acute cellular rejection of a kidney allograft? (Q879941)

A. B cells producing preformed antibodies

B. CD8■ cytotoxic T lymphocytes and CD4■ helper T cells

C. Natural killer (NK) cells only

D. Macrophages without T cell involvement

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A kidney transplant patient develops sudden anuria immediately after reperfusion. The graft is cyanotic and mottled. Biopsy shows fibrinoid necrosis of arteries and thrombi in arterioles, with neutrophilic infiltration. What type of rejection is most likely? (Q879955)

A. Hyperacute rejection

B. Acute cellular (T cell–mediated) rejection

C. Acute antibody-mediated rejection

D. Chronic rejection

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following organs are primarily affected in acute graft-versus-host disease (GVHD)? (Q879962)

A. Skin, liver (bile ducts), and intestines

B. Heart, lungs, and kidneys

C. Brain, pancreas, and spleen

D. Lymph nodes and bone marrow only

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 20-year-old girl was diagnosed with acute lymphoblastic leukaemia (ALL). Her medical team has determined that a bone marrow transplant is necessary to achieve remission and prevent disease recurrence. She has an identical twin sister, who is an eligible donor. What type of grafting was done on this patient? (Q845524)

A. Allograft

B. Autograft

C. Isograft

D. Xenograft

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the minimum HLA matching that should be achieved to proceed with the transplant in the pediatric population? (Q845526)

A. 4/6

B. 6/6

C. 6/8

D. 8/10

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old woman with end-stage renal disease recently received a compatible donor organ from her brother. The kidney transplant surgery proceeds as planned, but within minutes of reperfusion, the kidney becomes mottled, cyanotic and anuric. What is the cause for this presentation? (Q845528)

A. Preformed antibodies in the donor

B. Preformed antibodies in the recipient

C. Cytotoxic T-lymphocyte-mediated injury

D. CD4+ cells mediated inflammation

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old man, two weeks post-kidney transplant, presents with sudden oliguria, fever, and graft site swelling. Biopsy shows glomerular and peritubular capillary inflammation with complement deposition. What is the most likely diagnosis? (Q845530)

A. Acute humoral rejection

B. Acute calcineurin inhibitor nephrotoxicity

C. Acute cellular rejection

D. BK virus infection

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old male patient presents with a widespread rash, severe diarrhoea, and jaundice. He underwent bonemarrow transplantation for acute myeloid leukaemia and received cells from a matched, unrelated donor. Which is the most likely diagnosis? (Q845531)

A. Acute transplant rejection

B. Chronic transplant rejection

C. Graft-versus-host disease

D. Immune reconstitution inflammatory syndrome

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 55-year-old male patient who has undergone kidney transplantation is now presenting with signs of renal dysfunction. Which complement activation product is a known histological marker for the diagnosis of antibody-mediated rejection in transplant biopsies? (Q845532)

A. C3d

B. C5a

C. C3b

D. C4d

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient presented with oliguria for the last three days. She is a known case of diabetic nephropathy and underwent an allogeneic renal transplant four years ago. The physician suspects a possibility of graft rejection. Which of the following is not true regarding the suspected condition in this patient? (Q845533)

A. Predominantly antibody-mediated reaction

B. Manifests as interstitial fibrosis and narrowing of graft blood vessels

C. HPE shows duplication of the basement membrane

D. Its morphologic correlate in the lung is bronchiolitis obliterans

See Answer in Part B → Q10

Q37 (p. 293)					

Q1: A 78-year-old male presents with fatigue, breathlessness, and palpitations. On examination, he has pedal oedema, with a pulse rate of 55 bpm, BP of 100/70 mmHg, and oxygen saturation of 94%. ECG is normal, and echocardiography reveals restrictive cardiomyopathy. A cardiac biopsy stained with Congo red shows apple-green birefringence under polarised light. What is the most likely diagnosis? (Q857590)

A. Heart failure

B. Cardiac amyloidosis

C. Hemosiderosis

D. Dystrophic calcification

See Answer in Part B → Q1

@Neet_pg_bot

Q2: In a patient with Bare Lymphocyte Syndrome, graft-versus-host disease (GVHD) does not occur. Which of the following causes it? (Q855987)

A. Complement deficiency

B. Deficiency of CD4 T lymphocytes

C. MHC Class II deficiency in lymphocytes

D. MHC Class I deficiency in lymphocytes

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is not a part of innate immunity? (Q855074)

A. Alpha defensins

B. B lymphocytes

C. Gamma delta T lymphocytes

D. Alternate pathway

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following cytokines is not involved in the Th1 response? (Q855089)

A. IFN gamma

B. IL-2

C. IL-12

D. IL-4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A person was brought to the emergency department with facial swelling, itching, and hypotension following a bee sting. The mentioned clinical features are due to the increase in which of the following immunoglobulins? (Q857097)

A. IgA

B. IgE

C. IgM

D. IgG

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A Rh-negative mother delivered an Rh-positive baby, and Coomb's test was positive for the baby. What is the mechanism of hypersensitivity seen in this scenario? (Q857100)

A. Antigen-dependent cellular cytotoxicity

B. Antibody-dependent cellular cytotoxicity

C. Antigen-antibody immune complex deposition

D. CD4 T-cell-mediated cytokine release

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following conditions is associated with hypocalcemia, thymic hypoplasia, cardiac abnormalities, and deletion of chromosome 22q11.2? (Q857124)

A. Williams syndrome

B. Pitt syndrome

C. DiGeorge syndrome

D. Cri-du-chat syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 24-year-old female patient presented with a malar rash, recurrent oral ulcers, and multiple joint pains. She has a relevant past history and does not take any medication. Upon further investigations, thrombocytopenia was seen, and the anti-Smith (anti-Sm) antibody was positive. What is the most likely diagnosis? (Q857140)

A. Scleroderma

B. Sjögren syndrome

C. Systemic lupus erythematosus (SLE)

D. Rheumatoid arthritis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Xenograft is: (Q857173)

A. Graft across species

B. Grafts from the same species

C. Graft from the same individual

D. Graft between genetically identical individuals

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A child, upon disturbing a bee hive, had several stings. After a few minutes, the child developed symptoms of shock, respiratory failure, and vascular collapse. Which of the following is the principal mediator of this reaction? (Q857559)

A. Adrenaline

B. Histamine

C. Dopamine

D. Substance P

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A boy presents with recurrent episodes of melena. On examination, there is eczema of the skin with multiple petechiae. His platelet count is low, with normal RBC and WBC counts. Which of the following is the diagnostic investigation for this patient? (Q855956)

A. WASP gene mutation

B. Anti-platelet antibodies

C. Bone marrow biopsy

D. Electron microscopy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following mediators is involved in the early phase of type 1 hypersensitivity? Mast cell Histamine Neutrophils Prostaglandins Leukotrienes (Q855445)

A. 1, 5

B. 1, 2, 3, 4

C. 1, 2, 4, 5

D. 2, 3, 4

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A person was brought to the emergency department with facial swelling, itching, and hypotension following a bee sting. The mentioned clinical features are due to an increase in which immunoglobulin? (Q856690)

A. IgA

B. IgE

C. IgM

D. IgG

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Isotype switching is seen in: (Q856894)

A. Helper T cells

B. Activated B cells

C. Cytotoxic T cells

D. B cells

See Answer in Part B → Q14

@Neet_pg_bot

Q15: B-cells are induced to produce IgE by which of the following? (Q854863)

A. IL-2

B. IL-4

C. IL-1

D. IL-6

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A graft from an identical twin is called: (Q854871)

A. Allograft

B. Autograft

C. Isograft

D. Xenograft

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Graft from an identical twin is called: (Q859849)

A. Allograft

B. Autograft

C. Isograft

D. Xenograft

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A teenager developed swelling of the face, lips, and tongue and also found it difficult to breathe within a few minutes of consuming prawns. What type of hypersensitivity is seen here? (Q859855)

A. Type 1

B. Type 2

C. Type 3

D. Type 4

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which type of cells are implicated in the development of contact dermatitis in a 12-year-old boy who presented to the emergency department? (Q859906)

A. Helper T cells

B. Neutrophils

C. NK cells

D. Cytotoxic T cells

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A patient with a deficiency of CD40 is most likely to exhibit which of the following immunological abnormalities? (Q857448)

A. Absence of B cells

B. Absence of T cells

C. Elevated IgM levels

D. Elevated IgG levels

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A patient underwent a bone marrow transplant without HLA matching. In which of the following disorders transplant rejection does not occur: (Q865422)

A. Bare lymphocyte syndrome

B. Chediak Higashi syndrome

C. Wishkott Aldrich syndrome

D. Job’s syndrome

See Answer in Part B → Q21

@Neet_pg_bot

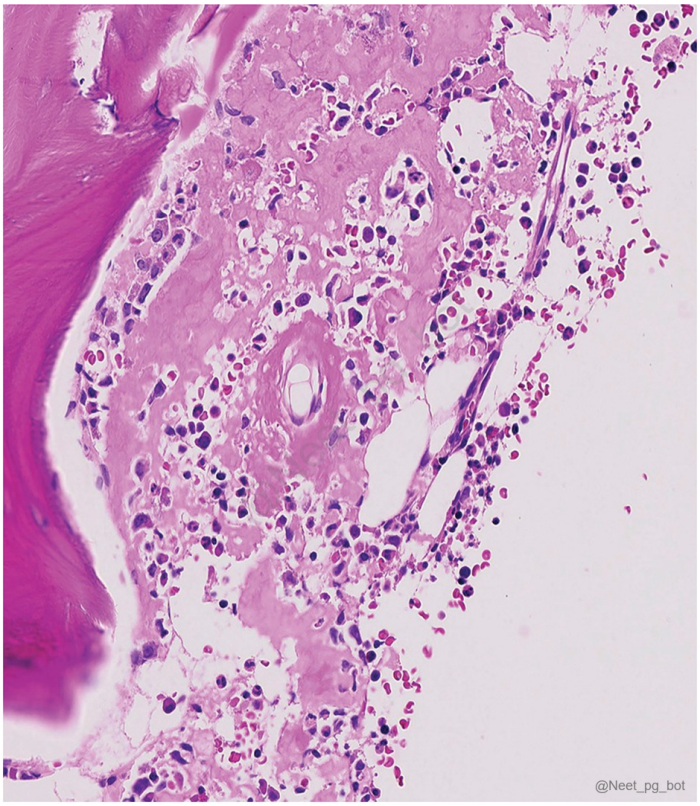
Q22: A patient presented to the OPD with hepatosplenomegaly, and his bone marrow showed 22% of plasma cells. Biopsy reveals pinkish acellular material deposition. What is the most likely diagnosis? (Q844184)

A. Myxoid degeneration of the bone marrow

B. Amyloidosis

C. Plasma cell leukemia

D. Hemolytic anemia



See Answer in Part B → Q22

@Neet_pg_bot

Q23: A child is brought to the OPD by his parents with complaints of recurrent infections. On mediastinal imaging, the thymus gland was found to be absent. Based on further investigation, ADA levels are low. What is the most likely diagnosis? (Q844212)

A. Bruton's hypogammaglobulinemia

B. Bare lymphocyte syndrome

C. DiGeorge syndrome

D. Severe combined immunodeficiency (autosomal recessive)

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 7-year-old boy presents with a history of recurrent bacterial and fungal infections, particularly involving the skin and respiratory tract. The patient's parents report that he has had multiple abscesses and lymphadenitis. Dihydrorhodamine test results show an abnormal pattern. What is the primary suspicion based on these findings? (Q860539)

A. CGD

B. SCID

C. Sialyl Lewis X

D. LAD

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following organs is a primary lymphoid organ? (Q860208)

A. Lymph node

B. Spleen

C. Thymus

D. MALT

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which of the following antibodies is specific for scleroderma? (Q857434)

A. Anti-topoisomerase/Anti-scl 70 antibody

B. Anti-La antibody

C. Anti-Jo-1 antibody

D. Anti-U1 RNP antibodies

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following genes is responsible for the regulation of T lymphocytes by the thymus? (Q857440)

A. AIRE

B. Notch 1

C. E2A

D. Rag1/2

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Blood transfusion reactions are mediated by which type of hypersensitivity reaction? (Q866752)

A. Type I

B. Type II

C. Type III

D. Type IV

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which type of hypersensitivity reaction is a type 2 lepra reaction? (Q820565)

A. Type I hypersensitivity

B. Type II hypersensitivity

C. Type III hypersensitivity

D. Type IV hypersensitivity

See Answer in Part B → Q29

@Neet_pg_bot

Q30: After class switching, a particular class of antibody is produced, but IgM and IgD are expressed concomitantly on the surface of a B cell due to which of the following phenomena? (Q854696)

A. Allelic exclusion

B. Alternate RNA splicing

C. Somatic hypermutation

D. Affinity maturation

See Answer in Part B → Q30

@Neet_pg_bot

Q31: What method is employed for the detection of autoantibodies? (Q854704)

A. Direct Immunofluorescence

B. ELISA

C. Indirect Immunofluorescence

D. FISH

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A young person with recurrent seasonal conjunctivitis presents with itchiness and eye-watering. What is the most likely cell involved in the immediate phase of this condition? (Q858100)

A. Eosinophils

B. Mast cells

C. Neutrophils

D. Lymphocytes

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which of the following is implicated in the pathogenesis of rheumatoid arthritis? (Q858104)

A. IgE-mediated

B. Defective cellular and humoral immunity

C. Autoimmunity

D. Chronic microbial infections

See Answer in Part B → Q33

@Neet_pg_bot

Q34: Which of the following is a marker of natural killer cells? (Q855942)

A. CD68

B. CD3

C. CD25

D. CD94

See Answer in Part B → Q34

@Neet_pg_bot

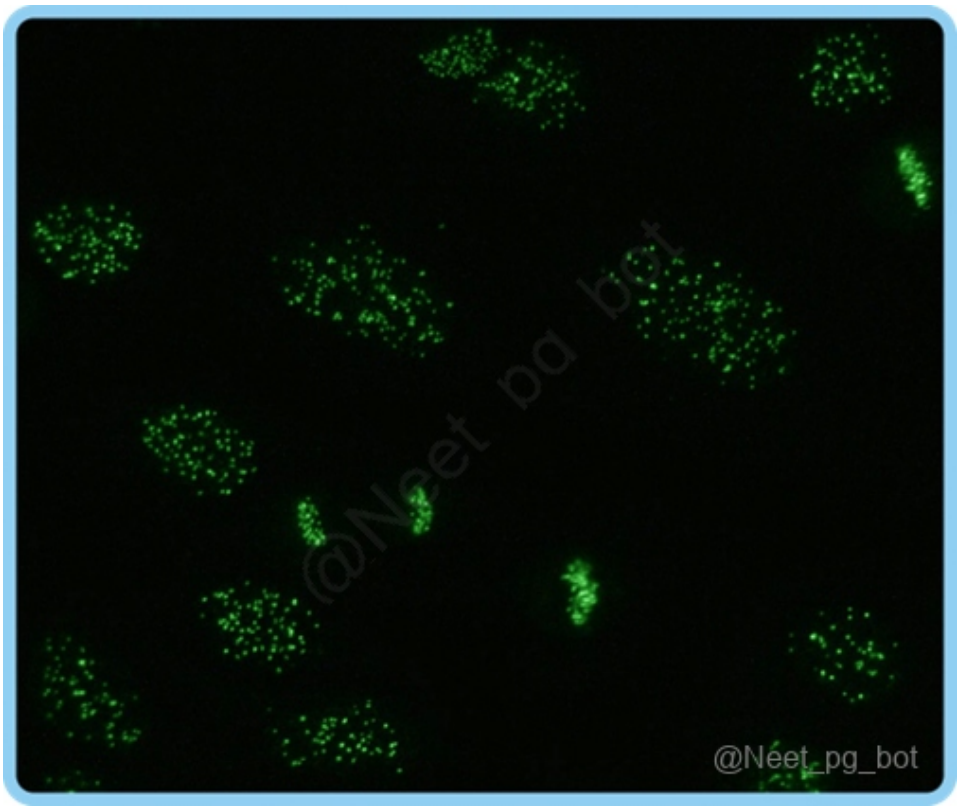
Q35: The below-given ANA pattern on immunofluorescence (IF) is seen; identify the pattern. (Q857429)

A. Nucleolar

B. Speckled

C. Centromeric

D. Diffuse



See Answer in Part B → Q35

@Neet_pg_bot

Q36: Which of the following cells is responsible for graft rejection? (Q793603)

A. Macrophages

B. T cells

C. B cells

D. Plasma cells

See Answer in Part B → Q36

@Neet_pg_bot

Q37: The X-ray of a middle-aged man showed multiple lytic lesions , following which a urine examination was done . The sample revealed Bence Jones proteins. Which is the

most common immunoglobulin associated with this condition ? (Q793750)

A. IgA

B. IgD

C. IgG

D. IgM

See Answer in Part B → Q37

[06_CVS_ Blood Vessels and Vasculitis] 026 Sclerosis And Vascular Tumors — Quick Jump

Q1 (p. 295) *Q2 (p. 296)* *Q3 (p. 297)* *Q4 (p. 297)* *Q5 (p. 298)* *Q6 (p. 300)*
Q7 (p. 300) *Q8 (p. 301)* *Q9 (p. 301)* *Q10 (p. 302)* *Q11 (p. 302)*

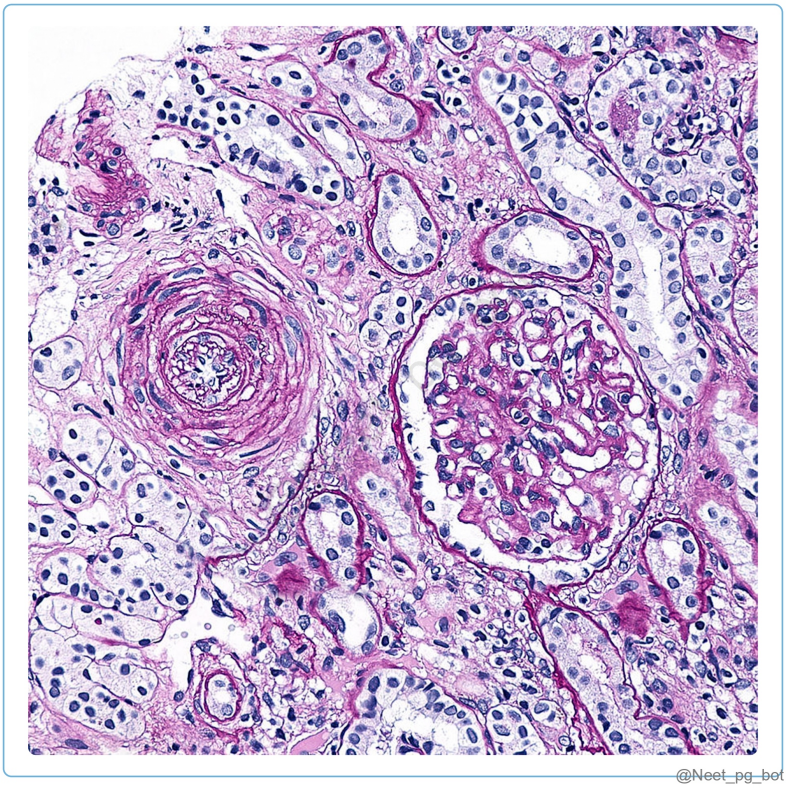
Q1: A 60-year-old male with a chronic history of diabetes, hypertension and hypercholesterolemia came to the clinic for follow-up. His BP has not been under control for many years. He has a vascular lesion similar to the image shown below. What does this image indicate? {{caption_text}} (Q845201)

A. Atheromatous plaques

B. Thick arterial wall due to deposition of pink, hyaline material

C. Onion-skin appearance

D. Lipid deposition within the vessel wall



See Answer in Part B → Q1

@Neet_pg_bot

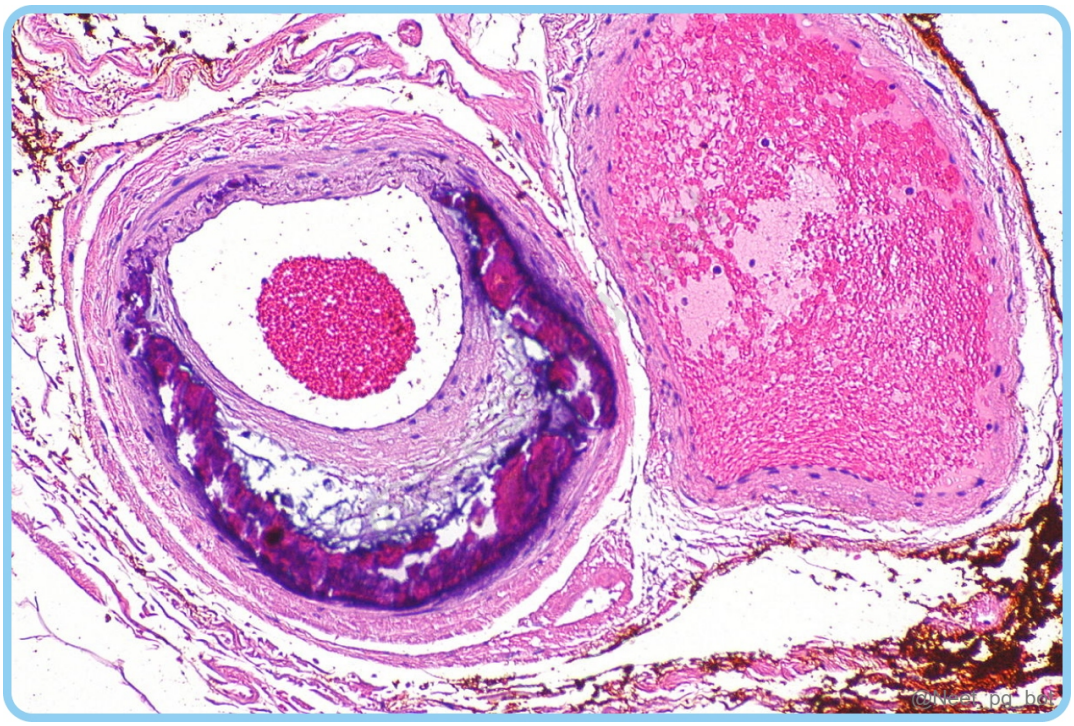
Q2: A 65-year-old male presents with high pulse pressure. Histopathological examination is shown below. The arteries appear thickened, but there is no significant luminal narrowing. Which of the following conditions is the likely cause? {{caption_text}} (Q845207)

A. Atherosclerosis

B. Monckeberg medial calcific sclerosis

C. Hyperplastic arteriosclerosis

D. Hyaline arteriosclerosis



See Answer in Part B → Q2

@Neet_pg_bot

Q3: Arrange the following steps of atherosclerosis formation in the correct order. Endothelial injury and dysfunction Accumulation of lipoproteins Platelet adhesion and factor release Smooth muscle and collagen formation (Q845209)

A. 1>2>3>4

B. 1>2>4>3

C. 2>3>4>1

D. 1>3>2>4

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old male presents with sudden-onset severe abdominal pain radiating to his back. On physical examination, a pulsatile mass is palpated in his abdomen. He

has a history of hypertension, hyperlipidemia, and smoking. Based on the clinical presentation and risk factors, which of the following is the most likely diagnosis? (Q845213)

A. Takayasu's arteritis

B. Diverticulitis

C. Abdominal aortic aneurysm

D. Pancreatitis

See Answer in Part B → Q4

@Neet_pg_bot

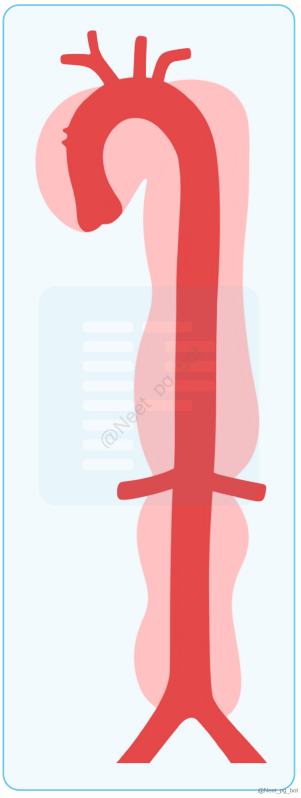
Q5: Match the following types of aortic dissections. a. {{caption_text}} 1. Stanford Type A b. {{caption_text}} 2. Debakey type I c. {{caption_text}} 3. Debakey II 4. Debakey III (Q845216)

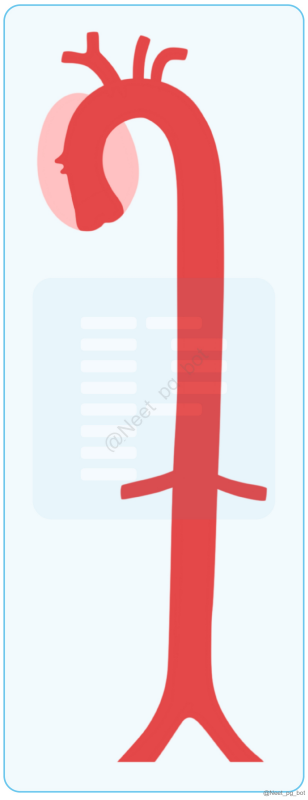
A. A-2, B-4, C-1

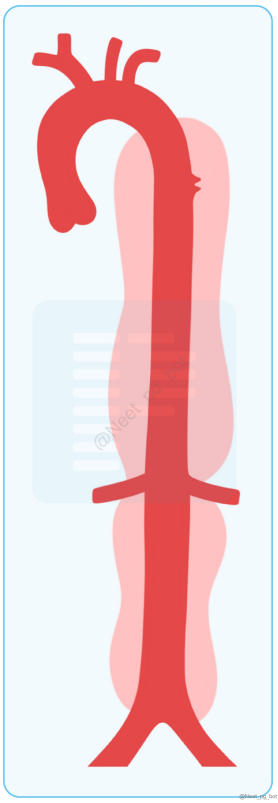
B. A-3, B-1, C-4

C. A-2, B-1, C-4

D. A-4, B-3, C-1







See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is an intermediate-grade vascular tumour? (Q845224)

A. Kaposi sarcoma

B. Angiosarcoma

C. Hemangiopericytoma

D. Pyogenic granuloma

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 6-month-old infant is brought to the clinic with a rapidly expanding, clearly defined, bright red lesion on the face. Upon examination, the lesion feels soft, yields to

pressure, and temporarily loses color when pressure is applied. Which of the following is the most likely diagnosis? (Q845227)

A. Pyogenic granuloma

B. Infantile hemangioma

C. Nevus flammeus

D. Venous malformation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 30-year-old patient presents with a history of multiple tumours in various organs, including the brain, retina, and kidneys. On examination, retinal angiomas and cerebellar hemangioblastomas are noted. The patient's family history reveals similar manifestations in relatives. Which of the following lesions is commonly associated with this syndrome? (Q845327)

A. Glioblastoma multiforme

B. Adenomatous polyps

C. Capillary hemangioma

D. Cavernous hemangioma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old individual complains of a throbbing mass on the tip of their index finger. Upon examination, the lesion is bluish and extremely tender to the touch. Which of the following is the most probable diagnosis? (Q845331)

A. Ganglion cyst

B. Bacillary angiomatosis

C. Glomus tumour

D. Cavernous lymphangioma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60-year-old HIV-positive patient presents with multiple reddish-purple nodules on the lower extremities. On examination, the lesions are non-tender, non-pruritic, and do not blanch with pressure. There is also evidence of mucosal involvement in the oral cavity. Which of the following is the most likely diagnosis? (Q845338)

A. Hemangiopericytoma

B. Hemangioendothelioma

C. Kaposi sarcoma

D. Angiosarcoma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 28-year-old woman, 20 weeks pregnant, presents with a painful, growing, reddish lump on her gums (as shown below) that bleeds when brushing or eating. The lesion is tender, and she denies any history of trauma or irritation. What is the most likely diagnosis? {{caption_text}} (Q846620)

A. Hemangiopericytoma

B. Kasabach-Merritt Syndrome

C. Angiosarcoma

D. Lobular Capillary Hemangioma

See Answer in Part B → Q11

Q19 (p. 312)	*Q20 (p. 313)*	*Q21 (p. 313)*			

Q1: Which of the following best describes using Triphenyl tetrazolium chloride (TTC) in myocardial infarction? (Q845321)

A. It is used to measure blood flow in coronary arteries

B. It helps visualize viable myocardial tissue after an infarction.

C. It acts as an anticoagulant to prevent clot formation.

D. It assists in the diagnosis of arrhythmias following a heart attack.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A pathology report of a heart specimen describes "brisk interstitial infiltrate of neutrophils" and "coagulative necrosis with loss of nuclei. What is the most likely age of this infarct? (Q884942)

A. 4-12 hours

B. 1-3 days

C. 7-10 days

D. >2 months

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 68-year-old woman is admitted with an acute anterior wall myocardial infarction. On hospital day 5, she suddenly develops hypotension and pulseless electrical activity. Bedside echocardiography shows a large pericardial effusion with tamponade physiology. At what time after myocardial infarction does this complication most commonly occur? (Q884940)

A. Within the first 2 days

B. 2-3 weeks

C. 3-7 days

D. After 3 weeks

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 62-year-old man presents with severe substernal chest pain that began 90 minutes ago. ECG shows ST-segment elevation in the inferior leads. Which of the following events is most likely occurring at this time in ischemic cardiac myocytes? (Q884937)

A. ATP reduced to 50% of normal

B. Loss of contractility

C. Irreversible cell injury

D. Microvascular injury

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which hormone is associated with an increased risk of myocardial infarction in post-menopausal women? (Q884936)

A. Progesterone

B. Estrogen

C. Prolactin

D. Oxytocin

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient with chronic lung disease presents with pedal oedema, raised JVP, and hepatomegaly. He is diagnosed with isolated right heart failure. What is the structural cause of his right-sided heart failure? (Q884935)

A. Left ventricular hypertrophy

B. Right ventricular hypertrophy and dilatation

C. Mitral stenosis

D. Decreased systemic vascular resistance

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is a cause of isolated right-sided heart failure? (Q884932)

A. Systemic hypertension

B. Mitral valve stenosis

C. Primary pulmonary hypertension

D. Aortic regurgitation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 68-year-old patient presents with exertional dyspnea. Echocardiography shows preserved ejection fraction with impaired left ventricular relaxation. He is diagnosed with left-sided diastolic heart failure (HFpEF). Which of the following is the most common cause of left-sided diastolic heart failure? (Q884931)

A. Hypertension

B. Cardiac amyloidosis

C. Ischemic heart disease

D. Constrictive pericarditis

See Answer in Part B → Q8

@Neet_pg_bot

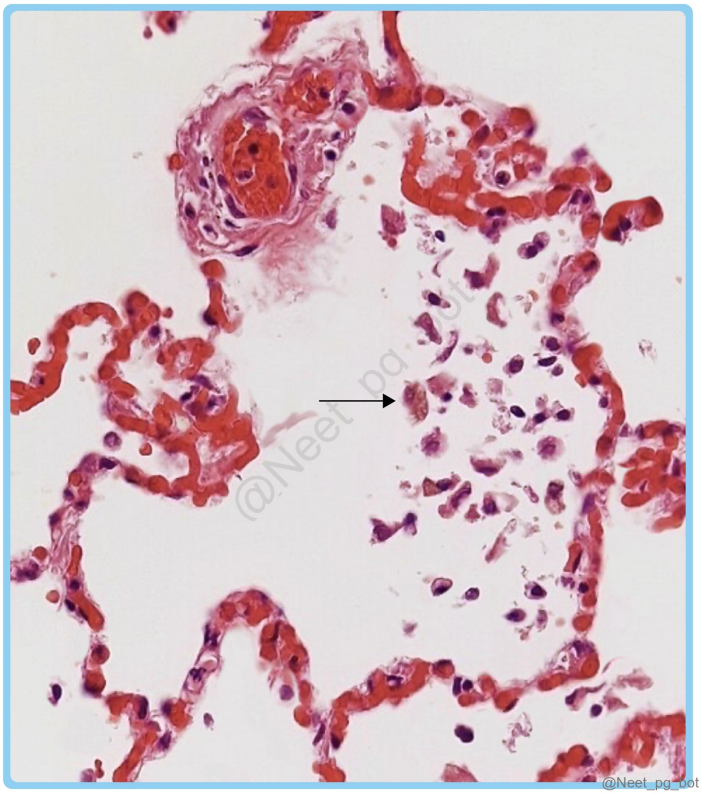
Q9: A patient with long-standing left-sided heart failure develops progressive dyspnea. Sputum cytology shows findings as shown in the image. What are these cells most appropriately termed? (Q884929)

A. Dust cells

B. Hemosiderin-laden macrophages

C. Foam cells

D. Langhans giant cells



See Answer in Part B → Q9

@Neet_pg_bot

Q10: A histologic examination of the heart in an elderly individual reveals several age-related changes. Which of the following is not typically seen in the ageing heart? (Q884928)

A. Lipofuscin deposition in myocytes

B. Transthyretin amyloid deposition

C. Decreased left atrial cavity size

D. Decreased left ventricular cavity size

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A histologic section of a normal cardiac valve is examined under microscopy. Which of the following correctly lists the layers of a normal cardiac valve? (Q884927)

A. Intima, media, adventitia

B. Fibrosa, spongiosa, ventricularis

C. Endocardium, myocardium, epicardium

D. Tunica interna, tunica externa

See Answer in Part B → Q11

@Neet_pg_bot

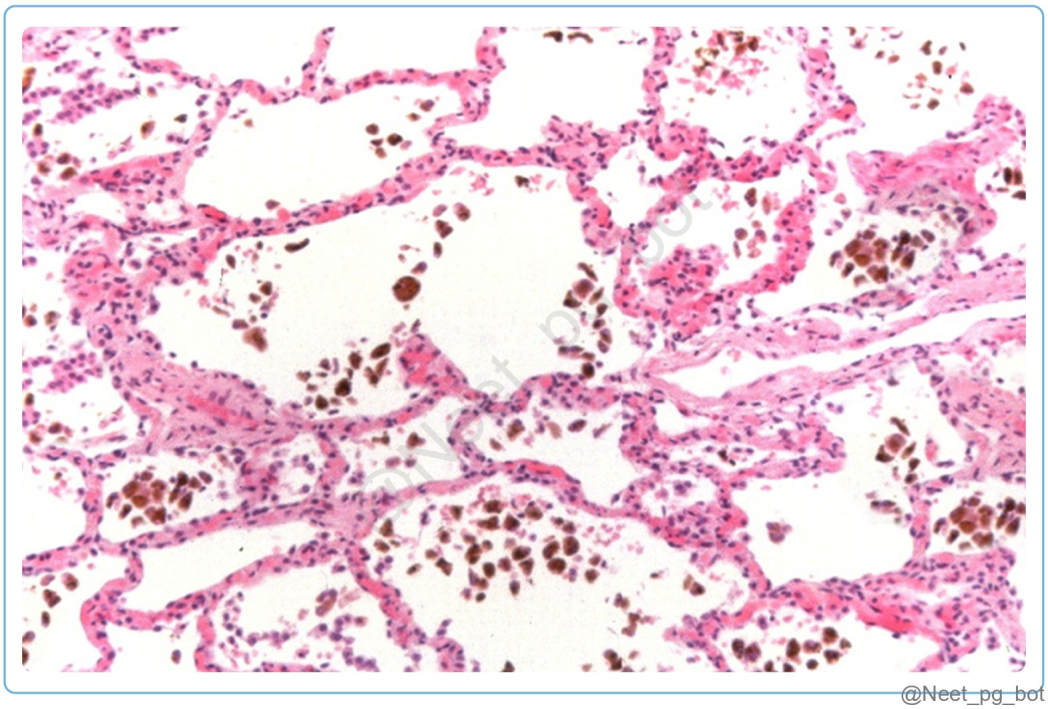
Q12: A 65-year-old male with a history of hypertension and coronary artery disease presents with worsening shortness of breath and orthopnea. Chest X-ray reveals pulmonary congestion. Bronchoalveolar lavage shows hemosiderin-laden macrophages, as shown in the image below. What is the most likely diagnosis? {{caption_text}} (Q845258)

A. Right-sided heart failure

B. Left-sided heart failure

C. Pulmonary embolism

D. Acute myocardial infarction



See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 58-year-old male presents with complaints of chest pain and shortness of breath. He had a history of MI one month ago, for which he received appropriate medical management. His vitals are stable, and his physical examination reveals a pericardial rub. An ECG shows diffuse ST-segment elevation. Which of the following is the most likely cause of this condition? (Q845320)

A. Ventricular aneurysm

B. Dressler syndrome

C. Arrhythmia

D. Myocardial rupture

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 55-year-old male with a history of hypertension and smoking presents with chest pain and shortness of breath. ECG shows ST-segment elevation in inferior leads. He undergoes PCI but, within hours, develops deteriorating cardiac function. What is the most likely primary mechanism of cardiac deterioration in this patient? (Q845317)

A. Oxidative stress

B. Intracellular calcium overload

C. Activation of coagulation cascade

D. Activation of the complement system

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which histopathological feature would not be expected in the myocardium within the first 24 hours after the infarction onset? (Q845315)

A. Coagulative necrosis

B. Marginal contraction band necrosis

C. Neutrophilic infiltration

D. Neovascularisation

See Answer in Part B → Q15

@Neet_pg_bot

Q16: At what phase of myocardial infarction does the myocardium exhibit Mottling with a yellow-tan infarct center? (Q845303)

A. 4-12 hours

B. 1-3 days

C. 7-10 days

D. 4-8 weeks

See Answer in Part B → Q16

@Neet_pg_bot

Q17: What histopathological changes are typically observed during the reversible phase of myocardial infarction? Mitochondrial swelling Sarcolemmal disruption Relaxation of myofibrils (Q845301)

A. 1, 2, and 3

B. 1 and 3

C. 2 and 3

D. Only 3

See Answer in Part B → Q17

@Neet_pg_bot

Q18: In a patient with acute myocardial infarction, which of the following is a characteristic change in LDH isoenzyme levels indicative of myocardial damage in this patient? (Q845299)

A. Elevated LDH2 levels

B. Decreased LDH1/LDH2 ratio

C. Increased LDH2/LDH1 ratio

D. Increased LDH1/LDH2 ratio

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 58-year-old man presents to the emergency department with sudden-onset chest pain radiating to his left arm and jaw, along with diaphoresis and anxiety. His vital signs show a blood pressure of 160/90 mmHg, heart rate of 110 bpm, and oxygen

saturation of 94% on room air. An ECG reveals ST-segment elevation in leads II, III, and aVF, suggestive of acute myocardial infarction (MI). Which of the following biomarkers is most reliable for confirming myocardial injury in this condition? (Q845297)

A. Myoglobin

B. CK-MB (Creatine Kinase-MB)

C. Cardiac-specific troponin I (cTn I)

D. Atrial natriuretic peptide (ANP)

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 50-year-old woman presents to the emergency department with recurrent episodes of chest pain radiating to her left arm and jaw that occur at rest and are not triggered by physical exertion. ECG during an episode shows transient ST-segment elevation. Troponin levels are normal. Which type of angina is most likely responsible for her symptoms? (Q845263)

A. Stable Angina

B. Unstable Angina

C. Silent Angina

D. Prinzmetal Angina

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following statements is incorrect regarding the pathologic changes in right-sided heart failure? (Q845262)

A. Nutmeg liver appearance.

B. Pretibial oedema is the hallmark of right-sided heart failure.

C. Fibrosis in periportal areas of the liver

D. Congestive splenomegaly due to portal hypertension

See Answer in Part B → Q21

• [06_CVS_ Blood Vessels and Vasculitis] 028 Rhd And Infective Endocarditis

« Back to Folder Directory

[06_CVS_ Blood Vessels and Vasculitis] 028 Rhd And Infective Endocarditis — Quick Jump

Q1 (p. 315) *Q2 (p. 315)* *Q3 (p. 316)* *Q4 (p. 316)* *Q5 (p. 317)* *Q6 (p. 317)*
Q7 (p. 318) *Q8 (p. 318)* *Q9 (p. 319)* *Q10 (p. 319)* *Q11 (p. 320)* *Q12 (p. 320)*
Q13 (p. 321)

Q1: Which of the following statements about rheumatic heart disease (RHD) is incorrect? (Q845229)

A. An abnormal immune response to Group A Streptococcus infection causes RHD.

B. RHD commonly affects the pulmonary valve, resulting in valvular stenosis or regurgitation.

C. Chronic inflammation and scarring of heart valves.

D. Prevented with timely treatment of streptococcal infections with antibiotics.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 10-year-old child presents to the clinic with complaints of shortness of breath and fatigue. Upon examination, a diastolic murmur along the left sternal border is detected. An echocardiogram reveals mitral valve stenosis and regurgitation, consistent with Rheumatic heart disease (RHD). What is the most common predisposing condition for this patient to develop RHD? (Q845231)

A. Streptococcal pharyngitis

B. Streptococcal skin infections

C. Streptococcal glomerulonephritis

D. All the above

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 7-year-old child presented to the clinic with fever, joint pain, and rash with a history of sore throat about three weeks ago, which resolved without treatment. Examination reveals a rash characterized by pink to red lesions with well-defined borders and tender, swollen joints. What is the primary mechanism underlying the development of acute rheumatic fever (ARF) in this patient following the untreated sore throat? (Q845232)

A. Direct invasion of tissues by streptococcal bacteria

B. Delayed hypersensitivity reaction to streptococcal exotoxins

C. Cross-reactivity between streptococcal antigens and host proteins

D. Activation of complement by streptococcal toxins

See Answer in Part B → Q3

@Neet_pg_bot

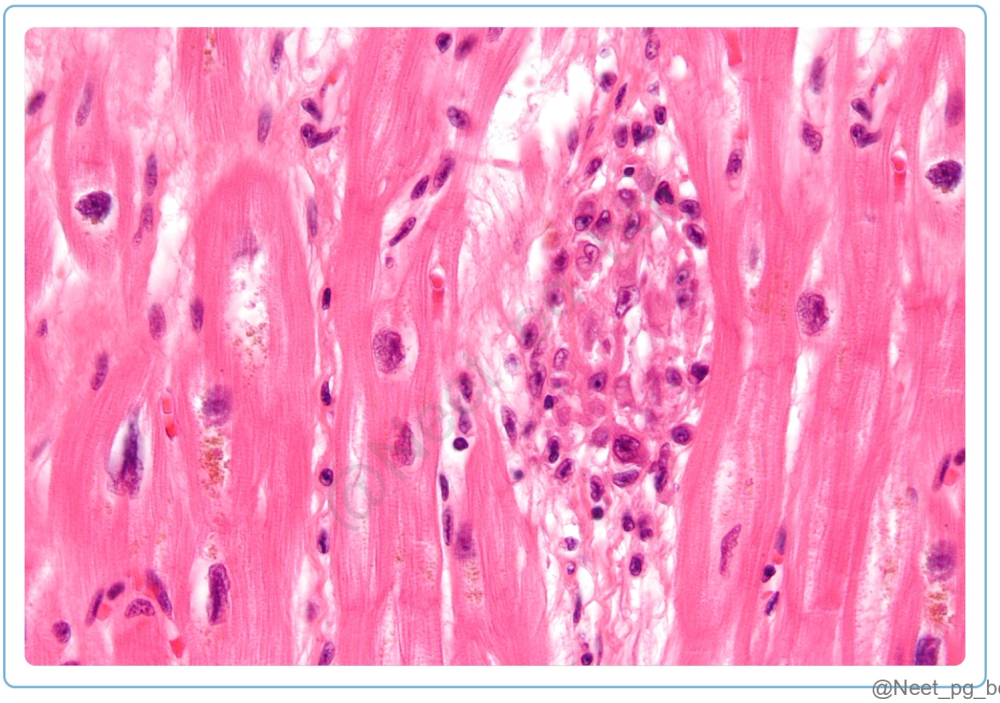
Q4: A 35-year-old male presented with severe dyspnea and a history of recurrent sore throat in childhood. An echocardiogram reveals thickened, immobile, prolapsed mitral valve leaflets. An endomyocardial biopsy reveals characteristic histopathological findings, as shown in the image. Which of the following is not a characteristic histopathological finding in this patient? {{caption_text}} (Q845235)

A. Presence of Anitschkow cells

B. Infiltration of lymphocytes, plasma cells, and macrophages

C. Presence of fibrinoid necrosis

D. Presence of granulation tissue



See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is a major criterion in the Jones criteria for diagnosing acute rheumatic fever (ARF)? (Q845241)

A. Polyarthralgia involving two or more joints

B. Fever (≥38.5°C)

C. Elevated acute phase reactants

D. Subcutaneous nodules over bony prominences

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 54-year-old man with a history of mitral valve prolapse presents to the clinic with fever and malaise following a recent dental procedure. On examination, a new regurgitant murmur is auscultated. Blood cultures are obtained, and subsequent

testing reveals the presence of gram-positive cocci in chains. Which of the following organisms is most likely responsible for the new onset murmur in this patient? (Q845246)

A. Staphylococcus aureus

B. Streptococcus viridans

C. Staphylococcus epidermidis

D. Enterococci

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following statements best describes the nature of vegetation in infective endocarditis (IE)? (Q845247)

A. Smooth and non-destructive lesions

B. Typically contain only fibrin and inflammatory cells

C. Prone to embolisation

D. Most commonly found on the tricuspid valve

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 30-year-old man with a history of intravenous drug use presents with fever, chills, and fatigue for the past week. On examination, the patient has multiple lesions on the palms and soles as shown below. The patient also has a new heart murmur. Blood cultures are positive for Staphylococcus aureus. What are these lesions shown below? {{caption_text}} (Q845249)

A. Splinter hemorrhages

B. Osler nodes

C. Janeway lesions

D. Roth spots

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not a predisposing factor for Nonbacterial Thrombotic Endocarditis (NBTE)? (Q845251)

A. Advanced malignancy

B. Antiphospholipid antibody syndrome

C. Systemic lupus erythematosus

D. Traumatic injury to the heart valves

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Match the following pathologies with the correct pattern of vegetative endocarditis caused by them: 1. Rheumatic Heart Disease a) Small, warty, sterile vegetations along the line of closure of valve leaflets 2. Infective Endocarditis b) Small, bland, sterile vegetation along the line of closure 3.Non-bacterial thrombotic endocarditis (NBTE) c) Small or medium-sized sterile vegetations on both sides of valvular leaflets. 4. Libman-Sacks endocarditis d) Large, bulky, infected, friable, irregular mass along the line of closure or on valvular cusps. (Q845253)

A. 1-a, 2-d, 3-c, 4-b

B. 1-a, 2-d, 3-b, 4-c

C. 1-b, 2-d, 3-c, 4-a

D. 1-d, 2-c, 3-b, 4-a

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following correctly lists the valves in order from most commonly to least commonly affected in chronic rheumatic heart disease? (Q889827)

A. Mitral > Aortic > Tricuspid > Pulmonary

B. Aortic > Mitral > Tricuspid > Pulmonary

C. Mitral > Tricuspid > Aortic > Pulmonary

D. Pulmonary > Tricuspid > Mitral > Aortic

See Answer in Part B → Q11

@Neet_pg_bot

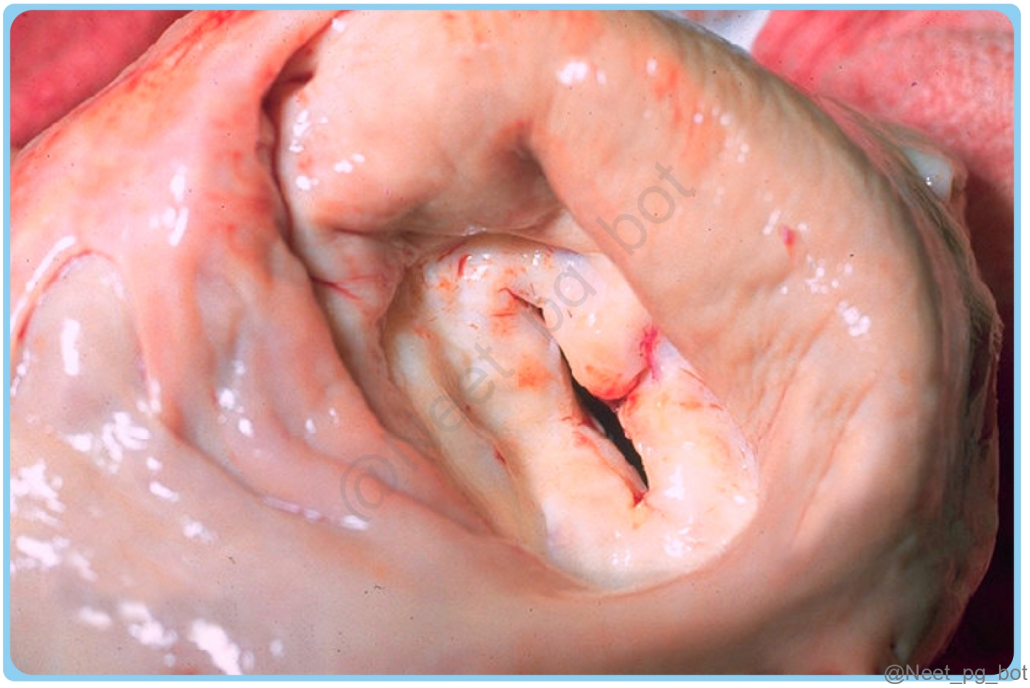
Q12: A 40-year-old woman with a history of Acute rheumatic fever in childhood had long-standing exertional dyspnea and palpitations. At autopsy, the mitral valve shows findings as shown. Which pathological process is primarily responsible for this deformity? (Q889828)

A. Vegetation formation

B. Myxomatous degeneration

C. Calcification and fibrosis

D. Fibrofatty replacement



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which organism is most commonly responsible for infective endocarditis in a previously normal valve? (Q889832)

A. Viridans streptococci

B. Staphylococcus aureus

C. Enterococcus faecalis

D. HACEK organisms

See Answer in Part B → Q13

Q1: A 30-year-old woman from a rural area presents with progressively worsening dyspnea on exertion and bilateral lower limb swelling for the past few months. She reports a history of recurrent fevers and weight loss over the past year. Physical examination reveals elevated jugular venous pressure, ascites, and hepatomegaly. Chest X-ray shows an enlarged cardiac silhouette. Echocardiography reveals restrictive filling patterns with apical obliteration and thickened endocardium. What is the most likely diagnosis? (Q845431)

A. Hypertrophic cardiomyopathy

B. Dilated cardiomyopathy

C. Endomyocardial fibrosis

D. Constrictive pericarditis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 6-month-old infant presents with progressive heart failure. Echocardiography shows diffuse fibroelastic thickening of the left ventricular endocardium with reduced ventricular compliance. There is a history of intrauterine viral exposure. Which infection is most commonly associated with this condition? (Q889821)

A. Rubella

B. Mumps

C. Epstein-Barr virus

D. Cytomegalovirus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 32-year-old man presents with progressive dyspnea. Labs show marked eosinophilia. Imaging shows endomyocardial fibrosis with mural thrombus. Which type of cardiomyopathy is most likely? (Q889817)

A. Dilated cardiomyopathy

B. Hypertrophic cardiomyopathy

C. Restrictive cardiomyopathy

D. Arrhythmogenic RV cardiomyopathy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 13-year-old boy presents with recurrent syncope and palpitations. He has tightly curled woolly hair since birth and diffuse palmoplantar keratoderma since early childhood. ECG shows T-wave inversion in V1-V3, and echocardiography reveals right ventricular dilatation. What is the most likely diagnosis? (Q889814)

A. Carvajal syndrome

B. Naxos disease

C. Noonan syndrome

D. Isolated ARVC

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following deficiencies is associated with the development of dilated cardiomyopathy? Thiamine deficiency Selenium deficiency Vitamin B12 deficiency Carnitine deficiency (Q889812)

A. 1, 2 and 4

B. 1 and 3

C. 2 and 3

D. 3 and 4

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 48-year-old man presents with progressive dyspnea and echocardiographic evidence of dilated cardiomyopathy; which of the following is the most likely risk factor? (Q889810)

A. Hypertension

B. Alcohol abuse

C. Hyperlipidemia

D. Rheumatic fever

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is the least common type of cardiomyopathy? (Q889806)

A. Dilated cardiomyopathy

B. Hypertrophic cardiomyopathy

C. Restrictive cardiomyopathy

D. Peripartum cardiomyopathy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old male presents with palpitations and dizziness during a soccer match. He is diagnosed with ARVC (Arrhythmogenic Right Ventricular Cardiomyopathy). Which of the following statements about this condition is true? Statement 1 - It is an autosomal recessive disorder Statement 2 - Associated with NAXOS syndrome Statement 3 - Marked by fatty infiltration and focal fibrosis within the ventricle Statement 4 - It involves mutation in Plakoglobin (Q846623)

A. 1, 2, 3

B. 1, 3, 4

C. 2, 3, 4

D. 1, 2, 3,4

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 6-month-old infant presents with cyanosis and respiratory distress. Physical examination reveals a murmur and a palpable liver edge. Echocardiography demonstrates multiple intracardiac masses located primarily in the ventricular walls. What is the most likely diagnosis? (Q845436)

A. Rhabdomyoma

B. Cardiac fibroma

C. Myxoma

D. Metastatic neuroblastoma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Identify the true statements regarding atrial myxoma. 1) It is the most common primary tumor of the heart in adults. 2) It is a malignant neoplasm. 3) It is associated with mutations in the GNAS1 gene. 4) 90% of these tumors arise from ventricles. 5) Histologically, it contains lepidic cells (Q845434)

A. 1,2,3

B. 1,2,3,4,5

C. 1,3,4

D. 1,3,5

See Answer in Part B → Q10

@Neet_pg_bot

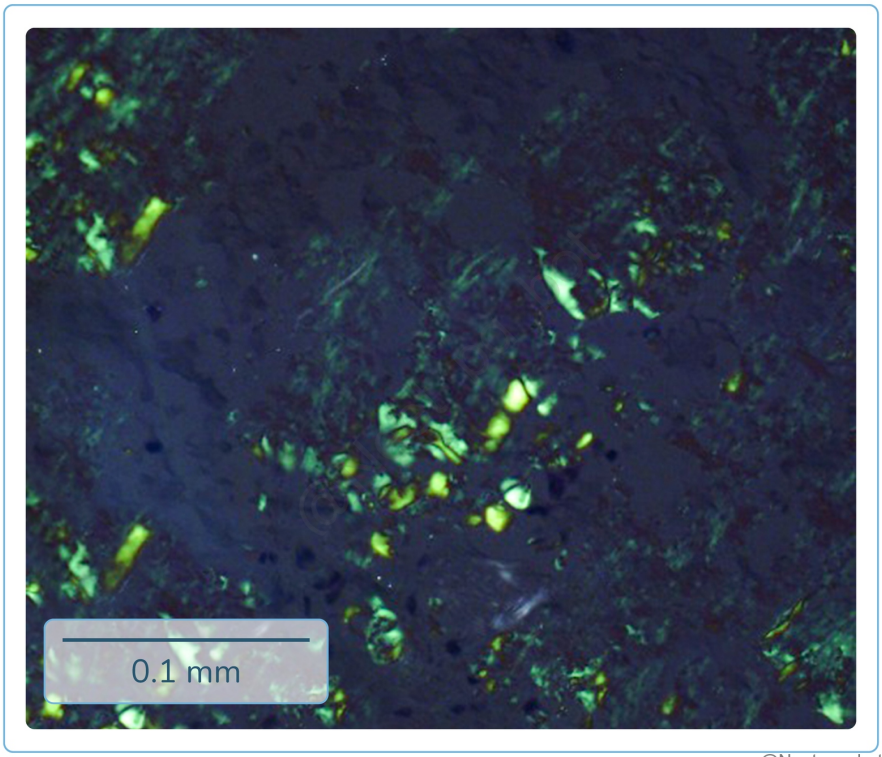
Q11: What is the most likely diagnosis based on the image given below? It is a stained specimen of endomyocardial tissue. {{caption_text}} (Q845433)

A. Hypertrophic cardiomyopathy

B. Dilated cardiomyopathy

C. Cardiac amyloidosis

D. Sarcoidosis



@Neet_pg_bot

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which viral organism is most commonly associated with myocarditis? (Q845392)

A. Influenza

B. Human immunodeficiency virus (HIV)

C. Coxsackievirus

D. Epstein-Barr virus (EBV)

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is not a cause for restrictive cardiomyopathy? (Q845429)

A. Hemochromatosis

B. Amyloidosis

C. Sarcoidosis

D. Alcohol

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 19-year-old boy collapsed during a football game and was brought dead to the hospital. Suspecting a heart condition, a biopsy was done, which showed asymmetric septal hypertrophy. Which of the following histological findings will not be seen in this condition? (Q845425)

A. Massive myocyte hypertrophy

B. Myofibre disarray

C. Fibrotic narrowing of small intramural arteries

D. Ninja star nuclei

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 22-year-old man presents to his cardiologist with complaints of exertional chest pain and shortness of breath. His family history is significant for the sudden cardiac death of his brother at the age of 28. Physical examination reveals a harsh systolic murmur and irregular heart sounds. Which of the following genes is most commonly involved in this condition? (Q845423)

A. Titin

B. Beta-myosin heavy chain

C. Troponin T

D. Alpha-tropomyosin

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following conditions is characterised by transient left ventricular dysfunction, often triggered by emotional or physical stress, presenting with symptoms mimicking acute coronary syndrome but with normal coronary arteries on angiography? (Q845401)

A. Acute Myocardial Infarction (AMI)

B. Takotsubo Cardiomyopathy (TCM)

C. Hypertrophic Cardiomyopathy (HCM)

D. Dilated Cardiomyopathy (DCM)

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55-year-old woman presents to the emergency department with sudden-onset chest pain and shortness of breath following the news of death of her son. An electrocardiogram shows ST-segment elevation in the anterior leads, and cardiac biomarkers are elevated. Coronary angiography reveals no significant coronary artery disease. Which of the following is the most likely underlying mechanism in this patient? (Q845400)

A. Excessive release of catecholamines

B. Viral myocarditis

C. Autoimmune response

D. Genetic predisposition

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following genes is most commonly associated with inherited forms of dilated cardiomyopathy? (Q845398)

A. BRCA1 gene

B. TTN gene

C. CFTR gene

D. SCN5A gene

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old male with a history of intravenous drug abuse, presenting with fever, malaise, and a new-onset heart murmur, reports recent injection site infections. On examination, there are multiple healing scars on the upper extremities, and a grade III/VI holosystolic murmur is auscultated at the left sternal border. His temperature is 38.5°C, heart rate is 110 bpm. Which criterion amongst the following is a major criterion for the condition diagnosed? (Q845397)

A. Fever of unknown origin lasting more than 7 days

B. IV drug abuse

C. Predisposing cardiac condition such as a prosthetic heart valve

D. Positive blood cultures for typical microorganisms persistently isolated from blood cultures

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is not a major criterion according to Jones Criteria for Rheumatic Heart Disease? (Q845395)

A. Polyarthritis

B. Carditis

C. Subcutaneous nodules

D. Fever

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following findings is most likely present in the myocardial biopsy of a Rheumatic Heart disease patient? (Q845394)

A. Fibrous thickening of the endocardium

B. Areas of lymphocytic infiltrates, Anitschkow cells and fibroblasts in all layers of the heart

C. Calcific nodules on the valve leaflets

D. Disruption of the endothelial lining of blood vessels

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following statements best describes the vegetation found in Infective Endocarditis compared to other conditions? (Q845393)

A. Vegetations in Infective Endocarditis are typically small, friable, sterile and composed of fibrin, and platelets.

B. Vegetations in Infective Endocarditis are large, verrucous, and primarily consist of fibrin, inflammatory cells, and microorganisms.

C. Nonbacterial Thrombotic Endocarditis (NBTE) commonly presents with small, non-sterile vegetations composed mainly of fibrin and platelets.

D. Libman-Sacks Endocarditis is characterised by tiny, marantic vegetations consisting of fibrin and micro-organisms.

See Answer in Part B → Q22

Q1: A 55-year-old female presents with hematuria, hemoptysis, and sinusitis. Renal biopsy reveals pauci-immune necrotising crescentic glomerulonephritis. What is the most likely diagnosis? (Q845459)

A. Wegener's Granulomatosis

B. Goodpasture Syndrome

C. Systemic Lupus Erythematosus (SLE)

D. Microscopic Polyangiitis (MPA)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 3-year-old child presents with persistent high fever, bilateral conjunctival erythema, strawberry tongue, erythema of palms and soles, desquamating rash, and cervical lymphadenopathy. This presentation is classically referred to as which of the following? (Q889802)

A. Mucocutaneous lymph node syndrome

B. Polyarteritis nodosa

C. Takayasu arteritis

D. Henoch-Schönlein purpura

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Anti-endothelial cell antibodies are most commonly associated with which of the following conditions? (Q889800)

A. Polyarteritis nodosa

B. Kawasaki disease

C. Takayasu arteritis

D. Granulomatosis with polyangiitis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 27-year-old woman presents with fatigue, weak upper limb pulses, and visual disturbances. Imaging reveals narrowing of major branches of the aorta. She is diagnosed with Takayasu arteritis. Which of the following statements is correct? (Q889799)

A. The renal artery is spared

B. It commonly involves the aortic arch

C. B-cell mediated disease

D. It is a medium vessel granulomatous vasculitis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 68-year-old woman presents with new-onset temporal headache, jaw claudication, and transient vision loss. ESR is elevated. Which of the following statements is correct regarding this condition? (Q889798)

A. A negative temporal artery biopsy excludes the diagnosis

B. The disease uniformly affects the entire length of the artery

C. A negative biopsy does not exclude the diagnosis

D. The aorta is spared

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 72-year-old woman presents with temporal headache, scalp tenderness, and transient visual disturbances. ESR is markedly elevated. Temporal artery biopsy confirms Giant cell arteritis. Which of the following statements is incorrect regarding this condition? (Q889797)

A. It commonly affects individuals older than 50 years

B. It is characterised by granulomatous inflammation with giant cells

C. It can also involve veins

D. Risk of vision loss

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 25-year-old girl with a history of asthma presents with wheezing and rhinitis. Lab reports show eosinophilia and antibodies against neutrophil myeloperoxidase. What is the most likely diagnosis? (Q845462)

A. Churg-Strauss syndrome

B. PAN

C. Buerger's disease

D. Wegener granulomatosis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 30-year-old male patient presents with recurrent oral ulcers, genital ulcers, and skin lesions on the lower extremities. He also complains of blurred vision and pain in his right eye. On examination, there are multiple oral and genital ulcers with posterior uveitis evident on ophthalmologic evaluation. Which of the following is false regarding the condition? (Q845461)

A. HLA B27 positivity

B. Painful scarring genital ulcers

C. Erythema nodosum

D. Positive pathergy test

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old female presents with rapidly progressive hematuria, hemoptysis, and peripheral neuropathy. Serological testing reveals the presence of perinuclear anti-neutrophil cytoplasmic antibodies (p-ANCA) targeting myeloperoxidase (MPO). What is the most likely diagnosis based on these serological findings? (Q845460)

A. Microscopic Polyangiitis

B. Granulomatosis with Polyangiitis

C. Eosinophilic Granulomatosis with Polyangiitis

D. Goodpasture Syndrome

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Weibel-Palade bodies consist of which of the following components? (Q845439)

A. Collagen

B. von Willebrand factor (vWF)

C. Platelet-derived growth factor (PDGF)

D. Tumor necrosis factor (TNF)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 10-year-old child presents with palpable purpura on the lower extremities, arthralgia, and abdominal pain. Laboratory tests show elevated serum IgA levels and red blood cell casts in urine. What is the most likely diagnosis? (Q845457)

A. Henoch-Schönlein Purpura

B. Systemic Lupus Erythematosus

C. Kawasaki Disease

D. Rheumatic Fever

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is a characteristic feature of Buerger disease? (Q845456)

A. Segmental fibrinoid necrosis of the media with focal transmural necrotising lesions

B. Segmental thrombosing vasculitis affecting small and medium-sized arteries

C. Granulomatous inflammation of vessel walls

D. Adventitial mononuclear infiltrates with perivascular cuffing of the vasa vasorum

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 42-year-old male heavy smoker presents with a history of recurrent episodes of pain and discolouration in his fingers and toes, particularly when exposed to cold temperatures. On examination, you notice superficial migratory thrombophlebitis in his lower extremities. Doppler ultrasound reveals segmental occlusions in the arteries of his lower limbs. Considering his clinical presentation, which of the following is the most likely diagnosis? (Q845455)

A. Thromboangiitis Obliterans

B. Raynaud's Phenomenon

C. Atherosclerosis

D. Giant Cell Arteritis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 3-year-old child presents with a high fever persisting for five days, along with bilateral conjunctival injection, strawberry tongue, and rash on the trunk and extremities. There is also swelling and erythema of the hands and feet. What is the most likely diagnosis? (Q845452)

A. Measles

B. Scarlet fever

C. Henoch-Schönlein purpura

D. Kawasaki disease

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 52-year-old woman presents with a 3-month history of muscle aches, joint pain, and numbness in her hands and feet and blood in stools. She also reports experiencing episodes of abdominal pain and nausea. Physical examination reveals decreased sensation in the distal extremities and decreased peripheral pulses.

Laboratory tests show elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Nerve conduction studies indicate peripheral neuropathy. What is the most likely diagnosis? (Q845449)

A. Polyarteritis nodosa (PAN)

B. Wegener's granulomatosis

C. Churg-Strauss syndrome

D. Giant cell arteritis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 28-year-old female presents to the outpatient department with complaints of fatigue, weight loss, and intermittent claudication in her upper limbs. On further questioning, she reports occasional headaches and dizziness. Physical examination reveals absent pulses in both brachial arteries and decreased blood pressure in the upper extremities compared to the lower extremities. Laboratory investigations show elevated ESR & CRP, and Doppler ultrasound shows diffuse narrowing and irregularities in the brachial and subclavian arteries. What is the most likely diagnosis? (Q845448)

A. Rheumatoid arthritis

B. Takayasu arteritis

C. Polyarteritis nodosa

D. Microscopic polyangiitis

See Answer in Part B → Q16

@Neet_pg_bot

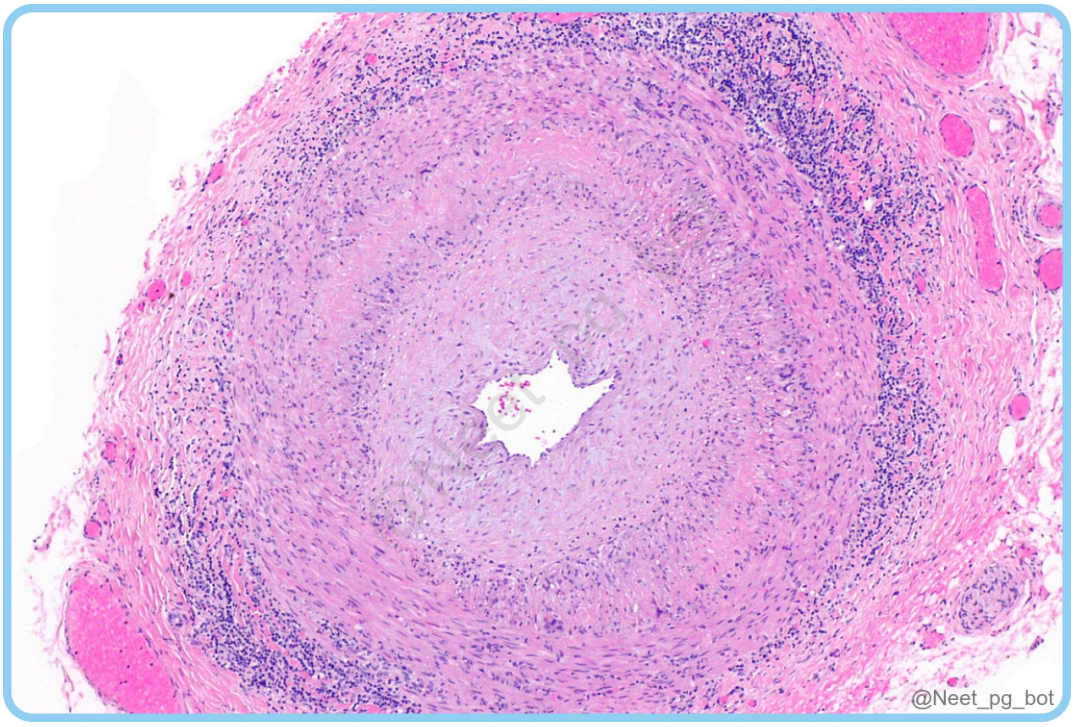
Q17: An arterial biopsy of an elderly male was performed and is shown below. What is the most likely diagnosis? {{caption_text}} (Q845445)

A. Giant cell arteritis

B. Takayasu arteritis

C. Polyarteritis nodosa

D. Microscopic polyangiitis



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 68-year-old woman presents to the emergency department with a three-week history of progressively worsening temporal headaches, jaw pain, and visual disturbances. On examination, her right temporal artery appears swollen and tender to palpation. Which of the following statements regarding this condition are false? (Q845441)

A. Involves large to medium-sized arteries

B. It is the most common cause of vasculitis in adults

C. It occurs as a result of a B cell-mediated immune response

D. It is associated with polymyalgia rheumatica

See Answer in Part B → Q18

Q1: Which of the following syndromes can lead to pulmonary hemorrhage in a patient and show p-ANCA positivity? (Q844207)

A. Monckeberg's Sclerosis

B. Microscopic polyangiitis

C. Wegener granulomatosis

D. Polyarteritis nodosa

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following statements regarding rheumatic fever are correct? (Q879221)

A. Characterized by the presence of Aschoff bodies

B. Caused by Group B β-hemolytic Streptococci

C. Manifests only as myocarditis

D. Associated with aortic valve rupture

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 65-year-old man was admitted to the emergency ward with severe, sudden-onset chest pain radiating to the left arm and profuse sweating. The ECG showed ST-segment elevation in precordial leads. The person succumbed after 3 hours. During the autopsy, his heart was taken out and immersed in a solution. The normal area of the heart turned brick-red, whereas the infarcted portion turned pale. Which of the following is a likely component of the solution? (Q859250)

A. Formalin

B. Triphenyl tetrazolium chloride

C. Ethanol

D. Glutaraldehyde

See Answer in Part B → Q3

@Neet_pg_bot

Q4: How is thrombosis initiated? (Q858519)

A. Platelet activation

B. Endothelial injury

C. Coagulation cascade

D. Vasoconstriction of vessels

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following features does the histology of the reperfused myocardium show? (Q854873)

A. Wavy fibres

B. Neutrophils in cardiac muscle

C. Swelling of cells

D. Eosinophilic contraction band

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 3-year-old child has been brought to the hospital with complaints of fever, rash, and swelling of her hands and feet for the past 5 days. There is desquamative skin rash, edema of hands and feet, erythema of palms and soles, oral erythema, and cervical lymphadenopathy. What is the likely condition? (Q854849)

A. Kawasaki disease

B. Measles

C. Scarlet fever

D. Henoch-Schonlein purpura

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Large, friable, irregular vegetation on heart valves is seen in which condition? (Q854841)

A. Infective endocarditis

B. Rheumatic heart disease

C. Libman-Sacks endocarditis

D. Non-bacterial thrombotic carditis

See Answer in Part B → Q7

@Neet_pg_bot

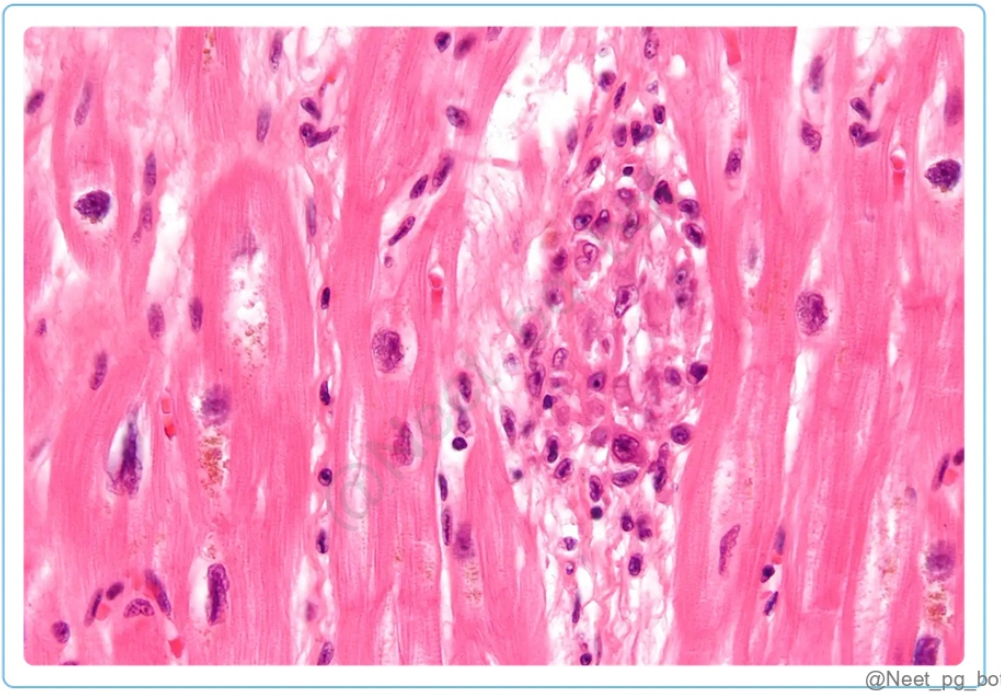
Q8: A 34-year-old female patient presented to the outpatient department with migratory arthritis, and examination revealed a pan-systolic murmur. An echocardiography was performed, which was suggestive of mitral regurgitation. A biopsy specimen was obtained, and the image is provided below. What is the most likely lesion shown in the histopathology slide? {{caption_text}} (Q856158)

A. Aschoff's bodies

B. Epithelioid granuloma

C. Granulomatous vasculitis

D. Granuloma inguinale



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A child is presenting with palpable blanching purpura, abdominal pain, and pain in the knee joint resulting from arthritis. Urine examination showed hematuria and proteinuria. What is the most likely diagnosis? (Q856146)

A. Immune thrombocytopenic purpura

B. Dengue

C. Churg-Strauss syndrome

D. Henoch-Schonlein purpura

See Answer in Part B → Q9

@Neet_pg_bot

Q10: What is the gold standard investigation for the diagnosis of myocarditis? (Q856719)

A. Endo-myocardial biopsy

B. Magnetic Resonance Imaging

C. Brain Natriuretic Peptide

D. LDH1 to LDH2 ratio

See Answer in Part B → Q10

@Neet_pg_bot

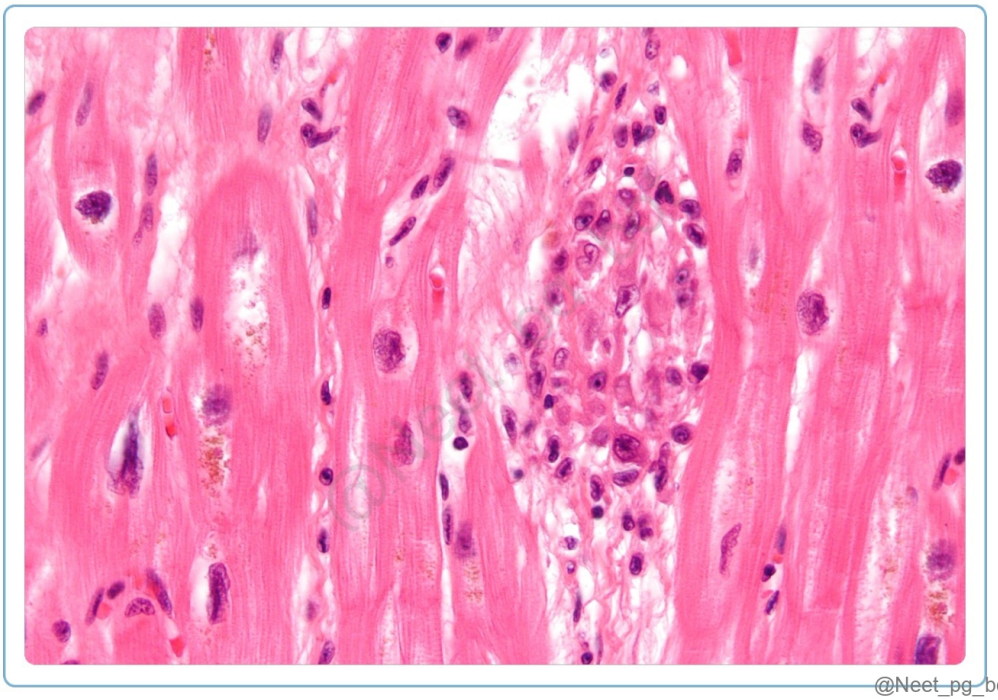
Q11: A patient presented with complaints of dyspnea on exertion for 1 month. Echocardiography showed the presence of mitral stenosis and left ventricular hypertrophy. Identify the histopathological finding given below and the probable diagnosis. (Q855407)

A. Aschoff body; Rheumatic heart disease

B. Calcification of valve; Mitral stenosis

C. Granuloma; Sarcoidosis

D. Non-caseating granuloma; Tuberculosis



See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following histopathological findings is not seen 12 hours after an ischemic injury to the heart? (Q857177)

A. Karyorrhexis of myocytes

B. Neocapillary invasion of myocytes

C. Hyper-eosinophilia of myocytes

D. Coagulation necrosis of myocytes

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 65-year-old man dies due to a myocardial infarction. Which stains can be used to see the infarct in the heart while conducting an autopsy? (Q858094)

A. Oil Red O

B. Triphenyl tetrazolium chloride

C. Sudan black B

D. Masson's trichrome

See Answer in Part B → Q13

@Neet_pg_bot

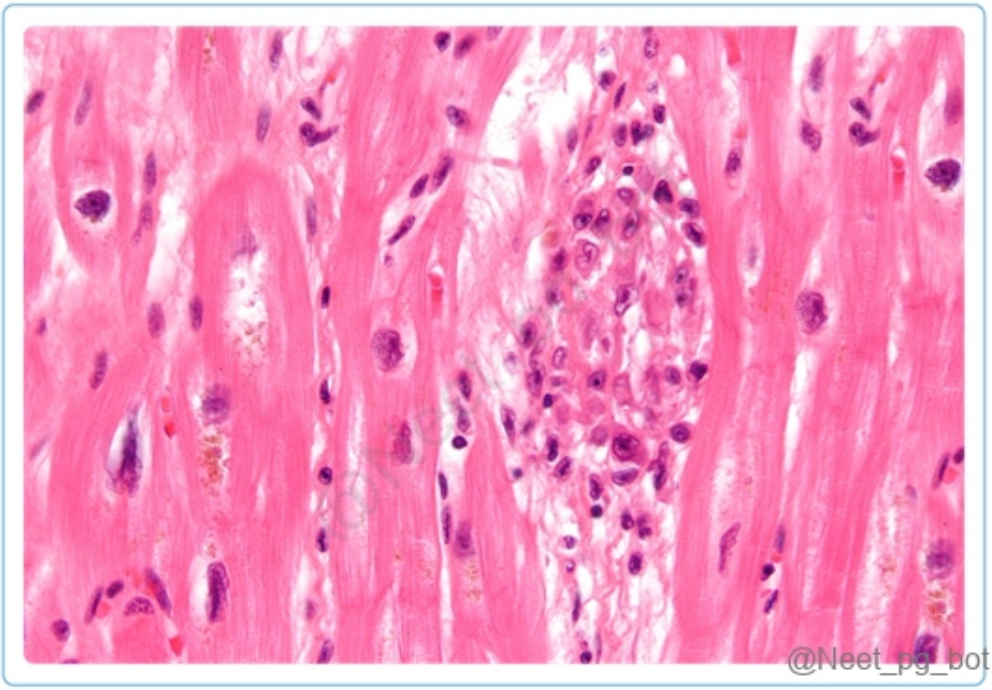
Q14: A 34-year-old female patient presented to the outpatient department with migratory arthritis, and examination revealed a pan-systolic murmur. An echocardiography was performed, which was suggestive of mitral regurgitation. A biopsy specimen was obtained, and the image is provided below. What is the most likely lesion shown in the histopathology slide? (Q858083)

A. Aschoff’s bodies

B. Epithelioid granuloma

C. Granulomatous vasculitis

D. Granuloma inguinale



See Answer in Part B → Q14

@Neet_pg_bot

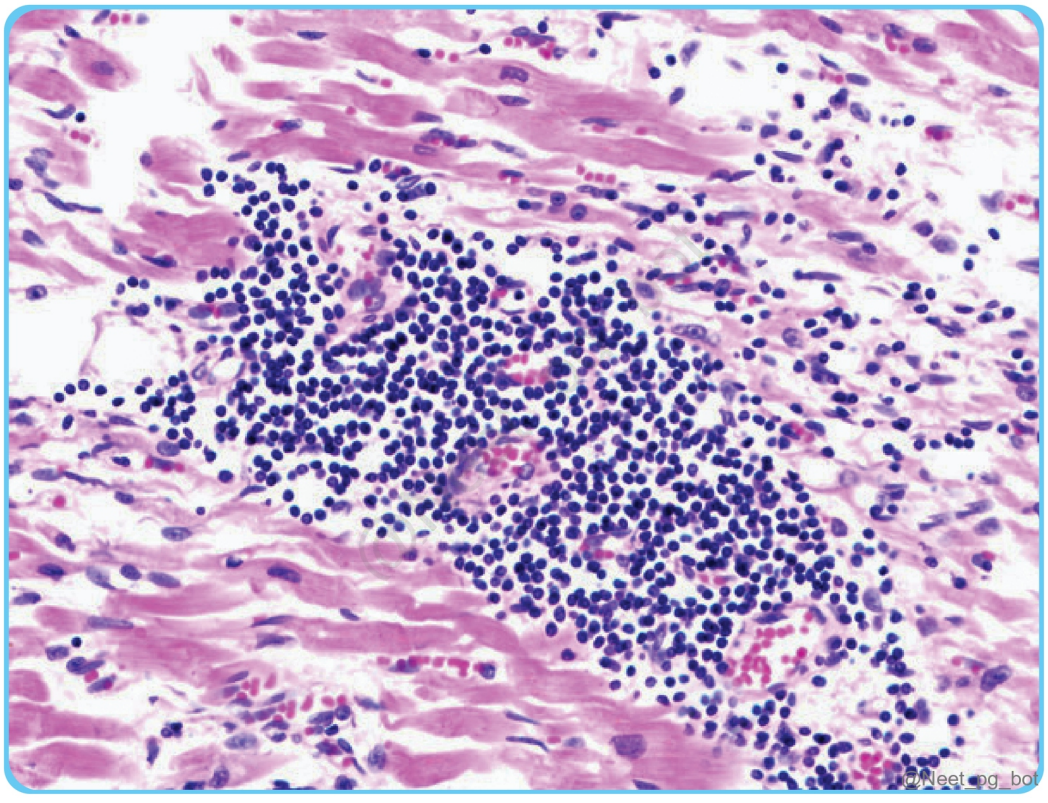
Q15: A 5-year-old child presents with fever, fatigue, and left ventricular dysfunction. An endomyocardial biopsy is shown below. What is the most likely diagnosis? (Q855420)

A. Acute rheumatic fever

B. Chagas cardiomyopathy

C. Pyogenic myocarditis

D. Lymphocytic myocarditis



See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is the earliest marker to rise in a case of myocardial infarction (MI)? (Q860196)

A. CKMB (Creatine Kinase-MB)

B. Troponin

C. LDH

D. Heart fatty acid binding protein

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 35-year-old patient presents with colicky abdominal pain, joint pain, and palpable purpura. Urinalysis shows only red blood cells with no other significant findings. Which of the following is the likely diagnosis? (Q860153)

A. IgA vasculitis

B. Granulomatosis with polyangiitis

C. Microscopic polyangiitis

D. Behçet's disease

See Answer in Part B → Q17

@Neet_pg_bot

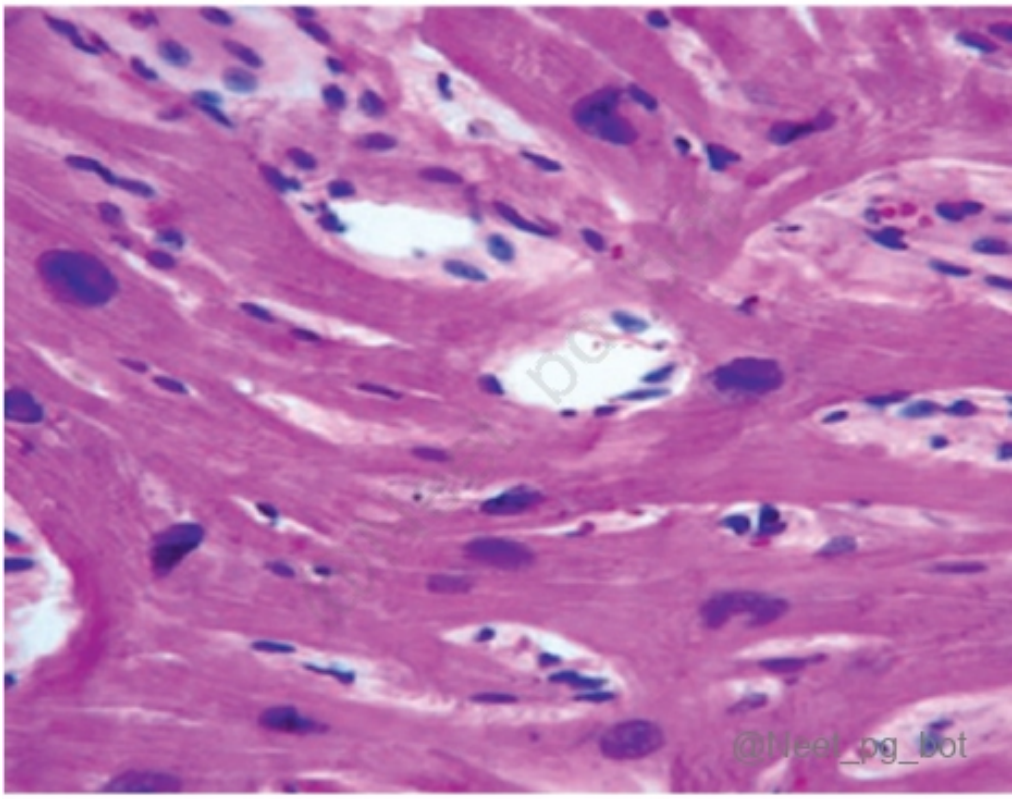
Q18: A 30-year-old football player is brought to the emergency department after he collapsed due to sudden cardiac arrest. Based on the biopsy findings of his cardiac tissue, what is the most likely cause of his death? (Q844091)

A. Hypertrophic obstructive cardiomyopathy

B. Dilated cardiomyopathy

C. Restrictive cardiomyopathy

D. Arrhythmogenic cardiomyopathy



See Answer in Part B → Q18

@Neet_pg_bot

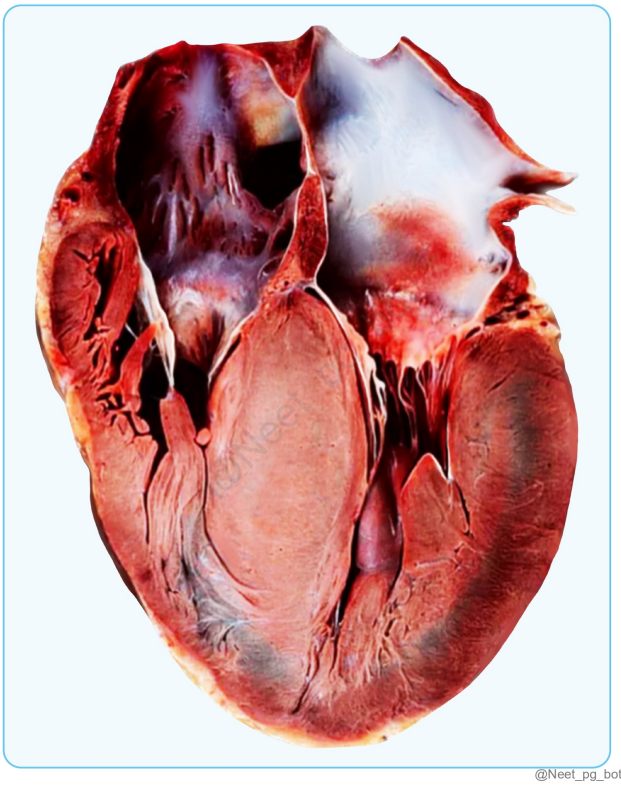
Q19: A 20-year-old athlete suddenly collapsed while playing football and was taken to the hospital, where he was declared dead. His autopsy image is given below. Which of the following is the most likely cause of death? (Q855424)

A. Valvular heart disease due to RHD

B. Sudden cardiac death due to arrhythmia

C. Sudden cardiac death due to hypertrophic cardiomyopathy

D. Sudden cardiac death due to atherosclerosis



See Answer in Part B → Q19

@Neet_pg_bot

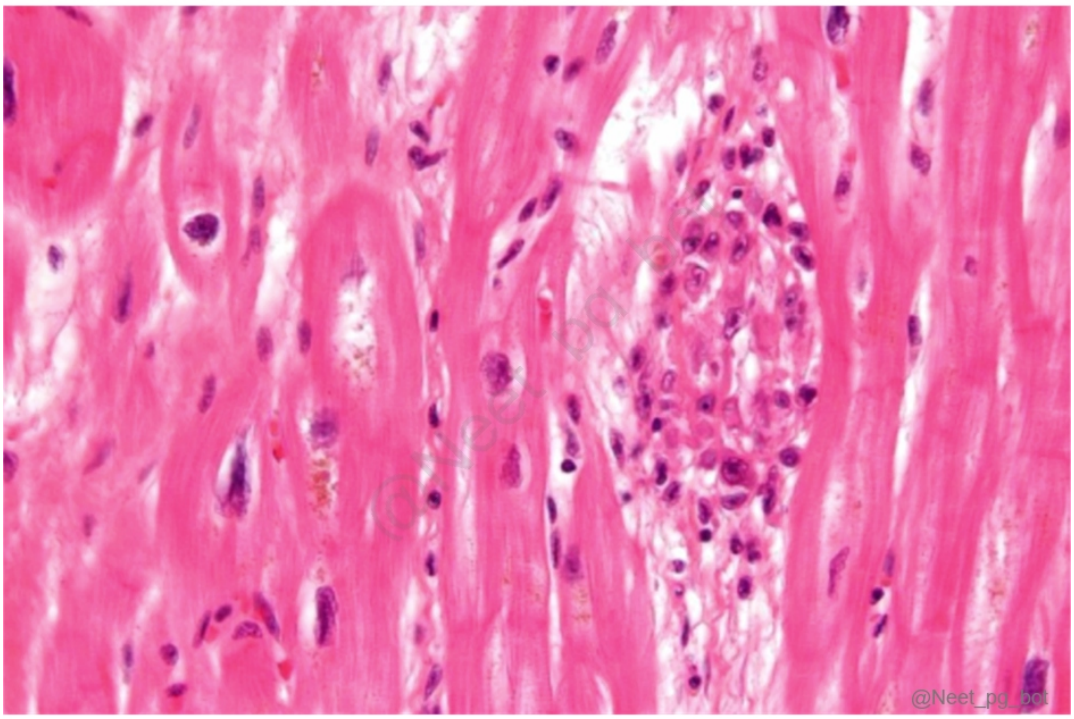
Q20: A 34-year-old female patient presented to the outpatient department with migratory arthritis , and examination revealed a pan-systolic murmur . An echocardiography was performed, which was suggestive of mitral regurgitation . A biopsy specimen was obtained, and the image is provided below. What is the most likely lesion shown in the histopathology slide? (Q799426)

A. Aschoff’s bodies

B. Epithelioid granuloma

C. Granulomatous vasculitis

D. Granuloma inguinale



See Answer in Part B → Q20

Q1: A 20-year-old male presented with cough and breathing difficulty and was diagnosed with emphysema after radiographic examination. Which of the following genetic conditions should be suspected as a possible cause? (Q845463)

A. Cystic fibrosis

B. Asthma

C. Alpha-1 antitrypsin deficiency

D. Bronchiectasis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Match the following types of emphysema with their characteristic features: Types of Emphysema Characteristic Features 1) Centriacinar emphysema A) Uniformly affects the entire acinus, commonly associated with alpha 1 antitrypsin deficiency 2) Panacinar emphysema B) Predominantly involves the upper lobes, often associated with bullae formation. Alveolar ducts and sacs are spared 3) Paraseptal emphysema C) Associated with scarring and fibrosis, often seen in patients with chronic inflammation or recurrent infections 4) Irregular emphysema D) Involves the distal airways and is often associated with spontaneous pneumothorax (Q845464)

A. 1-a, 2-c, 3-b, 4-d

B. 1-b, 2-a, 3-d, 4-c

C. 1-a, 2-b, 3-c, 4-d

D. 1-d, 2-b, 3-a, 4-c

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following mechanisms is not involved in the development of emphysema? (Q845465)

A. Toxic injury and inflammation leading to variable degrees of parenchymal destruction.

B. Protease-antiprotease imbalance with a relative deficiency of protective antiproteases.

C. The presence of T and B cells in affected parts of the lung indicates a robust adaptive immune response.

D. Oxidative stress induced by substances in tobacco smoke, alveolar damage, and inflammatory cells.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old man has been a heavy smoker for the past 40 years and presents with complaints of progressive shortness of breath, especially with exertion, and a chronic cough with occasional scanty sputum production. Physical examination reveals a barrel-shaped chest, decreased breathing sounds, and a prolonged expiratory phase. Based on the clinical presentation and history, what is the most likely diagnosis? (Q845466)

A. Chronic bronchitis

B. Emphysema

C. Pulmonary fibrosis

D. Asthma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old male patient presents with a history of chronic cough, increased sputum production, and shortness of breath. He reports that these symptoms have been present for several years and have gradually worsened over time. The patient is a lifelong smoker, having smoked one pack of cigarettes per day for the past 20 years. What is the likely diagnosis? (Q845469)

A. Emphysema

B. Asthma

C. Chronic bronchitis

D. Lung cancer

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is not true regarding chronic bronchitis? (Q845472)

A. Reid index >0.4

B. The most common cause is smoking

C. The most common cause of exacerbation is Haemophilus influenzae.

D. Recurrent, episodic attacks of wheezing, prolonged expiration, dyspnea (shortness of breath), and chest tightness.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 32-year-old female presents with recurrent episodes of wheezing, coughing, and shortness of breath. On further testing, a diagnosis of asthma was made. Which of the following best describes the underlying pathophysiological changes seen in this patient's condition? (Q845474)

A. Reduced goblet cell secretion

B. Thinning of the basement membrane

C. Increase in airway inflammation and remodeling

D. Decreased submucosal gland activity

See Answer in Part B → Q7

@Neet_pg_bot

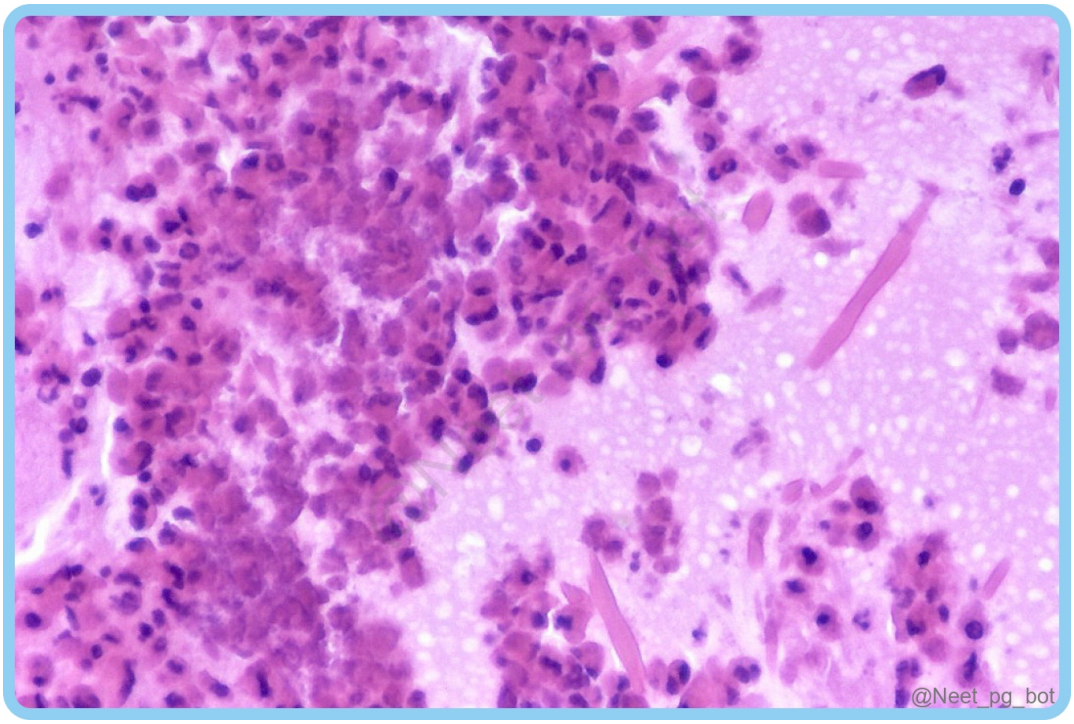
Q8: A 45-year-old male has a history of recurrent wheezing, coughing, and shortness of breath. His sputum microscopy, shown in the image below, reveals the following finding. Which best describes this finding? (Q845476)

A. Extrusion of mucus plugs from the subepithelial mucous gland ducts or bronchioles.

B. Ciliated columnar cells sloughed from the bronchial mucosa.

C. Polypoid plugs of loose organizing connective tissue within the bronchioles.

D. They are composed of Galectin 10.



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30-year-old patient presents with a history of recurrent wheezing, coughing, and shortness of breath. Upon further investigation, it is found that the patient has a family history of allergies and asthma. Which genetic factor is most likely co-related to the severity of this condition? (Q845477)

A. Variant IL-4 receptor gene

B. IL-13 polymorphism

C. ADAM33 polymorphism

D. YKL40 gene mutation

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old male presents to the emergency department with complaints of chronic cough with production of purulent sputum, intermittent hemoptysis, and recurrent respiratory infections over the past several years. He reports a history of childhood respiratory infections and no significant past medical history. Physical examination reveals coarse crackles and rhonchi on auscultation of the chest. Chest X-ray shows bilateral bronchial wall thickening and tram-line shadows. Which of the following is unlikely to be a cause for this condition? (Q845478)

A. Primary ciliary dyskinesia

B. Bronchial Asthma

C. Cystic fibrosis

D. Kartagener syndrome

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements accurately describes the pathophysiology of Kartagener's syndrome? (Q845479)

A. Mutation in the CFTR gene leading to impaired ciliary function.

B. Autosomal dominant inheritance pattern affecting the cilia in the respiratory tract.

C. The primary defect involves dynein arm proteins, leading to impaired ciliary motility.

D. Characterized by an excess of cilia in the respiratory epithelium.

See Answer in Part B → Q11

@Neet_pg_bot

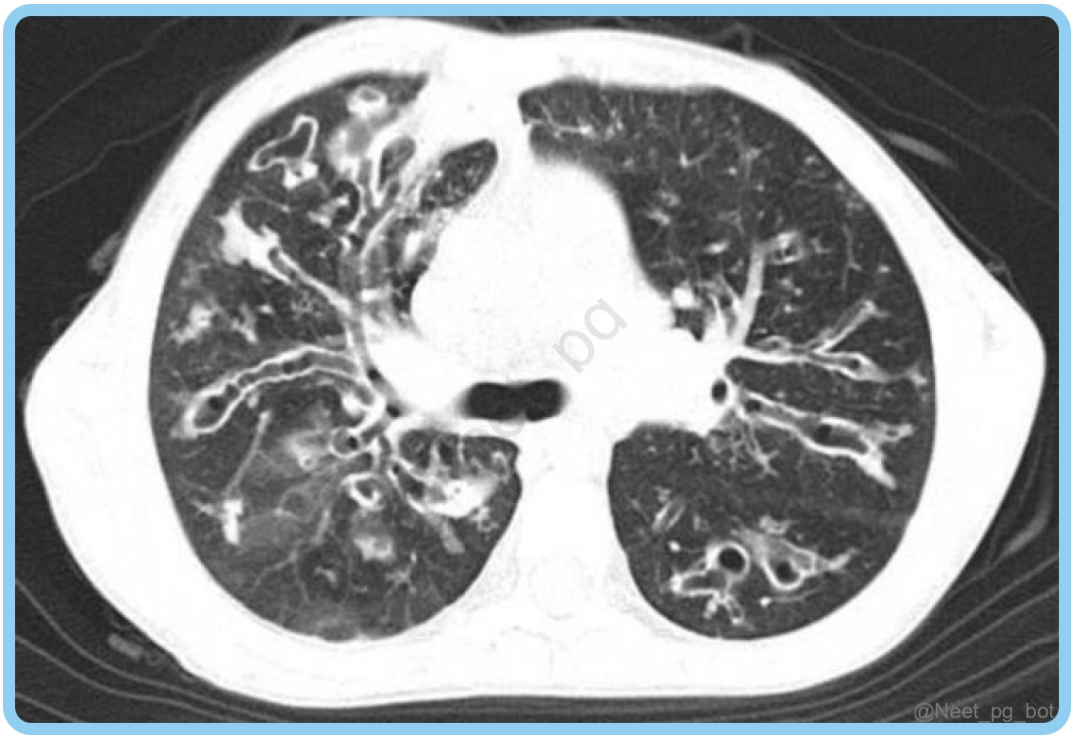
Q12: A 45-year-old male presents with a chronic cough productive of copious sputum. He reports frequent respiratory infections over the past several years. Physical examination reveals digital clubbing and coarse crackles on auscultation. An HRCT is done and shown below. Which of the following is the most likely diagnosis? (Q845480)

A. Tuberculosis

B. Asthma

C. Chronic obstructive pulmonary disease

D. Bronchiectasis



See Answer in Part B → Q12

@Neet_pg_bot

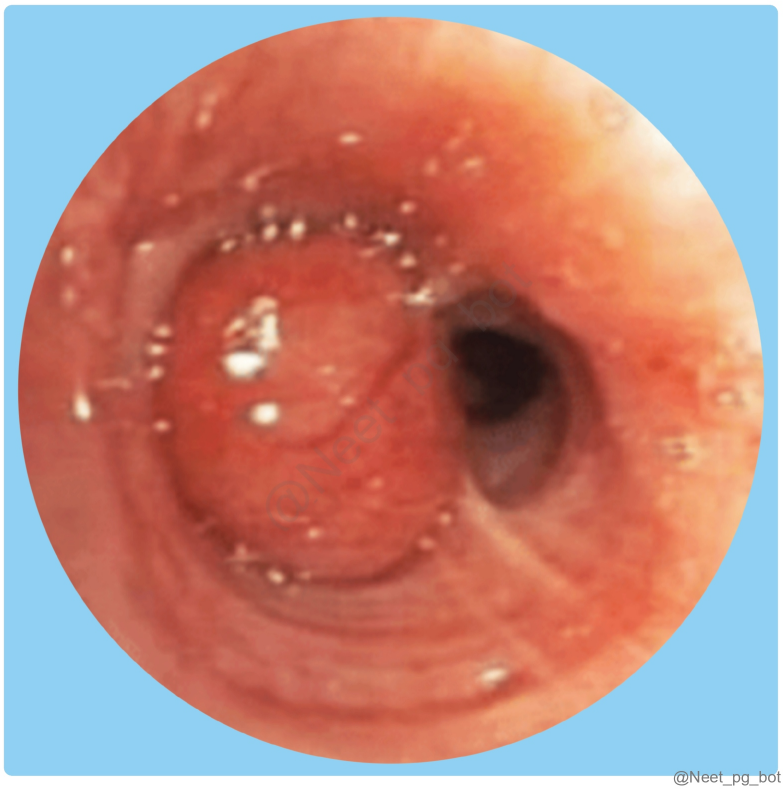
Q1: A 50-year-old female presents with a chronic cough and recurrent episodes of wheezing. Bronchoscopy reveals a "coat button lesion" within the bronchus, as shown in the image. Biopsy of the lesion shows nesting of cells with uniform round nuclei and moderate eosinophilic cytoplasm. What is the most likely diagnosis based on the described features? (Q845562)

A. Small cell lung carcinoma

B. Squamous cell carcinoma

C. Bronchial carcinoid tumor

D. Adenocarcinoma



See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following lung cancer subtypes has the highest mutational burden and is the most aggressive? (Q890492)

A. Adenocarcinoma

B. Squamous cell carcinoma

C. Small cell carcinoma

D. Large cell carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is the most common presenting symptom of lung carcinoma? (Q890491)

A. Cough

B. Hemoptysis

C. Chest pain

D. Weight loss

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following represents the most common histologic subtype of lung cancer worldwide? (Q890490)

A. Adenocarcinoma > Squamous cell carcinoma > Small cell carcinoma

B. Small cell carcinoma > Large cell carcinoma > Adenocarcinoma

C. Adenocarcinoma > Small cell carcinoma > Squamous cell carcinoma

D. Squamous cell carcinoma > Adenocarcinoma > small cell carcinoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the diagnosis for a patient who has a history of smoking 24 packs, is currently experiencing breathlessness and chest pain, and is found to have a lung tumor with positive chromogranin staining? (Q882173)

A. Adenocarcinoma

B. Squamous cell carcinoma

C. Mesothelioma

D. Small cell carcinoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is not an IHC marker for small-cell lung carcinoma? (Q846630)

A. Napsin A

B. Chromogranin

C. NSE

D. CD56

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 56-year-old male presents with persistent shoulder pain radiating to the ulnar aspect of the forearm and progressive weakness in his right hand. Examination reveals muscle wasting in the right hand. Imaging of the chest shows a mass at the apex of the right lung involving nearby neurovascular structures. Which syndrome is most likely associated with this presentation? (Q845630)

A. Horner syndrome

B. Superior vena cava (SVC) syndrome

C. Caplan syndrome

D. Carcinoid syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old woman has an incidental finding of a lung mass on imaging. CT scan reveals a well-circumscribed lesion with calcifications. Biopsy revealed spindle

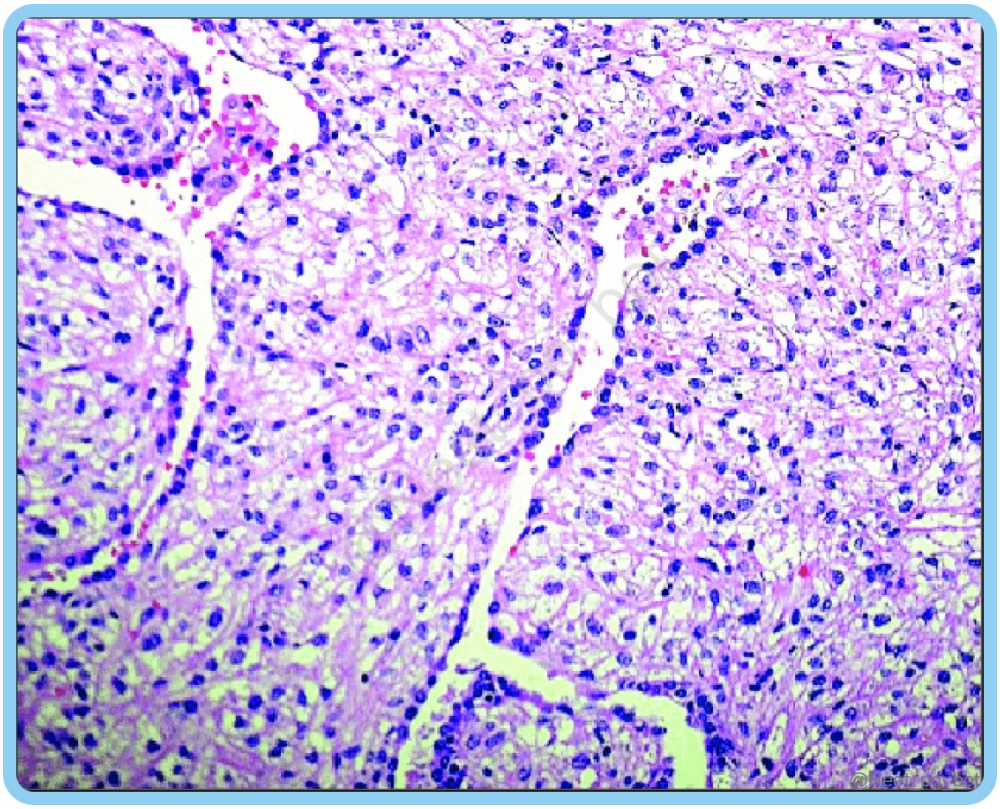
and epithelioid cells with an eosinophilic cytoplasm, perivascular growth, and positive HMB-45 staining. What is the most likely diagnosis? (Q845627)

A. Pulmonary hamartoma

B. Sugar tumour (PEComa)

C. Solitary fibrous tumour

D. Carcinoid tumour



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 55-year-old former shipyard worker presents with progressive dyspnea and left-sided chest pain for three months. He has a history of occupational asbestos exposure. Physical examination reveals decreased breath sounds over the left lung base. Imaging shows left-sided pleural thickening and effusion. Biopsy confirms mesothelioma. Which of the following statements is not accurate about mesothelioma and adenocarcinoma following asbestos exposure? (Q845595)

A. Adenocarcinoma often has a shorter latency period compared to mesothelioma following asbestos exposure.

B. Mesothelioma under electron microscopy, reveals non-branching microvilli.

C. Mesothelioma often presents with positive staining for calretinin and WT-1.

D. Adenocarcinoma is commonly associated with EGFR mutation.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old male presents with pleuritic chest pain and a pleural-based mass observed on imaging studies. Histopathological examination of a biopsy from the mass reveals spindle-shaped cells within a collagenous stroma. Which immunohistochemical marker would be most useful in differentiating solitary fibrous tumour (SFT) from mesothelioma? (Q845579)

A. CD34

B. Calretinin

C. WT1

D. TTF-1 (Thyroid transcription factor 1)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old nonsmoking woman presents with a persistent cough and hemoptysis. Imaging reveals a solitary pulmonary nodule in the right lung. Biopsy shows cells with neuroendocrine features, including round to oval nuclei, stippled chromatin, and abundant granular cytoplasm arranged in nests and trabeculae. Which cell type is most likely involved in the origin of this patient's lung tumour? (Q845564)

A. Type II pneumocytes

B. Clara cells

C. Kulchitsky cells

D. Alveolar macrophages

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old female presents progressive shortness of breath, especially on exertion, fatigue, and ankle swelling. Physical examination reveals elevated jugular venous pressure. Echocardiography shows right ventricular hypertrophy and elevated pulmonary artery pressure. Which of the following conditions can predispose her to this condition? (Q845467)

A. High altitude

B. Recurrent thromboembolic

C. Scleroderma

D. All the above

See Answer in Part B → Q12

@Neet_pg_bot

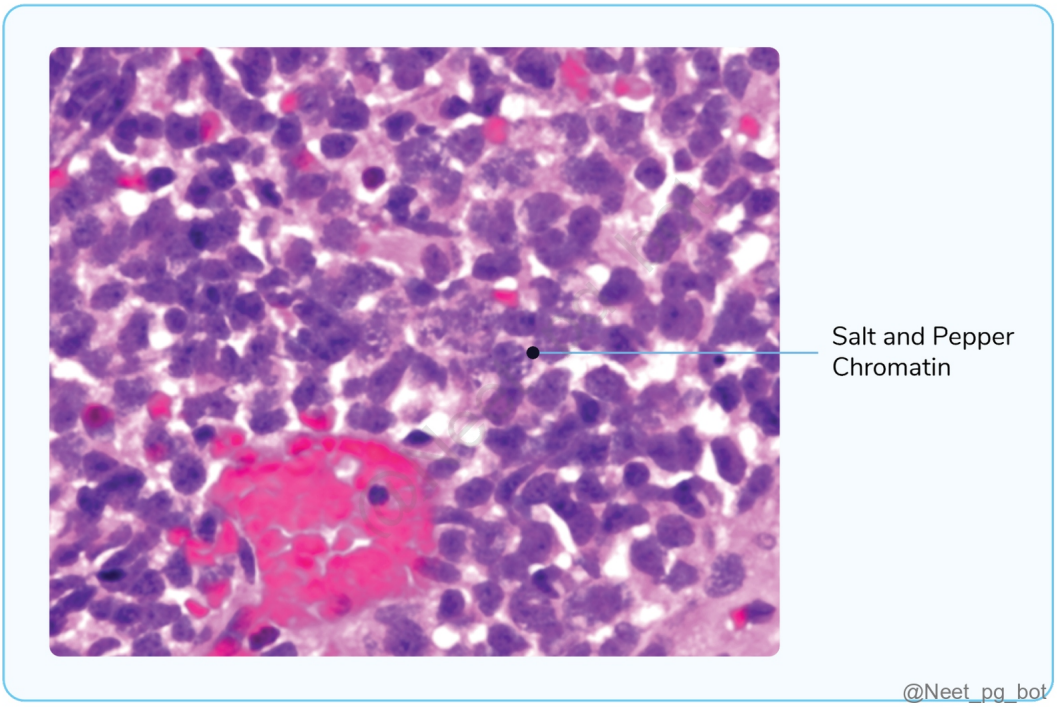
Q13: A 50-year-old heavy smoker presents with a persistent cough and unintentional weight loss. Imaging shows a right lung mass with mediastinal lymphadenopathy. Biopsy reveals small, round cells with scant cytoplasm and nuclei exhibiting a salt-and-pepper chromatin pattern. Immunohistochemistry (IHC) is positive for neuroendocrine markers. Which of the following features is incorrectly associated with this clinical condition? (Q845561)

A. Both glandular and squamous differentiation are seen

B. Encrustation of tumour cells along the blood vessels with DNA material

C. Presence of dense neurosecretory granules on electron microscopy

D. High proliferative index



See Answer in Part B → Q13

@Neet_pg_bot

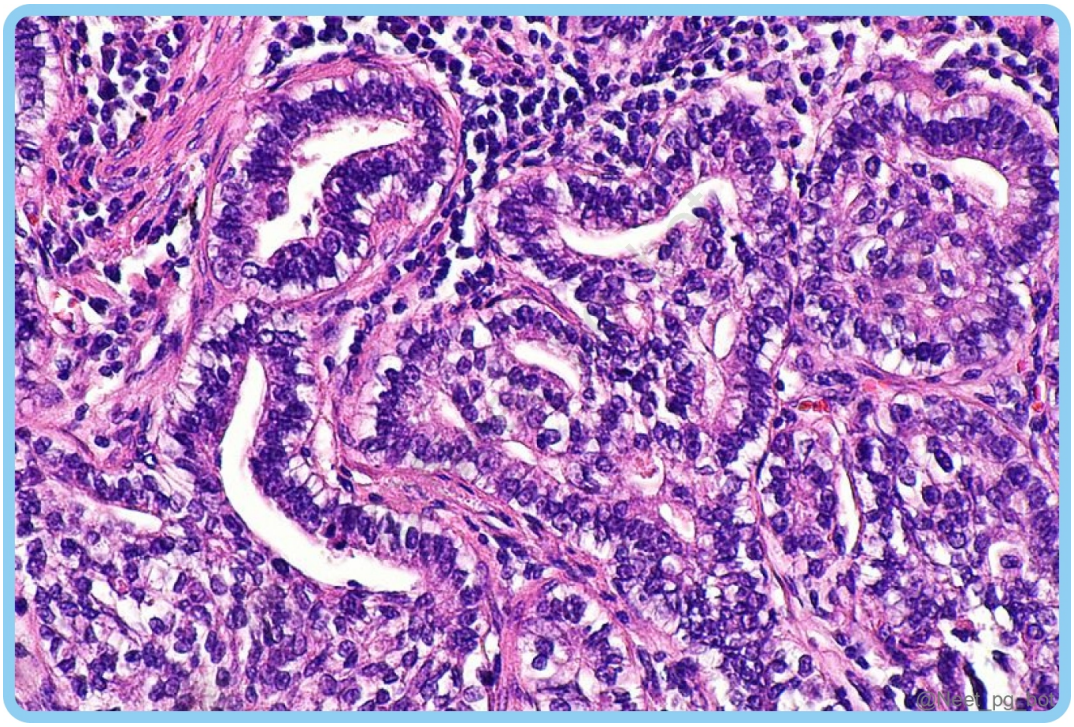
Q14: A 52-year-old male, non-smoker, presents with progressive shortness of breath, persistent dry cough, and chest pain. A CT scan reveals a peripheral mass in the lower lobe of left lung, and a biopsy of the nodule demonstrates a glandular pattern with mucinous differentiation, as shown in the image below. Which of the following markers is least likely to be positive in this patient's lung lesion? (Q845560)

A. TTF-1 (Thyroid Transcription Factor-1)

B. MUC1

C. Napsin A

D. Chromogranin



See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 59-year-old heavy smoker presents with loss of appetite and a persistent cough for the past few months. Imaging reveals a central lung mass involving the right bronchus and mediastinal lymph nodes. Immunohistochemical staining of a lung mass biopsy is positive for chromogranin and synaptophysin. Which set of genes is most likely involved in the underlying pathology of this patient's condition? P53 RB L-myc (Q845559)

A. 1, 2

B. 1, 2, 3

C. Only 2

D. 2, 3

See Answer in Part B → Q15

@Neet_pg_bot

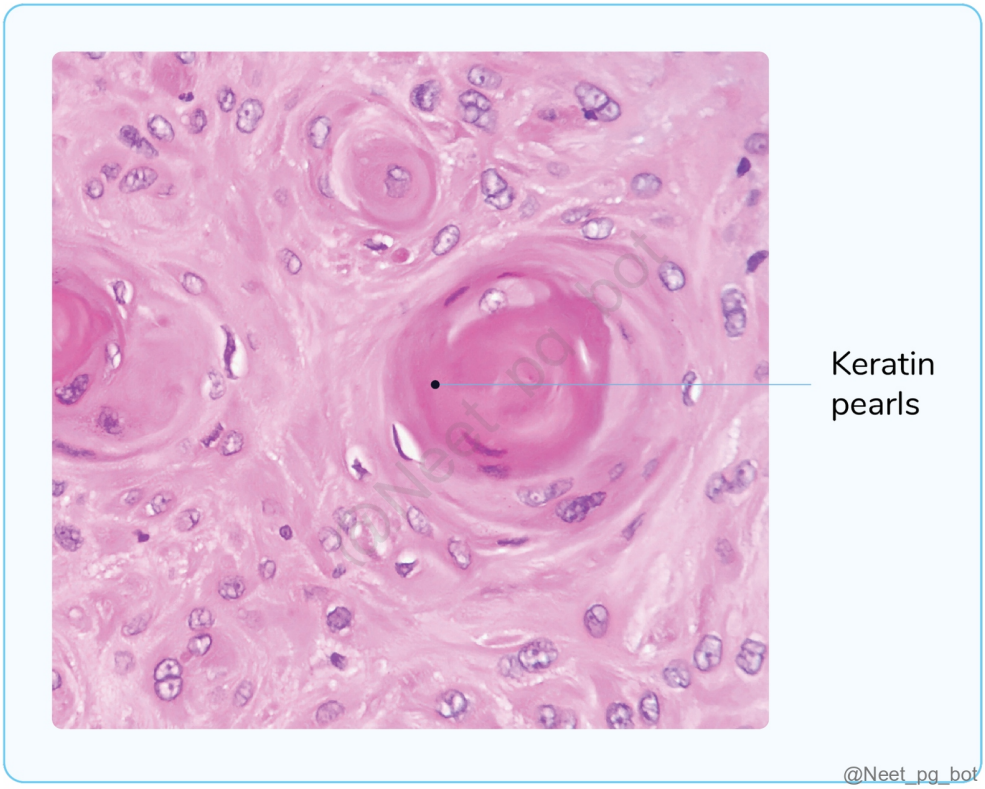
Q16: A 57-year-old male smoker with a persistent cough and weight loss is found to have a lung mass on imaging. The biopsy showed keratin pearls and intercellular bridges. Which of the following paraneoplastic syndromes is highly associated with this diagnosis? (Q845558)

A. Hypercalcemia

B. Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH)

C. Migratory thrombophlebitis

D. Cushing's syndrome



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 67-year-old male smoker presents with a persistent cough and weight loss. Imaging reveals a lung mass in the upper lobe of the right lung. The biopsy reveals typical features, including keratin pearls, intercellular bridges, and nests of malignant squamous cells with abundant eosinophilic cytoplasm. Based on this scenario, which of

the following statements is incorrect? (Q845557)

A. Keratin pearls are not seen in poorly differentiated squamous cell carcinoma.

B. p40 is the best marker for squamous cell carcinoma.

C. Squamous dysplasia is a precursor lesion of squamous cell carcinoma

D. The squamous cell carcinoma described is likely a peripheral lung lesion.

See Answer in Part B → Q17

@Neet_pg_bot

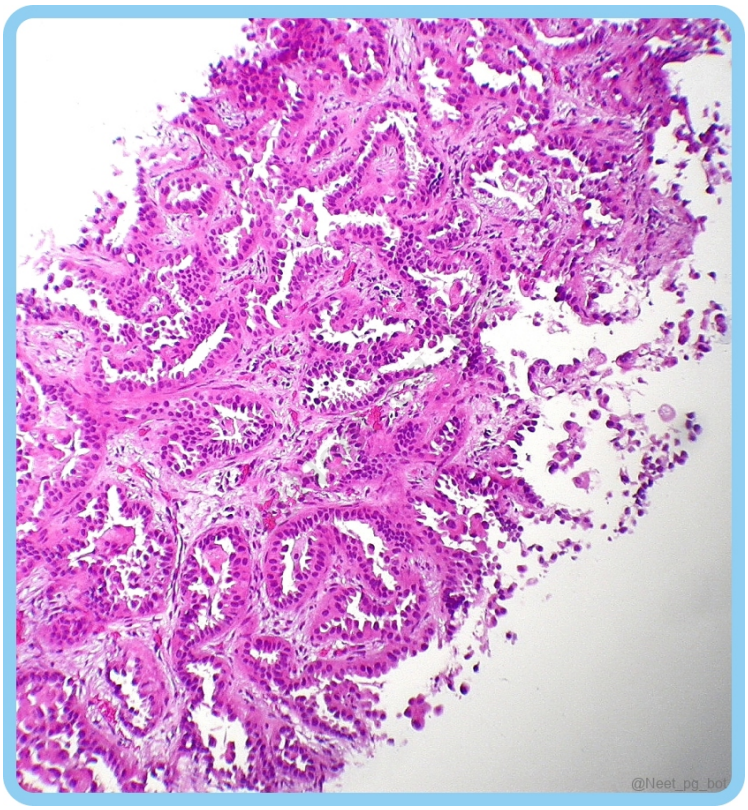
Q18: A 58-year-old male smoker presents with a persistent cough and mild shortness of breath. Chest imaging reveals a solitary pulmonary nodule. A biopsy is performed, and a histopathological examination of the lung tissue is shown in the image below. What is the most likely diagnosis? (Q845556)

A. Carcinoma in situ

B. Adenomatous hyperplasia

C. Adenocarcinoma in situ

D. Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia



See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 55-year-old male smoker presents to the clinic with chronic cough and hemoptysis. He has been smoking two packs of cigarettes per day for the past 30 years. Upon further evaluation, a biopsy reveals lung carcinoma. Which of the following statements regarding risk factors for lung carcinoma is false? (Q845473)

A. Smoking is a major risk factor for squamous cell carcinoma of the lung.

B. Smoking has no association with adenocarcinoma of the lung.

C. Smoking is a significant risk factor for small-cell lung carcinoma.

D. Asbestosis exposure, along with smoking, multiplies the risk of lung cancer.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old man presents with severe shortness of breath, cough, and fever after recent bacterial pneumonia. Physical examination shows tachypnea, hypoxia, and diffuse crackles on chest auscultation. Chest X-ray reveals bilateral opacities suggestive of pulmonary oedema. Histopathological examination of lung biopsy shows congested, edematous lungs with inflammation. Which histopathological finding is characteristic of the acute exudative stage in this patient's lung injury? (Q845471)

A. Proliferation of type II pneumocytes

B. Formation of fibrotic thickening in the alveolar septa

C. Presence of waxy hyaline membranes lining the alveolar walls

D. Resolution of granulation tissue in the alveolar spaces

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following statements regarding the pathogenesis sequence of non-cardiogenic pulmonary oedema (NCPE) and acute respiratory distress syndrome (ARDS) is incorrect? Endothelial activation is the hallmark of pathogenesis. Release of cytokines by alveolar epithelial cells Macrophage activation resulting in the release of IL-8 and TNF Recruitment of lymphocytes by IL-8 (Q845470)

A. 1 and 3

B. 1, 2 and 3

C. 2 and 4

D. 1 and 4

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 45-year-old woman presents with progressive shortness of breath and fatigue. On examination, she has elevated jugular venous pressure and a loud pulmonary component of the second heart sound. Echocardiography reveals right ventricular

hypertrophy and dilation. Which of the following statements is correct regarding the vascular changes of this condition? (Q845468)

A. BMPR2 mutations result in endothelial and vascular smooth muscle cell apoptosis.

B. Classic atherosclerotic changes are commonly observed in pulmonary arteries.

C. Plexiform lesions are early changes of pulmonary hypertension.

D. Pulmonary arterioles show medial hypertrophy and intimal fibrosis, narrowing the lumens.

See Answer in Part B → Q22

Q7 (p. 378) *Q8 (p. 381)* *Q9 (p. 381)* *Q10 (p. 381)*

Q1: Ciliocytophthoria is seen in? (Q845391)

A. Kartagener syndrome

B. Cystic fibrosis

C. Situs inversus

D. Acute respiratory infection

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is false regarding extralobular sequestration? (Q845396)

A. It is external to the lung.

B. It most commonly presents as a mass lesion.

C. It most often occurs in older children.

D. It has a separate pleural covering.

See Answer in Part B → Q2

@Neet_pg_bot

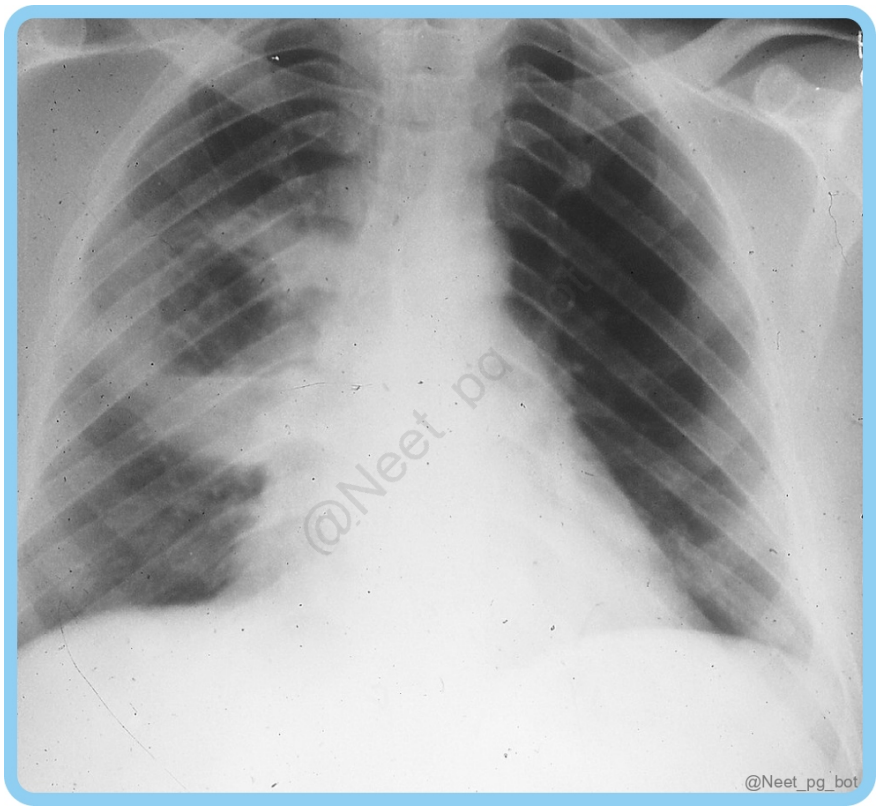
Q3: A 65-year-old female presents to the clinic with a productive cough, fever, and fatigue for the past two weeks. She has a history of poorly controlled diabetes mellitus and reports recent hospitalisation for a urinary tract infection. On physical examination, coarse crackles are auscultated over the right lower lung fields. The chest X-ray is shown below. Which of the following is the most common risk factor for developing this condition? (Q845399)

A. Antecedent primary lung infection

B. Aspiration of infective material

C. Septic embolism

D. Neoplasia



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 29-year-old previously healthy male presents with a one-week history of progressively worsening dry cough, fever, and shortness of breath. He denies any

recent travel but mentions attending a crowded social gathering a week ago. He is febrile, tachypneic, and has crackles on auscultation. Laboratory investigations reveal leukocytosis. A chest X-ray demonstrates patchy infiltrates in the lower lobes bilaterally. Which of the following features is not associated with this condition? (Q845402)

A. Inflammatory changes are confined to the pulmonary interstitium.

B. Neutrophils are involved in this infection.

C. It is associated with viral infections

D. It is also known as walking pneumonia.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Red hepatisation of the lungs is seen on which day? (Q845405)

A. 1-2

B. 2-4

C. 5-7

D. Beyond 7 day

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old male with a long-standing history of chronic alcohol abuse presents with a one-week history of high-grade fever, productive cough with thick, mucoid, blood-tinged "currant jelly" sputum, and right-sided pleuritic chest pain. He reports frequent binge drinking episodes and he had several recent episodes of aspiration while intoxicated. On examination, he appears ill, with a temperature of 39.5°C, tachypnea, and signs of consolidation over the right upper lung fields. Laboratory investigations reveal leukocytosis with neutrophilia and elevated inflammatory markers. Chest X-ray shows bulging of right upper lobe fissure consistent with a dense

lobar consolidation. What is the most likely organism implicated in this condition? (Q845409)

A. Mycoplasma pneumoniae

B. Legionella pneumophila

C. Moraxella catarrhalis

D. Klebsiella pneumoniae

See Answer in Part B → Q6

Q1: Which immunologic abnormalities are observed in the local milieu of sarcoid granulomas? (Q845654)

A. Accumulation of CD8+ T cells and increased CD8/CD4 T-cell ratio

B. Oligoclonal expansion of B-cell subsets

C. Increased levels of Th1 cytokines such as IL-4 and IL-10

D. Accumulation of CD4+ T cells and increased CD4/CD8 T-cell ratios

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 40-year-old male presents with fever, bilateral hilar lymphadenopathy, erythema nodosum, and acute polyarthritis affecting ankles and knees. He has a history of recurrent uveitis. Laboratory tests show elevated serum angiotensin-converting enzyme (ACE) levels and hypercalcemia. What is the most likely diagnosis? (Q845655)

A. Lupus pernio

B. Lofgren's syndrome

C. Mikulicz syndrome

D. Systemic Lupus Erythematosus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: In a histopathological examination of a lung biopsy from a patient with suspected sarcoidosis, which of the following microscopic features would be most characteristic and supportive of the diagnosis? (Q845656)

A. Macrophages with abundant cytoplasm containing dusty brown pigment

B. Non-necrotizing granulomas with asteroid bodies and Schaumann bodies

C. Coalescent tubercles with central caseation

D. Curschmann spirals and Charcot-Leyden crystals

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male presents with a chronic cough, dyspnea, and chest tightness. On examination, fine crackles are heard bilaterally. A lung biopsy reveals collections of carbon-laden macrophages within the respiratory bronchioles and alveolar ducts, along with focal fibrosis and occasional small granulomas. Which of the following is not a condition associated with this patient? (Q845657)

A. Anthracosis

B. Simple Coal Worker’s Pneumoconiosis

C. Complicated coal Worker’s pneumoconiosis

D. Psittacosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 50-year-old sandblaster presents with chronic cough, dyspnea, and chest pain. Further investigation reveals a history of prolonged exposure to sandblasting. He has also worked for several years in mines, where he was exposed to chronic asbestos and

beryllium. A chest X-ray was taken, which is shown below. What is the most likely diagnosis? (Q845658)

A. Byssinosis

B. Silicosis

C. Asbestosis

D. Berylliosis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is not a cause of eggshell calcification? (Q845659)

A. Silicosis

B. Sarcoidosis

C. Post-radiation therapy

D. Metastatic lymph nodes

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following forms of asbestos is more toxic? (Q845660)

A. Serpentine

B. Amphibole

C. Chrysolite

D. Erionite

See Answer in Part B → Q7

@Neet_pg_bot

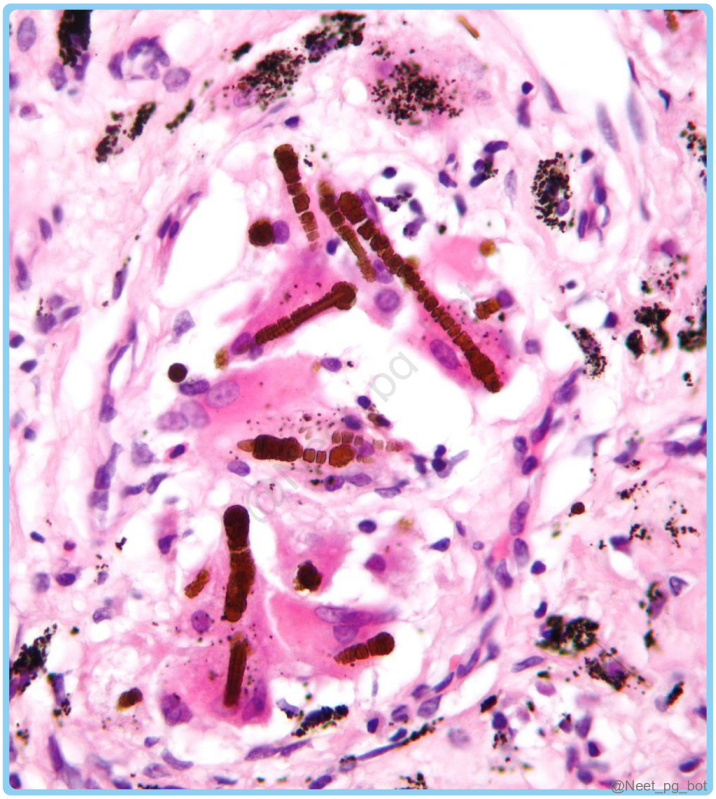
Q8: A patient has been experiencing dyspnea for the past few weeks. A biopsy of his lungs has revealed the finding given below. What is the characteristic finding shown below in this patient? (Q845661)

A. Creola body

B. Schaumann body

C. Ferruginous body

D. Asteroid body



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 55-year-old male presents to the clinic with complaints of persistent chest pain, shortness of breath, and unexplained weight loss. He was chronically exposed to minerals when he worked as a shipbuilder. Imaging studies revealed a growth that was subjected to needle biopsy. What is the most common lung malignancy associated with his occupational exposure? (Q845662)

A. Squamous cell carcinoma

B. Adenocarcinoma

C. Mesothelioma

D. Small cell cancer

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Match the following occupational lung diseases with their characteristics. A) Byssinosis 1. Iron exposure B) Bagassosis 2. Monday disease C) Siderosis 3. Non-caseating granuloma. D) Berylliosis 4. Sugarcane dust exposure (Q845663)

A. A-4, B-2, C-1, D-3

B. A-2, B-4, C-1, D-3

C. A-3, B-1, C-4, D-2

D. A-2, B-1, C-4, D-3

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is incorrect about mesothelioma? (Q846631)

A. Most specific cancer associated with asbestos exposure

B. Can lead to frozen hemithorax

C. Leads to a mediastinal shift

D. Not associated with smoking

See Answer in Part B → Q11

Q1: A chronic smoker who worked in a cement factory for 20 years developed mesothelioma. It is due to? (Q855446)

A. Silicosis

B. Asbestosis

C. Coal worker pneumoconiosis

D. Bagassosis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is a post-mortem finding seen in the lung after the death of a patient from COVID-19 after a week? (Q855970)

A. Fresh and old intra-alveolar hemorrhage

B. Thick layer of fibrin

C. Perivascular cuffing

D. Pulmonary artery hypertrophy with increased resistance

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 30-year-old woman with a long history of dyspnea, chronic cough with sputum, and wheezing died of respiratory failure following a bout of lobar pneumonia. She was not a smoker or an alcoholic. The lung at autopsy is shown in the image below. Which of the following is most likely to cause the pathological changes shown? (Q854883)

A. Alpha-1 antitrypsin deficiency

B. Cystic fibrosis

C. Mutation in dynein arms

D. Antibodies against type-IV collagen

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male presents with a chronic cough, shortness of breath, and chest pain. He has a history of working in construction for several decades, where he was exposed to asbestos. Physical examination reveals decreased breath sounds over the

lower lung fields. A chest X-ray shows bilateral, diffuse interstitial opacities. Pulmonary function tests reveal a restrictive pattern. High-resolution computed tomography (HRCT) of the chest demonstrates "honeycombing" in the lung parenchyma. What is the diagnosis? (Q856495)

A. Tuberculosis

B. Chronic Obstructive Pulmonary Disease (COPD)

C. Asbestosis

D. Pneumonia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: The most common lung finding in a COVID-19 infection is: (Q856477)

A. Pulmonary infarction

B. Diffuse alveolar damage

C. Endothelial injury

D. Fibrin clots

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 42-year-old female patient presents with a cough, a low-grade fever, and hemoptysis. Investigations reveal a cavitary lesion on her right lung apex, which, on biopsy, reveals caseous necrosis. The underlying pathophysiology is: (Q856728)

A. Enzyme degradation

B. Type-4 hypersensitivity reaction

C. Fibrinoid deposition

D. Sudden cut off of blood supply

See Answer in Part B → Q6

@Neet_pg_bot

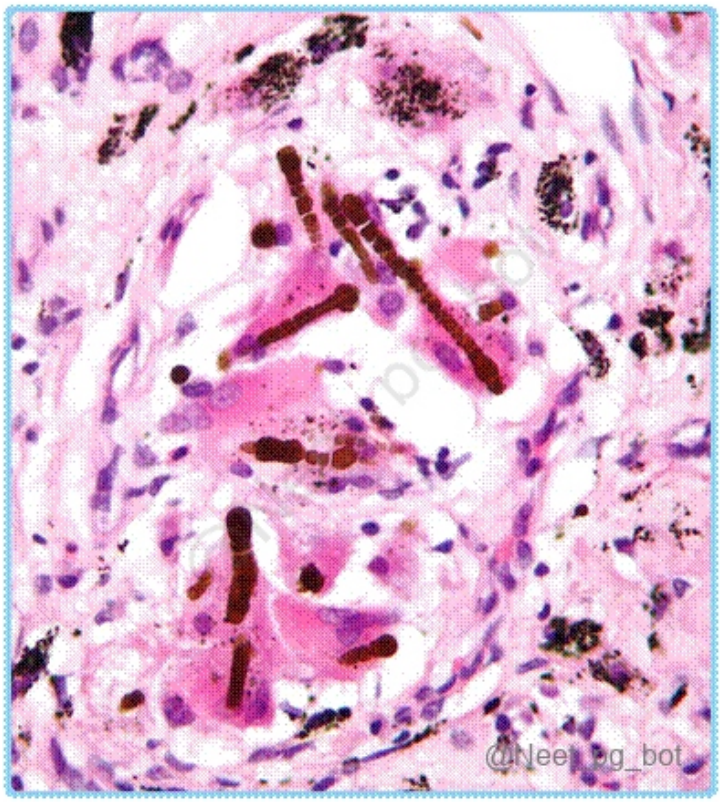
Q7: A person working in an industry for a long time develops progressive breathlessness. The histopathological image of his lung biopsy is given below. What industry was the person most likely working in? (Q856697)

A. Silica

B. Asbestos

C. Coal dust

D. Cotton



See Answer in Part B → Q7

@Neet_pg_bot

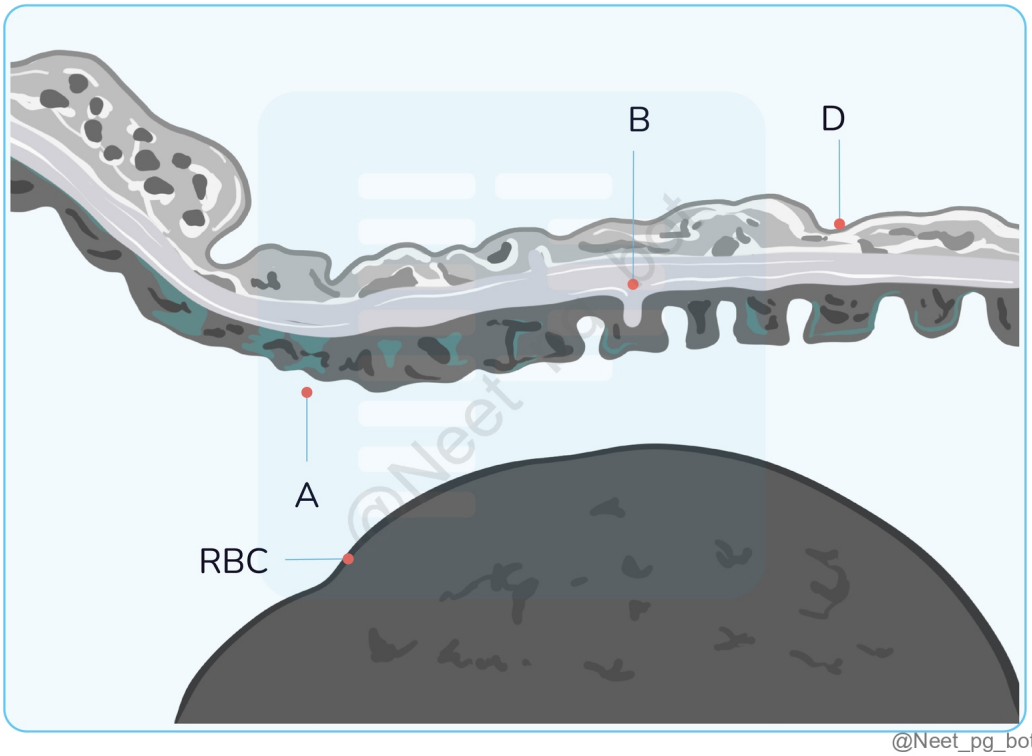
Q8: Below is an electron microscopic image of lung tissue. A patient infected with SARS-CoV2 presents with ARDS. The infection would affect and expand in which of the following labelled layers? (Q855415)

A. B

B. A

C. D

D. None of the above



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old patient who has been working in a factory for the past 20 years presents with breathlessness. HRCT of the chest shows pleural thickening and fibrosis. What is the person suffering from? (Q857611)

A. Asbestosis

B. Coal worker pneumoconiosis

C. Silicosis

D. Berylliosis

See Answer in Part B → Q9

@Neet_pg_bot

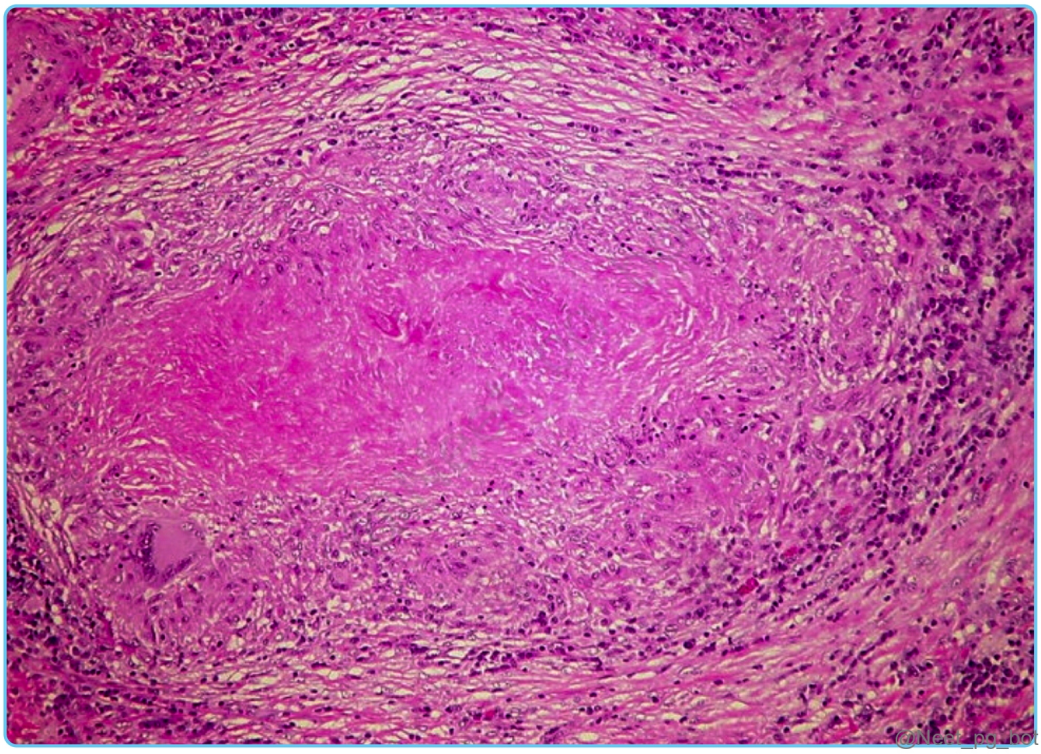
Q10: A 12-year-old child presents with a persistent cough for 15 days. Upon examination, cervical lymphadenopathy is observed. A lymph node biopsy image is given below. What is the most likely diagnosis? (Q857586)

A. Tuberculosis

B. Leprosy

C. Sarcoidosis

D. Syphilis



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A middle-aged man working in the sandblasting industry developed hemoptysis and a productive cough. A chest x-ray is suggestive of tuberculosis. Which of the following is associated with the same? (Q857109)

A. Asbestosis

B. Silicosis

C. Anthracosis

D. Siderosis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the diagnosis for a patient with a history of smoking 24 packs, currently experiencing breathlessness and chest pain, and found to have a lung tumour with positive chromogranin staining? (Q855092)

A. Adenocarcinoma

B. Squamous cell carcinoma

C. Mesothelioma

D. Small cell carcinoma

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A chronic smoker who worked in a cement factory for the past 20 years developed mesothelioma. This association is most likely due to? (Q866738)

A. Bagassosis

B. Silicosis

C. Asbestosis

D. Adenocarcinoma

See Answer in Part B → Q13

@Neet_pg_bot

Q14: An elderly male smoker presents with a chronic cough, significant weight loss, and fatigue. The serum calcium level is raised. A lung biopsy reveals large atypical cells with hyperchromasia. What is the probable diagnosis? (Q855423)

A. Large cell neuroendocrine tumour

B. Small cell carcinoma

C. Adenocarcinoma

D. Squamous cell carcinoma

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 30-year-old patient arrives at the emergency room with complaints of respiratory discomfort. The patient has been experiencing shortness of breath, coughing, and chest pain for the past few weeks. The patient's medical history is unremarkable, and there is no significant smoking history. Upon further investigation, a lung biopsy is performed, and microscopic examination reveals the presence of asteroid bodies. What is the most likely diagnosis for this patient? (Q820569)

A. Sarcoidosis

B. RA

C. Sjogren syndrome

D. SLE

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the following: A. Caplan’s syndrome 1. Found first in coal worker B. Asbestosis 2. Crazy pavement C. Mesothelioma 3. Involves lower lobe D. Silicosis 4. Pleural effusion (Q857428)

A. A-1, B-3, C-4, D-2

B. A-2, B-4, C-1, D-3

C. A-3, B-2, C-1, D-4

D. A-4, B-1, C-2, D-3

See Answer in Part B → Q16

@Neet_pg_bot

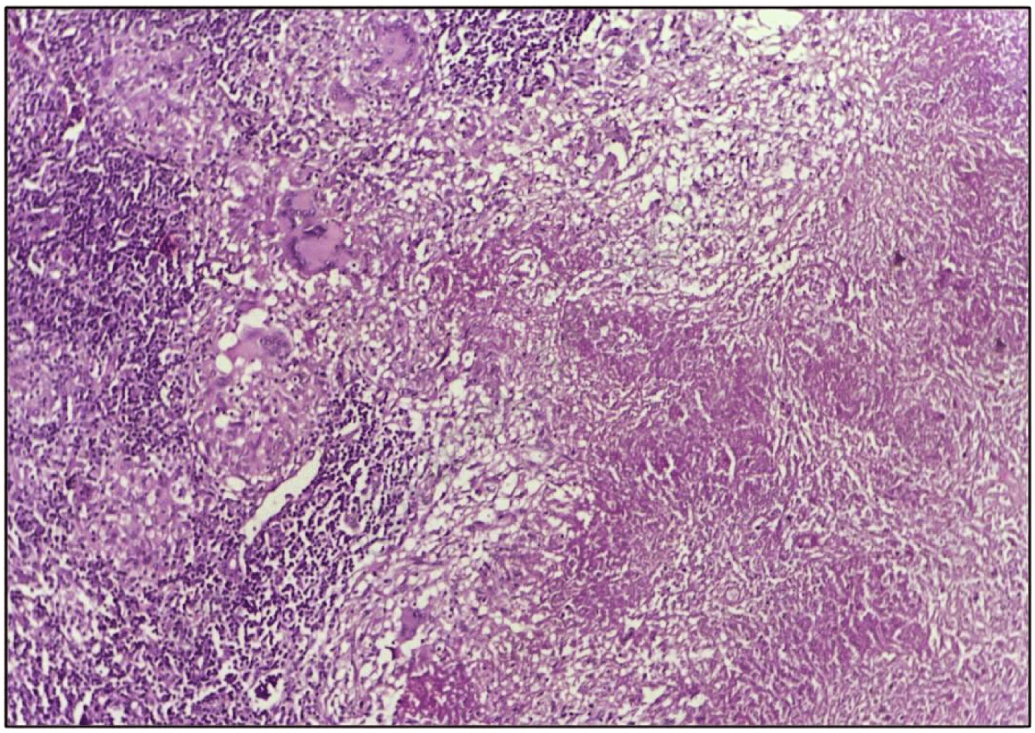
Q17: What is the most probable diagnosis based on the provided histopathology of the enlarged cervical lymph node? (Q840059)

A. Sarcoidosis

B. Tuberculosis

C. Histoplasmosis

D. Brucellosis



See Answer in Part B → Q17

@Neet_pg_bot

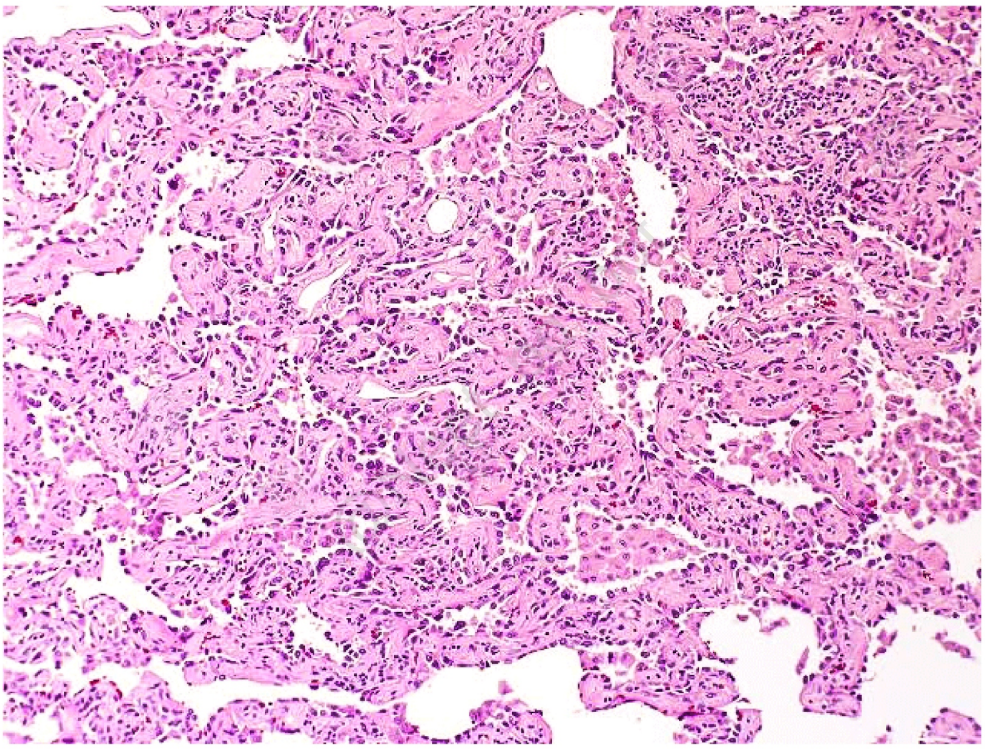
Q18: Based on the biopsy image given below, what is the most probable diagnosis? (Q840057)

A. Adenocarcinoma

B. Squamous cell carcinoma

C. Small cell carcinoma

D. Large cell carcinoma



@Neet_pg_bot

See Answer in Part B → Q18

@Neet_pg_bot

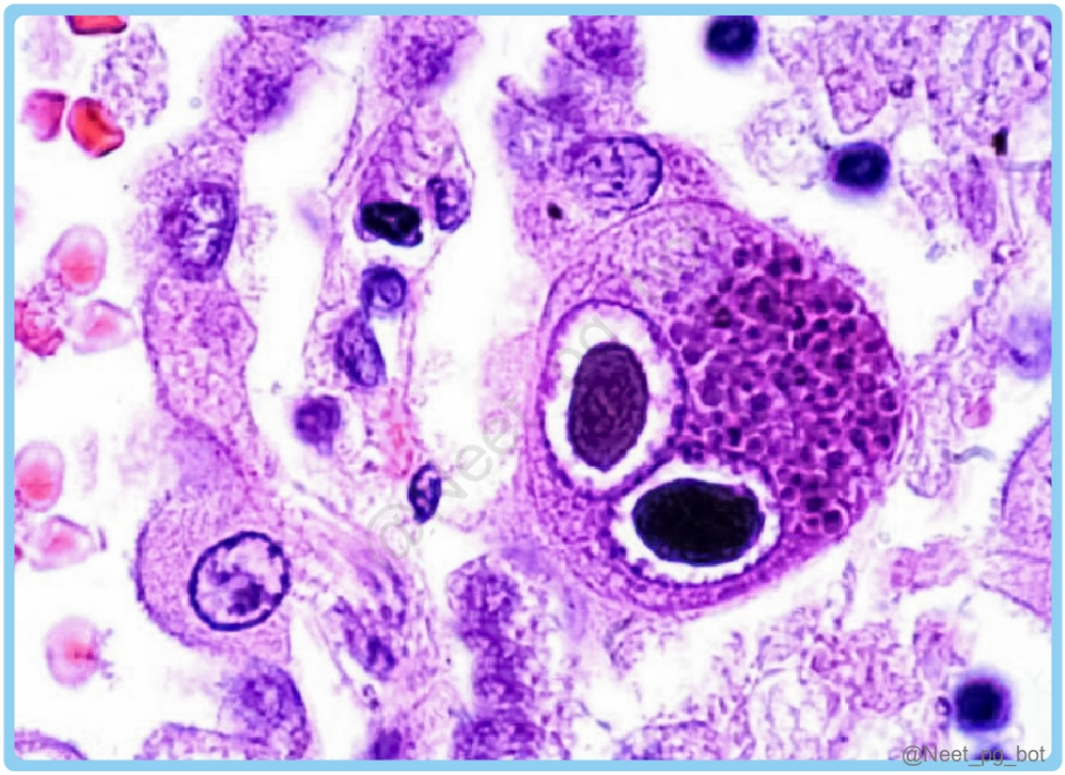
Q19: A 65-year-old patient on immunosuppressive therapy presents with a cough, fever, and pneumonia. A biopsy reveals the given findings. Which organism is responsible for the infection? (Q860561)

A. EBV

B. CMV

C. Pox virus

D. Chickenpox



See Answer in Part B → Q19

@Neet_pg_bot

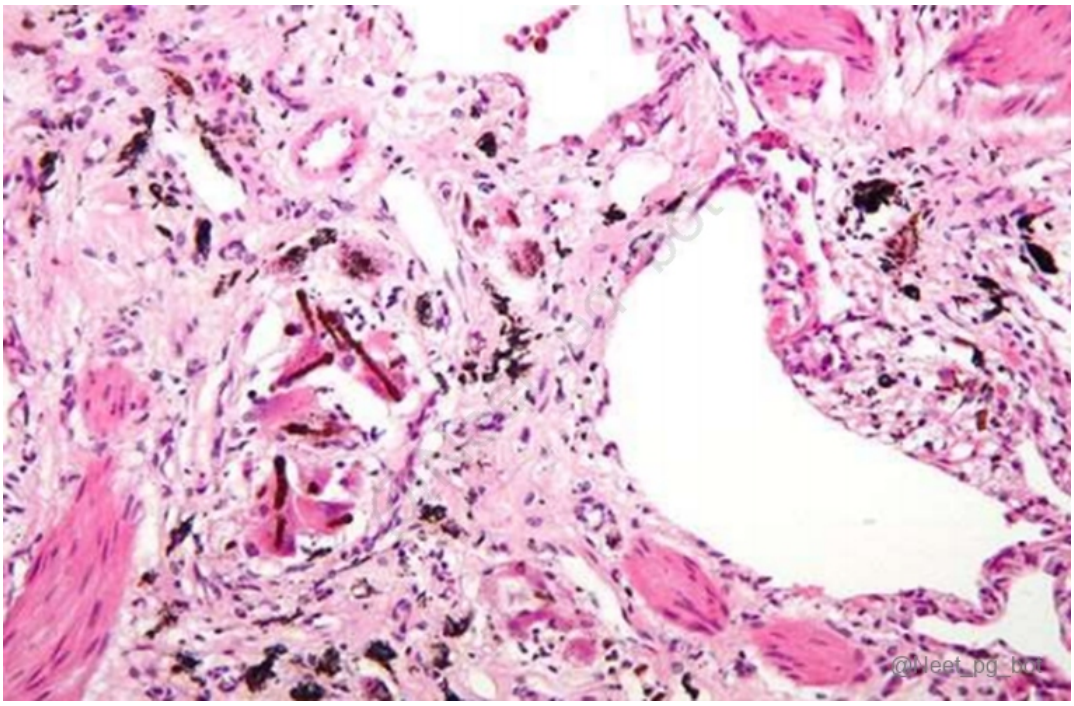
Q20: A patient presented with interstitial lung disease with an occupational history of working in a factory for 20 years and underwent a biopsy. Based on the findings, what is the most likely diagnosis? (Q844241)

A. Stanosis

B. Silicosis

C. Byssinosis

D. Asbestosis



See Answer in Part B → Q20

@Neet_pg_bot

Q21: A patient presents with respiratory distress and is diagnosed with pan-acinar emphysema. Which deficiency is responsible for his condition? (Q844156)

A. Type 1 surfactant

B. Type 2 surfactant

C. Alpha-1 antitrypsin deficiency

D. Albumin

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A male patient is diagnosed with ARDS and is not responding to oxygen therapy. What is the role of IL-8 in ARDS? (Q844145)

A. Endothelial cell activation

B. Neutrophil recruitment

C. Macrophage activation

D. Promotion of surfactant production

See Answer in Part B → Q22

@Neet_pg_bot

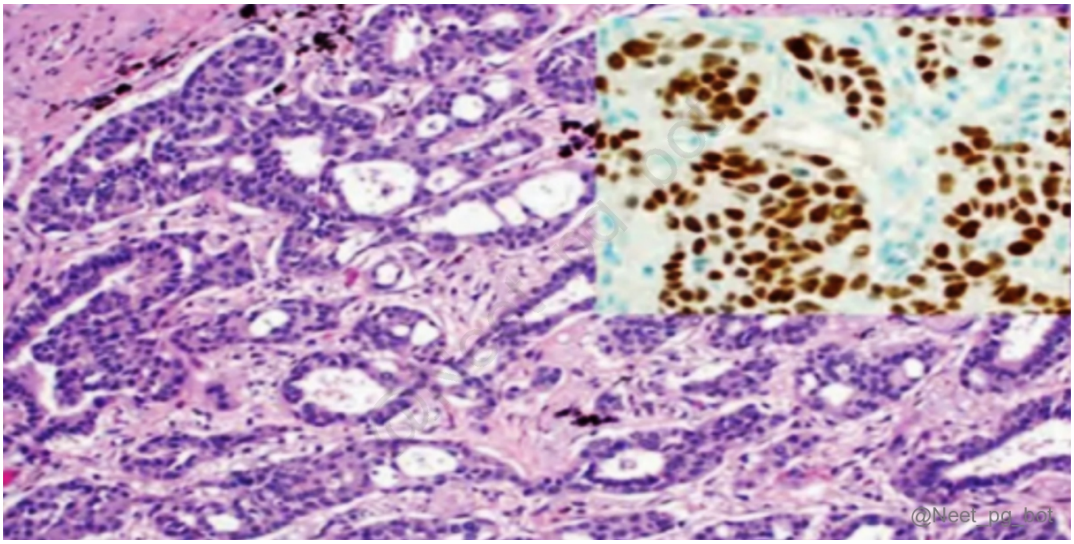
Q23: TTF-1 immunohistochemical marker is associated with which of the following cancers? (Q844039)

A. Squamous cell carcinoma

B. Lung adenocarcinoma

C. Small cell carcinoma

D. Large cell carcinoma



See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 40-year-old female patient presents with skin lesions, respiratory symptoms, and enlarged lymph nodes. Skin lesions appear as raised, erythematous nodules, and a

chest X-ray shows bilateral hilar lymphadenopathy. A biopsy of the affected tissues is performed. Microscopic examination reveals the presence of granulomas without central necrosis. What is the most likely histological finding in this scenario? (Q820587)

A. Caseating granuloma

B. Stellate granuloma

C. Non-caseating granuloma

D. Eosinophilic granuloma

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which malignancy is most commonly associated with asbestosis? (Q857561)

A. Mesothelioma

B. Anthracosis

C. Hepatocellular carcinoma

D. Renal cell carcinoma

See Answer in Part B → Q25

[08_Salivary Glands] 037 Salivary Gland Pathology — Quick Jump

Q1 (p. 404) *Q2 (p. 405)* *Q3 (p. 405)* *Q4 (p. 406)* *Q5 (p. 406)* *Q6 (p. 407)*
Q7 (p. 408) *Q8 (p. 408)*

Q1: A 28-year-old female presents with a painless, bluish, fluctuant and translucent swelling on the lower lip that enlarges with eating or pressure, as shown in the image below. She reports a history of accidentally biting her lip frequently. What histopathological feature would be expected on biopsy of the lesion? (Q845534)

A. Mucin-filled cavity surroundedby granulation tissue and chronic inflammatory cells.

B. Proliferation of ductal cells within fibrous connective tissue

C. Epithelial dysplasia and atypical cells.

D. Eosinophilic granuloma with multinucleated giant cells

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 40-year-old female presents with a slowly growing painless mass in her left parotid gland region that has been present for several months. On examination, a firm, mobile, non-tender mass is palpable in the preauricular area. Fine needle aspiration cytology (FNAC) reveals epithelial and myoepithelial cells in a chondromyxoid background. What is the most likely diagnosis? (Q845535)

A. Pleomorphic adenoma

B. Warthin tumor

C. Mucoepidermoid carcinoma

D. Adenoid cystic carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

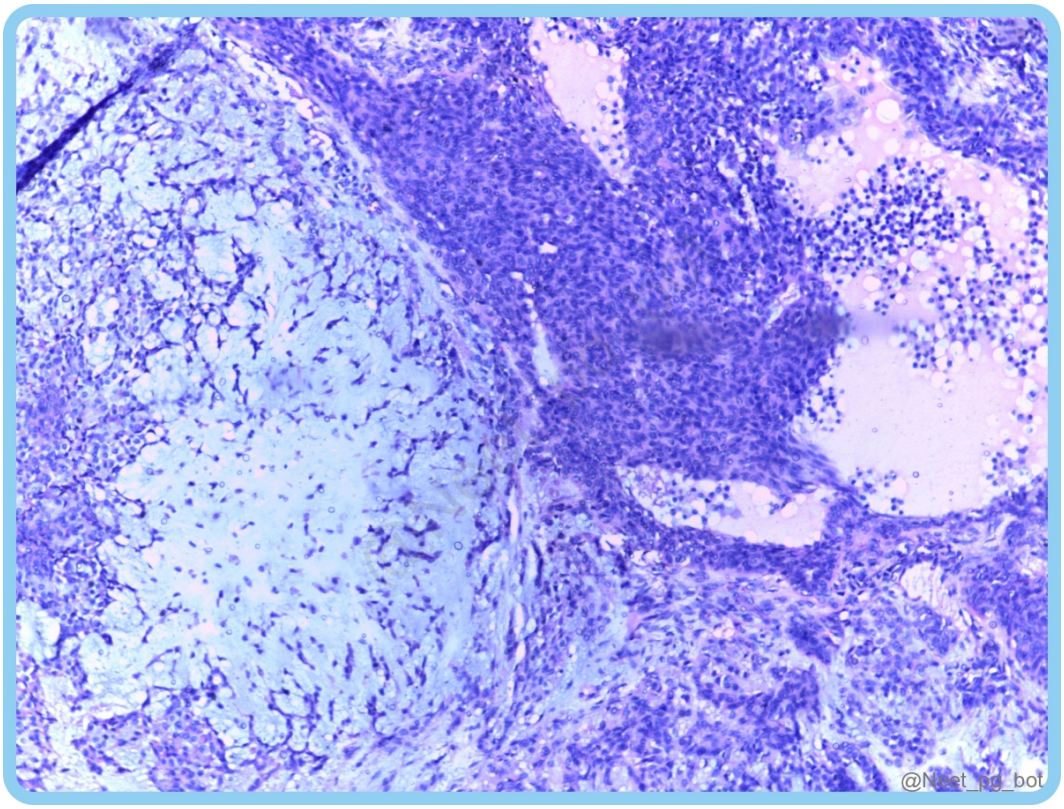
Q3: A 45-year-old female presents with a painless, slowly growing mass in her left parotid gland. Examination reveals a firm, mobile mass. Biopsy confirms pleomorphic adenoma with characteristic islands of cartilage and foci of bone in a myxoid stroma. Which of the following is incorrect regarding this condition? (Q845536)

A. Mostly found in the parotid gland

B. Mixed tumours with ductal, myoepithelial and mesenchymal cells

C. Radiation exposure is a risk factor

D. Down-regulation of PLAG1 results in abnormal cell proliferation



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male has a painless, slowly enlarging mass in the left parotid gland over several years. Examination reveals a firm, mobile, non-tender mass. Histological findings confirm pleomorphic adenoma. Which factor is associated with an increased risk of malignant transformation in pleomorphic adenomas? (Q845537)

A. Younger age of the patient

B. Larger size of the tumour

C. Increased age of the lesion

D. Presence of hyalinized stroma within the tumour

See Answer in Part B → Q4

@Neet_pg_bot

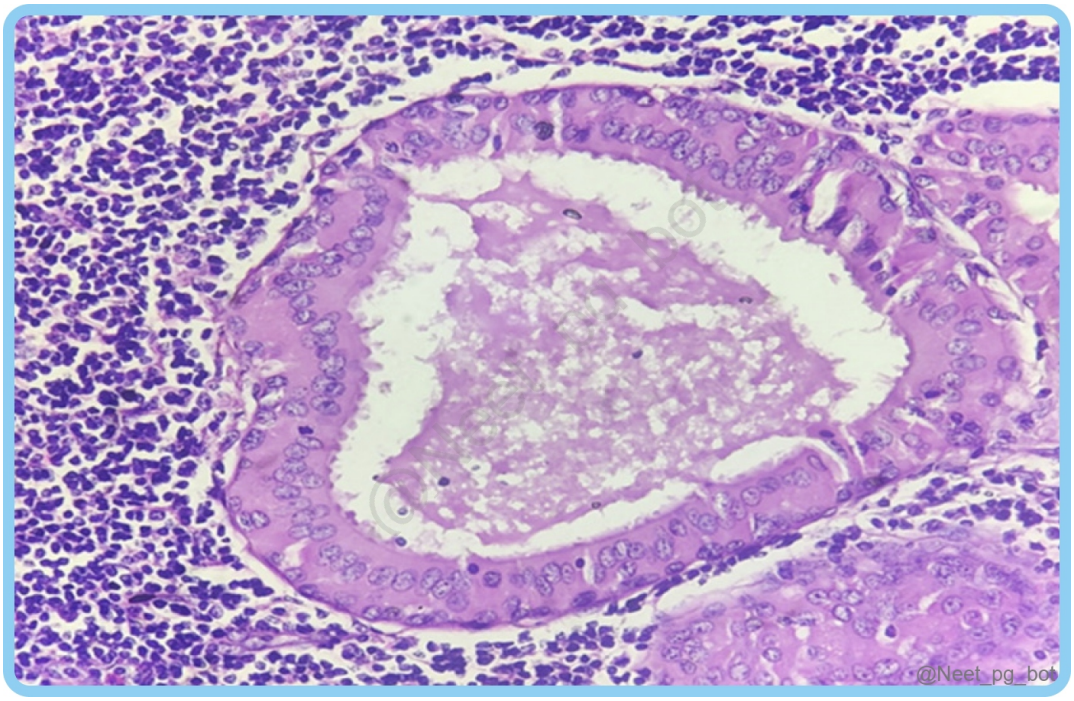
Q5: A 50-year-old male smoker presents with a painless swelling in the parotid region. Fine needle aspiration cytology (FNAC) reveals murky fluid. Which of the following histopathological features is true regarding this condition? (Q845538)

A. Proliferation of squamous epithelial cells with keratinisation

B. Oncocytic cells with double-layered lining

C. Neuroendocrine differentiation

D. Papillary architecture with psammoma bodies



See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following statements about Warthin's tumour is true? (Q845539)

A. It is the most common malignant tumour of the salivary glands.

B. They are typically located in the parotid gland.

C. It is more common in females.

D. Associated with human papillomavirus (HPV) infection.

See Answer in Part B → Q6

@Neet_pg_bot

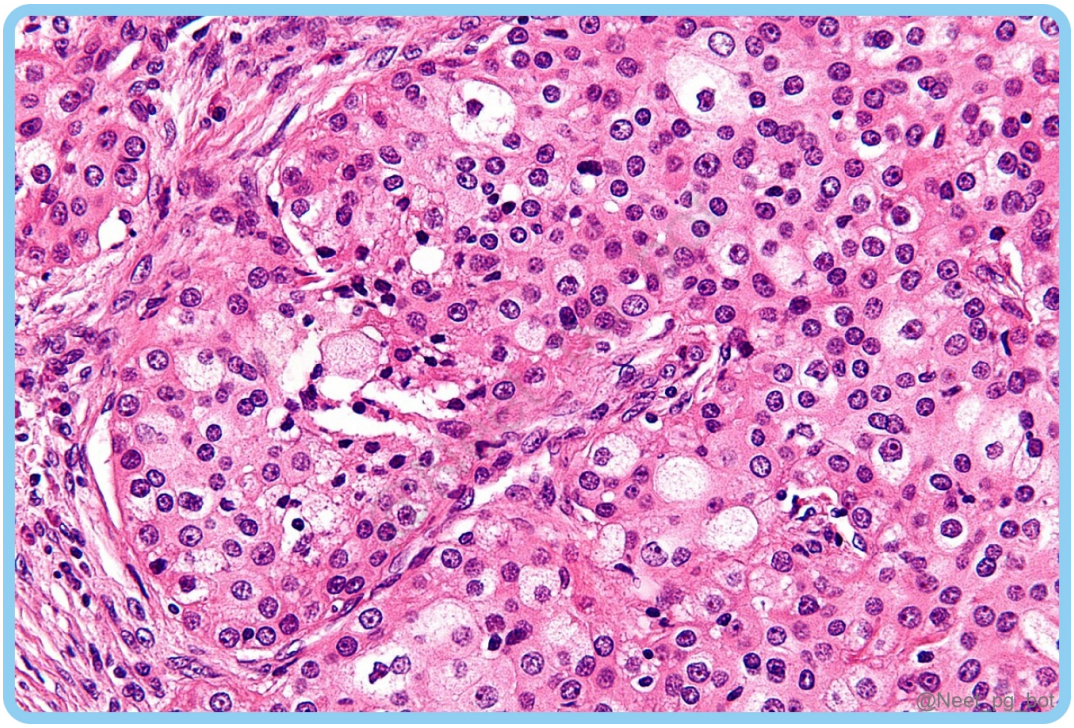
Q7: A 45-year-old female presents with a slow-growing painless mass in the left submandibular gland region. Imaging studies reveal a solid lesion with cystic components. Fine needle aspiration cytology (FNAC) shows a mixture of mucin-producing, epidermoid, and intermediate cells. A histopathology image is given below. Which of the following features is true regarding this condition? (Q845540)

A. Most commonly found in the sublingual salivary glands.

B. Most are associated with a (11;19) translocation.

C. Encapsulated tumours.

D. Histologically characterized by the presence of spindle cells



See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old male presents with a slowly enlarging painless mass in the right parotid gland region. Imaging studies reveal a solid tumour with a characteristic "Swiss cheese" appearance on MRI. Fine needle aspiration cytology (FNAC) shows basaloid cells with cribriform and tubular patterns. Which of the following statements is true regarding this condition? (Q845541)

A. Most commonly occur in the parotid and submandibular glands.

B. MYB-NFIB gene rearrangements are present in all cases

C. Encapsulated lesions with a smooth surface.

D. Tend to grow rapidly and have a high mitotic rate.

See Answer in Part B → Q8

Q1: A middle-aged woman presents with dry eyes and dry mouth. Laboratory tests reveal positive anti-Ro (SSA) and anti-La (SSB) antibodies. What is the most likely underlying pathological mechanism? (Q866381)

A. Destruction of exocrine glands by neutrophils

B. IgE-mediated hypersensitivity reaction

C. Lymphocytic infiltration and destruction of salivary and lacrimal glands

D. Deposition of amyloid in salivary glands

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Warthin's tumor is also called? (Q820513)

A. Adenolymphoma

B. Pleomorphic adenoma

C. Mucoepidermoid carcinoma

D. Acinic cell carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following features is not observed in pleomorphic adenoma? (Q855079)

A. Myoepithelial cells

B. Keratin pearls

C. Chondroid differentiation

D. Perineural invasion

See Answer in Part B → Q3

Q1: Which of the following statements regarding the layers of the digestive tract is incorrect? (Q845634)

A. The mucosa is the first layer of the digestive tract.

B. The submucosa is absent in the gallbladder.

C. The muscularis propria is present throughout the GIT.

D. The esophagus lacks the submucosal layer.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 58-year-old male presents with chronic heartburn and regurgitation. Upper endoscopy reveals the presence of Barrett's esophagus. What is the primary cellular change seen in this condition? (Q845637)

A. Metaplasia of squamous epithelium

B. Dysplasia of squamous epithelium

C. Hyperplasia of columnar epithelium

D. Hypertrophy of columnar epithelium

See Answer in Part B → Q2

@Neet_pg_bot

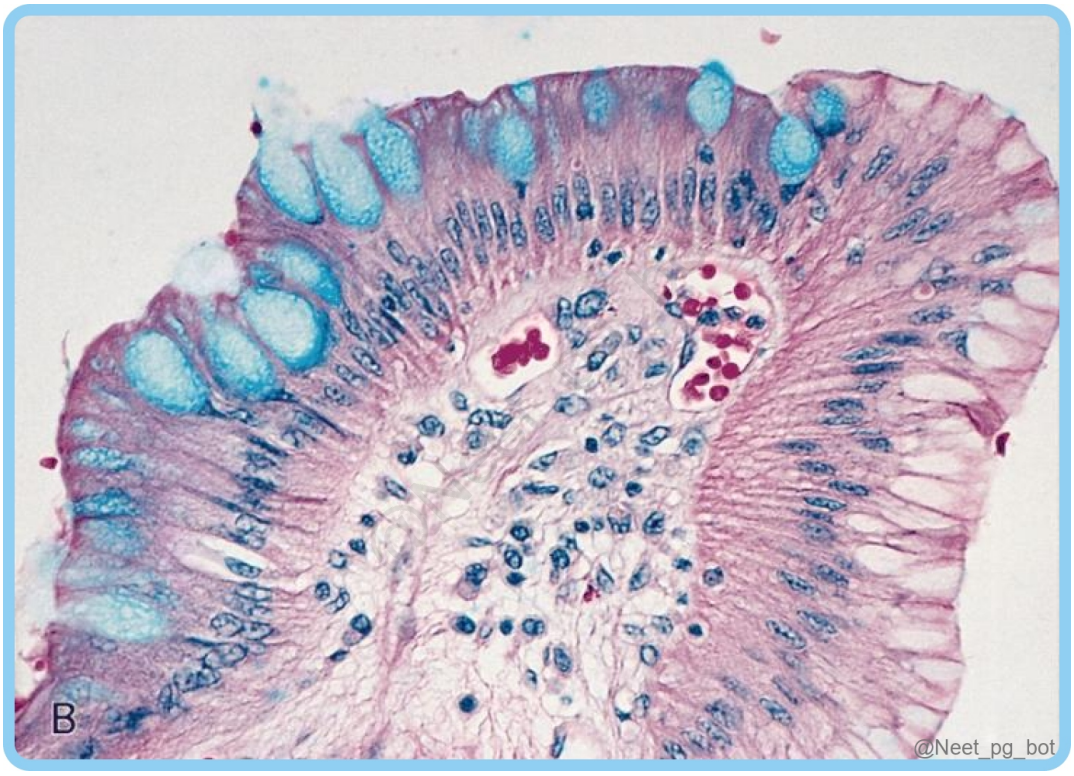
Q3: A 50-year-old male presents with chronic heartburn for two years. An endoscopy is performed, and the biopsy of the esophageal specimen stained with special stain is shown below. Which of the following conditions is the patient at an increased risk of? (Q845640)

A. Squamous cell carcinoma

B. Adenocarcinoma

C. Plummer Vinson syndrome

D. MALToma



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A woman presented with dysphagia to solids for a month. On examination, there are multiple lesions on the lips. An endoscopy reveals obstructive lesions in the upper oesophagus. Which of the following additional findings can be seen in this patient? (Q845641)

A. Development of GI polyps

B. Degeneration of nitric oxide–producing neurons

C. Iron deficiency anemia

D. Apple core appearance on imaging

See Answer in Part B → Q4

@Neet_pg_bot

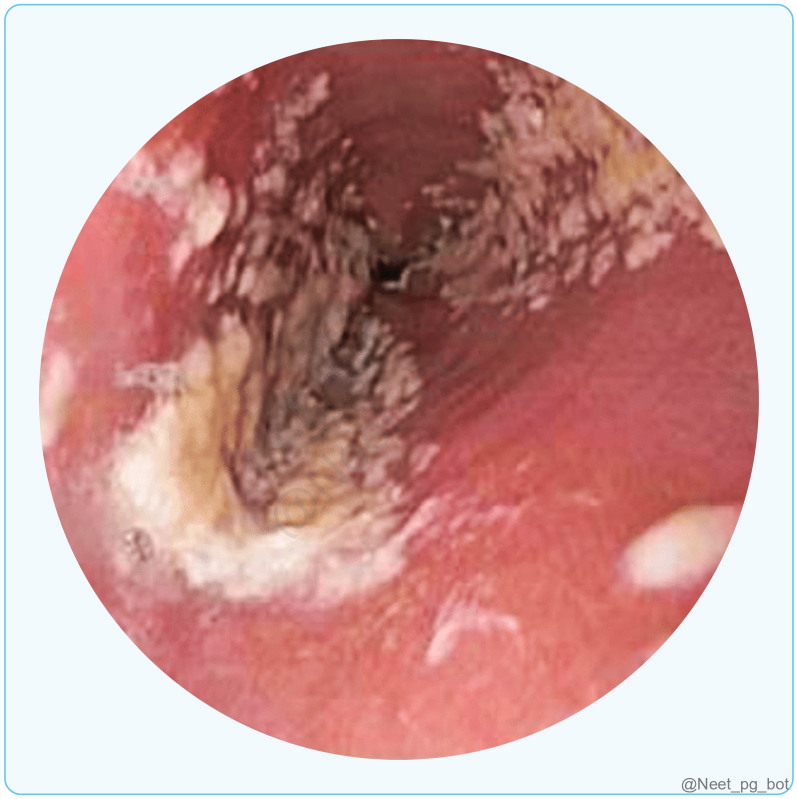
Q5: A 45-year-old male presents with complaints of severe odynophagia, retrosternal chest pain, and difficulty in swallowing solids and liquids for the past week. He has a history of untreated HIV infection with a CD4 count of 80 cells/mm^3. An upper gastrointestinal endoscopy image is shown below. What is the most likely diagnosis? (Q845642)

A. CMV esophagitis

B. HSV esophagitis

C. Eosinophilic esophagitis

D. Candida esophagitis



See Answer in Part B → Q5

@Neet_pg_bot

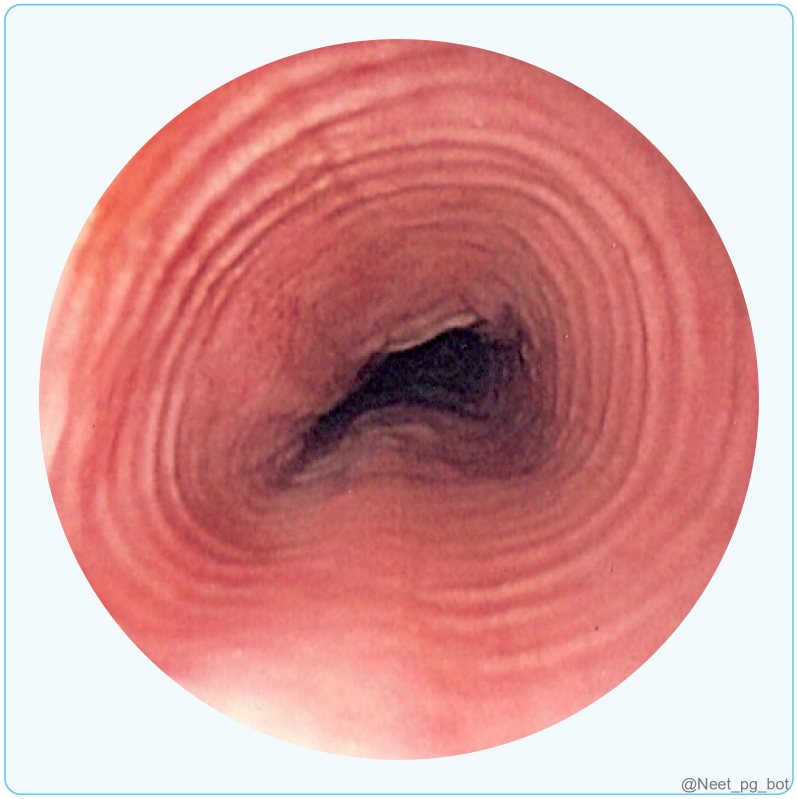
Q6: Which of the following is true regarding the condition shown in the endoscopic image below? (Q845643)

A. Its cause is primarily infectious.

B. Characteristic rat tail appearance.

C. Interleukin 5 has a major role in pathogenesis.

D. Diagnosed by observing at least ten lymphocytes/HPF.



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Identify the correct statement/s regarding carcinoma of the oesophagus SCC is more common in the lower two-thirds of the oesophagus Smoking increases the risk of both SCC and adenocarcinoma H. pylori is associated with a decreased risk of oesophageal adenocarcinoma Adenocarcinoma is the overall most common type SCC is linked to fermented milk- mursik, which contains acetaldehyde (Q845644)

A. 1, 3, 5

B. 2, 3, 5

C. 1, 2, 4

D. 2, 4, 5

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the most common site of fistulization in congenital GI anomalies? (Q890287)

A. Ileum

B. Colon

C. Esophagus

D. Stomach

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Heterotopic (ectopic) gastric mucosa most commonly occurs in which of the following locations? (Q890289)

A. Cervical oesophagus

B. Rectum

C. Ileum (outside Meckel diverticulum)

D. Colon

See Answer in Part B → Q9

@Neet_pg_bot

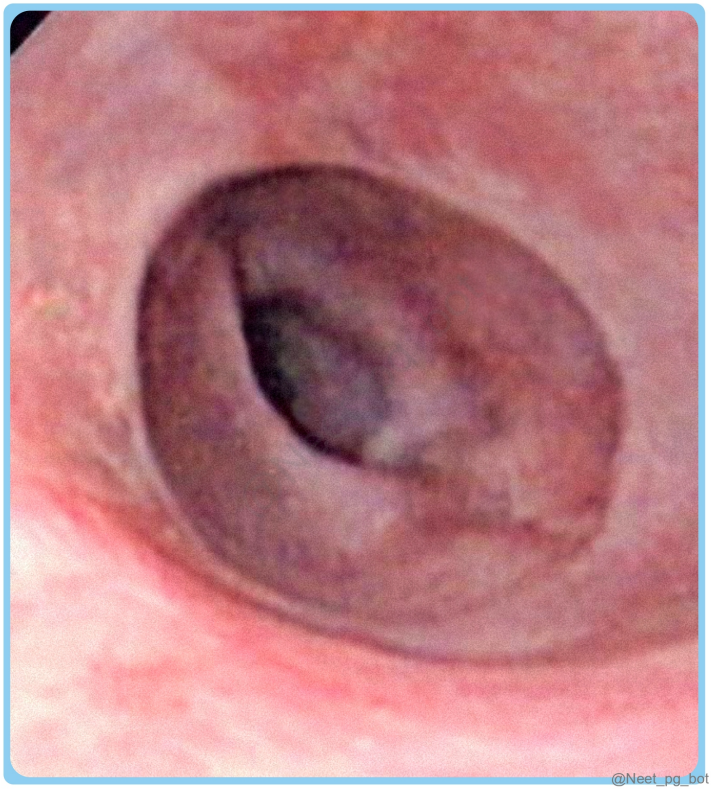
Q10: A 48-year-old man has intermittent dysphagia to solids with occasional food impaction. Endoscopy shows a thin ring, as shown in the image, at the gastroesophageal junction. What is the diagnosis? (Q890292)

A. Esophageal web

B. Achalasia

C. Schatzki ring

D. Type A ring



See Answer in Part B → Q10

@Neet_pg_bot

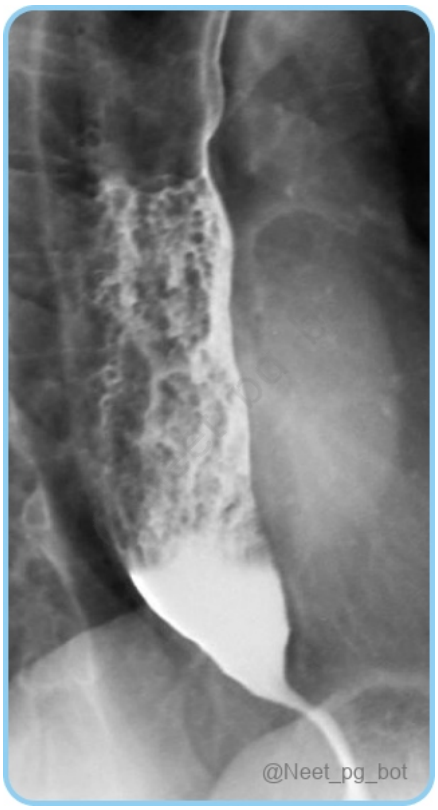
Q11: A 40-year-old man from rural South America presents with progressive dysphagia to solids and liquids and chronic constipation. Imaging shows findings as shown. What is the mechanism of his oesophageal disease? (Q890295)

A. Degeneration of nitric oxide-producing neurons

B. Autoimmune destruction of inhibitory neurons

C. Destruction of the myenteric plexus

D. Smooth muscle fibrosis



See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following statements regarding primary achalasia is incorrect? (Q890298)

A. Degeneration of nitric oxide-producing inhibitory neurons

B. May involve degeneration of the dorsal motor nucleus of the vagus

C. Not associated with autoimmune conditions

D. Loss of LES relaxation

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements regarding eosinophilic esophagitis is incorrect? (Q890302)

A. Commonly associated with atopic disorders

B. Characterised by superficial intraepithelial eosinophils

C. Strongly associated with Barrett's oesophagus

D. Endoscopic dilation relieves dysphagia but not inflammation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following statements regarding Mallory-Weiss tear is incorrect? (Q890305)

A. Usually longitudinal and located near the GEJ

B. Commonly result from severe retching or vomiting

C. Transmural perforation of the oesophageal wall

D. Most cases resolve without surgical intervention

See Answer in Part B → Q14

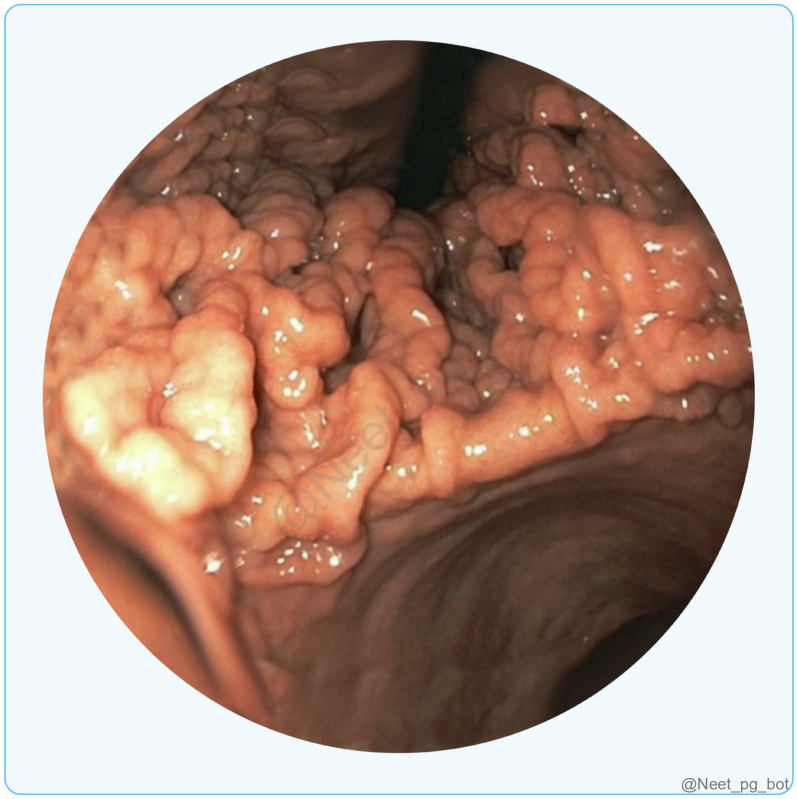
Q1: A 45-year-old patient presents with persistent abdominal discomfort, nausea, weight loss, and occasional diarrhoea. He was recently diagnosed with a viral infection. The following gross image of the gastric mucosa is observed upon upper gastrointestinal endoscopy. Which of the following is correct regarding the patient's condition? (Q845222)

A. Associated with excessive secretion of TNF-α.

B. Histopathologically, villous atrophy is observed.

C. Increases the risk of gastric carcinoma.

D. More common in females and can cause protein-losing enteropathy.



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60-year-old man presents with vague abdominal discomfort and early satiety. Imaging reveals a large mass in the gastric fundus. He undergoes surgical resection of the mass, and histopathology confirms a gastrointestinal stromal tumor (GIST). Which of the following factors is a favorable prognostic indicator of this condition? (Q845244)

A. Tumor size > 10 cm

B. Epithelioid cell type

C. Gastric location

D. Intestinal location

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following markers will help confirm the diagnosis of GIST in C-kit negative cases? (Q845242)

A. CD34

B. DOG1

C. S-100

D. CD117

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is the most common mutation found in GIST (Gastrointestinal Stromal Tumor)? (Q845238)

A. KIT mutation

B. PDGFRA mutation

C. SDH mutation

D. BRAF mutation

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 55-year-old man with intermittent abdominal pain, nausea, and early satiety has a palpable epigastric mass. Imaging shows a well-defined, heterogeneously enhancing stomach mass, and endoscopic biopsy reveals CD117-positive spindle cells. What is the likely origin of this condition? (Q845236)

A. Cajal cells

B. Goblet cells

C. Paneth cells

D. G cells

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old male presents with episodes of flushing, sweating, and colicky abdominal pain. Upper gastrointestinal endoscopy reveals a yellow-tan intramural mass in the stomach. Biopsy revealed sheets of uniform cells with scant granular cytoplasm. What is the most likely diagnosis? (Q845234)

A. Carcinoid tumor

B. Gastric outlet obstruction

C. Hypertrophic pyloric stenosis

D. Crohn's disease

See Answer in Part B → Q6

@Neet_pg_bot

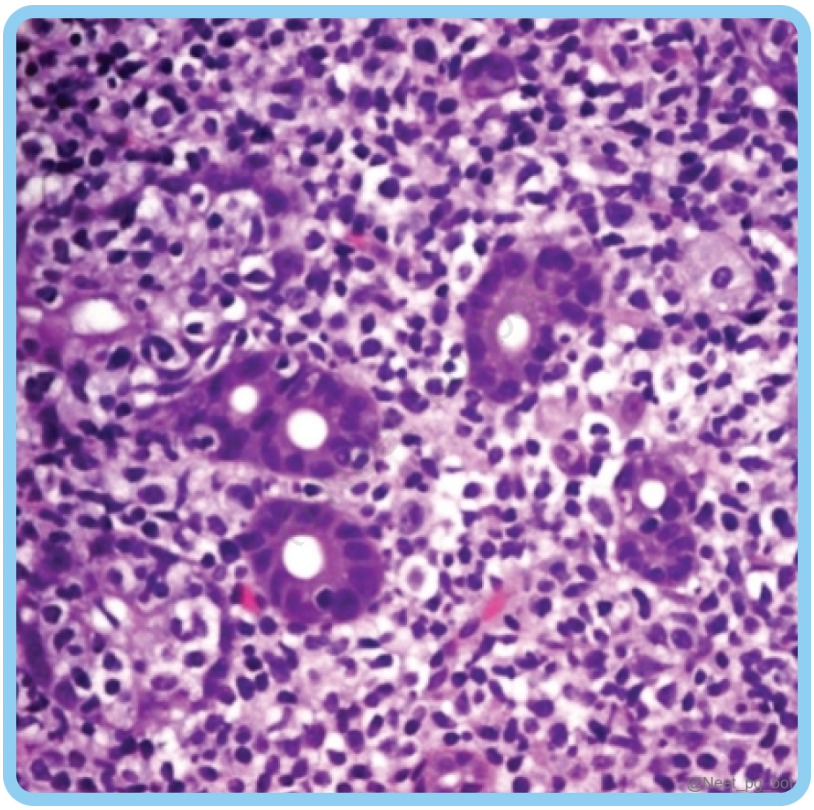
Q7: A 48-year-old female presents with recurrent abdominal pain, bloating, and early satiety for the past few months. Endoscopic biopsy revealed lympho-epithelial lesions with infiltration of small lymphoid cells. Which of the following statements is true regarding this condition? (Q845233)

A. Dense neutrophilic infiltrate

B. Reactive-appearing T-cell follicles seen

C. Plasmacytic differentiation seen

D. Presents as discrete small nodules in the GI tract



See Answer in Part B → Q7

@Neet_pg_bot

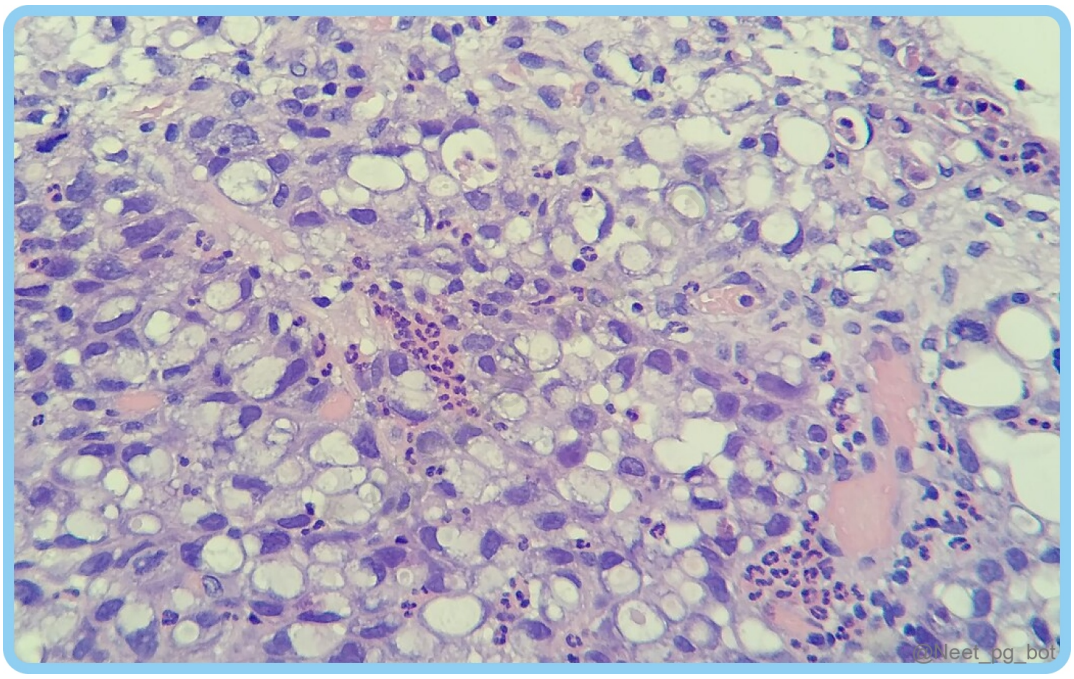
Q8: A 45-year-old female has a history of intermittent epigastric discomfort, nausea, and early satiety. Upper endoscopy reveals gastric wall thickening with a leather bottle appearance. Biopsy of the lesion shows signet ring cells infiltrating the gastric mucosa. What is the most likely diagnosis? (Q845228)

A. Intestinal-type gastric adenocarcinoma

B. Diffuse-type gastric adenocarcinoma

C. Peptic ulcer disease

D. Gastric lymphoma



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old male presents with a history of epigastric pain, unintentional weight loss, and early satiety over the past few months. An upper GI endoscopy revealed a nodular mass on the gastric wall, and a biopsy revealed well-differentiated glandular structures with intestinal metaplasia. Which of the following is least likely associated with this condition? (Q845226)

A. Helicobacter pylori (H. pylori) infection

B. APC gene mutation

C. CDH-1 gene mutation

D. High intake of smoked or pickled foods

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is NOT a recognised risk factor for gastric adenocarcinoma? (Q845225)

A. Alcohol

B. Hot beverages

C. Blood group O

D. H. pylori

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45 y/o male presents with recurrent episodes of abdominal pain and persistent heartburn. Upper gastrointestinal endoscopy reveals multiple duodenal ulcers. Lab investigations show elevated serum gastrin levels (> 1000 pg/ml). Which features are most likely associated with the patient's condition? (Q845223)

A. Presence of gastrin-secreting tumors in the stomach

B. Presence of erosive esophagitis and hiatal hernia

C. Hyperplasia of parietal cells within the stomach

D. Association with MEN2 gene mutation

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which cells are primarily responsible for secreting neutral mucin that forms a protective layer in the stomach? (Q845197)

A. Parietal cells

B. Chief cells

C. Foveolar cells

D. Enterochromaffin cells

See Answer in Part B → Q12

@Neet_pg_bot

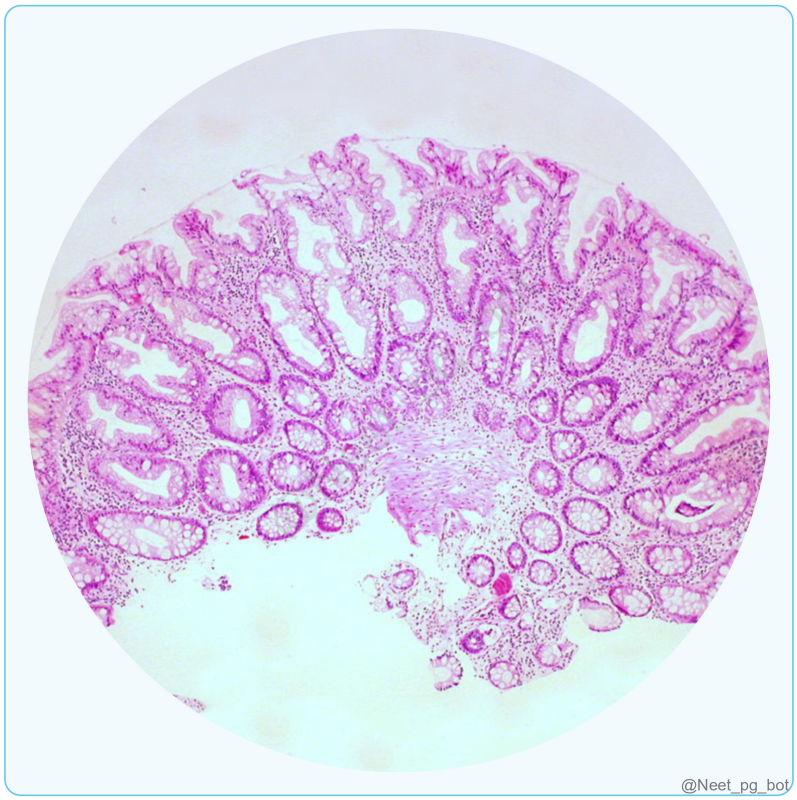
Q13: A 58-year-old female presents with recurrent epigastric discomfort and intermittent nausea. Histopathological examination of gastric biopsy samples reveals irregular, cystically dilated, and elongated foveolar glands. She also has a history of untreated H. pylori infection. What type of lesions is most likely to be associated with these findings? (Q845219)

A. Hyperplastic polyps

B. Gastric adenomas

C. Inflammatory fibroid polyps

D. Juvenile polyps



See Answer in Part B → Q13

@Neet_pg_bot

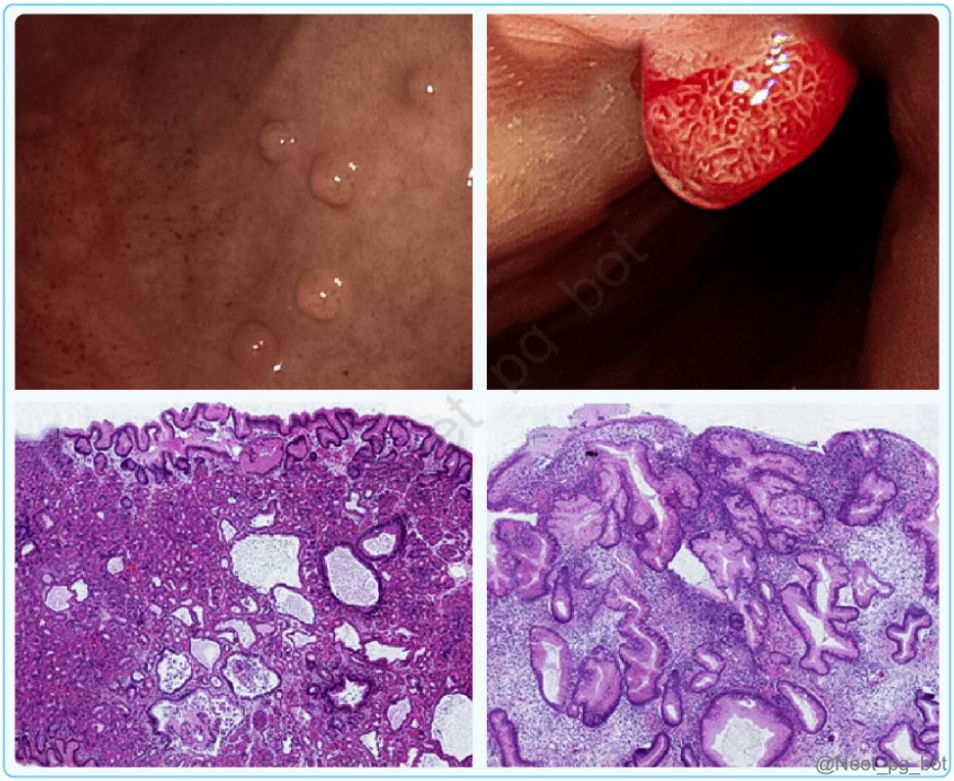
Q14: A 60-year-old man on long-term proton pump inhibitor therapy for acid reflux undergoes an upper gastrointestinal endoscopy for recurrent epigastric discomfort. The endoscopy reveals smooth-surfaced lesions in the gastric body and fundus. Which statement about these findings is likely correct? (Q845215)

A. PPIs decrease gastrin secretion, reducing the risk of fundic gland polyps

B. Fundic gland polyps are commonly associated with H. pylori infection.

C. Composed of cystically dilated glands lined by parietal, chief, and foveolar cells.

D. Sporadic fundic gland polyps carry a significant risk of neoplasia.



See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which type of gastritis is associated with a distinctive endoscopic appearance characterised by thickened folds, small nodules, and central aphthous ulceration affecting the entire stomach? (Q845214)

A. Eosinophilic gastritis

B. Lymphocytic gastritis

C. Granulomatous gastritis

D. Chemical gastritis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45-year-old female presents with chronic epigastric pain, nausea, and occasional vomiting. Upper gastrointestinal endoscopy reveals diffuse mucosal atrophy. Biopsy confirms chronic gastritis. Which of the following is a characteristic feature of Chronic Gastritis Type A? (Q845212)

A. Predominantly affects the antrum of the stomach

B. Autoimmune destruction of parietal cells

C. Associated with H. pylori infection

D. Increased risk of gastric carcinoma

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55-year-old patient presents with recurrent epigastric pain and signs of gastrointestinal bleeding. An upper endoscopy reveals gastric ulcers, and a biopsy is performed for further evaluation. Which stain is best for identifying the causative organism in this condition? (Q845210)

A. Z-N stain

B. Wright stain

C. Modified Giemsa stain

D. Gram stain

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is NOT a protective factor against Peptic Ulcer Disease? (Q845208)

A. Mucus

B. Bicarbonate

C. COX-1

D. Pepsin

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old man experiences recurrent upper abdominal pain worsened after meals, unresponsive to over-the-counter antacids. Which of the following is NOT typically a risk factor for the patient's presentation? (Q845206)

A. Helicobacter pylori infection

B. Cocaine use

C. Cigarette smoking

D. Obesity

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old female with traumatic brain injury undergoes emergency craniotomy and is now intubated in the neurosurgical ICU. She suddenly develops hematemesis despite stabilisation. What is the most likely cause of the patient's bleeding? (Q845205)

A. Curling ulcer

B. Cushing ulcer

C. Gastric antral vascular ectasia (GAVE)

D. Dieulafoy lesions

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55-year-old male presents to the gastroenterology clinic with complaints of persistent abdominal pain, nausea, and unintentional weight loss over the past three months. His medical history is significant for peptic ulcer disease and he is a former smoker. An upper endoscopy reveals multiple gastric lesions, and a biopsy is taken for histological examination. The results indicate the presence of gastric adenocarcinoma, and positive for Helicobacter pylori. Which protein produced by Helicobacter pylori is primarily associated with this condition? (Q845199)

A. Urease

B. CagA

C. SRC

D. SHP2

See Answer in Part B → Q21

Q1 (p. 433) *Q2 (p. 433)* *Q3 (p. 434)* *Q4 (p. 435)* *Q5 (p. 436)* *Q6 (p. 436)*
Q7 (p. 436) *Q8 (p. 437)* *Q9 (p. 437)* *Q10 (p. 438)* *Q11 (p. 438)* *Q12 (p. 438)*
Q13 (p. 439) *Q14 (p. 439)*

Q1: During a routine colonoscopy of a 60-year-old male, a small polyp is identified in the colon. Subsequent biopsy results confirm the presence of a hyperplastic polyp. Which characteristic is typically associated with this condition? (Q845256)

A. Commonly found in the right colon

B. Pathogenesis involves increased epithelial cell turnover

C. Lacks malignant potential

D. Histologically composed of immature goblet cells

See Answer in Part B → Q1

@Neet_pg_bot

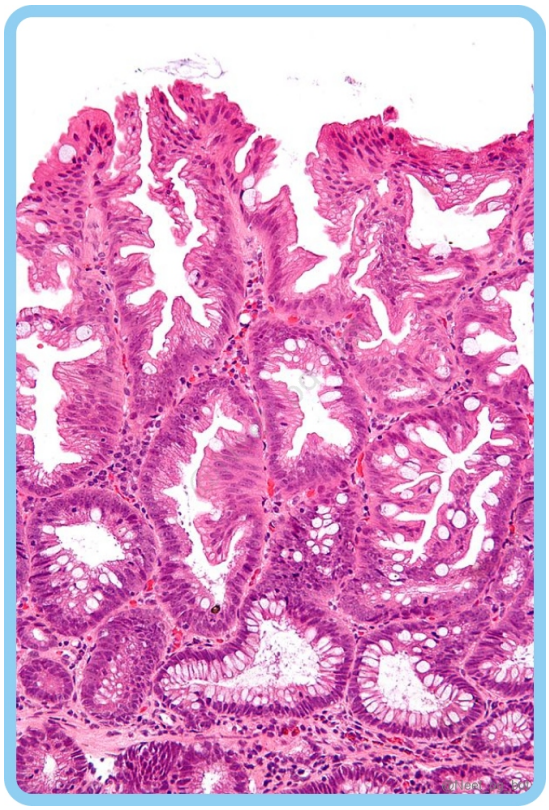
Q2: A 55-year-old man undergoes a routine colonoscopy. During the procedure, a polyp is discovered. Histological examination reveals serrated architecture, as shown in the image. Which of the following is true about this polyp? (Q845259)

A. It has malignant potential

B. Predominantly found in the left colon

C. Serrated architecture is limited to the surface of the lesions

D. Do not require surveillance or follow-up after detection



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 4-year-old girl presents to the OPD with complaints of rectal bleeding and abdominal pain for the past six months. Investigations reveal approximately 40 hamartomatous colon polyps. The biopsy shows cystic spaces with dilated glands filled with mucin and inflammatory debris. What is the most likely diagnosis for this patient? (Q845265)

A. Familial adenomatous polyposis

B. Adenocarcinoma colon

C. Juvenile polyposis syndrome

D. Sessile Serrated Adenoma

See Answer in Part B → Q3

@Neet_pg_bot

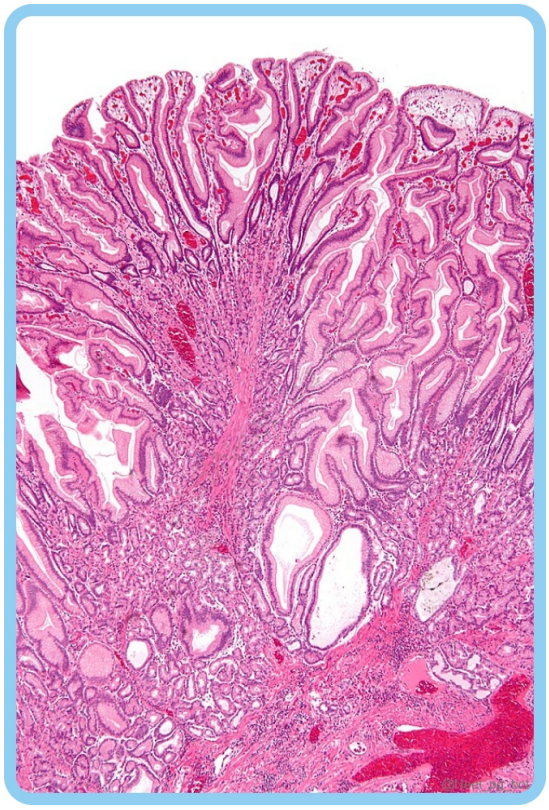
Q4: A 13-year-old female presents to the OPD due to abdominal pain and blood in stools. On examination, she had pigmented macules on her lips and oral mucosa. Endoscopy reveals multiple large, pedunculated polyps in the small intestine which shows an arborizing pattern of smooth muscle and glands lined by normal epithelium. Which of the following statements is incorrect about this condition? Autosomal dominant disorder Polyps are more common in the colon Increased risk of developing colon, pancreatic, and breast cancers Gain-of-function mutation in STK11 gene (Q845268)

A. 1 and 2

B. 2 and 4

C. 3 and 4

D. 1 and 3



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 58-year-old female presents with weight loss, nail changes, alopecia, and skin hyperpigmentation. Colonoscopy reveals multiple hamartomatous polyps in the intestine. Family history is negative for intestinal cancers. What is the most likely diagnosis? (Q845281)

A. Tuberous sclerosis

B. Bannayan-Ruvalcaba-Riley Syndrome

C. Cowden syndrome

D. Cronkhite-Canada Syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 20-year-old man with a family history of colorectal carcinoma presents with chronic abdominal discomfort and occasional rectal bleeding.Upon further evaluation, a mutation in APC gene is identified leading to a diagnosis of Familial Adenomatous Polyposis. Which of the following statement is true regarding FAP? (Q845282)

A. Mutation in 6th chromosome

B. 50 % risk of colon cancer if untreated

C. Presence of a minimum of 100 polyps

D. Congenital atrophy of the retinal pigment epithelium

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 28-year-old woman presents with a history of unexplained weight loss along with multiple sebaceous cysts on her face and scalp. She has a family history of colorectal cancer. Upon further examination, she is found to have a bony lesion on her jaw. What is the most likely diagnosis? (Q845283)

A. Turcot syndrome

B. Gardner syndrome

C. Lynch syndrome

D. MUTYH Associated Polyposis (MAP)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 6 cm polyp is identified in the descending colon during a routine colonoscopy. Histological examination reveals villous architecture with high-grade dysplasia. Based on this scenario, which factors most strongly correlate with the risk of malignancy in colorectal adenomas? (Q845284)

A. Presence of villous architecture

B. Size of the adenoma

C. Histologic grade of dysplasia

D. Location within the gastrointestinal tract

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient underwent genetic testing after being diagnosed with colon cancer. Testing reveals a mutation associated with Hereditary Nonpolyposis Colorectal Cancer (HNPCC). Which of the following genes is defective in this patient? (Q845285)

A. SMAD4, BMPR1

B. STK11

C. APC, MUTYH

D. MLH1, MSH2

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old male presents to the clinic with complaints of recurrent abdominal discomfort and changes in bowel habits over the past few months. Further investigation with colonoscopy confirmed the presence of adenocarcinoma. Which of the following factors is most closely associated with this condition? (Q845286)

A. Use of aspirin

B. Estrogen replacement therapy

C. High intake of unabsorbable vegetable fiber

D. High consumption of red meat

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 55-year-old female presents with abdominal pain, changes in bowel habits, unintended weight loss. A previous colonoscopy showed a polyp, but a recent one confirmed colorectal adenocarcinoma. Which gene mutations are characteristically associated with development of colorectal adenocarcinoma? (Q845287)

A. APC, TGFBR2, SMAD2, and BAX

B. TP53, BRAF, TGFBR2, and BAX

C. APC, KRAS, SMAD4 and TP53

D. APC, KRAS, TP53, and MYC

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old female presents with abdominal pain, changes in bowel habits, and weight loss. Her mother and aunt were diagnosed with endometrial and ovarian cancer in their 50s. A colonoscopy and a biopsy confirm well-differentiated

adenocarcinoma. Which genetic pathway is most likely associated with adenocarcinoma in this patient? (Q845290)

A. APC/β-catenin pathway

B. TGF-β signaling pathway

C. DNA mismatch repair pathway

D. BAX pathway

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is the most common site of metastasis for colon adenocarcinoma? (Q845291)

A. Brain

B. Lungs

C. Bones

D. Liver

See Answer in Part B → Q13

@Neet_pg_bot

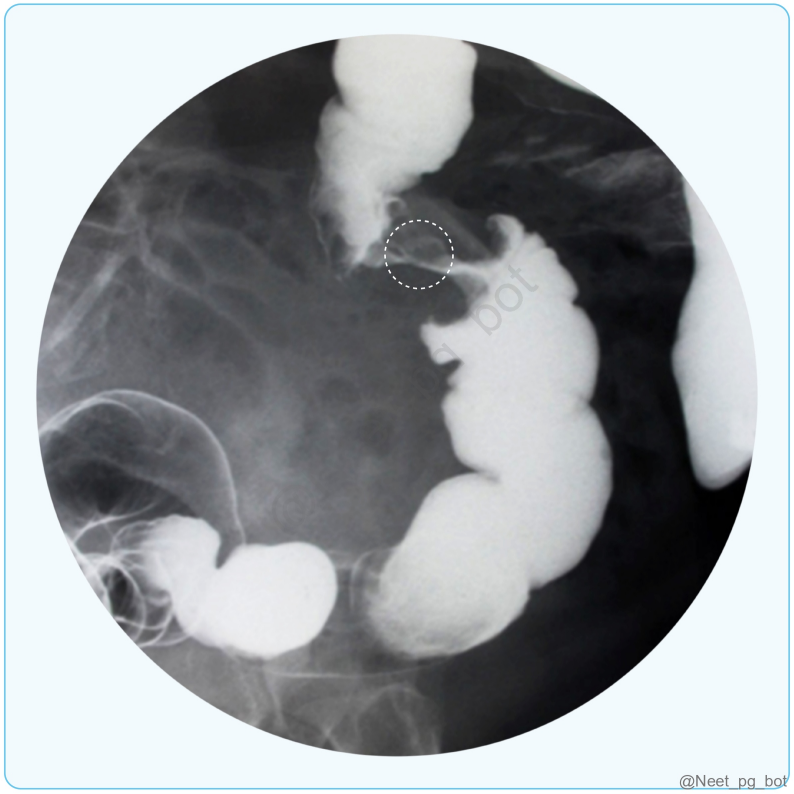
Q14: A 60-year-old male presents with abdominal pain, altered bowel habits and 5kg weight loss in one month. A barium enema study showed the following finding. Which of the following statements is true about the patient's condition? (Q845293)

A. Presents asweakness due to iron deficiency anemia

B. Leads to a napkin-ring constriction and luminal narrowing

C. Growth tends to be polypoidal (growth is into the wall of the intestine?)

D. HPE commonly shows signet-ring cells



See Answer in Part B → Q14

@Neet_pg_bot

• [09_Gastrointestinal Tract] 042 Malabsorption Syndrome Celiac Disease And Ibd

« Back to Folder Directory

[09_Gastrointestinal Tract] 042 Malabsorption Syndrome Celiac Disease And Ibd — Quick Jump

Q1 (p. 441) *Q2 (p. 441)* *Q3 (p. 442)* *Q4 (p. 443)* *Q5 (p. 443)* *Q6 (p. 444)*
Q7 (p. 445) *Q8 (p. 445)* *Q9 (p. 446)* *Q10 (p. 447)* *Q11 (p. 448)* *Q12 (p. 448)*
Q13 (p. 449) *Q14 (p. 449)*

Q1: A 47-year-old male presents with chronic diarrhoea, unintentional weight loss, joint pain, pallor, and generalised weakness. Upper GI endoscopy and biopsy revealed characteristic histopathological findings suggestive of Whipple's disease. Which of the following histopathological features would have led to the diagnosis? (Q845296)

A. Foamy macrophages filled with PAS-positive granules

B. Villous atrophy and blunting of the small intestinal mucosa

C. Lymphoplasmacytic infiltrate in the lamina propria

D. Presence of caseating granulomas and acid-fast bacilli

See Answer in Part B → Q1

@Neet_pg_bot

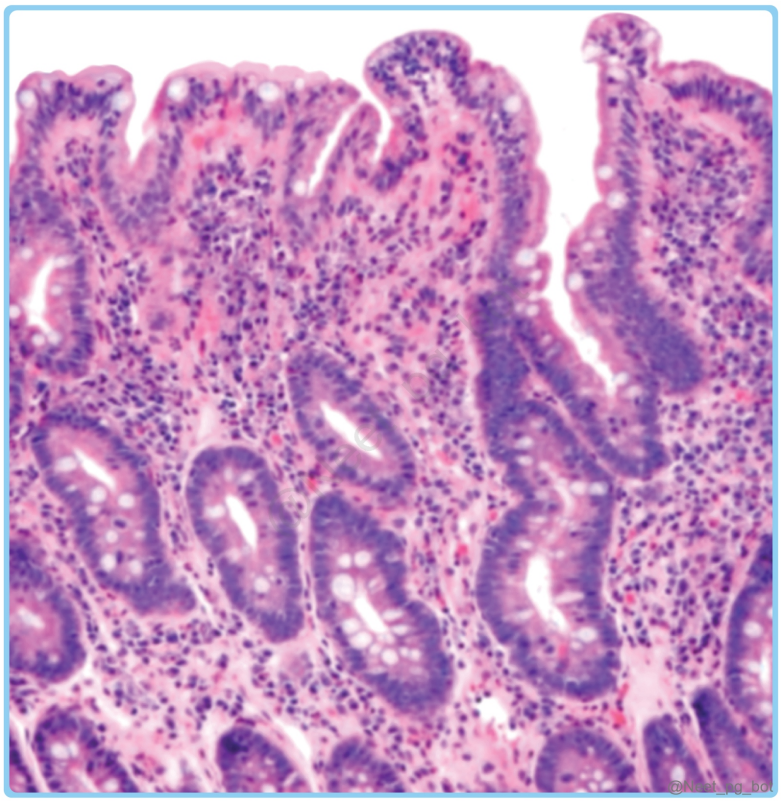
Q2: A 35-year-old female presents with chronic diarrhoea, abdominal bloating, and unintended weight loss. She reports discomfort after consuming gluten-containing foods. Laboratory tests show elevated tissue transglutaminase (tTG) and anti-endomysial antibodies (EMA) levels, prompting a small intestinal biopsy via upper endoscopy. Which of the following combinations of histopathological features will be seen in this condition? Intraepithelial CD8+ T Lymphocytes Crypt hyperplasia Villous atrophy Decreased mitotic activity Inflammatory cell infiltration in lamina propria (Q845302)

A. 1, 2, 3

B. 1, 2, 3, 4

C. 2, 4, 5

D. 1, 2, 3, 5



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old woman presents to the clinic with a history of chronic abdominal pain and diarrhoea, worsening notably after consuming wheat-based foods. Physical examination reveals signs suggestive of malabsorption. Considering celiac disease as a possible diagnosis, which of the following statements regarding its pathogenesis is NOT correct? (Q845306)

A. Gliadin peptides in the lamina propria are deamidated by tissue transglutaminase.

B. HLA-DR2 or HLA-DR8 significantly influences celiac disease susceptibility.

C. Gliadin peptides may induce epithelial cells to express IL-15, activating CD8+ lymphocytes.

D. Type 1 diabetes, Sjögren syndrome, and IgA nephropathy are associated with celiac disease.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old female who recently returned from a tropical region presents with persistent diarrhoea, weight loss, fatigue, anaemia, and vitamin deficiencies, along with a small intestine biopsy findings of villous atrophy and chronic mucosal inflammation. Which part of the gastrointestinal tract is typically NOT affected in this condition? (Q845307)

A. Duodenum

B. Jejunum

C. Ileum

D. Colon

See Answer in Part B → Q4

@Neet_pg_bot

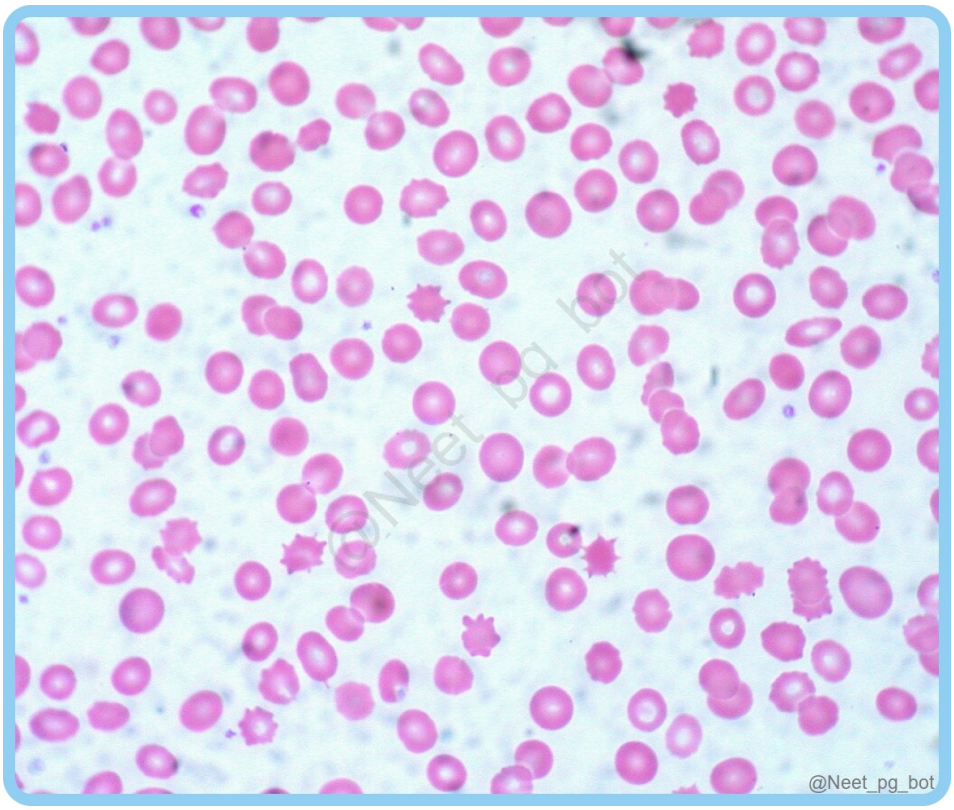
Q5: A 6-month-old infant presents with failure to thrive, chronic diarrhoea, and poor weight gain. A peripheral blood smear revealed a characteristic appearance, as shown in the image below. Biochemical investigations reveal very low levels of triglycerides, cholesterol, and fat-soluble vitamins. Which genetic mutation is most likely responsible for these findings? (Q845309)

A. APOB gene mutation

B. MTTP gene mutation

C. MYO5B gene mutation

D. LPL gene mutation



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 4-week-old infant presents with severe watery diarrhoea and failure to thrive since birth. Stool studies are negative for pathogens. A small bowel biopsy shows villous atrophy, cytoplasmic inclusion bodies within enterocytes, and reduction of microvilli on the enterocyte surface. Which of the following statements is true regarding this condition? (Q845310)

A. It is characterised by the absence of ganglion cells in the distal part of the colon.

B. It is associated with mutations in the MYO5B or STX3 genes.

C. Histological findings include villous atrophy and crypt hyperplasia.

D. It is commonly caused by rotavirus infection, which leads to persistent diarrhoea.

See Answer in Part B → Q6

@Neet_pg_bot

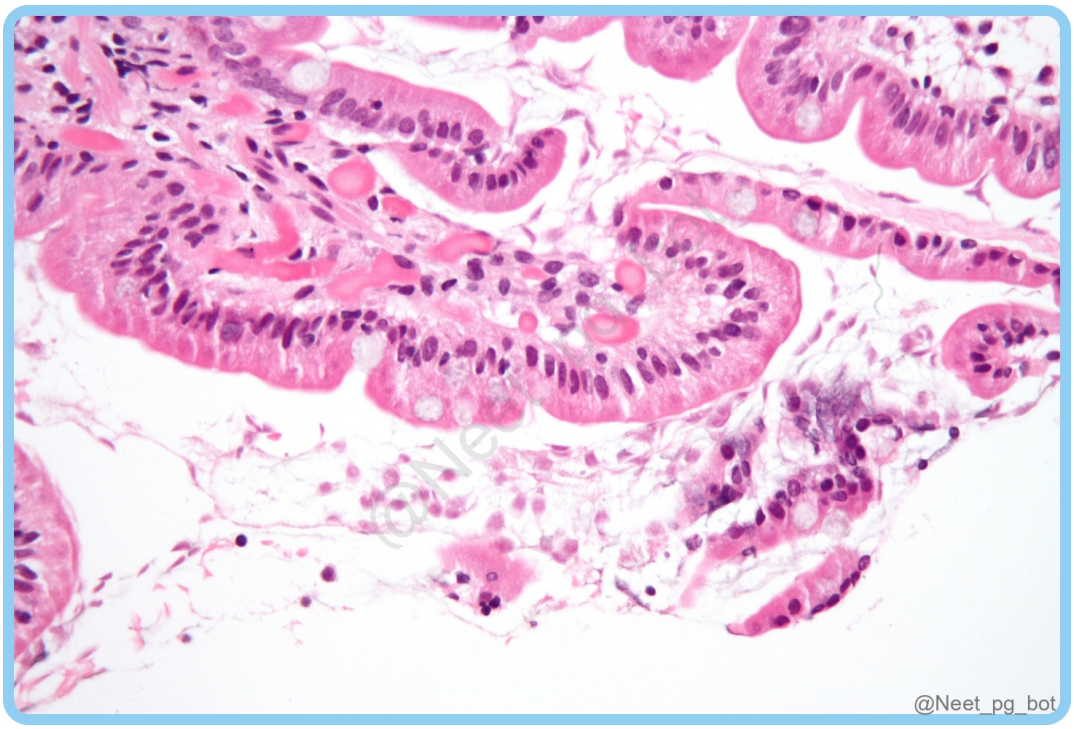
Q7: A 28-year-old female presents with foul-smelling, greasy diarrhoea, bloating, and abdominal cramps following a hiking trip in a remote area. Stool microscopy reveals cysts containing motile trophozoites. A duodenal biopsy shows luminal organisms, as shown in the image, without tissue invasion. Based on the clinical presentation and biopsy findings, what is the most likely causative organism? (Q845312)

A. Cryptosporidium

B. Tropheryma whipplei

C. Entamoeba histolytica

D. Giardia lamblia



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which type of ulcer is characterised by flask shaped, multiple punched-out ulcers with undermined edges and necrotic bases on histopathological examination? (Q845325)

A. TB ulcer

B. Typhoid ulcer

C. Amoebic ulcer

D. Peptic ulcer

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old patient presents with severe diarrhoea and abdominal pain after completing a course of broad-spectrum antibiotics for a respiratory infection. Stool studies detect the presence of Clostridioides difficile (C. difficile) toxin. A colonoscopy revealed diffuse yellowish plaques covering the colonic mucosa, as shown in the image. Which inflammatory cell type predominantly infiltrates the lamina propria and surface epithelium in this condition? (Q845329)

A. Lymphocytes

B. Eosinophils

C. Neutrophils

D. Plasma cells

See Answer in Part B → Q9

@Neet_pg_bot

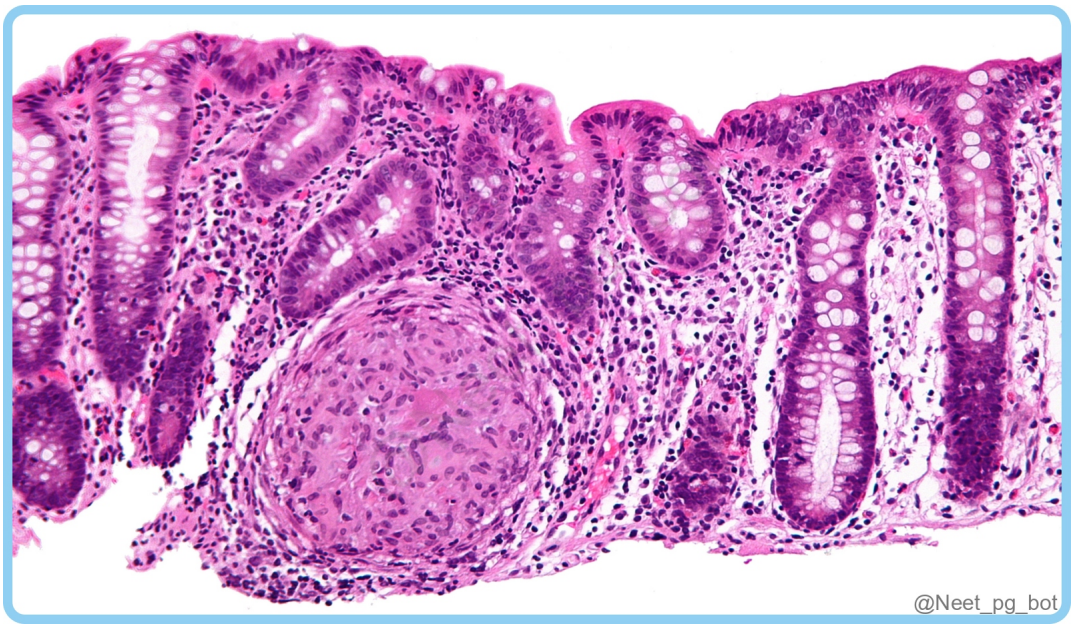
Q10: A 32-year-old man presents with chronic abdominal pain, diarrhoea, weight loss, and occasional blood in the stool. A colonoscopy reveals skip lesions with areas of normal mucosa alternating with segments, cobblestoning and deep linear fissuring ulcers in the patchy terminal ileum and colon. The histopathological findings from the affected area are shown below. What histopathological features are observed in this patient's condition? (Q845333)

A. Presence of noncaseating granulomas

B. Smooth transition between ulcerated and adjacent normal mucosa

C. Absence of metaplastic changes in the epithelium

D. Uniform distribution of inflammation throughout the affected areas



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 32-year-old male presents with a 6-month history of abdominal pain, diarrhoea, and weight loss. A colonoscopy reveals findings consistent with Crohn's diseaseWhat histological features would you observe in this patient's biopsy? (Q845339)

A. Inflammation is limited superficial layer

B. Fibrosis is not seen

C. Ulcers are limited to mucosa

D. Ulcers can extend beyond the mucosa

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which statement is true regarding inflammatory bowel disease (IBD) pathogenesis? (Q845341)

A. NOD2 polymorphisms are closely associated with Crohn's disease in Asian populations.

B. ATG16L1 mutation promotes ATG16L1 degradation and enhances autophagy.

C. Dysbiosis is often established at disease presentation in IBD.

D. All of the above

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements regarding ulcerative colitis and Crohn's disease is true? (Q845344)

A. Ulcerative colitis is characterised by skip lesions, whereas Crohn’s disease typically presents with continuous inflammation.

B. Cobblestone appearance is a feature seen in ulcerative colitis and Crohn's disease but is more commonly associated with Crohn's disease.

C. Ulcerative colitis typically begins in the rectum and extends proximally, whereas Crohn's disease can involve any part of the GI tract with rectal sparing.

D. Fistulae, strictures, and abscesses are more commonly seen in ulcerative colitis than in Crohn's disease.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 32-year-old male presents to the outpatient clinic with a 5-day history of non-bloody, watery diarrhea. He reports that he recently returned from a hiking trip in a rural area where he drank water from a nearby stream. On examination, he appears dehydrated but is otherwise stable. A stool sample was sent for analysis, which revealed the presence of oocysts. Which of the following is the most likely cause of this patient's gastrointestinal symptoms? (Q846629)

A. Cryptosporidium

B. Microsporidium

C. Giardia lamblia

D. Entamoeba histolytica

See Answer in Part B → Q14

@Neet_pg_bot

Q1: Which of the following is a sensitive and specific marker of intestinal inflammation? (Q858080)

A. Procalcitonin

B. Fecal lactoferrin

C. Tissue transglutaminase IgA

D. High-sensitivity C-reactive protein

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 12-year-old boy presents with multiple dark-brown macules around the lips and oral mucosa. Upper GI endoscopy shows numerous hamartomatous polyps in the jejunum. Which of the following statements regarding this condition are correct? Autosomal recessive inheritance Presence of congenital retinal pigmentation (CRPE) Loss-of-function mutation in the STK11 gene. Arborising pattern due to the proliferation of smooth muscle in the polyp histology (Q879201)

A. 1, 2

B. 1, 3, 4

C. 3, 4

D. 2, 3, 4

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is a characteristic feature of Barrett's oesophagus? (Q859302)

A. Squamous metaplasia

B. Severe dysplasia

C. Intestinal metaplasia

D. Cuboidal metaplasia

See Answer in Part B → Q3

@Neet_pg_bot

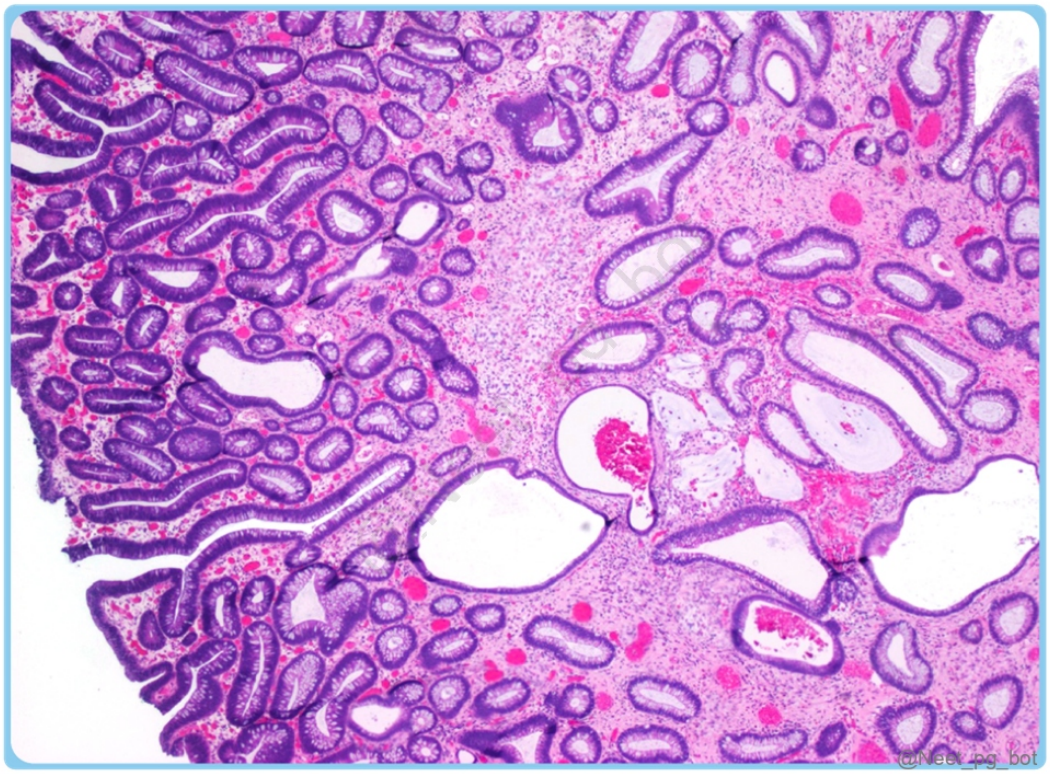
Q4: A 5-year-old child was admitted to the hospital with a history of prolapsing rectal mass and painless rectal bleeding. The histopathological image of the mass is shown below. What is the most likely diagnosis? (Q858520)

A. Peutz-Jegher syndrome

B. Villous adenoma

C. Juvenile polyp

D. Tubular adenoma



See Answer in Part B → Q4

@Neet_pg_bot

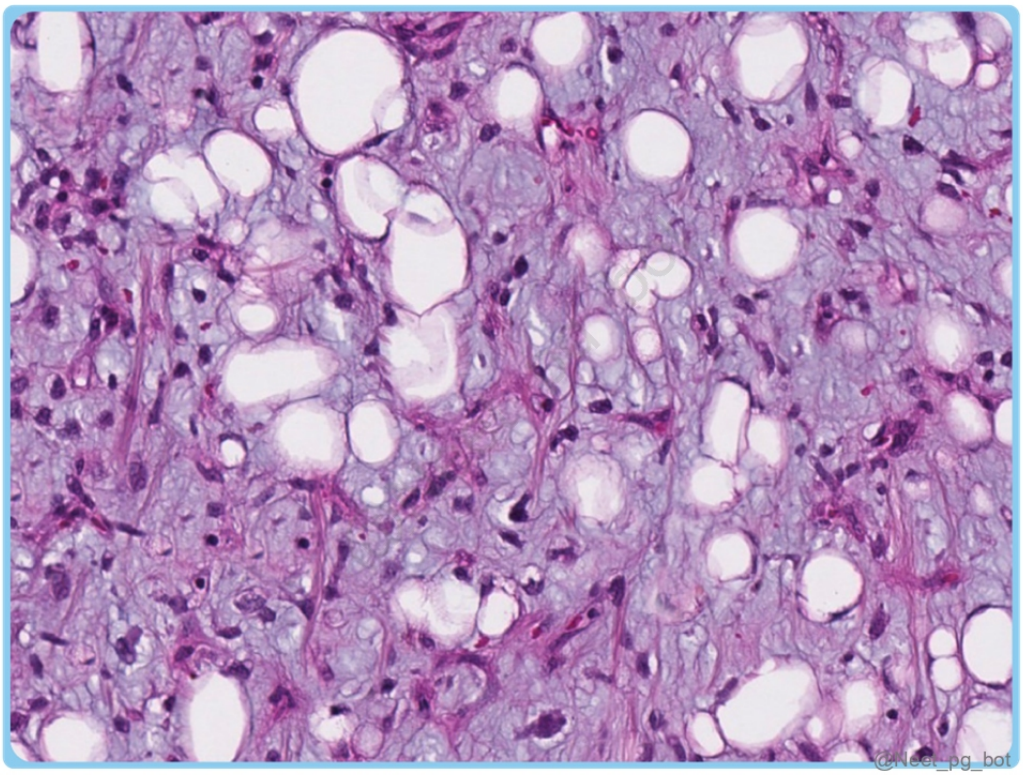
Q5: A 50-year-old man presented with a retroperitoneal mass. A biopsy of the lesion is shown in the image below. Molecular analysis revealed t(12;16). What is the most likely condition? (Q858516)

A. Myxoid liposarcoma

B. Lipoma

C. Spindle lipoma

D. Polymorphic lipoma



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 30-year-old female presents with chest pain, recurrent heartburn, and dysphagia. A barium swallow shows a bird beak sign. Which of the following statements is true regarding the condition in this patient? (Q854892)

A. Relaxation of LES

B. Increased peristalsis

C. Decreased release of NO and VIP in the distal esophagus

D. Decreased tone of LES

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is true about the pathogenesis of Hirschsprung disease? (Q854856)

A. Failure of migration of neural crest cells

B. Increase in ganglion cells

C. Visceral myopathy

D. Obstruction by inflammatory strictures

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 20-year-old patient presents with a history of malabsorption, diarrhea, and poor appetite. A duodenal biopsy shows crypt hyperplasia, villi atrophy, and CD8+ cells in the lamina propria. What is the most probable diagnosis? (Q854843)

A. Environmental enteropathy

B. Celiac disease

C. Whipple’s disease

D. Chronic pancreatitis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following statements regarding Peutz-Jeghers syndrome is correct? An arborizing pattern of smooth muscle Loss of heterozygosity in STK11 gene Multiple GI polyps Autosomal recessive inheritance Congenital hypertrophy of retinal pigmental epithelium is seen (Q856473)

A. 2, 4, 5

B. 1, 2, 3

C. 1, 3, 4

D. 2, 3, 5

See Answer in Part B → Q9

@Neet_pg_bot

Q10: The cells lining the isthmus of gastric pits are: (Q856472)

A. Chief cells

B. Stem cells

C. Parietal cells

D. Mucous cells

See Answer in Part B → Q10

@Neet_pg_bot

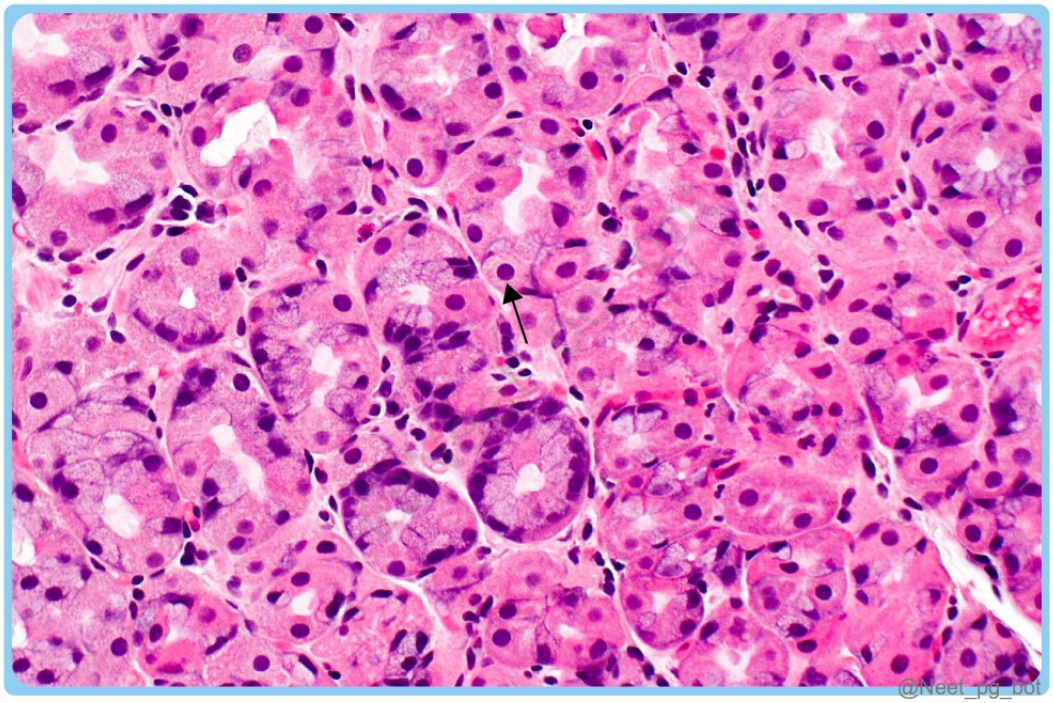
Q11: The absence of the structure will be present in all except: (Q856471)

A. Pernicious anemia

B. Autoimmune Metaplastic Atrophic Gastritis

C. Vitamin B12 Deficiency

D. Zollinger-Ellison syndrome



See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is true about celiac disease? (Q856469)

A. Most common cause of malnutrition in developing countries

B. Can be diagnosed with CECT

C. Improves with food rich in carbohydrates

D. Increased risk of GI lymphoma

See Answer in Part B → Q12

@Neet_pg_bot

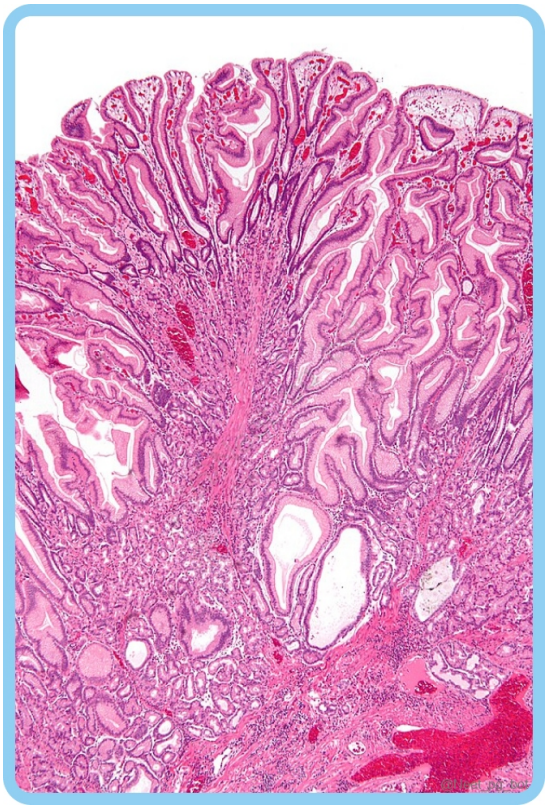
Q13: A 17-year-old boy presented with intussusception and was taken up for surgery. He was found to have multiple polyps. The resected section was sent for histopathology, and the whole mount image of the specimen is given below. Identify the lesion. (Q855425)

A. Tubulovillous adenoma

B. Hamartomatous polyp

C. Adenocarcinoma

D. Hyperplastic polyp



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following set of statements is true about familial adenomatous polyposis (FAP)? It is autosomal recessive. If not treated, 100% of the cases progress to adenocarcinoma of the colon. Polyps do not arise after puberty. It is associated with congenital hypertrophy of the retinal pigment epithelium. (Q855122)

A. 2 and 4

B. 1 and 4

C. 2 and 3

D. 3 and 4

See Answer in Part B → Q14

@Neet_pg_bot

Q15: In Barrett's oesophagus, which of the following epithelial transformations occurs? (Q866674)

A. Columnar to squamous epithelium

B. Squamous to intestinal columnar epithelium

C. Transitional to squamous epithelium

D. Cuboidal to columnar epithelium

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following diet is not advised in celiac sprue disease? (Q820577)

A. Rice

B. Wheat

C. Dhal

D. Ragi

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following intestinal pathologies is associated with dermatitis herpetiformis? (Q860249)

A. Ulcerative colitis

B. Whipple’s disease

C. Celiac disease

D. Crohn’s disease

See Answer in Part B → Q17

@Neet_pg_bot

Q18: In contrast with Ulcerative colitis, which of the following is Crohn's disease is likely to show? (Q840077)

A. Seldom presents with daily hematochezia

B. Increased frequency of perianal fistula

C. Continuous lesion

D. Increased risk of colon cancer

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following is not associated with GIST? (Q840010)

A. PDGFR Beta

B. SDH

C. c- KIT

D. NRG-1

See Answer in Part B → Q19

@Neet_pg_bot

Q20: An adult man presents with a protruding abdomen, diarrhea, visual disturbances and neurological manifestations. Based on the given peripheral smear,

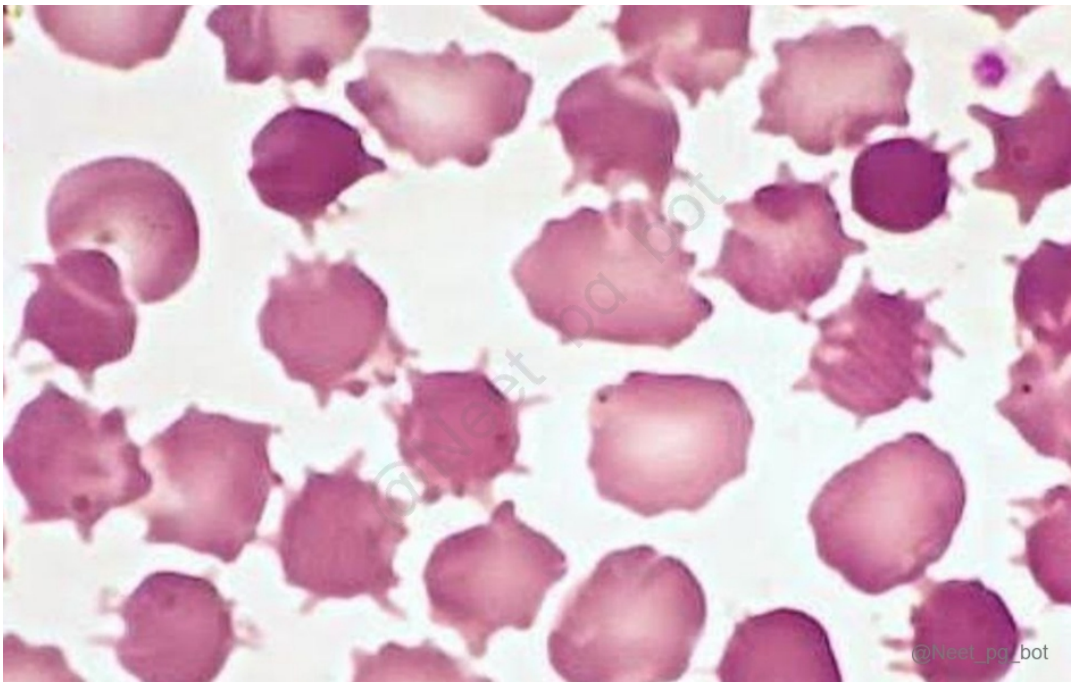
what is the most likely diagnosis? (Q844190)

A. Abetalipoproteinemia

B. Whipple’s disease

C. Menetrier's Disease

D. Uremia



See Answer in Part B → Q20

@Neet_pg_bot

Q21: A child presents with itchy lesions and diarrhea and has been advised to follow a gluten-free diet. What is the most likely diagnosis? (Q844098)

A. Celiac disease

B. Whipple's disease

C. Crohn's disease

D. Ulcerative colitis

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which vitamin is to be supplemented in a patient following gastrectomy? (Q844083)

A. Vitamin A

B. Vitamin B1

C. Vitamin C

D. Vitamin B12

See Answer in Part B → Q22

@Neet_pg_bot

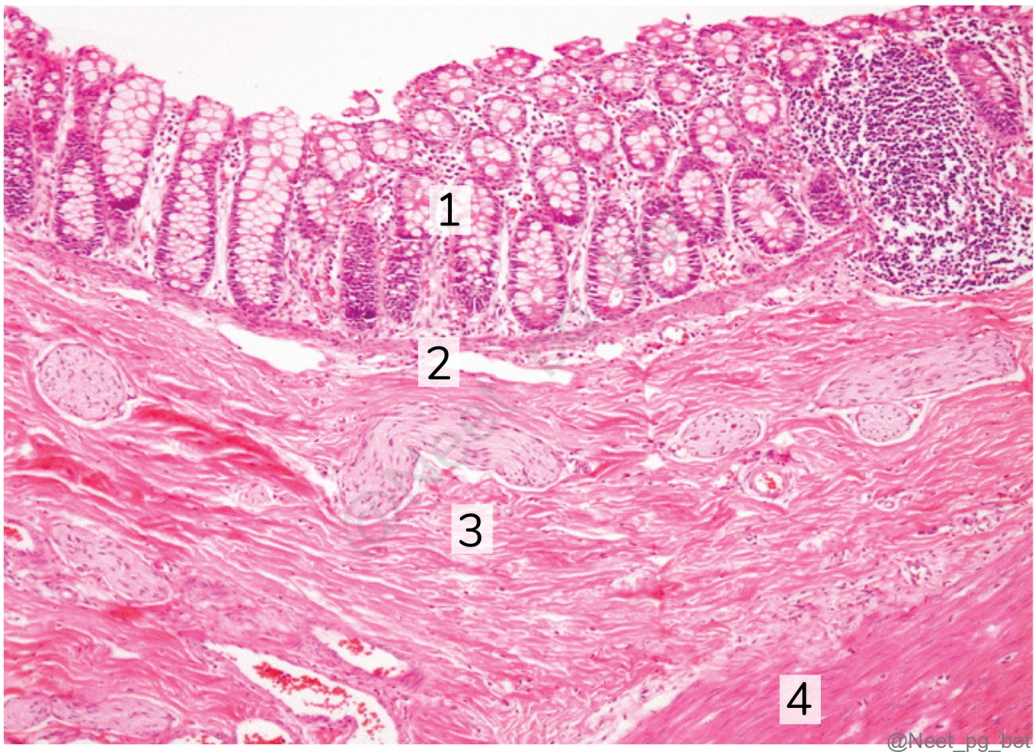
Q23: A child presents with failure to pass stools and is diagnosed with Hirschsprung disease. Which among the following layers of the colon will show congenital absence of neurons? (Q844079)

A. 1 & 2

B. 2 & 3

C. 3 & 4

D. 1 & 4



See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following antibodies is associated with celiac disease? (Q843987)

A. Anti-TTG

B. ANCA

C. ASCA

D. AMA

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Match the following diseases with their respective gene mutation: 1. Familial adenomatous polyposis i. SMAD4 2. Juvenile polyposis ii. STK11 3. Tuberous sclerosis iii. APC gene 4. Peutz-Jeghers syndrome iv. TSC1 (Q853371)

A. A-i, B-ii, C-iii, D-iv

B. A-ii, B-iii, C-i, D-iv

C. A-iii, B-i, C-iv, D-ii

D. A-iv, B-ii, C-iii, D-i

See Answer in Part B → Q25

@Neet_pg_bot

Q26: What is the eye manifestation seen in HLA B27-positive patients with ulcerative colitis? (Q866755)

A. Uveitis

B. Conjunctivitis

C. Scleritis

D. Iridocyclitis

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Hereditary non-polyposis colorectal cancer (HNPCC), also known as Lynch syndrome, is caused by mutations in which type of genes? (Q866735)

A. APC

B. MMR

C. MYC

D. TERT1

See Answer in Part B → Q27

Q1: Which of the following conditions is not typically associated with Mallory-Denk bodies? (Q845632)

A. Wilson’s Disease

B. Hemochromatosis

C. Indian childhood cirrhosis

D. Alpha-1 antitrypsin deficiency

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following combinations represents the organs involved in hereditary hemochromatosis? Liver Pancreas Myocardium Basal ganglia (Q890275)

A. 1, 2, and 3 only

B. 1 and 4 only

C. 2 and 4 only

D. 1, 2, 3, and 4

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following statements regarding secondary hemochromatosis is not true? (Q890274)

A. Bantu siderosis is caused by decreased iron excretion

B. Neonatal hemochromatosis is not a hereditary disorder

C. It can occur after repeated blood transfusions

D. Disease manifests after approximately 20 g of iron accumulation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is the major life-threatening complication of hereditary hemochromatosis? (Q890273)

A. Hepatocellular carcinoma

B. Acute liver failure

C. Splenic rupture

D. Autoimmune hepatitis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 42-year-old man presents with fatigue, skin hyperpigmentation, and newly diagnosed diabetes mellitus. Laboratory studies show elevated serum ferritin and transferrin saturation. The gene responsible for this condition is located on which chromosome? (Q890272)

A. Chromosome 6

B. Chromosome 7

C. Chromosome 18

D. Chromosome 21

See Answer in Part B → Q5

@Neet_pg_bot

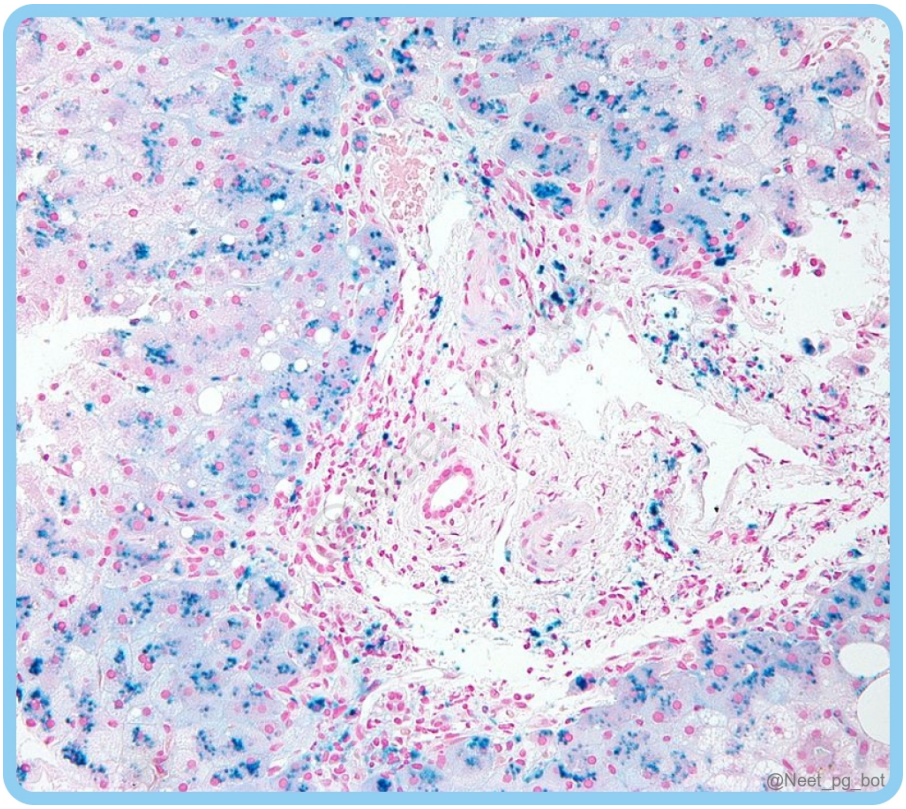
Q6: ■ A 45-year-old man presents with fatigue, diabetes mellitus, and skin hyperpigmentation. Liver biopsy shows findings as shown. Micronodular cirrhosis is present with minimal inflammation. What is the most likely diagnosis? (Q890271)

A. Wilson disease

B. Primary biliary cholangitis

C. Hereditary hemochromatosis

D. α1-antitrypsin deficiency



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following findings is wrong regarding the diagnosis of Wilson's disease? (Q890270)

A. KF rings on slit lamp examination

B. Increased hepatic copper content on liver biopsy

C. Increased urinary copper excretion

D. Elevated serum ceruloplasmin levels

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 14-year-old boy is diagnosed with Wilson's disease. Genetic testing in the patient identifies a pathogenic mutation in the ATP7B gene. His asymptomatic sibling is evaluated for family screening. Which of the following is the most appropriate test to screen this first-degree relative? (Q890269)

A. Serum ceruloplasmin measurement

B. 24-hour urinary copper excretion

C. Targeted genetic testing for the familial ATP7B mutation

D. Slit-lamp examination for Kayser-Fleischer rings

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not typically associated with developing fatty liver disease? (Q845639)

A. Hepatitis B

B. Hepatitis C

C. Type 2 diabetes

D. Alcoholism

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is typically observed in liver biopsy findings of acute hepatitis A infection? (Q845638)

A. Interface hepatitis

B. Councilman bodies

C. Ground glass hepatocytes

D. Bridging fibrosis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What is the most likely autoantibody detected in Type I autoimmune hepatitis (AIH)? (Q845636)

A. Anti-LKM 1

B. Anti-smooth muscle antibodies (ASMA)

C. Anti-Liver Cytosol 1 (ACL-1)

D. Anti-cyclic citrullinated peptide (anti-CCP)

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old male with diabetes mellitus presents with fatigue and abdominal discomfort. He denies any history of alcohol consumption. Laboratory tests show elevated serum AST and ALT levels. Imaging reveals hepatic steatosis. Which of the following is consistent with the patient's presentation? (Q845635)

A. AST/ALT > 2 with obesity

B. AST/ALT > 2 without alcohol intake

C. AST/ALT < 1 with diabetes mellitus

D. AST/ALT < 1 without dyslipidemia

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following changes is reversible with alcohol abstinence? (Q845633)

A. Perivenular fibrosis

B. Periportal fibrosis

C. Bridging fibrosis

D. Micronodular cirrhosis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which cells are primarily involved in the fibrosis in liver cirrhosis? (Q845617)

A. Kupffer cells

B. Pit cells

C. Stellate cells

D. Hepatocytes

See Answer in Part B → Q14

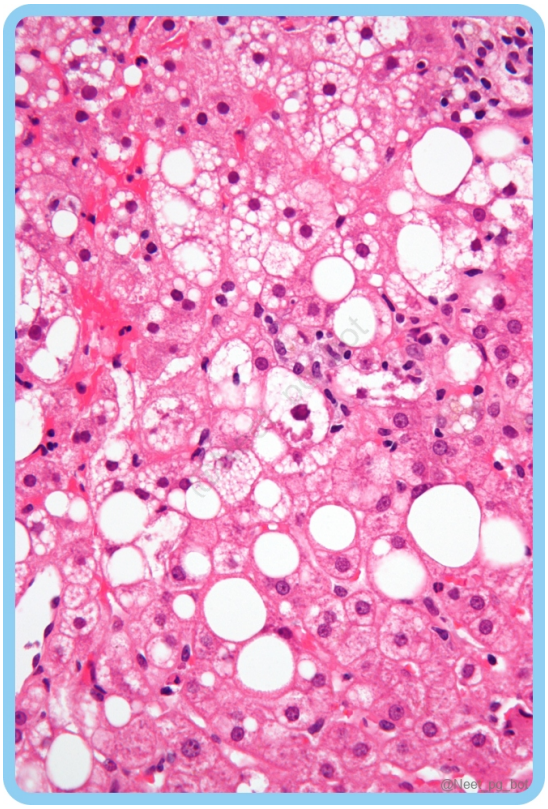
Q15: A 51-year-old male with a history of chronic alcohol use presents with fatigue, abdominal discomfort, and unintentional weight loss. A biopsy of the liver was done. Which of the following histopathological features is characteristic of the condition depicted in the biopsy image? (Q845631)

A. Mallory-Denk bodies

B. Ground-glass hepatocytes

C. Councilman bodies

D. Glycogenated hepatocytes



See Answer in Part B → Q15

Q16: A 60-year-old male presents with abdominal distension and jaundice. Examination reveals hepatosplenomegaly. Lab tests show elevated liver enzymes and decreased albumin levels. Imaging shows nodules <3mm throughout the liver. Which of the following conditions can present with these findings? (Q845629)

A. Viral hepatitis

B. Drug-induced hepatitis

C. Hemochromatosis

D. Wilson disease

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following is the manifestation of increased estrogen levels in Cirrhosis? (Q845628)

A. Increased PT and aPTT

B. Flapping tremors

C. Palmar erythema

D. Jaundice

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following stains would be most useful for highlighting collagen deposition in the fibrotic areas of the liver? (Q845626)

A. Periodic acid-Schiff (PAS) stain

B. Masson's trichrome stain

C. Masson's fontana stain

D. Congo red stain

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which type of collagen is predominantly involved in the fibrotic process of cirrhosis? (Q845625)

A. Collagen Type I and III

B. Collagen Type I and IV

C. Collagen Type II and III

D. Collagen Type II and IV

See Answer in Part B → Q19

@Neet_pg_bot

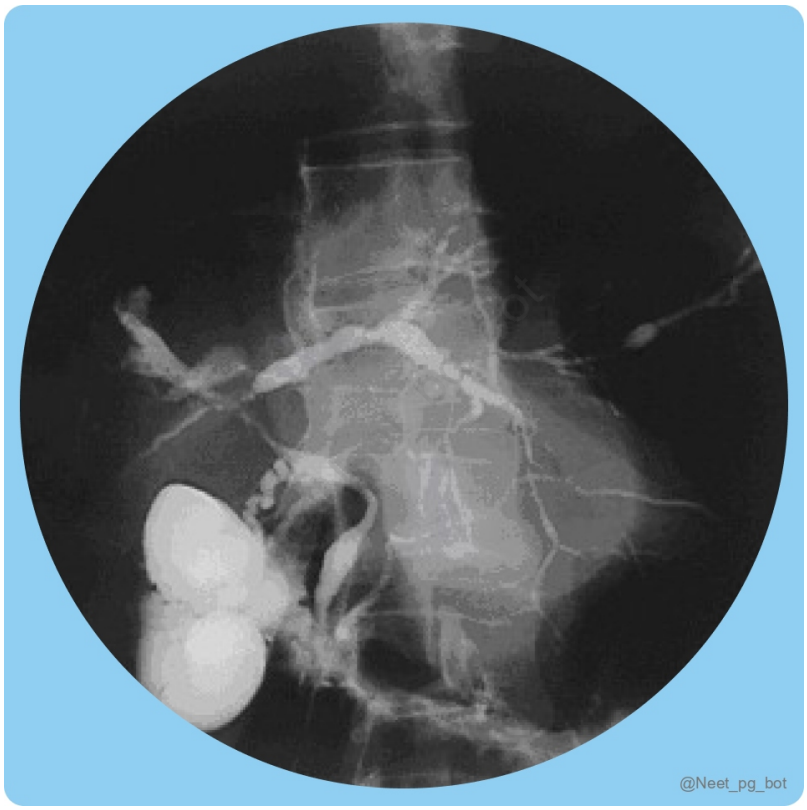
Q20: A 45-year-old male presents with fatigue, pruritus, and jaundice. He has a history of ulcerative colitis. Laboratory tests reveal elevated liver enzymes and conjugated hyperbilirubinemia. MRCP and Histopathological findings from liver biopsy are given below. Which condition is most likely responsible for these findings? (Q845624)

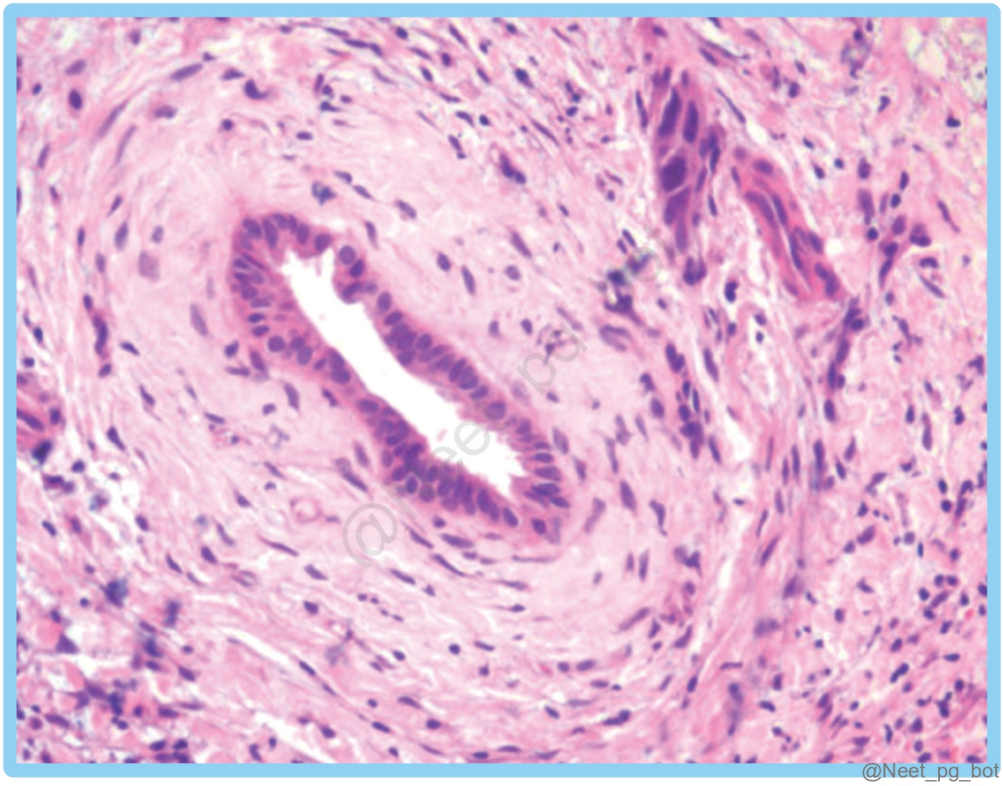
A. Clonorchis/Opisthorchis infection

B. Primary Biliary Cholangitis

C. Primary Sclerosing Cholangitis

D. Biliary stone obstruction





See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old male presents with chronic jaundice and mild abdominal discomfort. Examination revealed hepatomegaly. Lab tests indicate elevated levels of direct bilirubin. Upon liver biopsy, a pigmented liver is observed. What is the most likely underlying mechanism for these clinical and pathological findings? (Q845623)

A. Deficiency of UDP glucuronosyl transferase (UGT)

B. OATP transporter defect

C. MRP2 (Multidrug resistance-associated protein 2) defect

D. Deficiency of biliverdin reductase

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 2-week-old infant presents with persistent jaundice since birth and markedly elevated unconjugated bilirubin levels (>20 mg/dL) despite exposure to sunlight. Genetic testing confirms homozygosity for a specific mutation. What is the likely diagnosis? (Q845622)

A. Criggler-Najjar syndrome type 1

B. Criggler-Najjar syndrome type 2

C. Gilbert syndrome

D. Rotor syndrome

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which change can be seen in a structure that connects hepatocytes with cholangiocytes? (Q845620)

A. Liver regeneration

B. Amyloid deposition

C. Bile synthesis

D. Fibrosis

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which zone of the liver lobule is primarily affected by toxins and drug metabolism? (Q845619)

A. Zone 1 (periportal zone)

B. Zone 2 (midzonal zone)

C. Zone 3 (centrilobular zone)

D. Entire lobule uniformly

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following cytokines is not typically involved in promoting fibrogenesis and hepatic stellate cell activation in chronic liver diseases? (Q845618)

A. Interleukin-6 (IL-6)

B. Platelet-Derived Growth Factor (PDGF)

C. Interleukin-10 (IL-10)

D. Transforming Growth Factor Beta (TGF-β)

See Answer in Part B → Q25

Q13 (p. 486)

Q1: Which of the following mutations is responsible for hereditary haemochromatosis? (Q845720)

A. ATP7B mutation

B. HFE mutation

C. SERPINA 1 mutation

D. UGT1A1 mutation

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 48-year-old man comes to the OPD with complaints of excessive thirst, excessive micturition, and increased hunger. He also states that his skin colour has changed in the past six months. He is icteric on examination, and his skin examination reveals findings similar to those in the image below. What is the most likely cause of the change in his skin colour? (Q845722)

A. Excessive melanin production due to adrenal insufficiency

B. Excessive deposition of melanin and iron in the skin

C. Insulin resistance

D. Excessive deposition of bilirubin in the skin

See Answer in Part B → Q2

@Neet_pg_bot

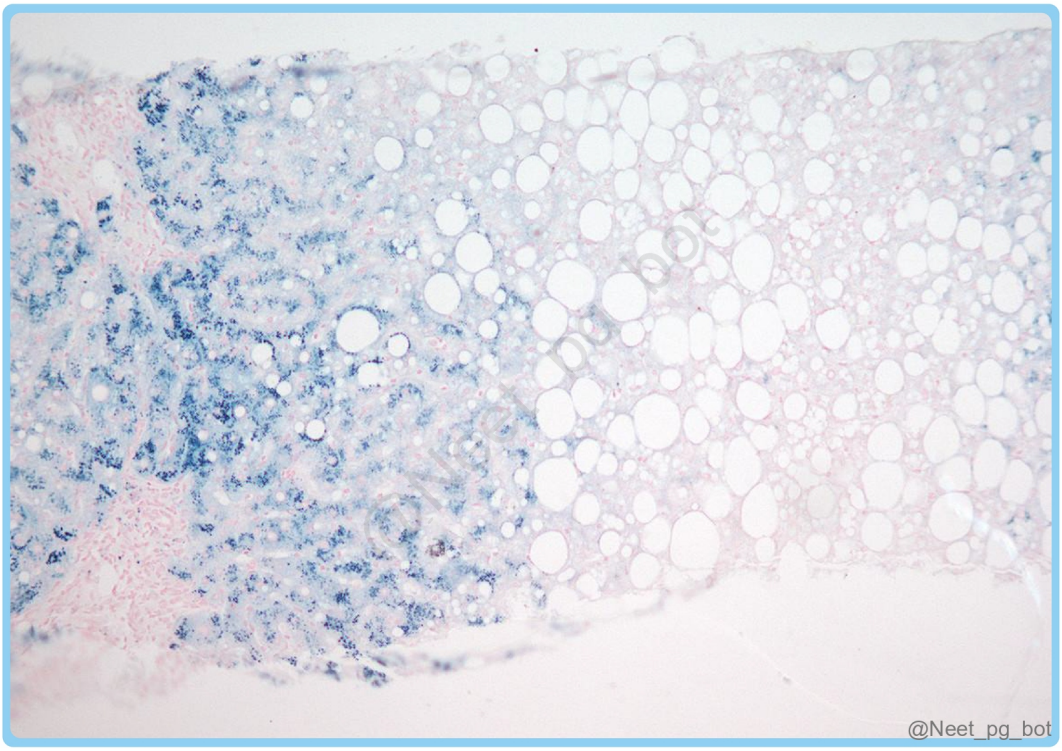
Q3: A 38-year-old female presents with fatigue, joint pain, and bronze skin pigmentation. Labs show a heterozygous mutation in the HFE gene. The histopathology image is shown below. Which of the following is the best screening test for this condition? (Q845725)

A. Serum ferritin level

B. Transferrin saturation

C. Liver function tests

D. Genetic testing for the HFE gene



See Answer in Part B → Q3

@Neet_pg_bot

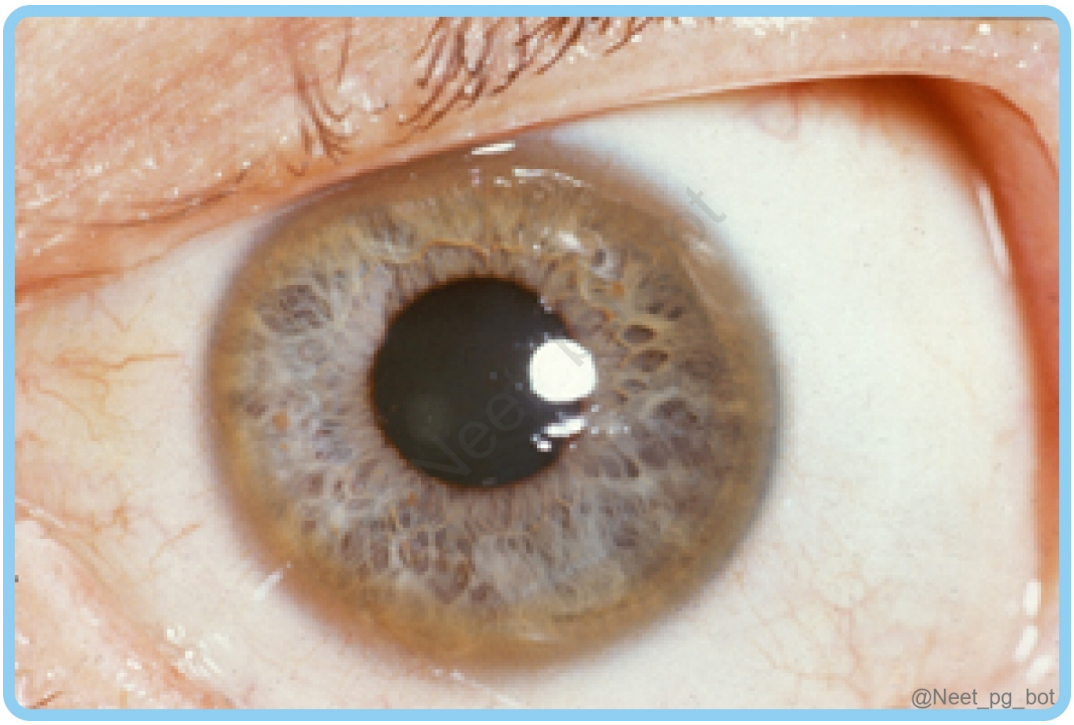
Q4: A 25-year-old patient presents with a history of tremors, dysarthria, and personality changes. Serum ceruloplasmin levels were found to be low. Based on the image below, what ocular finding is associated with the underlying condition? (Q845727)

A. Arcus senilis

B. Kayser-Fleischer rings

C. Roth spots

D. Horner's syndrome



See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following tests is the most specific for confirming the diagnosis of Wilson’s Disease? (Q845730)

A. Serum Ceruloplasmin

B. Urinary excretion of copper

C. LFT

D. Liver Biopsy

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which special stain is commonly used to aid in the diagnosis of Wilson's disease? (Q845731)

A. Oil Red O stain

B. Periodic acid-Schiff (PAS) stain

C. Rubeanic acid stain

D. Prussian blue stain

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 50-year-old male presents with a history of chronic alcohol abuse and complains of right upper quadrant abdominal pain. On examination, hepatomegaly is noted. Laboratory investigations show elevated liver enzymes. Gross feature of the liver has a characteristic mottled appearance. Based on these findings and the image below, what is the most likely diagnosis? (Q845733)

A. Cirrhosis

B. Hepatitis

C. Nutmeg Liver

D. Liver Abscess

See Answer in Part B → Q7

@Neet_pg_bot

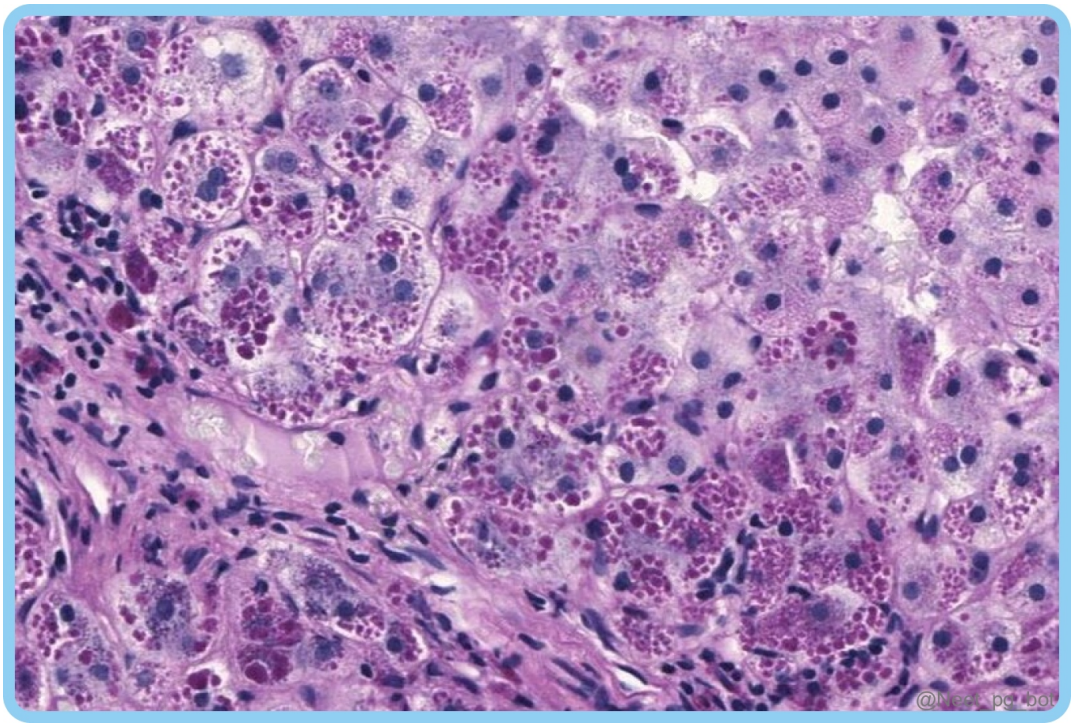
Q8: A 25-year-old female presents with fatigue, jaundice, and abdominal pain. On examination, hepatomegaly is noted. Hepatocytes show globular inclusions which are strongly periodic acid–Schiff (PAS)-positive. Her sibling died of the same liver condition a few years back. What is the primary function of the enzyme implicated in this condition ? (Q845735)

A. Inhibits neutrophil elastase

B. Stimulates neutrophil elastase

C. Stimulates matrix metalloproteinase activity

D. Regulates aminotransferase activity



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 50-year-old patient with a history of recurrent biliary colic and cholangitis undergoes cholecystectomy. Multiple stones are retrieved intraoperatively, and an image of the stones is provided for reference. Which of the following is true about the type of pigmented stones likely seen in this patient? (Q845738)

A. Predominantly found in western populations

B. Associated with metabolic syndrome

C. Found in sterile bile

D. Seen in obesity

See Answer in Part B → Q9

@Neet_pg_bot

Q10: All the following infections are associated with an increased risk of pigmented gallstones, except? (Q845740)

A. Escherichia coli

B. Ascaris lumbricoides

C. Clonorchis sinensis

D. Aspergillus flavus

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following conditions is not a complication associated with gallstones? (Q845741)

A. Acute pancreatitis

B. Gall bladder carcinoma

C. Bouveret syndrome

D. Budd-Chiari syndrome

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old patient presents to the OPD with severe right upper quadrant pain radiating to the right shoulder, accompanied by nausea and vomiting. Clinical examination revealed a positive result for a clinical test shown in the image down below. An ultrasound of the abdomen shows an enlarged and tense gallbladder. Which of the following findings is most likely associated with this patient's condition? (Q845742)

A. Xanthogranulomatous cholecystitis

B. Rokitansky-Aschoff sinuses

C. Subserosal fibrosis

D. Subserosal haemorrhages

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which condition is characterised by extensive dystrophic calcification of the gallbladder wall? (Q845743)

A. Porcelain gallbladder

B. Gangrenous cholecystitis

C. Acute cholecystitis

D. Hyalinizing cholecystitis

See Answer in Part B → Q13

Q1: Which of the following is the most common benign tumor of the liver? (Q845809)

A. Cavernous hemangioma

B. Hepatoblastoma

C. Klatskin tumor

D. Hepatic adenoma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 30-year-old woman presents to the emergency department with severe abdominal pain and signs of hypovolemic shock. She has a history of long-term contraceptive pill use. Imaging studies reveal a large hepatic mass with evidence of haemorrhage. Laboratory tests show elevated liver enzymes. What is the likely diagnosis based on her clinical presentation and medical history? (Q845810)

A. Angiosarcoma

B. Hepatic adenoma

C. Hepatoblastoma

D. Cholangiocarcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 25-year-old sexually active woman who has been on OCP for the past 4 years comes to the ER with severe abdominal pain and features of hypovolemic shock. Ultrasound reveals a large hemorrhagic hepatic mass and fluid in the peritoneum. What is the most probable diagnosis? (Q845811)

A. Hepatocyte nuclear factor 1-alpha (HNF1α)-inactivated hepatocellular adenoma

B. β-Catenin–activated hepatocellular adenoma

C. Nodular regenerative hyperplasia (NRH).

D. Focal Nodular Hyperplasia

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following conditions presents with a central stellate scar? (Q845812)

A. Metastatic liver lesion

B. Focal Nodular Hyperplasia

C. Liver abscess

D. Liver Cirrhosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: All of the following increases the risk of Hepatocellular carcinoma, except? (Q845813)

A. Alcohol

B. NASH (Non-Alcoholic Steatohepatitis)

C. Hemochromatosis

D. Gilbert's syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is true regarding the fibrolamellar variant of hepatocellular carcinoma ? (Q845814)

A. Not associated with Hepatitis B, C

B. Increased AFP levels

C. Hematogenous spread

D. Poor prognosis

See Answer in Part B → Q6

@Neet_pg_bot

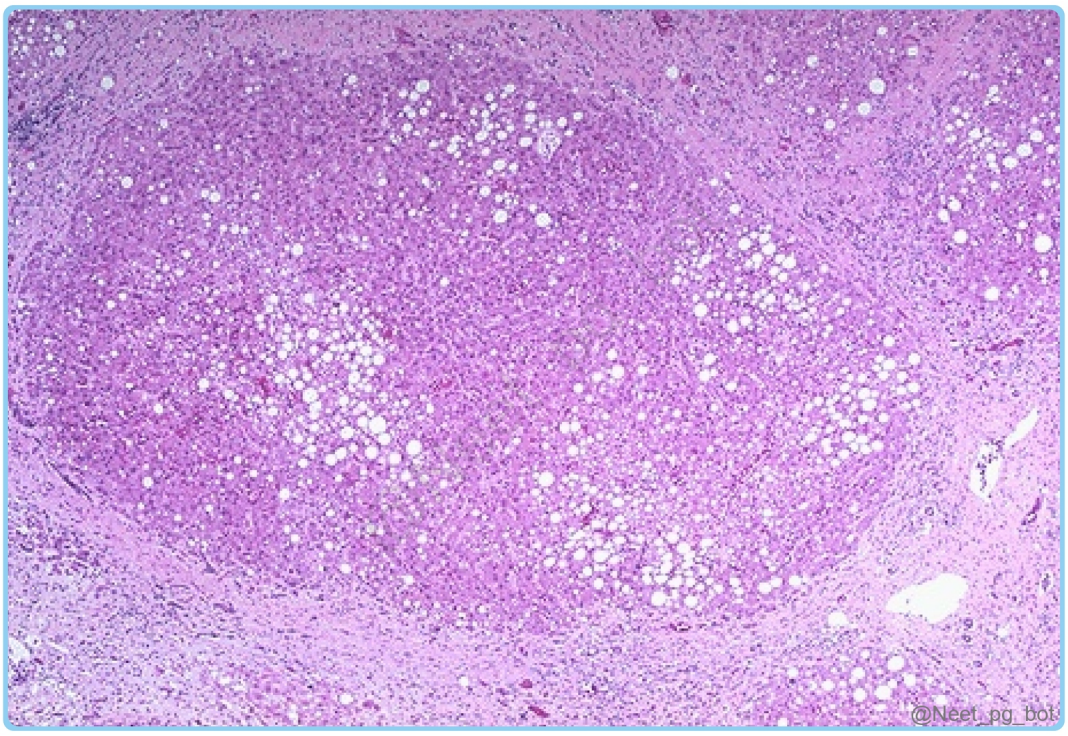
Q7: A patient with a longstanding history of alcoholism is admitted with jaundice, abdominal distension & weight loss. A liver biopsy done during his previous admission showed the following changes, and suspicion of malignant transformation is raised now. Elevation of which of the following markers will support the differential? HepPar-1 Alpha-fetoprotein (AFP) Glypican-3 (GPC3) CA 15-3 Tissue polypeptide antigen (Q845816)

A. 1, 2 and 4

B. 1, 2 and 3

C. 2, 4 and 5

D. 2, 3 and 4



See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 2-year-old child presented with progressive jaundice for the past 2 months. Initial investigations were done, and subsequent histopathological examination of liver biopsy showed changes consistent with hepatoblastoma. Which of the following additional biomarkers will be elevated in this child? (Q845817)

A. CA 19-9

B. AFP

C. Neurotensin

D. CEA

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not a genetic mutation associated with hereditary pancreatitis? (Q845818)

A. PRSS1

B. SPINK1

C. CFTR

D. BRCA1

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following factors is most strongly associated with the development of acute pancreatitis in adult males? (Q845819)

A. Gallstone disease

B. Alcohol

C. Trauma

D. HIV infection

See Answer in Part B → Q10

@Neet_pg_bot

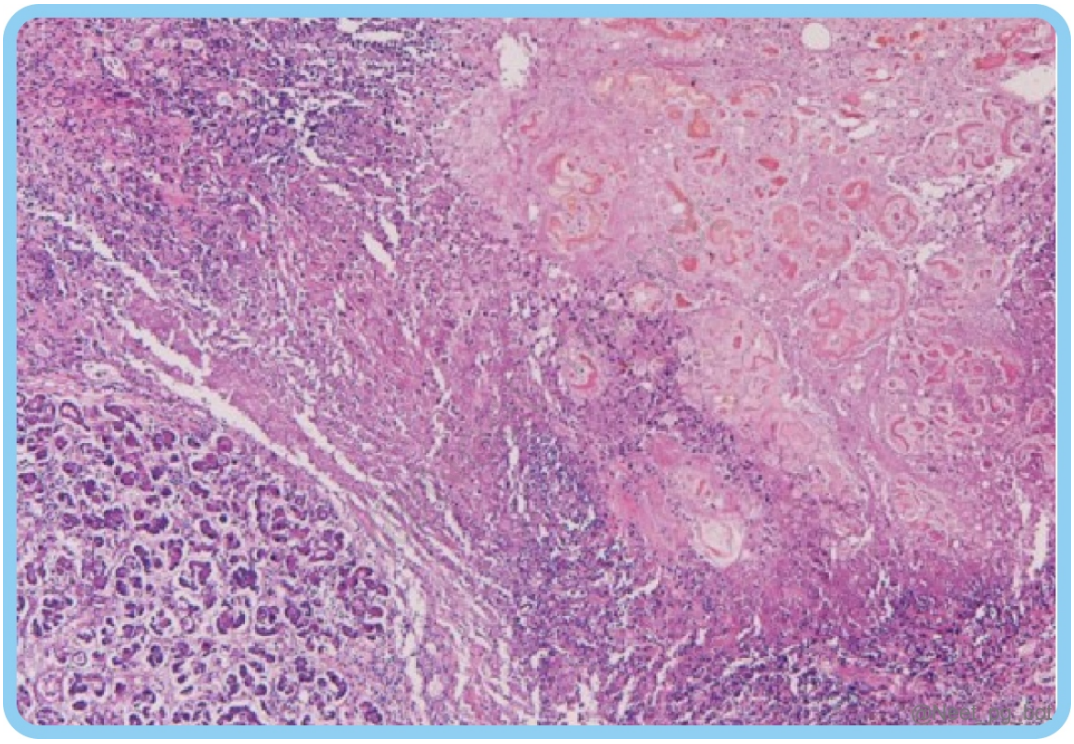
Q11: A 45-year-old female presented with a history of type-2 diabetes and hypertension presented to hospital with a 3 day history of generalized weakness, diffuse abdominal pain and altered mental status. Upon examination, her GCS was 10 with diffuse abdominal tenderness. Investigations showed elevated glucose, creatinine, lipase, and calcium levels. Histopathological examination suggests which of the following associated findings in this patient? (Q845820)

A. Pancreatic hyperplasia

B. Destruction of pancreatic beta cells

C. Intracellular activation of enzymes

D. Fibrosis of pancreatic ducts



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A female patient presents with progressive jaundice and weight loss for the past six months. She also complains of low grade upper abdominal pain. Lab investigation revealed a random blood sugar of 320mg/dL and a raised serum Ig-G4 levels and a USG scan showed a mass like lesion over the head of pancreas. Based on these findings which of the following is the most likely finding in the histopathological examination ? (Q846627)

A. Pleomorphic cuboidal to columnar epithelial cells

B. Necrotic changes in the acini and ducts

C. Honeycombing appearance with cuboidal epithelium

D. Swirling fibrosis with inflammation of veins

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements about pancreatic cystic neoplasms is true? (Q846628)

A. Serous cystadenomas are commonly malignant.

B. Mucinous cystic neoplasms (MCNs) occur predominantly in males.

C. Intraductal papillary mucinous neoplasms (IPMNs) have a risk of malignant transformation.

D. Mucinous cystic neoplasms typically have a central scar on imaging.

See Answer in Part B → Q13

Q1: A 58-year-old male with history of multiple sexual partners presented with anorexia and jaundice. The biopsy shows ground-glass opacity in the cells. What is the most probable diagnosis? (Q866753)

A. Hepatitis A

B. Hepatitis B

C. Hepatitis C

D. Hepatitis D

See Answer in Part B → Q1

@Neet_pg_bot

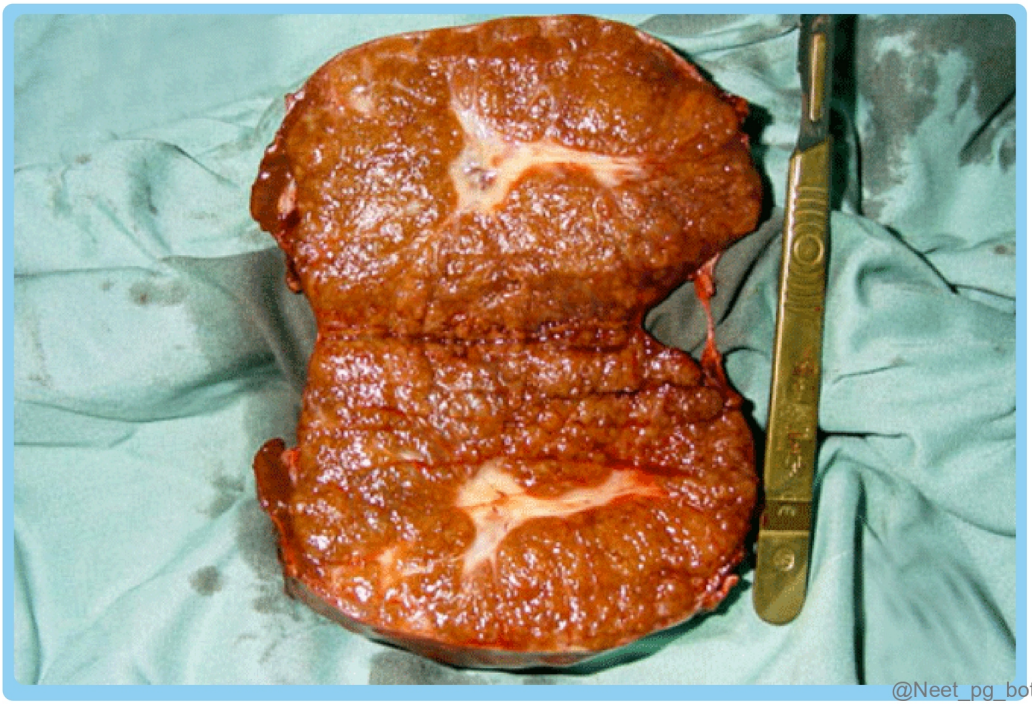
Q2: A cut section of liver is shown below. What is the likely diagnosis? (Q866392)

A. Hepatic adenoma

B. Hepatocellular carcinoma

C. Focal nodular hyperplasia

D. Hemangioma



See Answer in Part B → Q2

@Neet_pg_bot

Q3: An alcoholic patient presents with lower back pain and fever. During history-taking, he mentions experiencing similar episodes in the past with elevated amylase levels. Which type of necrosis is likely to be present in the peri-pancreatic fat? (Q860168)

A. Fibrinoid necrosis

B. Fat necrosis

C. Coagulative necrosis

D. Liquefactive necrosis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is associated with conjugated hyperbilirubinemia? (Q860186)

A. Crigler Najar -1 syndrome

B. Crigler Najar -2 syndrome

C. Gilbert syndrome

D. Dubin-Johnson syndrome

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old patient with a history of chronic liver disease presents with symptoms of nausea, vomiting, edema, and ascites. On examination, his liver function tests are severely deranged. Further investigation reveals a diagnosis of hepatocellular carcinoma. The pathogenesis of this condition is most likely related to: (Q820599)

A. Benzol

B. Arsenic

C. Aflatoxin

D. Vinyl chloride

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What is the most likely diagnosis for a 25-year-old male who presented with fever and has the following viral marker results: HBsAg: Positive and IgM anti-HBc antibody: Positive (Q830720)

A. Acute hepatitis

B. Chronic hepatitis

C. Window period

D. Persistent infection

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is the best serum marker for alcoholic liver disease? (Q854711)

A. SGPT

B. SGOT

C. Carbohydrate-deficient transferrin (CDT)

D. Serum Bilirubin

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following cells plays a key role in phagocytosis and chronic inflammation in the liver? (Q858141)

A. Hepatocytes

B. Ito cells

C. Sinusoidal endothelial cells

D. Kupffer cells

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient suffering from cholelithiasis underwent cholecystectomy. The image of the specimen is shown below. Which of the following is the correct diagnosis? (Q855934)

A. Chronic cholecystitis

B. Gallbladder cholesterol polyp

C. Carcinoma gallbladder

D. Strawberry gallbladder

Q10: What is the gene mutation seen in hemochromatosis? (Q857113)

A. HFE

B. PTEN

C. ATP7B gene

D. MRP2 protein

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 30-year-old female presenting with an unsteady gait, forgetfulness, labile moods, and Kayser-Fleischer rings was diagnosed with Wilson's disease. Which of the following options correctly indicates the gene mutated in this condition and its location? (Q857558)

A. ATP7B gene on chromosome 13

B. ATP7A gene on chromosome X (Xq21.1)

C. ATP7B gene on chromosome 17

D. ATP7A gene on chromosome 17

See Answer in Part B → Q11

@Neet_pg_bot

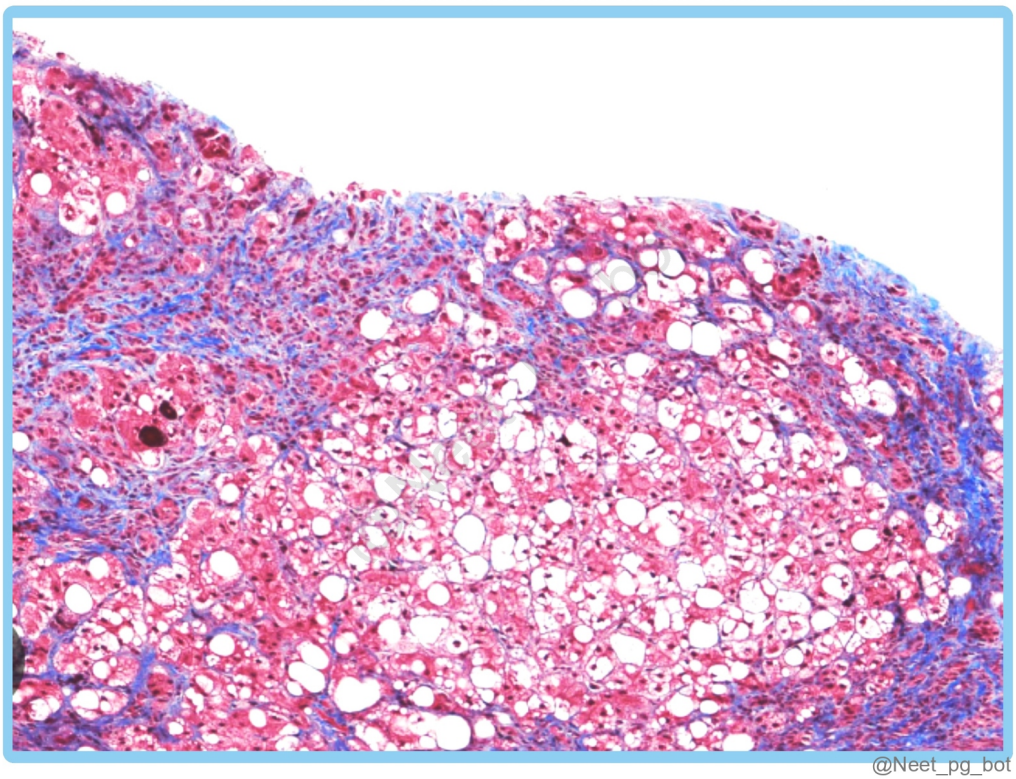
Q12: A patient with cirrhosis and ascites presented to you. The gross appearance of his liver is shown below. Which of the following is true about it? (Q855403)

A. Dark areas represent necrosis, white areas represent viable liver

B. Dark areas represent viable liver tissue, white areas represent necrosis

C. White areas represent central hepatocytes

D. Dark areas represent peri-portal hepatocytes



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is associated with hepatic angiosarcoma? (Q859271)

A. Iron

B. Copper

C. Zinc

D. Arsenic

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Macrophages play an important role in phagocytosis and chronic inflammation. Which of the following cells perform the same function in the liver? (Q859301)

A. Hepatocytes

B. Merkel cells

C. Sinusoid all cells

D. Kupffer cells

See Answer in Part B → Q14

@Neet_pg_bot

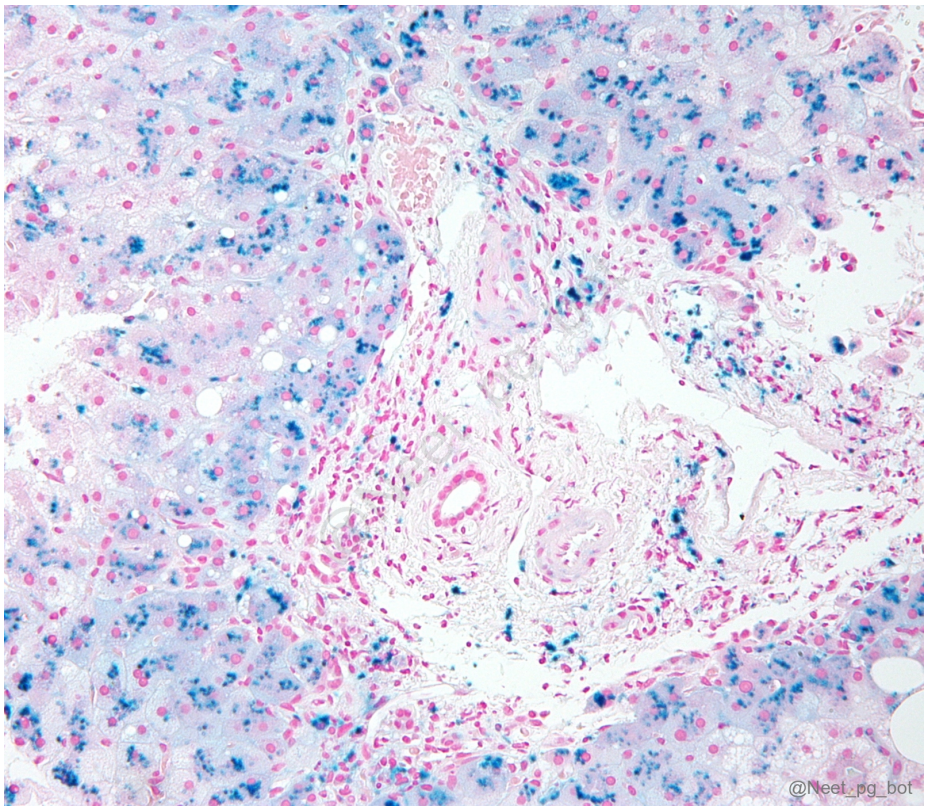
Q15: A 55-year-old man is found to have hepatomegaly on physical examination. He also complains of having dark tan skin despite avoiding sun exposure . His liver microscopy is given on the slide below. What is this patient most likely suffering from? (Q793776)

A. Wilson’s disease

B. Autoimmune hepatitis

C. α-1 antitrypsin deficiency

D. Hemochromatosis



See Answer in Part B → Q15

@Neet_pg_bot

Q16: A health care worker has been found to be seropositive for HBsAg, HBeAg, and anti-HBc IgM, indicating an acute HBV infection with high infectivity. A liver biopsy in such cases is likely to show all the following except: (Q793793)

A. Ballooning change of hepatocytes

B. Ground glass hepatocytes

C. Focal or spotty necrosis

D. Confluent necrosis of hepatocytes

See Answer in Part B → Q16

Q1: Which of the following statements regarding the glomerular basement membrane (GBM) is true? (Q845679)

A. The GBM is primarily composed of collagen type I and elastin.

B. The GBM is a selective barrier between the glomerular capillaries and Bowman's capsule.

C. Thickening of the GBM is a characteristic feature of minimal change disease.

D. The GBM is impermeable to large molecules such as albumin.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following kidney findings will be seen in malignant hypertension? (Q845680)

A. Putty kidney

B. Leather grain kidney

C. Flea-bitten kidney

D. Waxy kidney

See Answer in Part B → Q2

@Neet_pg_bot

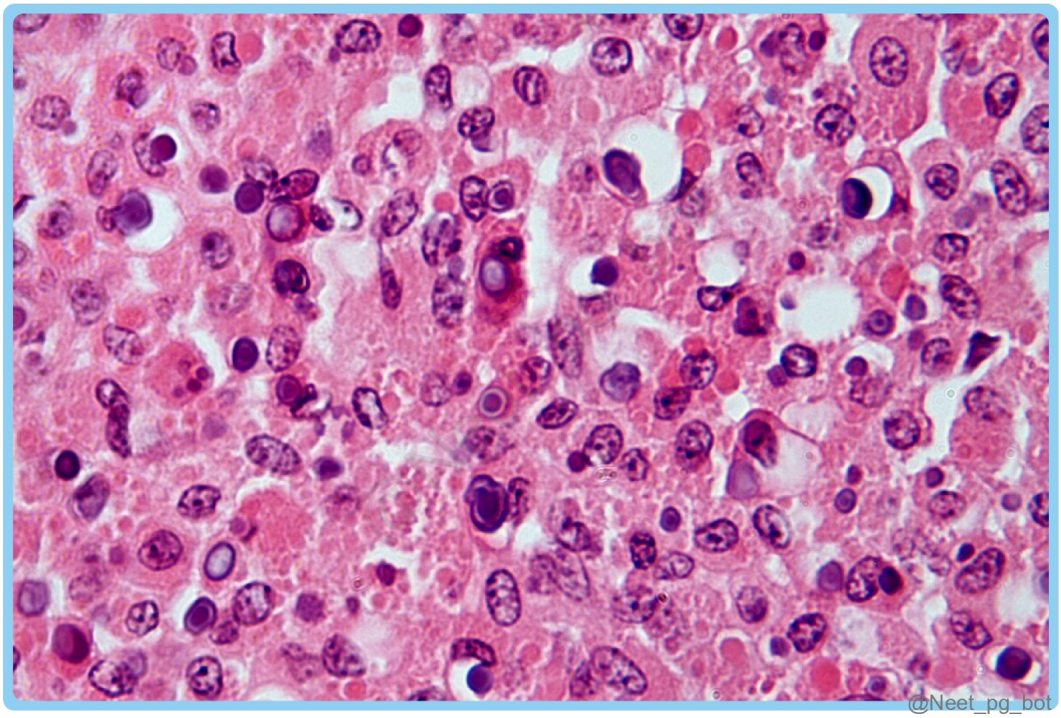
Q3: A 60-year-old female presents with a history of recurrent urinary tract infections and lower abdominal pain. Upon physical examination, palpable masses are noted in the pelvis. Urinalysis reveals persistent pyuria. A biopsy was done on the bladder lesions, which is shown below. Which of the following conditions is most likely responsible for the patient's presentation? (Q845681)

A. Bladder carcinoma

B. Malakoplakia

C. Schistosomiasis

D. Tuberculous cystitis



See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following statements are true regarding autosomal dominant polycystic kidney disease? 1) The gene associated with this condition is seen on chromosome 6. 2) The affected protein is fibrocystin. 3) It is associated with cyst formation in other organs. 4) The most common cause of death in these patients is

hypertensive heart disease. (Q845682)

A. 1,2,3,4

B. 3,4

C. 2,3

D. 2,3,4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Match the following types of renal crystals with their characteristics Types of Renal Crystals Characteristics 1. Calcium Oxalate Monohydrate A. Coffin lid-shaped crystals, commonly found in alkaline urine 2.. Uric Acid B. Rhomboid-shaped crystals, typically seen in acidic urine. 3. Cystine C. Dumbbell or ovoid-shaped crystals are often colourless in acidic urine. 4. . Struvite (Magnesium Ammonium Phosphate) D. Hexagonal plates, often associated with acidic urine (Q845683)

A. 1-D, 2-B, 3-C, 4-A

B. 1-A, 2-B, 3-D, 4-C

C. 1-C, 2-B, 3-D, 4-A

D. 1-C, 2-D, 3-B, 4-A

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old woman presents with complaints of severe lower abdominal pain, dysuria, and hematuria. She has a history of recurrent urinary tract infections (UTIs). Urinalysis reveals a high pH of 8.5 and the presence of white blood cells. Microscopic examination of the urine sediment shows the following finding. Which of the following is the most likely underlying cause of the patient's current presentation? (Q845684)

A. Hypercalcemia

B. Hyperuricemia

C. Infection with urease-producing bacteria

D. Cystinuria

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Match the following renal casts with the conditions they are associated with: Renal Cast Type Condition Associated 1. Hyaline casts A. Nephrotic syndrome 2. Muddy Granular casts B. Chronic Renal Failure 3. Waxy casts C. Acute tubular necrosis 4. Fatty casts D. Fever (Q845685)

A. 1-C, 2-A, 3-B, 4-D

B. 1-B, 2-D, 3-C, 4-A

C. 1-D, 2-C, 3-B, 4-A

D. 1-D, 2-A,3-C, 4-B

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old male presents with confusion, nausea, and abdominal pain after consuming antifreeze due to stress. Urinalysis reveals elevated BUN and creatinine. Microscopic examination is shown below. Identify the type of cast. (Q845687)

A. Hyaline casts

B. Granular casts

C. Waxy casts

D. Muddy brown casts

See Answer in Part B → Q8

@Neet_pg_bot

Q9: All of the following are true about medullary sponge kidney except: (Q845692)

A. It is more common in adults.

B. It is characterised by dilated collecting ducts in the renal medulla.

C. It is caused by an autoimmune destruction of renal tubules.

D. Cysts are lined by cuboidal epithelium.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old man presents with generalised oedema and frothy urine. Laboratory evaluation shows hypoalbuminemia and hyperlipidemia. Urinalysis reveals heavy proteinuria. What is the minimum daily urinary protein loss required to define nephrotic syndrome in adults? (Q889840)

A. 2.5 g/day

B. 3 g/day

C. 3.5 g/day

D. 4 g/day

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following mutations are associated with nephrotic syndrome? Nephrin Podocin ACTN4 INF2 TRPC6 (Q889842)

A. 1 and 2 only

B. 1, 2 and 5 only

C. 1, 2, 3 and 4 only

D. 1, 2, 3, 4 and 5

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 42-year-old man with nephrotic syndrome presents with generalised oedema and frothy urine. Laboratory tests reveal hypoalbuminemia and marked hyperlipidemia. He is noted to have an increased risk of thrombosis. Which of the following plasma proteins is increased in nephrotic syndrome? (Q889844)

A. Antithrombin III

B. Albumin

C. Fibrinogen

D. Immunoglobulin G

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 40-year-old man presents with nephrotic-range proteinuria. Renal biopsy shows focal and segmental glomerulosclerosis. You are reviewing conditions associated with secondary FSGS. Which of the following is not associated with FSGS? (Q889847)

A. Reflux nephropathy

B. Sickle cell disease

C. ACTN4 mutation

D. Minimal change disease

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following FSGS variants is associated with the best prognosis, and which is associated with the worst prognosis? (Q889849)

A. Hilar variant - Best; Cellular variant - Worst

B. Tip lesion variant - Best; Collapsing variant - Worst

C. Collapsing variant - Best; Tip lesion variant - Worst

D. Cellular variant - Best; Hilar variant - Worst

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following conditions is characterised by the absence of mesangial immune complex deposits? (Q889850)

A. IgA nephropathy

B. Lupus nephritis (Class II)

C. Henoch-Schönlein Purpura

D. Anti-GBM disease

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A child with nephrotic syndrome undergoes serum protein electrophoresis. Which protein is increased? (Q889852)

A. Albumin

B. α1-antitrypsin

C. α2-macroglobulin

D. IgG

See Answer in Part B → Q16

Q13 (p. 520)	*Q14 (p. 520)*	*Q15 (p. 521)*	*Q16 (p. 522)*	*Q17 (p. 523)*	*Q18 (p. 524)*

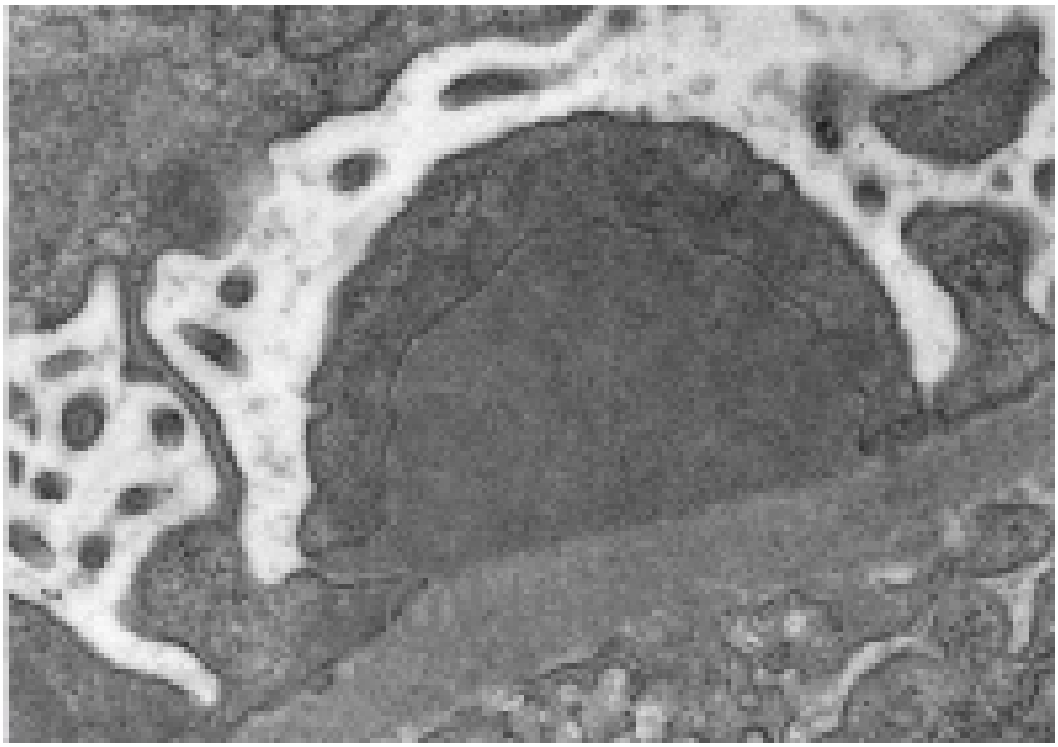
Q1: A 9-year-old boy is brought to the clinic with swelling around the eyes, dark "tea-colored" urine, and decreased urine output. His mother reports that he had a skin infection (impetigo) about 3 weeks ago. On examination, he has mild periorbital edema and elevated blood pressure. Urinalysis shows RBC casts and mild proteinuria. Serum studies reveal low C3 complement levels. A renal biopsy is performed, and electron microscopy reveals following changes. Which of the following is the most likely diagnosis? (Q845704)

A. IgA nephropathy

B. Post-streptococcal glomerulonephritis

C. Membranous nephropathy

D. Minimal change disease



See Answer in Part B → Q1

@Neet_pg_bot

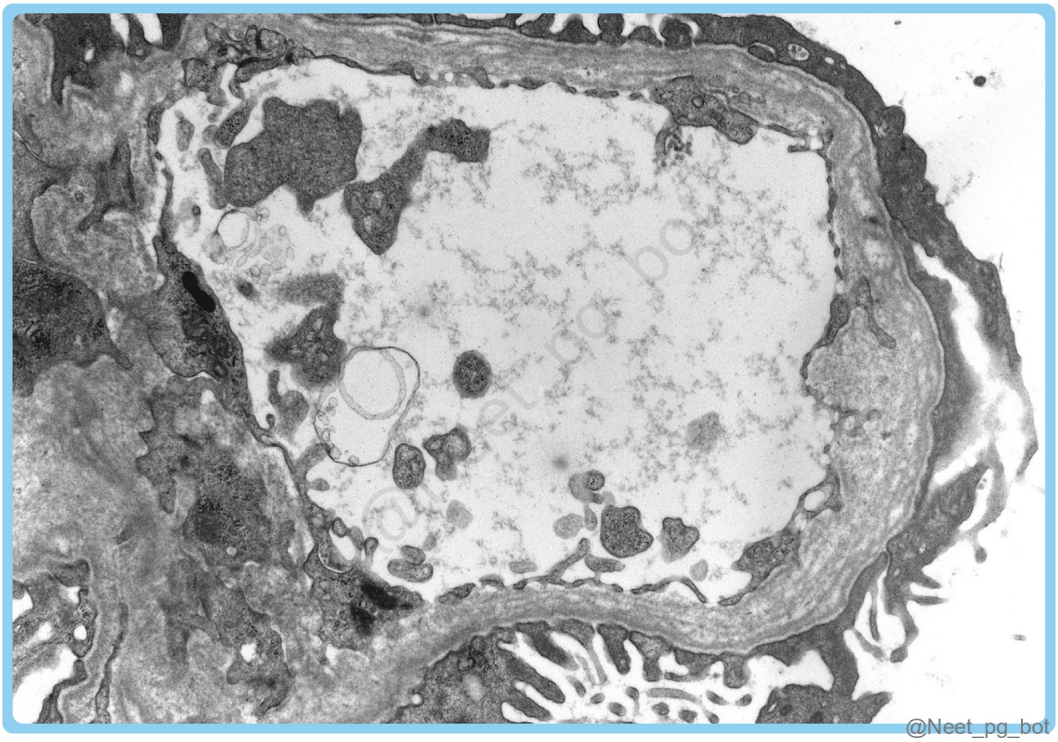
Q2: A 12-year-old male child presents to the clinic with a history of progressive hearing loss, blurred vision, and recurrent episodes of hematuria over the past few months.Electron microscopy reveals the 'basketweave' appearance of GBM. Which of the following morphological findings is responsible for this appearance? (Q846662)

A. Effacement of podocyte foot processes

B. Thickening of the glomerular basement membrane with subepithelial electron-dense deposits

C. Irregular thickening, thinning, and splitting of the glomerular basement membrane

D. Mesangial expansion with GBM thickening and eosinophilic nodular glomerulosclerosis



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old patient with a history of poorly controlled diabetes presents with worsening kidney function. Upon examination, renal biopsy reveals glomerular changes consistent with diabetic nephropathy. Which histological findings would be least likely to be observed in the glomeruli of this patient's kidney biopsy? (Q846670)

A. Kimmelstiel-Wilson nodule

B. Diffuse glomerulosclerosis

C. Arteriolar hyalinosis

D. Armani-Ebstein lesion

See Answer in Part B → Q3

@Neet_pg_bot

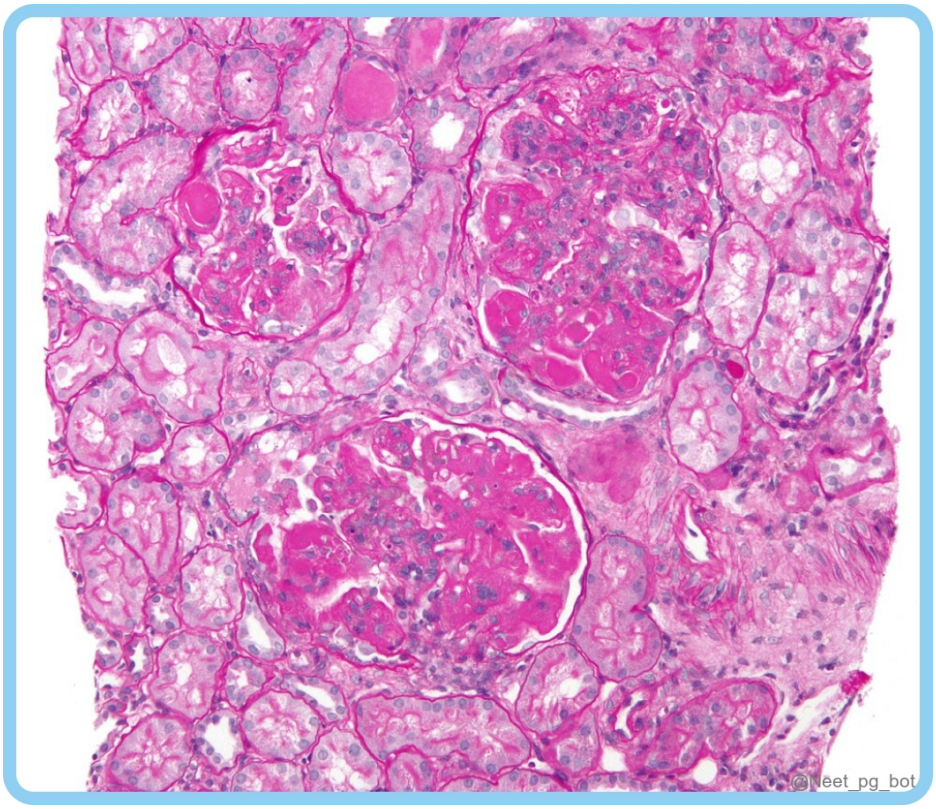
Q4: A 32-year-old female presents with a history of joint pain, skin rash, and recent onset of shortness of breath. Lab investigations reveal elevated anti-double-stranded DNA antibodies and low complement levels. A kidney biopsy shows >50% involvement of glomeruli with wire loop lesions on light microscopy. Which type of lupus nephritis is most likely observed in the biopsy findings? (Q846669)

A. Class III

B. Class IV

C. Class V

D. Class VI



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old male presents with generalised oedema and frothy urine. Laboratory investigations reveal significant proteinuria and hypoalbuminemia. A kidney biopsy reveals diffuse thickening of GBM, a spike and dome pattern on the

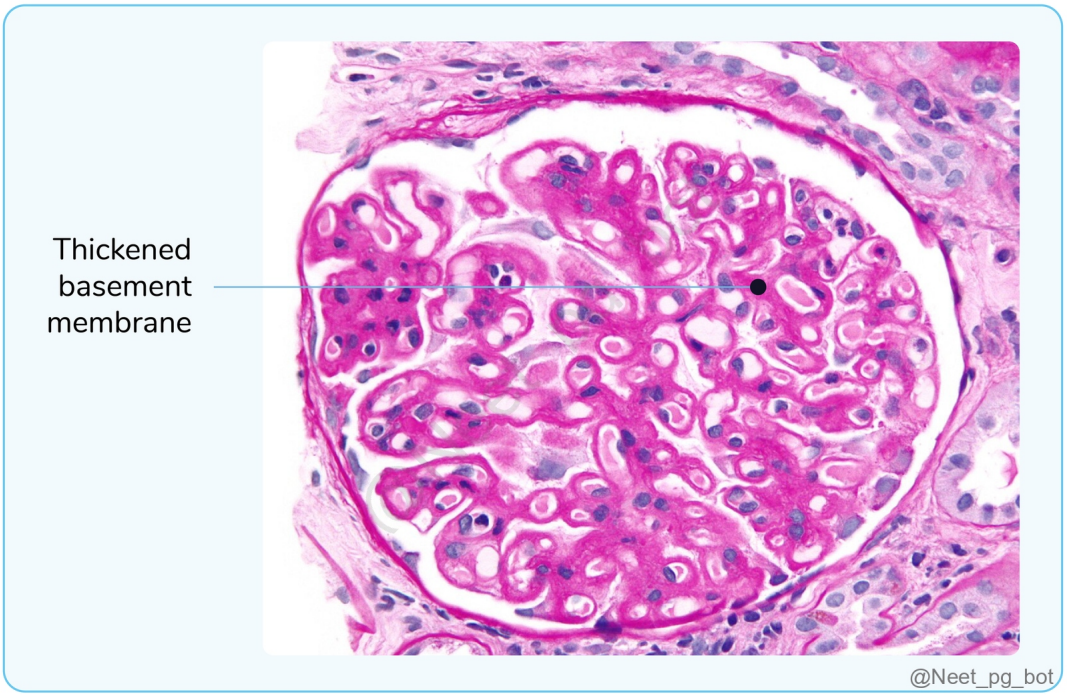
silver stain and subepithelial deposits on electron microscopy. Which of the following genetic mutations is most likely associated with this condition? (Q846668)

A. Mutation in PLA2R

B. Mutation in LAMB2 gene

C. Mutations in APOL1 gene

D. Mutations in CFH gene



See Answer in Part B → Q5

@Neet_pg_bot

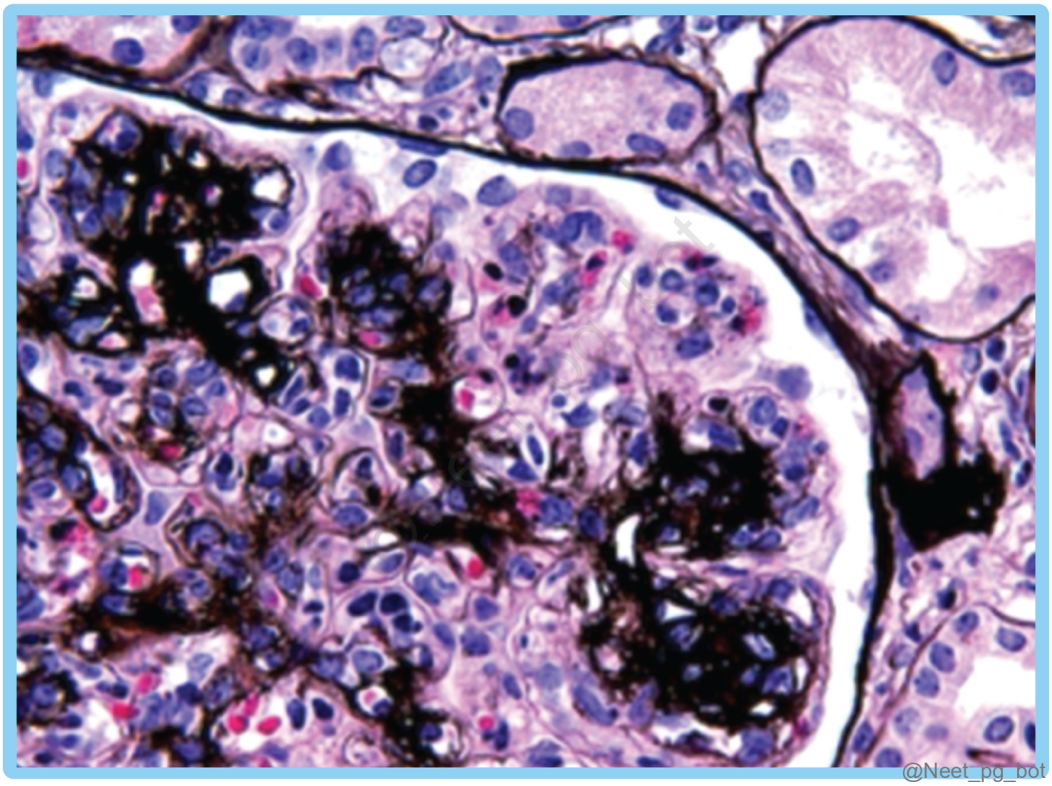
Q6: A 25-year-old female presents with edema, hypertension, significant proteinuria, and hematuria. Kidney biopsy reveals mesangial and endocapillary hypercellularity with mesangial and subendothelial electron-dense deposits, tram track appearance on silver stains and granular staining for IgG and C3 on Immunofluorescence. What is the most likely diagnosis? (Q846667)

A. Type I Membranoproliferative Glomerulonephritis

B. Type II Membranoproliferative Glomerulonephritis

C. Membranous Nephropathy

D. Focal Segmental Glomerulosclerosis



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which genetic mutation is responsible for a syndrome of steroid-resistant nephrotic syndrome of childhood onset? (Q846666)

A. NPHS1

B. NPHS2

C. α-actinin 4

D. TRPC6

See Answer in Part B → Q7

@Neet_pg_bot

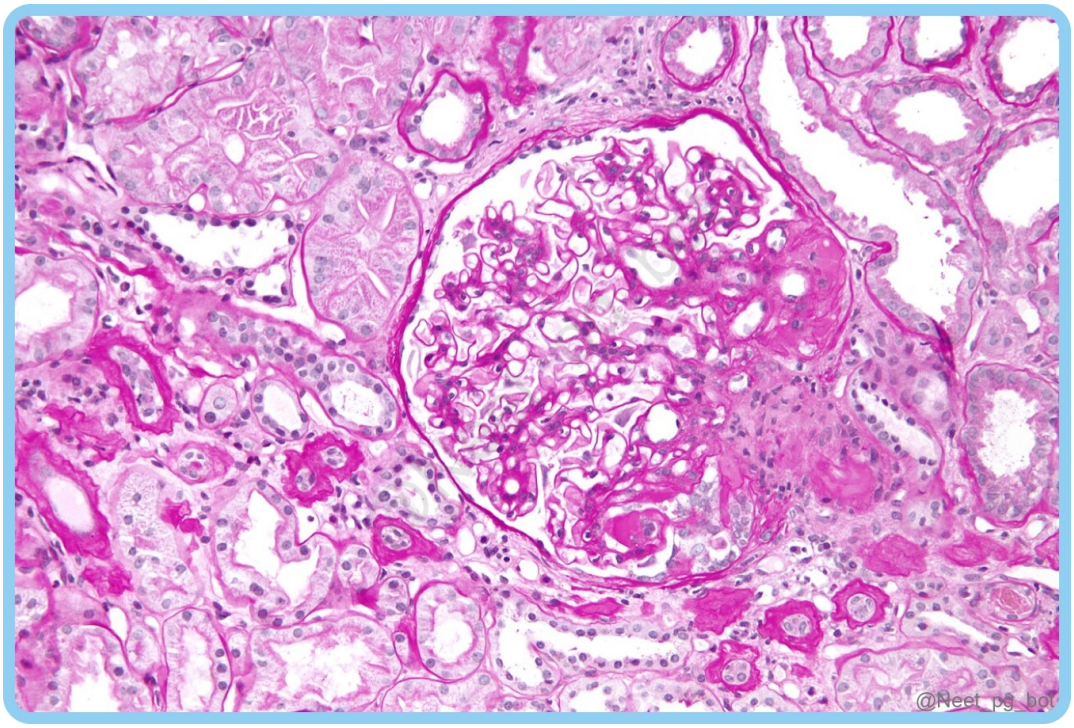
Q8: A 35-year-old man presents with swelling around his eyes, ankles, and abdomen, along with frothy urine. Urinalysis shows proteinuria, elevated serum creatinine, and BUN levels. Image of renal biopsy is given below. Which of the following is not an established cause of this condition? (Q846665)

A. Diabetes mellitus

B. HIV infection

C. Hypertension

D. Sickle cell anaemia



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 6-year-old boy presents with sudden generalised oedema and frothy urine. Urinalysis reveals heavy proteinuria without hematuria. Renal biopsy widespread effacement of podocyte foot processes on electron microscopy. Which of the following is true regarding this condition? (Q846664)

A. Lipid deposition within glomerular capillaries (tubular cells)

B. Immunofluorescence microscopy reveals granular deposition of IgG and C3 in the glomeruli.

C. Good response to corticosteroid therapy

D. Non-selective proteinuria

See Answer in Part B → Q9

@Neet_pg_bot

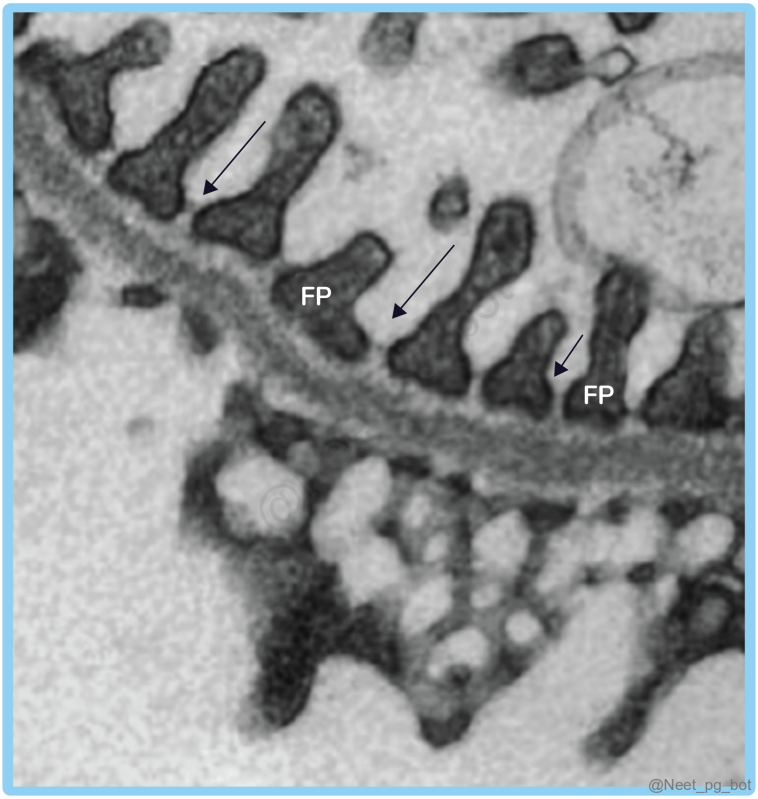
Q10: A 7-year-old girl with a recent upper respiratory tract infection presents with generalised swelling and reduced urine output. Urinalysis reveals proteinuria without blood cells or casts. Electron microscopy findings show flattening, retraction, and swelling of podocytes. Which light microscopy findings is characteristic of this condition? (Q846663)

A. Glomerulosclerosis

B. Normal glomeruli

C. Fibrinoid necrosis in glomeruli

D. Wire looping of capillaries



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 15-year-old boy presents with complaints of blurred vision, hearing loss, and recurrent episodes of hematuria. Genetic testing reveals a mutation in Type 4 collagen. Which of the following genetic mutations is observed in the patient? (Q846661)

A. COL4A3 gene

B. COL4A4 gene

C. COL4A5 gene

D. All of the above

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 32-year-old male presents with painless hematuria post-upper respiratory infections, normal vital signs, and no oedema. Urinalysis reveals red blood cell casts and further investigation shows elevated serum creatinine and mild proteinuria. Renal biopsy confirms glomerulonephritis. What is the most common type of glomerulonephritis in this case? (Q846660)

A. IgA nephropathy

B. Post-Streptococcal glomerulonephritis

C. Minimal change disease

D. Membranous nephropathy

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old male presents with recurrent hematuria following upper respiratory infections and intermittent proteinuria. Renal biopsy shows mesangial IgA deposits on immunofluorescence and electron-dense deposits in the mesangium on electron microscopy. What is the most likely diagnosis? (Q846659)

A. Berger’s Disease

B. Alport syndrome

C. Membranous nephropathy

D. Buerger's Disease

See Answer in Part B → Q13

@Neet_pg_bot

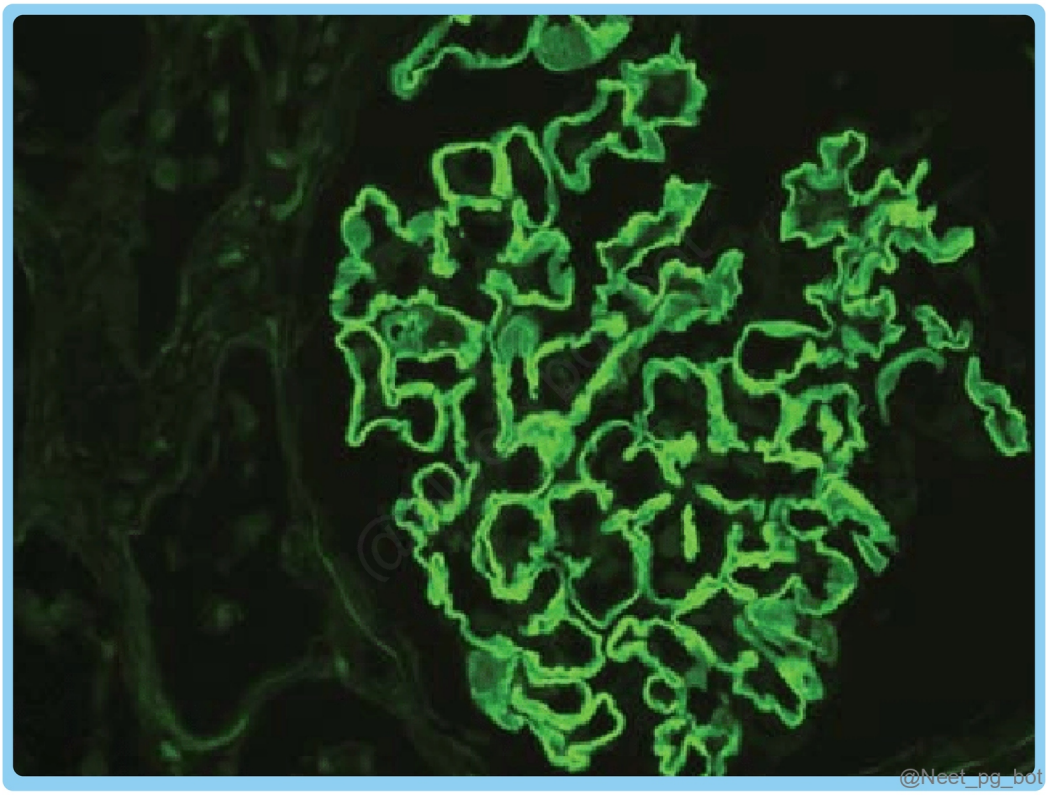
Q14: A 30-year-old male presents with increasing shortness of breath and hemoptysis. Lab tests show elevated serum creatinine and hematuria. Renal biopsy reveals linear immunofluorescence along the glomerular basement membrane and subepithelial and intramembranous electron-dense deposits on electron microscopy. Which of the following statements regarding the diagnosis is not true? (Q846658)

A. It is a Type III hypersensitivity reaction

B. Defective α3 chain of collagen IV

C. Linear immunofluorescence is due to IgG deposition

D. The most common cause of death is uremia.



See Answer in Part B → Q14

@Neet_pg_bot

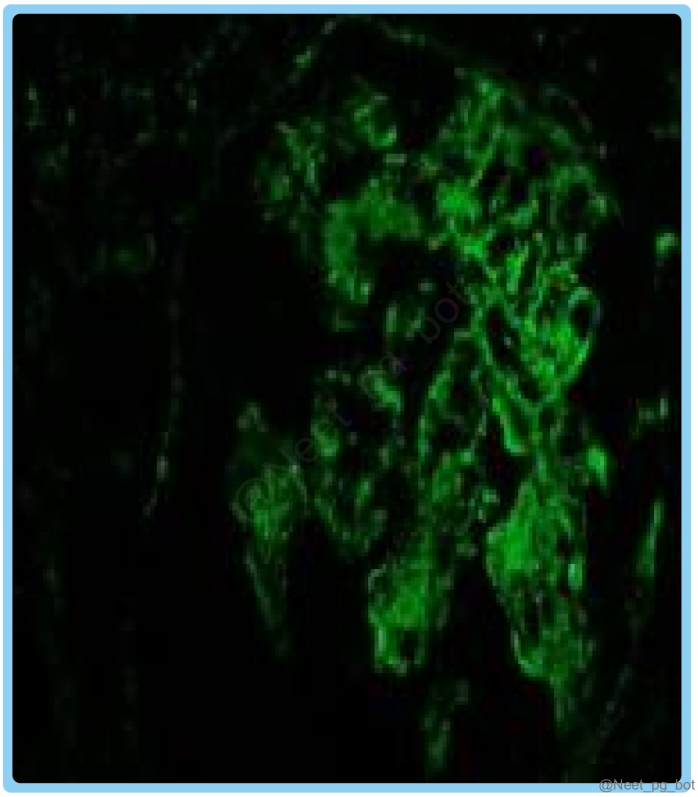
Q15: A 9-year-old boy presents with a recent sore throat, dark urine, fatigue, eye puffiness, and mild limb swelling. Urinalysis reveals hematuria, proteinuria, and red blood cell casts. Serum creatinine levels are slightly elevated. A renal biopsy shows the immunofluorescence image provided below. Which condition is not typically associated with this pattern of rapidly progressive glomerulonephritis? (Q846657)

A. Wegeners granulomatosis

B. Henoch-Schonlein purpura

C. Systemic lupus erythematosus

D. Ig A Nephropathy



See Answer in Part B → Q15

@Neet_pg_bot

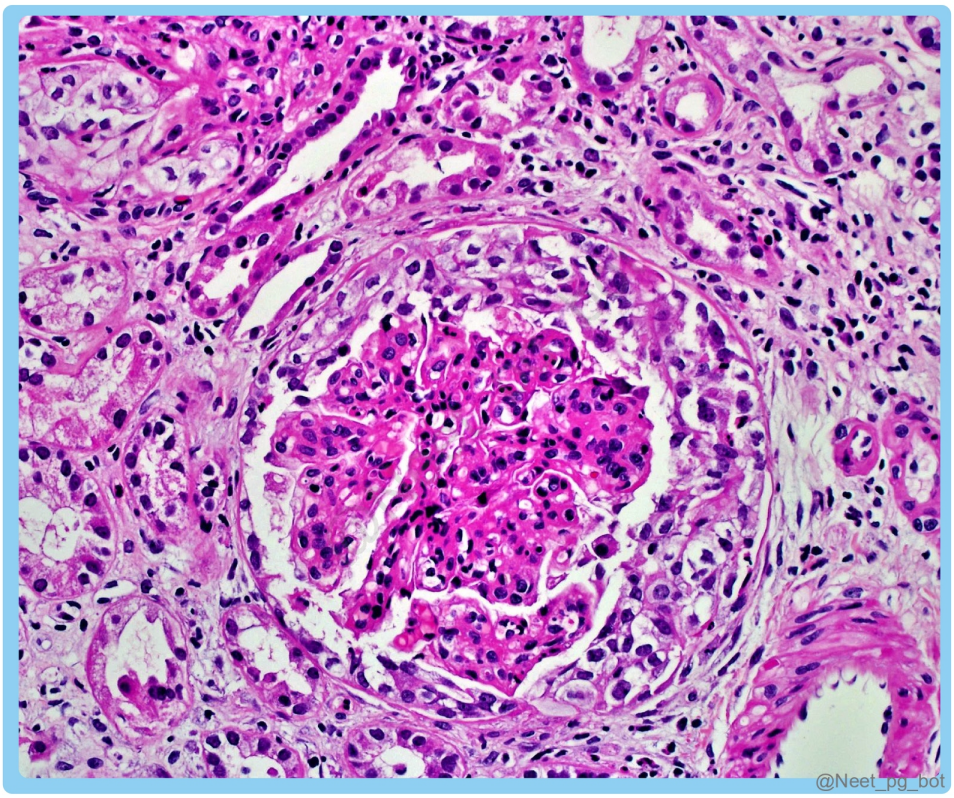
Q16: A 32-year-old woman with a history of SLE presents with fatigue, decreased urine output, and facial swelling. Lab tests show elevated serum creatinine, proteinuria, and hematuria. A renal biopsy is performed, and the histopathological examination image is attached. Which statement is true regarding this condition? (Q846656)

A. >50% of glomeruli showing crescents is diagnostic.

B. More the number of crescents, better the prognosis.

C. Crescents are composed solely of endothelial cells.

D. Primarily caused by bacterial infections.



See Answer in Part B → Q16

@Neet_pg_bot

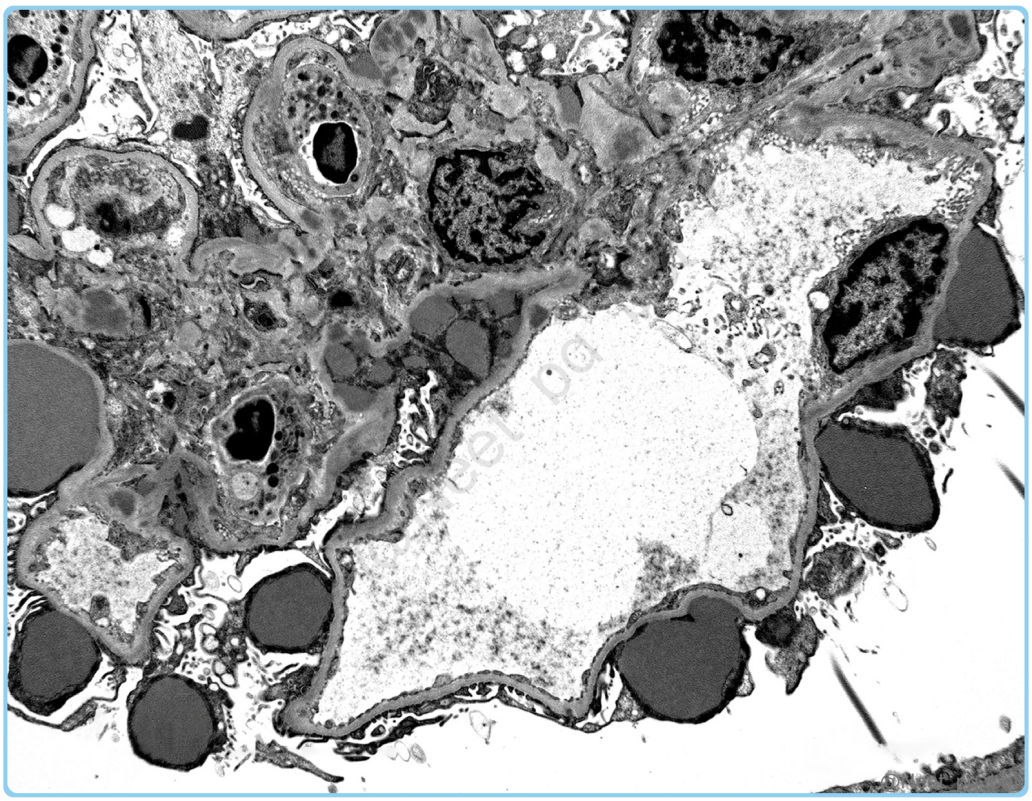
Q17: A 10-year-old boy presents with dark-coloured urine and puffiness around his eyes following a recent sore throat and skin infection. Laboratory tests show elevated serum creatinine, hematuria, and proteinuria. Renal biopsy image is given below. Which condition is most likely associated with these findings? (Q846655)

A. IgA nephropathy

B. Membranoproliferative glomerulonephritis

C. Post-streptococcal glomerulonephritis

D. Alport syndrome



See Answer in Part B → Q17

@Neet_pg_bot

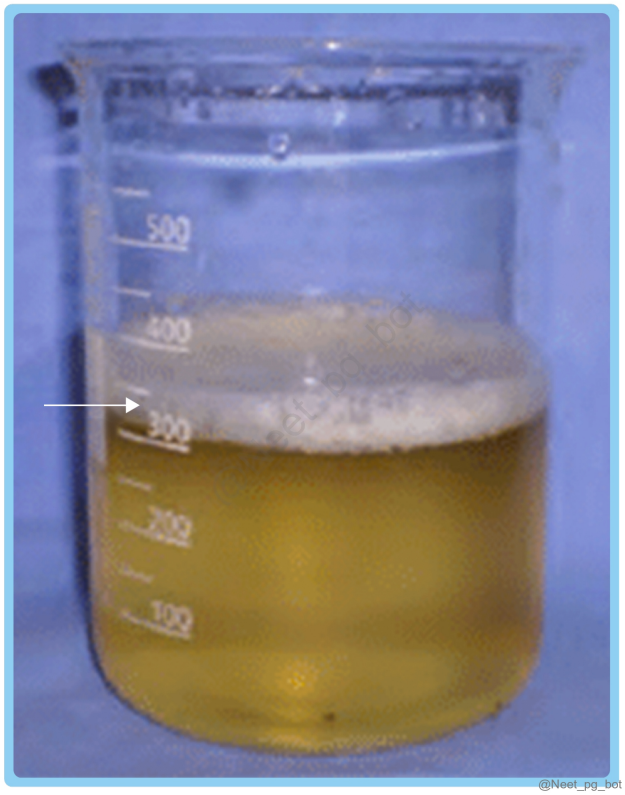
Q18: A 45-year-old patient presents with complaints of frothy urine, as shown below, and severe generalised oedema. On physical examination, there is marked swelling in the legs and abdomen. Laboratory tests reveal significant proteinuria (3+ on dipstick) and hypoalbuminemia. Which of the following findings can be typically observed in this patient? {{caption_text}} (Q846653)

A. Azotemia

B. Hyperlipidemia

C. Red cell casts in the urine

D. Hypertension



See Answer in Part B → Q18

• [11_Renal System] 050 Renal Urinary Tract Tumors

« Back to Folder Directory

[11_Renal System] 050 Renal Urinary Tract Tumors — Quick Jump

Q1 (p. 526) *Q2 (p. 527)* *Q3 (p. 527)* *Q4 (p. 528)* *Q5 (p. 528)* *Q6 (p. 529)*
Q7 (p. 529) *Q8 (p. 530)* *Q9 (p. 531)* *Q10 (p. 531)* *Q11 (p. 531)* *Q12 (p. 532)*
Q13 (p. 532) *Q14 (p. 533)* *Q15 (p. 533)* *Q16 (p. 533)*

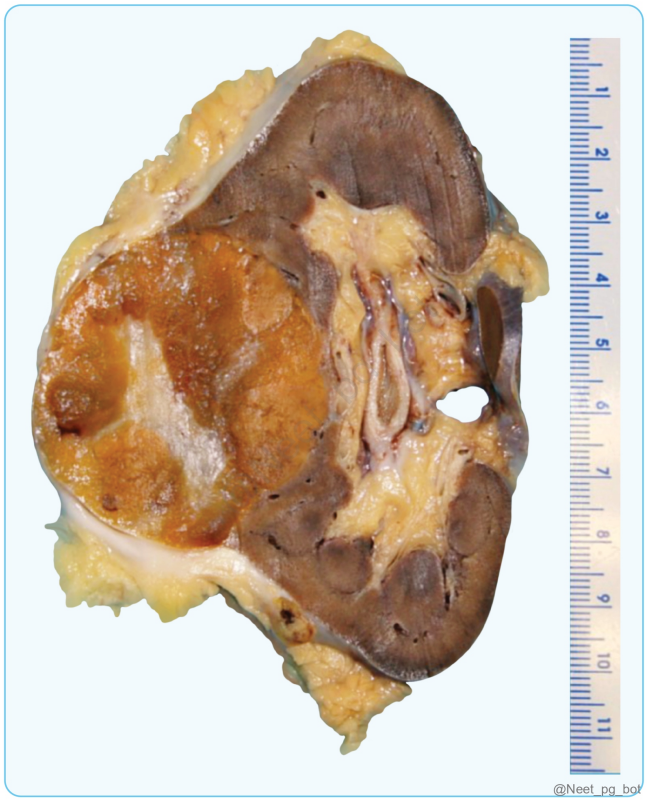
Q1: A 65-year-old diabetic male presented to the hospital complaining of chronic abdominal discomfort and unexplained weight loss over the past few months. A palpable firm mass was detected on the left upper quadrant upon physical examination. Ultrasound revealed a large mass in the left upper pole of the kidney. Due to suspicion of renal malignancy, the patient underwent a left nephrectomy. Based on the specimen obtained, what is the most likely diagnosis? {{caption_text}} (Q845695)

A. Renal oncocytoma

B. Epithelioid angiomyolipoma

C. Clear cell carcinoma

D. Urothelial carcinoma



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A child presents with hematuria and fever for the past 4 months. On examination, a mass-like structure was felt at the right flank. Which of the following features is not associated with this condition? (Q845709)

A. Gonadal dysgenesis and renal failure

B. Cryptorchidism and absent iris

C. Bilateral malar and mandibular hypoplasia

D. Adrenal cytomegaly and macroglossia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A renal biopsy specimen has to be examined under microscopy for the presence of nephroblastoma. Presence of which of the following findings is less likely suggestive of the same? (Q845713)

A. Neuropils

B. Small blue cells

C. Adipose tissue

D. Myxoid stroma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A histopathological report of renal biopsy done on a child states, “tumour cells suggestive of nephroblastoma along with adjacent sclerotic rests”. What is the risk associated with the presence of such sclerotic rests? (Q845744)

A. Presence of anaplasia

B. Pulmonary metastasis

C. Contralateral tumour

D. Associated lymphoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements regarding renal cell carcinoma is false? (Q845745)

A. Clear cell RCC is the most common type overall.

B. Papillary RCC is most commonly associated with dialysis patients.

C. Medullary RCC is commonly seen in sickle cell trait patients.

D. Papillary RCC has the best prognosis.

See Answer in Part B → Q5

@Neet_pg_bot

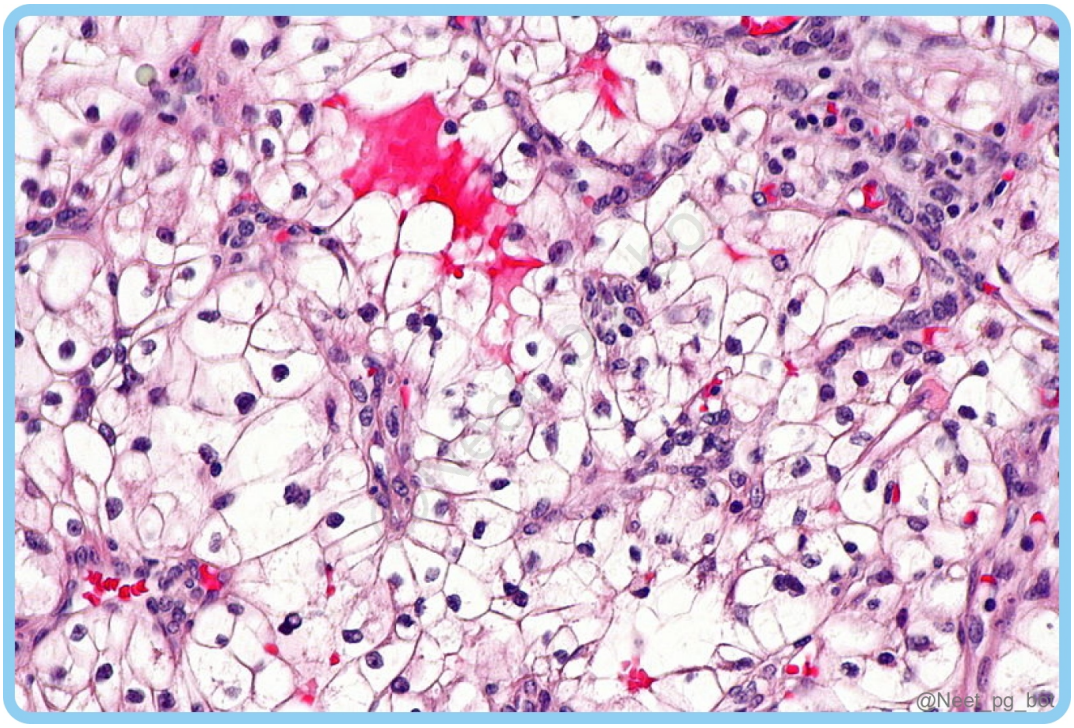
Q6: A 45-year-old female died within a few months after being diagnosed with renal cell carcinoma. The autopsy revealed a yellowish, spherical neoplasm in one pole of the kidney. The tumour cells invaded the renal vein and inferior vena cava. Histopathology is shown below. What is the most likely diagnosis? {{caption_text}} (Q845896)

A. Collecting duct RCC

B. Papillary RCC

C. Clear cell RCC

D. Chromophobe RCC



See Answer in Part B → Q6

@Neet_pg_bot

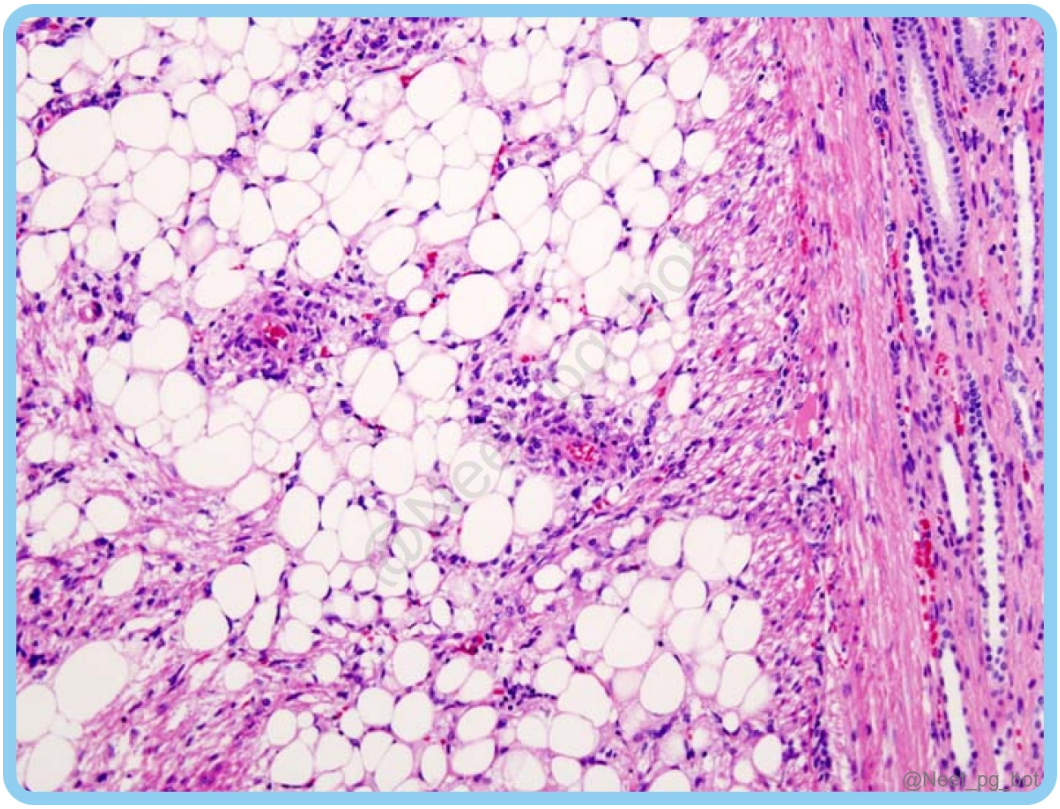
Q7: A 36-year-old woman presents with intermittent flank pain and occasional gross hematuria. Laboratory tests show normal renal function. A renal biopsy of a mass lesion reveals a mixture of mature adipose tissue, thick-walled blood vessels, and bundles of smooth muscle cells. All are true regarding this condition except: {{caption_text}} (Q846649)

A. Commonly associated with tuberous sclerosis

B. More prevalent in males than females

C. Mostly a benign tumor

D. High susceptibility to spontaneous hemorrhage



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Hobnail nuclei are seen in which type of renal cell carcinoma? (Q846650)

A. Clear cell renal cell carcinoma.

B. Papillary renal cell carcinoma.

C. Chromophobe renal cell carcinoma.

D. Collecting duct carcinoma.

See Answer in Part B → Q8

@Neet_pg_bot

Q9: On histological examination, which of the following types of renal cell carcinoma shows large cells with a plant-cell-like appearance with a perinuclear halo? (Q846651)

A. Papillary RCC

B. Clear cell RCC

C. Chromophobe RCC

D. Medullary RCC

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Multiple losses of entire chromosomes are seen in which type of Renal Cell Carcinoma? (Q846652)

A. Papillary RCC

B. Clear cell RCC

C. Chromophobe RCC

D. Collecting duct RCC

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements regarding Wilms' tumour is incorrect? (Q889878)

A. It is associated with WAGR syndrome

B. Associated with triphasic morphology

C. The most common renal tumour in children

D. WT1 mutations are present in >80% of sporadic cases

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 4-year-old child undergoes nephrectomy for a Wilms tumour. Histology shows large hyperchromatic pleomorphic nuclei with abnormal mitotic figures. The tumour shows a poor response to preoperative chemotherapy. Which of the following best explains the chemotherapy resistance in this tumour? (Q889881)

A. Gain-of-function mutation in β-catenin

B. Loss of the WT1 tumour suppressor gene

C. Mutation of TP53 leading to defective apoptosis

D. IGF2 overexpression due to an imprinting abnormality

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 4-year-old child is diagnosed with Wilms tumour. Histology and genetic studies are reviewed to assess prognosis. Which of the following is not associated with poor prognosis in Wilms tumour? (Q889883)

A. Anaplastic histology

B. Loss of heterozygosity at chromosomes 1p and 16q

C. Gain of chromosome 1q

D. Triphasic histology

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following most reliably differentiates renal papillary adenoma from papillary renal cell carcinoma? (Q889885)

A. Presence of papillary architecture

B. Low-grade nuclear features

C. Tumour size cut-off

D. Presence of psammoma bodies

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 50-year-old man with recurrent pneumothorax and multiple facial fibrofolliculomas is found to have bilateral renal masses. Genetic testing reveals an FLCN mutation. Which renal cell carcinoma (RCC) is most commonly associated with the most probable condition? (Q889889)

A. Clear cell RCC

B. Papillary RCC

C. Chromophobe RCC

D. Collecting duct carcinoma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 13-year-old girl presents with painless hematuria. Imaging shows a renal mass. Biopsy reveals nested and tubulopapillary architecture. Immunostaining is

positive for TFE3. What is the most likely diagnosis? (Q889892)

A. Clear cell renal cell carcinoma

B. Papillary renal cell carcinoma

C. Chromophobe renal cell carcinoma

D. Xp11 translocation renal cell carcinoma

See Answer in Part B → Q16

@Neet_pg_bot

Q1: A 48-year-old man presents with facial puffiness, frothy urine, hypertension, a history of hepatitis B infection, and microscopic hematuria. A kidney biopsy reveals a spike and dome pattern. What is the most likely diagnosis? (Q855413)

A. Minimal change disease

B. Membranous nephropathy

C. Focal segmental glomerulosclerosis

D. PSGN-associated disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 40-year-old man has been diagnosed with solid cancer of the bowel. He also experienced massive proteinuria a few months after the initial diagnosis of cancer. What do you think is the likely cause of the development of urinary findings? (Q859258)

A. Membranous nephropathy

B. Focal segmental glomerulosclerosis

C. Membranoproliferative glomerulonephritis

D. Dense deposit disease

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Effacement of podocyte foot processes is seen in which of the following diseases? (Q858521)

A. Steroid-resistant glomerulonephritis

B. Minimal change disease

C. Rapidly progressive glomerulonephritis

D. Chronic glomerulonephritis

See Answer in Part B → Q3

@Neet_pg_bot

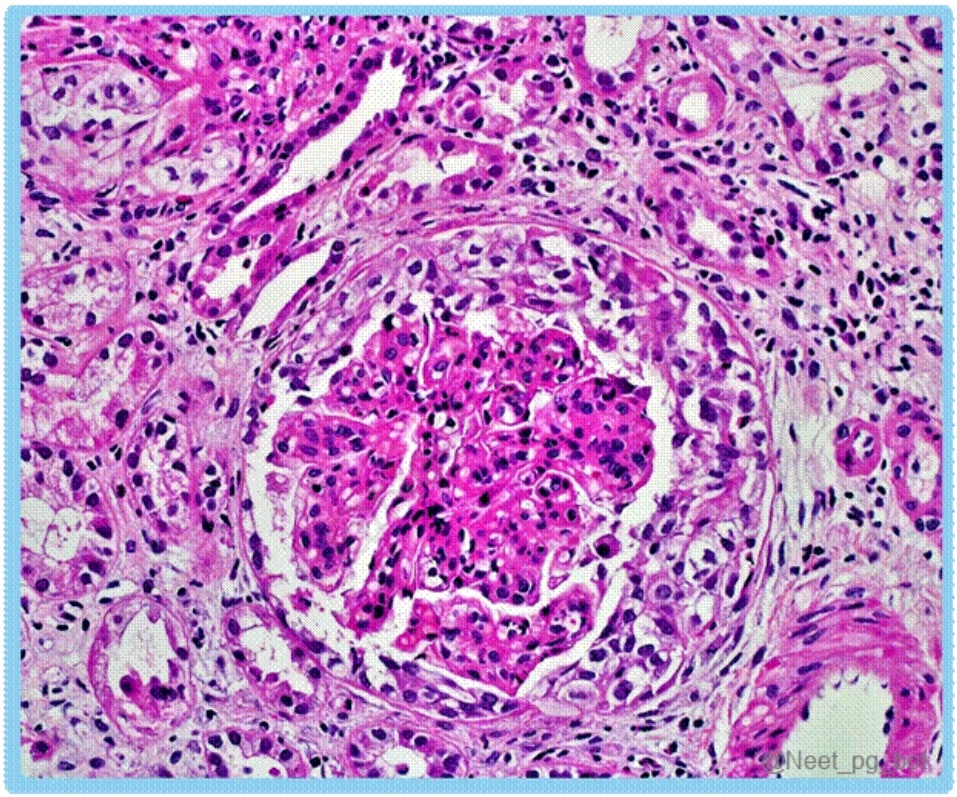
Q4: A 51-year-old male patient presents with complaints of hematuria. On examination, he is normotensive and has pedal edema. Investigations reveal that the patient has no glycosuria and a creatinine level of 9. His renal biopsy finding is given below. Which of the following investigations should be done to identify the disease? (Q854838)

A. ANA

B. Anti-GBM antibodies

C. HIV RNA

D. Urine immunoelectrophoresis



See Answer in Part B → Q4

@Neet_pg_bot

Q5: Membranoproliferative glomerulonephritis is seen in which of the following conditions? HIV SLE CLL Hepatitis B (Q856912)

A. 1, 2, 3

B. 1, 2, 3, 4

C. 2, 3, 4

D. 1, 2

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What type of urinary casts would you expect in a patient diagnosed with Fabry's disease? (Q856895)

A. Waxy cast

B. RBC cast

C. WBC cast

D. Maltese cross cast

See Answer in Part B → Q6

@Neet_pg_bot

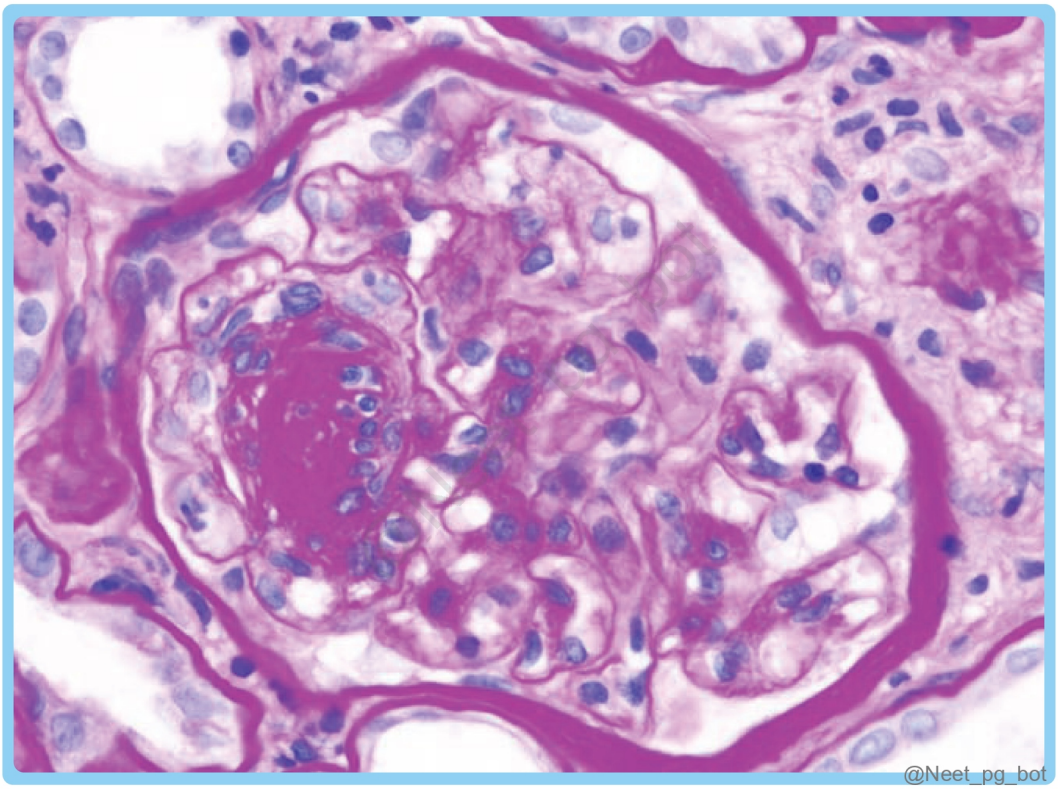
Q7: What is the most characteristic feature of diabetic nephropathy, as shown below? {{caption_text}} (Q857168)

A. Kimmelstiel Wilson nodules

B. Armanni Ebstein change

C. Aschoff nodule

D. Anitschkow cell



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements is/are true regarding clear cell carcinoma of the kidney? Most common primary renal malignancy Associated with the loss of the short arm of chromosome 3 Not associated with paraneoplastic syndrome The classic triad of flank pain, palpable mass, and hematuria is seen. (Q855070)

A. 1, 2, 4

B. 2, 3

C. 1, 3

D. 1, 4

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Tamm-Horsfall protein is a major component of which of the following? (Q858118)

A. Mural thrombi

B. Curschmann spirals

C. Renal casts

D. Bence-Jones proteins

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient with renal disease undergoes a biopsy. On Congo red staining, the deposits show apple-green birefringence under polarised light. What is the most likely diagnosis? (Q866678)

A. Amyloidosis

B. Minimal change disease

C. Diabetic nephropathy

D. Membranous nephropathy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following will increase in size on electrophoresis in Nephrotic syndrome? (Q854702)

A. Gamma globulin

B. Alpha 2 globulin

C. Beta globulin

D. Albumin

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 47-year-old male with 400 ml urine output per 24 hrs. On histology, he had RPGN with Pauci immune glomerulonephritis with crescents. What is the main etiology? (Q854698)

A. Anti GBM

B. ANCA

C. Anti PLA2R

D. ANA

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the most likely diagnosis for a 9-year-old boy who presents with hematuria, hypertension, facial puffiness for 3 days, and a recent history of throat infection two weeks ago, with urine examination showing albumin positivity? (Q830713)

A. Group B beta-hemolytic streptococci

B. Staphylococcus aureus

C. Group A beta-hemolytic streptococci

D. Staphylococcus epidermidis

See Answer in Part B → Q13

@Neet_pg_bot

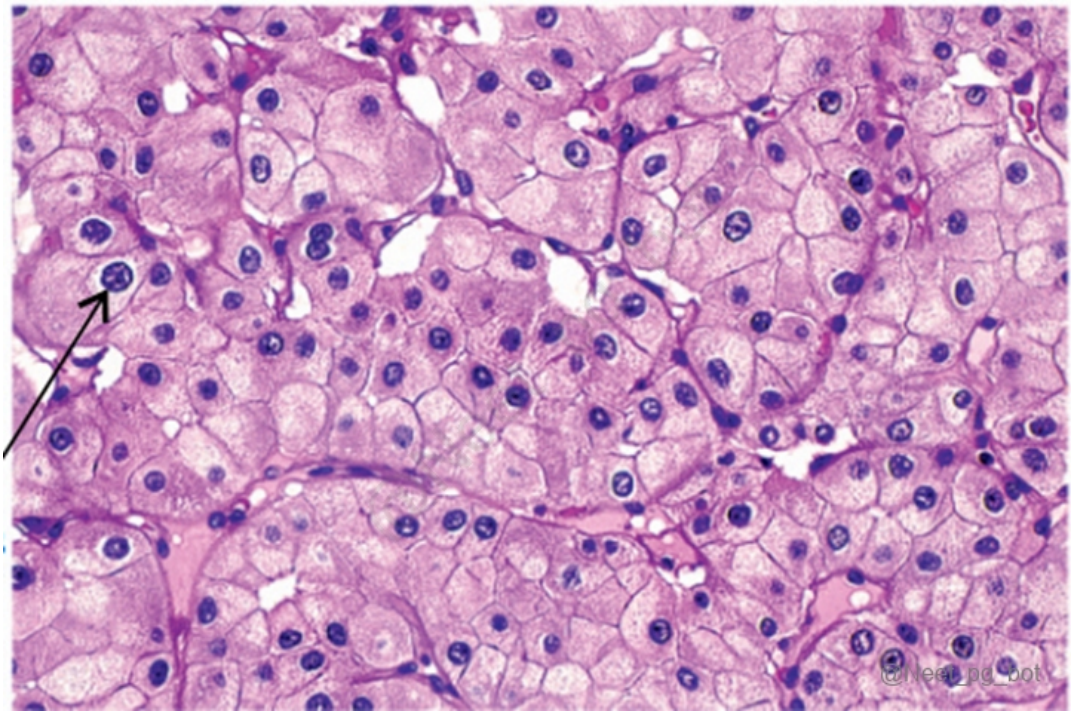
Q14: A patient presents with hematuria and flank pain. A renal mass is shown in the image provided. What is the likely diagnosis? (Q844158)

A. Clear cell carcinoma

B. Papillary renal cell carcinoma

C. Chromophobe renal cell carcinoma

D. Bellini duct carcinoma



See Answer in Part B → Q14

@Neet_pg_bot

Q15: A patient presents with a cerebellar mass and a renal tumor, along with a similar family history. Which of the following is responsible for his findings? (Q844087)

A. VHL disease

B. NF

C. TSC

D. Li Fraumeni syndrome

See Answer in Part B → Q15

@Neet_pg_bot

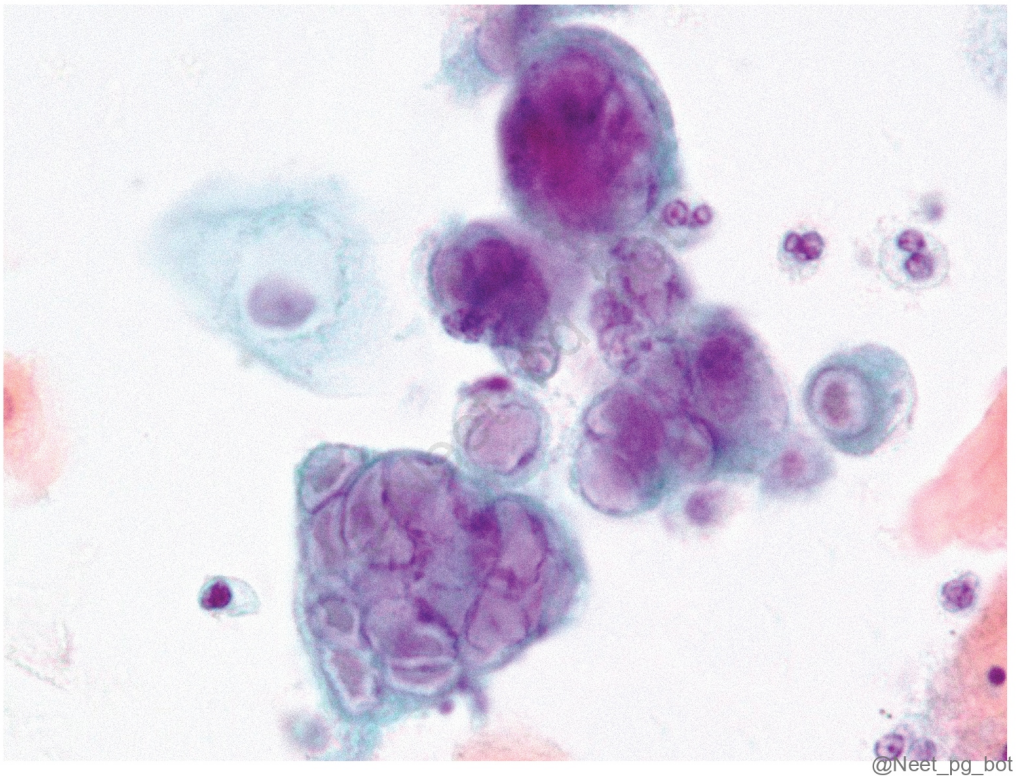
Q16: A female presents to the OPD with complaints of dysuria. Based on the microscopic examination, what is the most likely diagnosis? (Q844068)

A. HSV

B. CMV

C. HPV

D. Trichomonas



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A pediatric patient presents with cola-coloured urine, high blood pressure, and periorbital oedema. Laboratory tests reveal a creatinine level of 2.5 mg/dL, which rises to 4.5 mg/dL after 3 weeks despite treatment. What electron microscopic finding is most likely in this patient? (Q855409)

A. Subendothelial deposits

B. Subepithelial deposits

C. Crescent formation

D. Mesangial deposits

See Answer in Part B → Q17

[12_Genital System] 052 Pathology Of Male Genital Tract — Quick Jump

Q1 (p. 545)	*Q2 (p. 545)*	*Q3 (p. 546)*	*Q4 (p. 546)*	*Q5 (p. 547)*	*Q6 (p. 547)*
Q7 (p. 547)	*Q8 (p. 548)*	*Q9 (p. 549)*	*Q10 (p. 549)*	*Q11 (p. 550)*	*Q12 (p. 551)*
Q13 (p. 552)	*Q14 (p. 553)*	*Q15 (p. 554)*	*Q16 (p. 555)*	*Q17 (p. 555)*	

Q1: A 42-year-old male presents with testicular pain and swelling. Physical examination reveals a palpable mass. Subsequent biopsy of the mass provides important diagnostic insights. Which of the following statements regarding sex cord-stromal tumours in males are true? A) They are classified into three main subtypes: Leydig cell and Sertoli cell tumours and yolk sac tumours. B) Sertoli cell tumours are commonly associated with hormonal abnormalities. C) Histologically, Leydig cell tumors demonstrate golden pigment with reinke crystals with eosinophilic cytoplasmic inclusions. D) Sertoli cell tumours are often associated with Carney's complex and are typically malignant. (Q845855)

A. A, B, C

B. A, C, D

C. C

D. A, B, C, D

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 32-year-old male presents with multiple, small, flesh-coloured growths on the shaft of his penis. A biopsy is performed, and histopathology reveals hyperkeratosis, acanthosis, and koilocytosis. Which of the following is the most likely causative agent of his condition? (Q845863)

A. HPV 6 and 11

B. Treponema pallidum

C. HSV 2

D. Chlamydia trachomatis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 65-year-old male presents with difficulty in urination and frequent nocturia. Digital rectal examination reveals a firm, irregular prostate. A subsequent prostate-specific antigen (PSA) test shows elevated levels. A transrectal ultrasound-guided prostate biopsy is performed, and the pathology report provides a Gleason score. Which of the following statements regarding the Gleason score in prostate cancer diagnosis is correct for this patient? (Q845862)

A. The Gleason score indicates the stage of prostate cancer.

B. A Gleason score of 6 suggests a poorly differentiated tumor with a high risk of metastasis.

C. The Gleason score is determined by adding the two least common Gleason grades found in the tumor.

D. The Gleason score is irrelevant in determining the treatment approach for prostate cancer.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 60-year-old male presents with increased frequency, nocturia, and weak urine stream. DRE reveals a firm nodule. A prostate biopsy is performed, and the histology image shows complex, branching papillary structures lined by pseudostratified columnar epithelium.What is the most likely diagnosis? (Q845861)

A. Benign Prostatic Hyperplasia (BPH)

B. Prostate Adenocarcinoma-Ductal Type

C. Prostatic Intraepithelial Neoplasia (PIN)

D. Chronic Prostatitis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is a new biomarker used in Prostatic Cancer? (Q845860)

A. NMP22

B. Thymidine kinase

C. NKX 3.1

D. PLAP

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is a protective factor associated with prostate cancer? (Q845859)

A. Age over 60 years

B. Family history of prostate cancer

C. High intake of red meat

D. Adequate levels of vitamin D

See Answer in Part B → Q6

@Neet_pg_bot

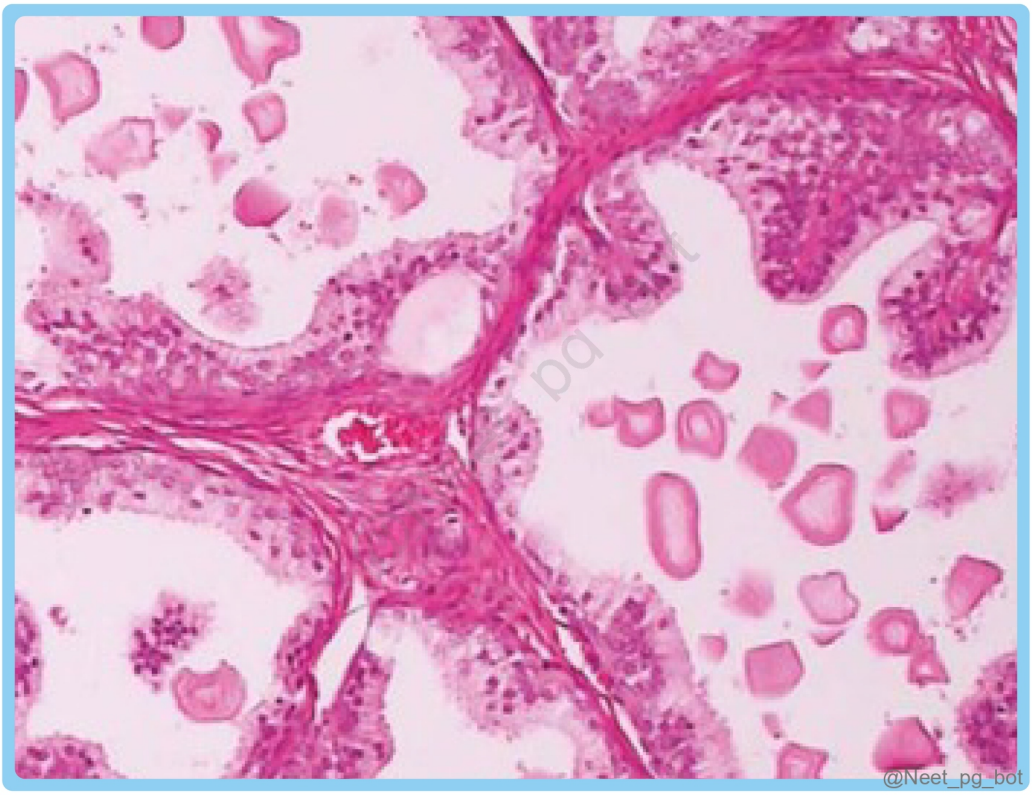
Q7: A 65-year-old man presents with complaints of increased frequency and urgency of urination, particularly at night. He also mentions a feeling of incomplete bladder emptying and a weak urine stream. The patient's PSA level is within normal limits. The histopathology image is given below. Based on the diagnosis, which of the following is true? (Q845858)

A. Infiltration of lymphocytes

B. Presence of atypical cells with high mitotic activity

C. Increased number of stromal and epithelial cells

D. Dysplastic changes in the glandular architecture



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which zone of the prostate is primarily affected by benign prostatic hyperplasia (BPH), and which zone is more commonly associated with prostate cancer? (Q845857)

A. Central zone & Peripheral zone

B. Peripheral zone & Transitional zone

C. Transitional zone & Peripheral zone

D. Peripheral zone & Central zone

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Match the following tumour markers (Column A) with the corresponding testicular tumour types (Column B). Column A (Tumor Markers) Column B (Testicular Tumor Types) 1. Alpha-fetoprotein (AFP) A. Seminoma 2. Beta-human chorionic gonadotropin (β-hCG) B. Embryonal Carcinoma 3. CD-30 C. Yolk sac tumour 4. Placental alkaline phosphatase (PLAP) D. Choriocarcinoma 5. Cytokeratin E. Teratoma (Q845856)

A. 1-A, 2-B, 3-C, 4-D, 5-E

B. 1-C, 2-D, 3-A, 4-B, 5-E

C. 1-C, 2-D, 3-B, 4-A, 5-E

D. 1-B, 2-A, 3-D, 4-C, 5-B

See Answer in Part B → Q9

@Neet_pg_bot

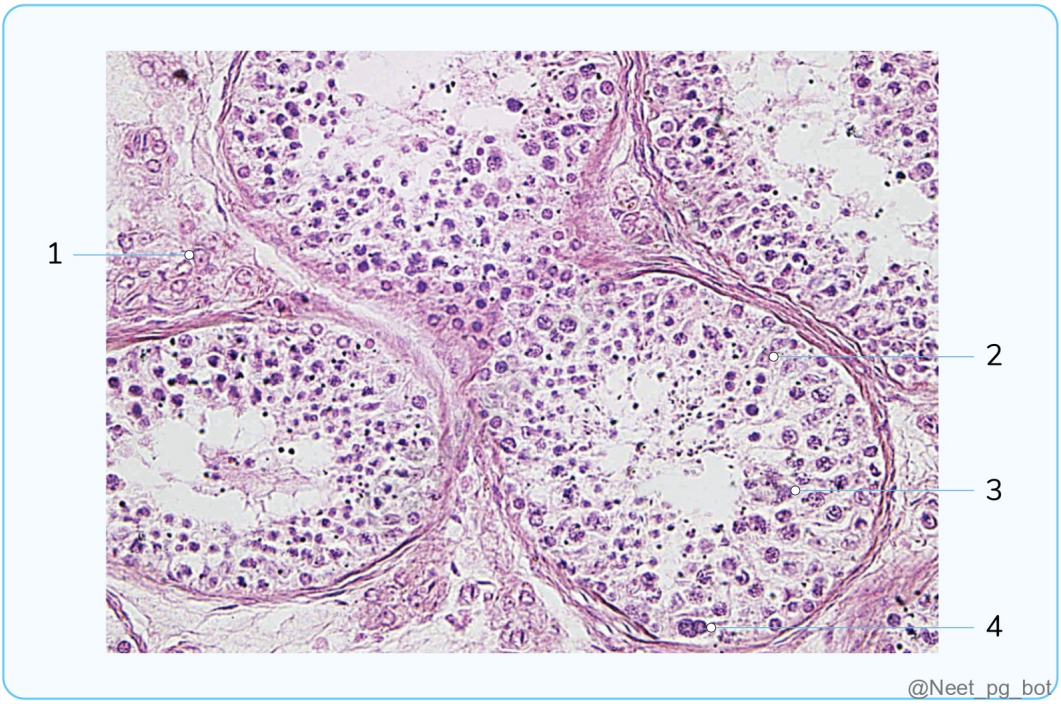
Q10: The histological examination of a normal testis is given in the image below. Which of the following callouts is responsible for maintaining the blood testis barrier? (Q845847)

A. 1

B. 2

C. 3

D. 4



See Answer in Part B → Q10

@Neet_pg_bot

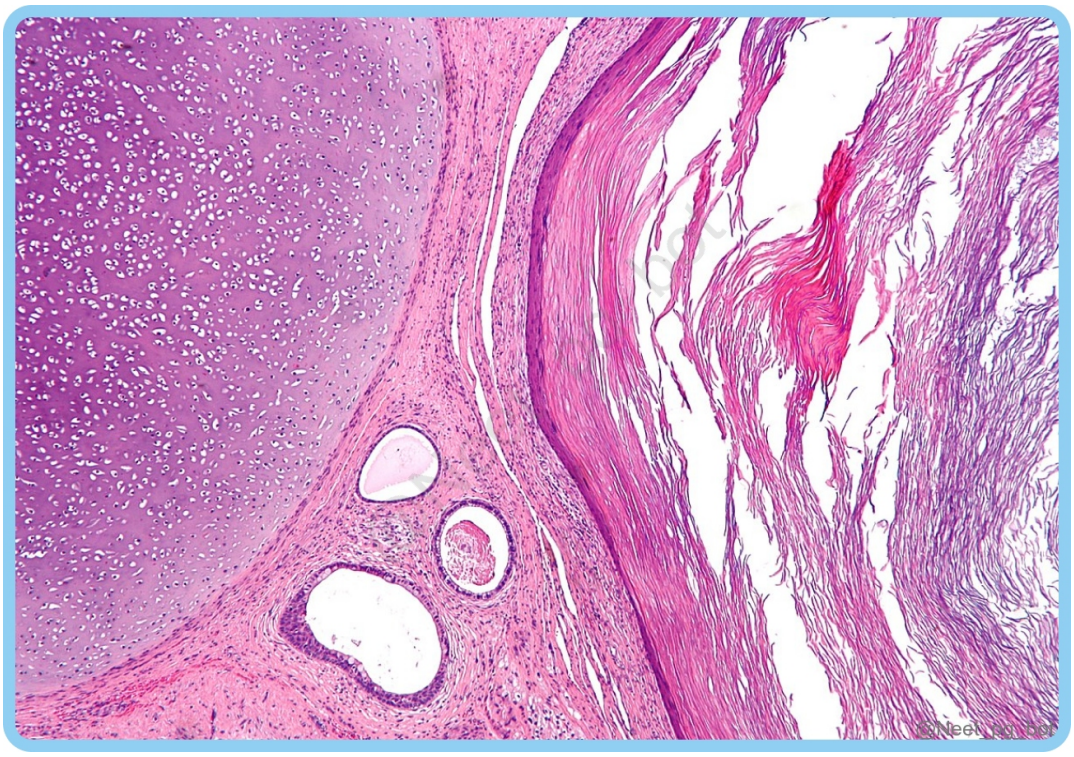
Q11: A 10-month-old boy was referred to the hospital with non-palpable right testes. The physical examination revealed no jaundice, palpable left testes, or right-sided abdominal mass. Subsequent surgical excision of the mass revealed a cystic mass with keratinous debris, and a biopsy image of the specimen was obtained. All of the following statements regarding this condition are true except? (Q845854)

A. Typically present as well-defined, encapsulated masses with cystic and solid components.

B. Often associated with areas of haemorrhage and necrosis.

C. Histologically, it contains differentiated cells or organoid structures embedded in a fibrous or myxoid stroma.

D. Demonstrate homogeneous appearance and are mostly found malignant in young children.



See Answer in Part B → Q11

@Neet_pg_bot

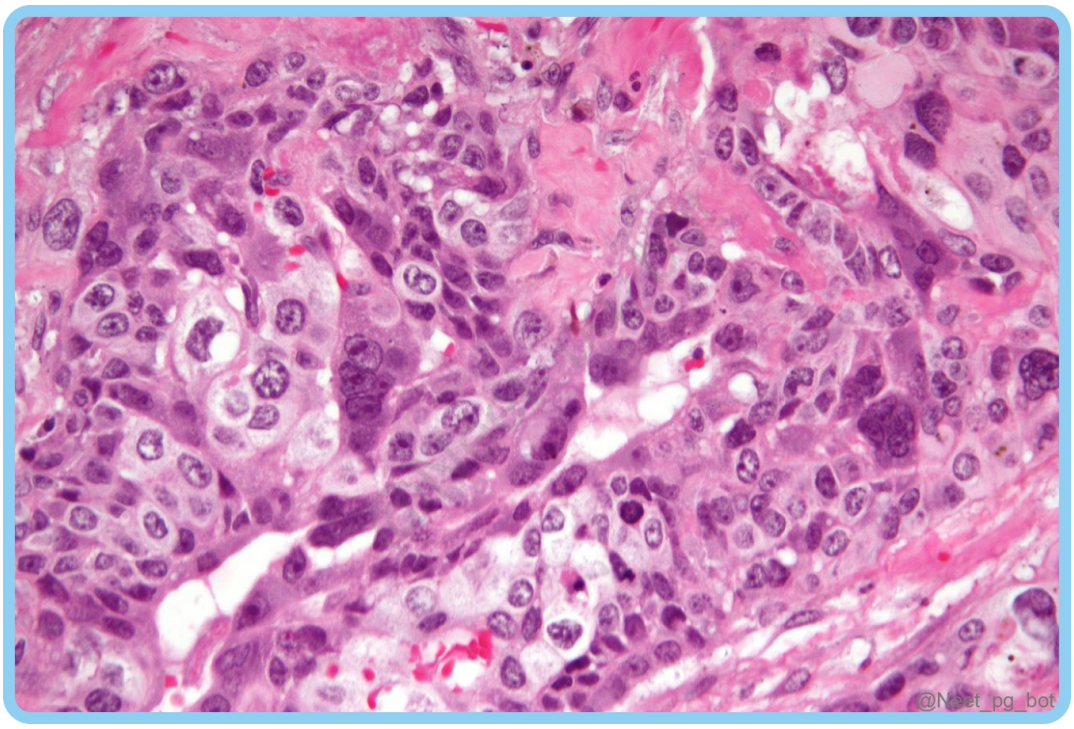
Q12: A 30-year-old male presents with a rapidly enlarging testicular mass associated with testicular pain and gynecomastia. He reports associated mild hemoptysis for the last 4 days. A biopsy of the mass is performed, and both gross and microscopic images are obtained. What is the most likely diagnosis based on the clinical presentation? (Q845853)

A. Choriocarcinoma

B. Embryonal Carcinoma

C. Seminoma

D. Yolk Sac Tumor



See Answer in Part B → Q12

@Neet_pg_bot

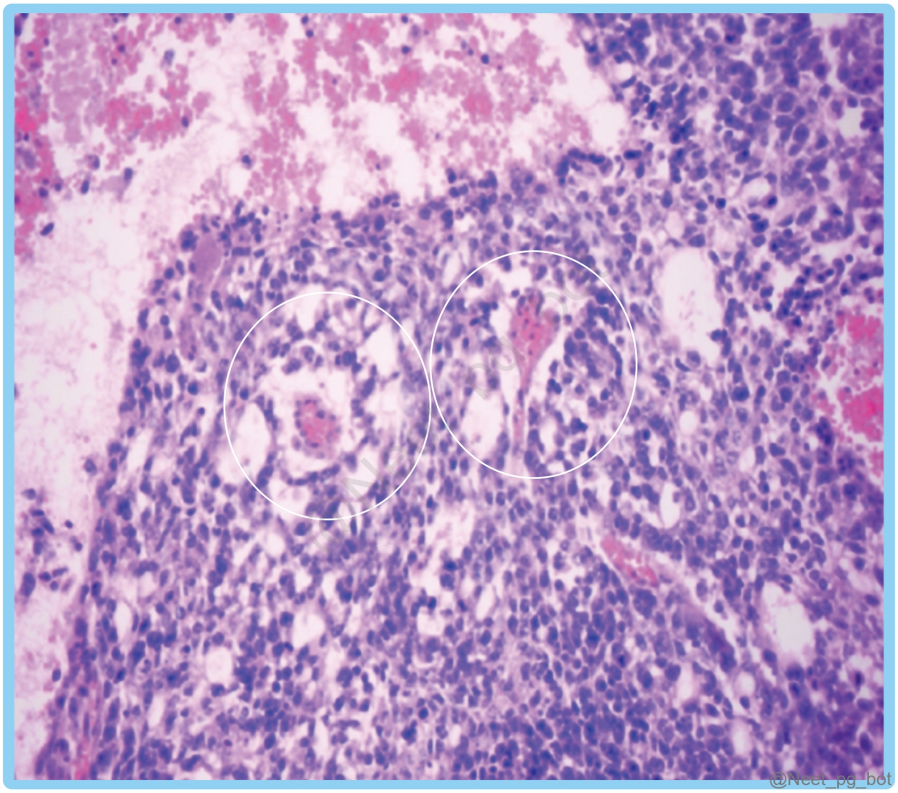
Q13: A 10-year-old male with a painless testicular mass for the past few months. On examination, the right testis was enlarged and the transillumination test was negative. A biopsy of the mass was performed and is shown below. What is the most likely diagnosis? (Q845852)

A. Hydrocoele

B. Yolk Sac tumour

C. Choriocarcinoma

D. Germ Cell tumour



See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 65-year-old male presents to the hospital with a painless scrotal mass. Ultrasound scan reveals a solid testicular mass suspicious for a spermatocytic tumour. Upon further examination, the following histological findings are identified except? (Q845851)

A. Associated with gain of function mutation

B. Presence of inflammatory infiltrates and syncytiotrophoblasts

C. Presence of three intermixed cell distinct cell populations on microscopy

D. Low risk of metastasis following surgical resection

See Answer in Part B → Q14

@Neet_pg_bot

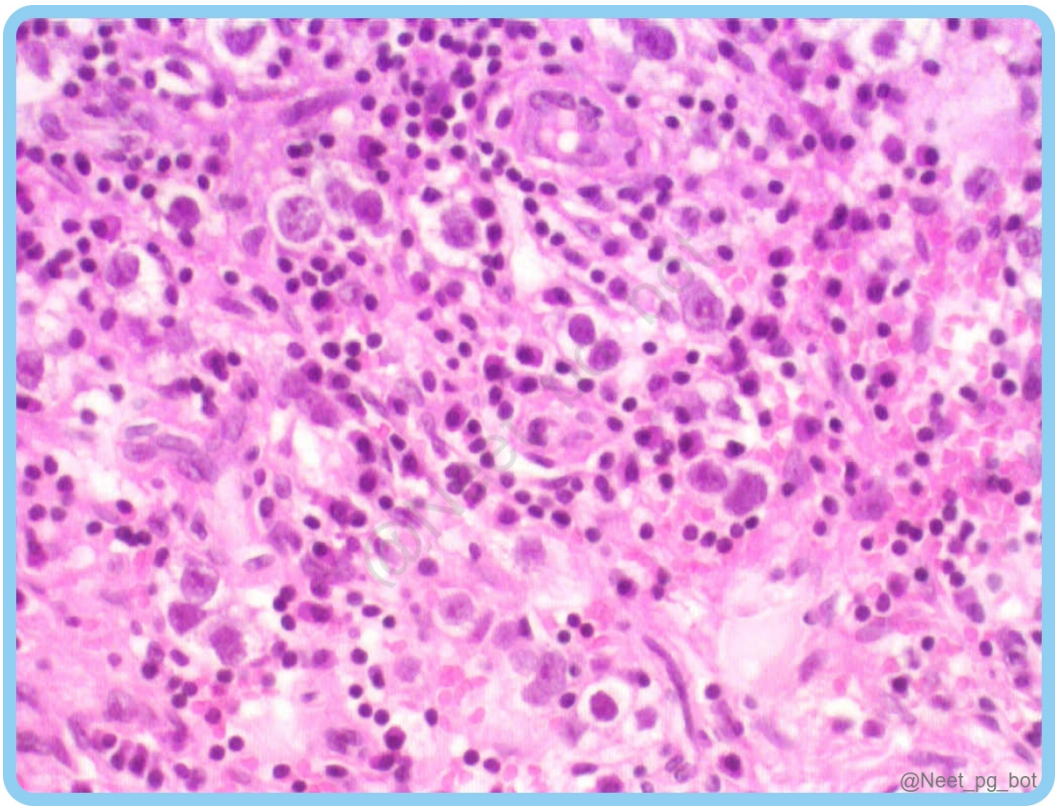
Q15: A patient underwent unilateral orchiectomy for a swelling in the right testis. The specimen is sent for histopathological examination, and its microscopic appearance is depicted in the image below. Which of the following statements is true regarding the diagnosis? (Q845850)

A. 3 different sizes of tumour cells are seen

B. Schiller-Duval bodies are present

C. Tumor cells are arranged in sheets

D. Tumor cells have a watery-clear cytoplasm



See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a germ cell tumour? (Q845849)

A. Teratoma

B. Embryonal carcinoma

C. Spermatocytic seminoma

D. Sertoli cell tumour

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 1-year-old boy is brought to the pediatric clinic by his parents, who are concerned about the absence of his left testicle in the scrotum. On physical

examination, the right testicle is palpable in the scrotum, but the left is not. All are true regarding this condition except? (Q845848)

A. It can occur in association with hypospadias.

B. The most common site of arrest of descent is the inguinal canal.

C. It is very commonly associated with a well-defined hormonal disorder.

D. The Leydig cells appear prominent.

See Answer in Part B → Q17

Q1: Which of the following is not a part of the vaginal epithelium? (Q845578)

A. Superficial squamous cells

B. Intermediate squamous cells

C. Columnar cells

D. Parabasal cells

See Answer in Part B → Q1

@Neet_pg_bot

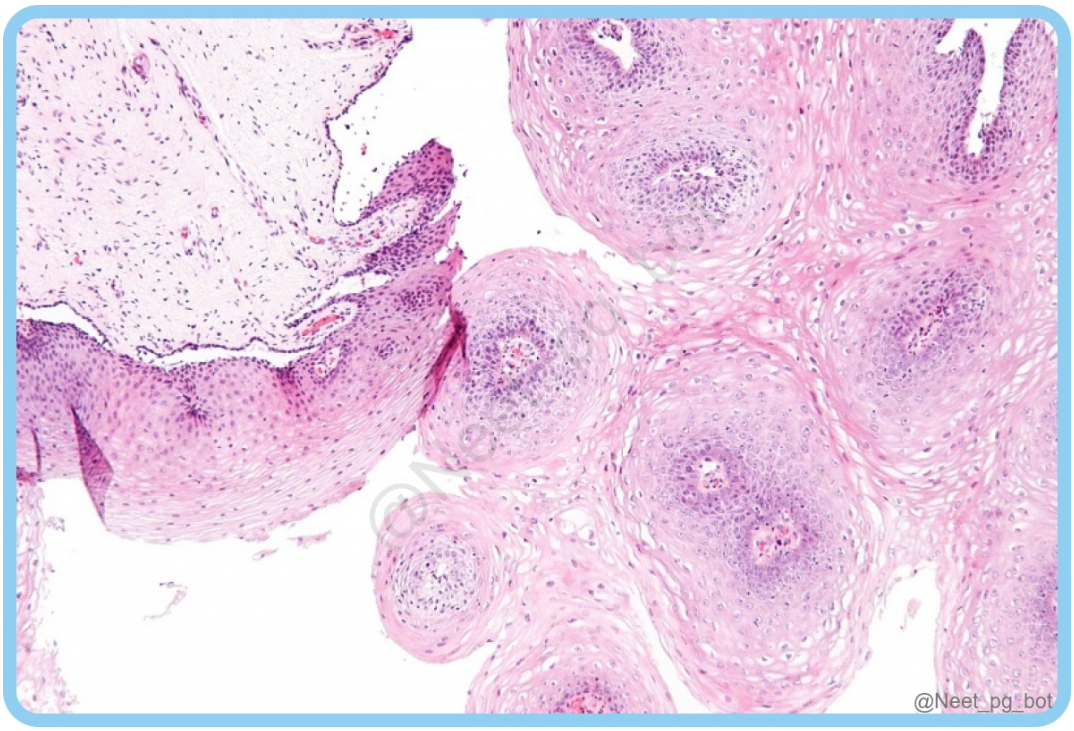
Q2: Which strain of the HPV virus is responsible for causing Condyloma acuminatum? (Q845605)

A. HPV 6 & 11

B. HPV 16 & 18

C. HPV 6 & 16

D. HPV 11 & 18



See Answer in Part B → Q2

@Neet_pg_bot

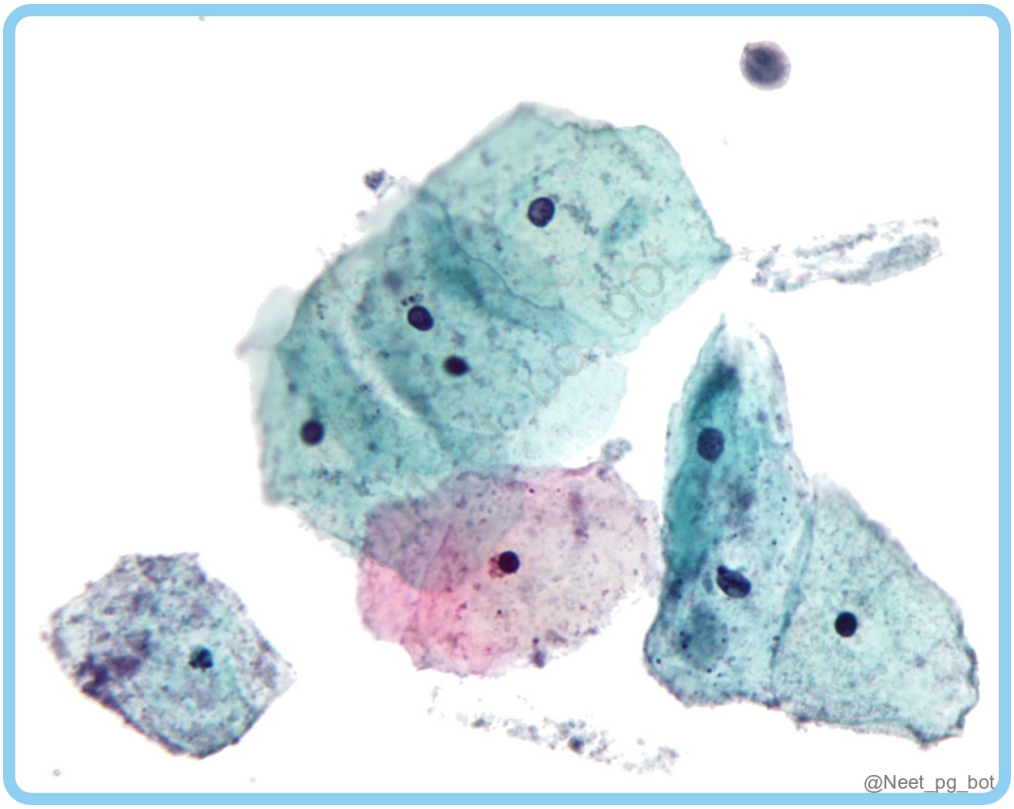
Q3: A 25-year-old sexually active female presents with foul-smelling vaginal discharge and dysuria. Upon examination of the cervix, the following appearance is noted. Wet mount microscopy reveals the findings shown in the image below. Which of the following is most likely responsible for this presentation? (Q845606)

A. Trichomonas vaginalis

B. Candida

C. Herpes simplex virus

D. Human Papilloma virus



See Answer in Part B → Q3

@Neet_pg_bot

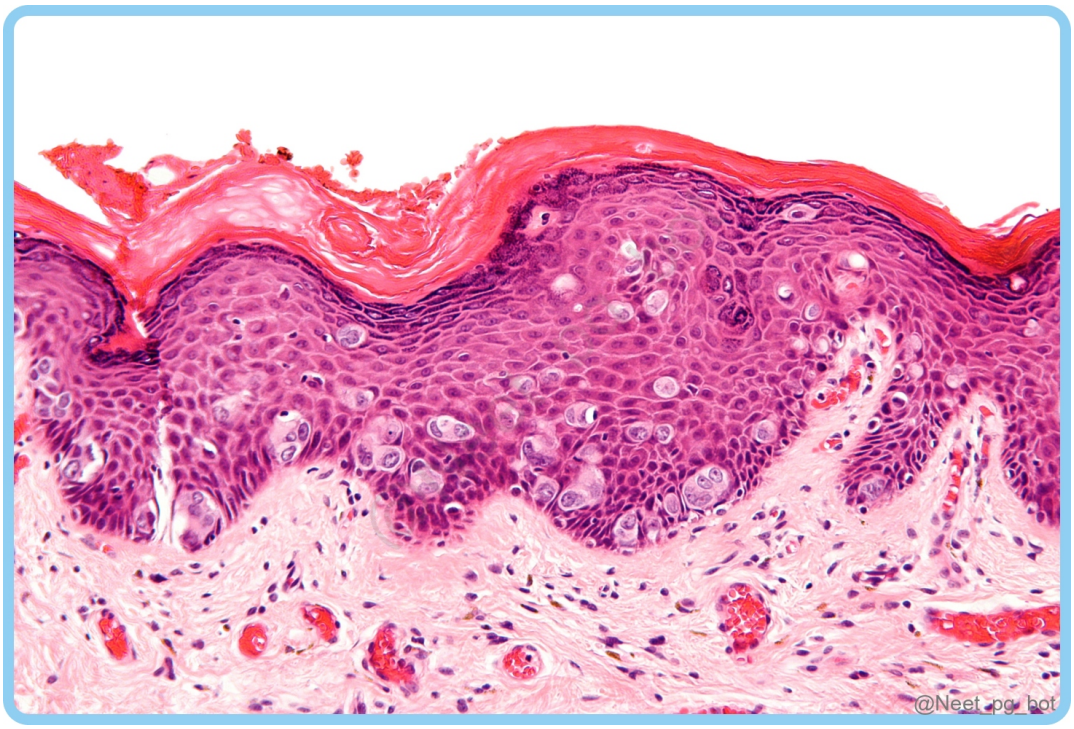
Q4: A 58-year-old woman complains of persistent itching and redness in her vulvar area. On examination, well-defined, erythematous plaques with an eczematous appearance are noted. A biopsy reveals large cells with pale cytoplasm and positive staining for mucopolysaccharides. Immunohistochemical analysis shows positive staining for cytokeratin 7. Based on these findings, what is the most likely diagnosis? (Q845607)

A. Bowen's disease of the vulva

B. Extramammary Paget's disease

C. Papillary Hidradenoma

D. Squamous cell carcinoma



See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following has a strong association with clear cell adenocarcinoma of the vagina? (Q845608)

A. Male partner who has multiple sexual partners

B. In utero exposure to diethylstilbestrol

C. HPV infection

D. Sexual activity at a young age

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 4-year-old girl presents to the pediatric clinic with complaints of vaginal bleeding and a visible mass protruding from her vagina. On examination, a polypoid mass with a "grape-like" appearance is observed. A biopsy is taken, and

immunohistochemical staining is positive for desmin. Which of the following will show as a biopsy finding? (Q845609)

A. Cells with small protrusions of cytoplasm from one end

B. Marked atypia of cells with numerous keratin pearls

C. Columnar mucinous epithelium

D. Fibrous stroma covered by mucus-secreting endocervical glands

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is an advantage of liquid-based cytology (LBC) over the conventional Pap smear? (Q845610)

A. Cost-effective

B. More widely available in resource-limited settings

C. Adequacy of 8,000-12,000 epithelial cells

D. Allows simultaneous HPV testing

See Answer in Part B → Q7

@Neet_pg_bot

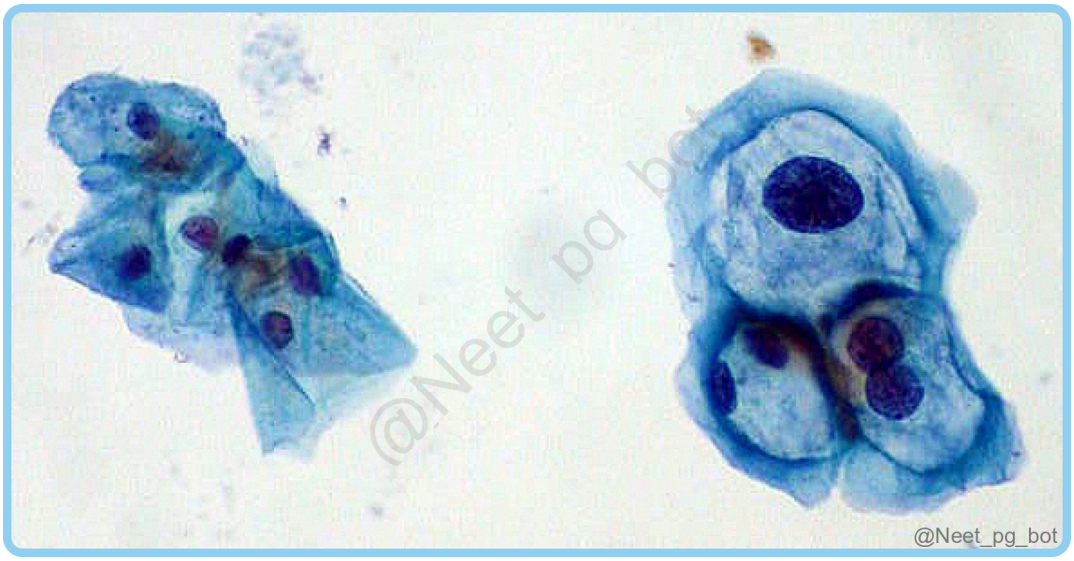
Q8: A 45-year-old woman comes to the OPD for regular Pap smear screening. The smear suggests a low-grade squamous intraepithelial lesion. Which of the following abnormal cell types was most likely seen on the smear? {{caption_text}} (Q845611)

A. Doderlein cells

B. Hobnail cells

C. Arias-Stella reaction cells

D. Koilocytes



See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following risk factors is not typically associated with cervical cancer? (Q845612)

A. Smoking

B. Multiple sexual partners

C. Oral contraceptive pill use

D. Nulliparity

See Answer in Part B → Q9

@Neet_pg_bot

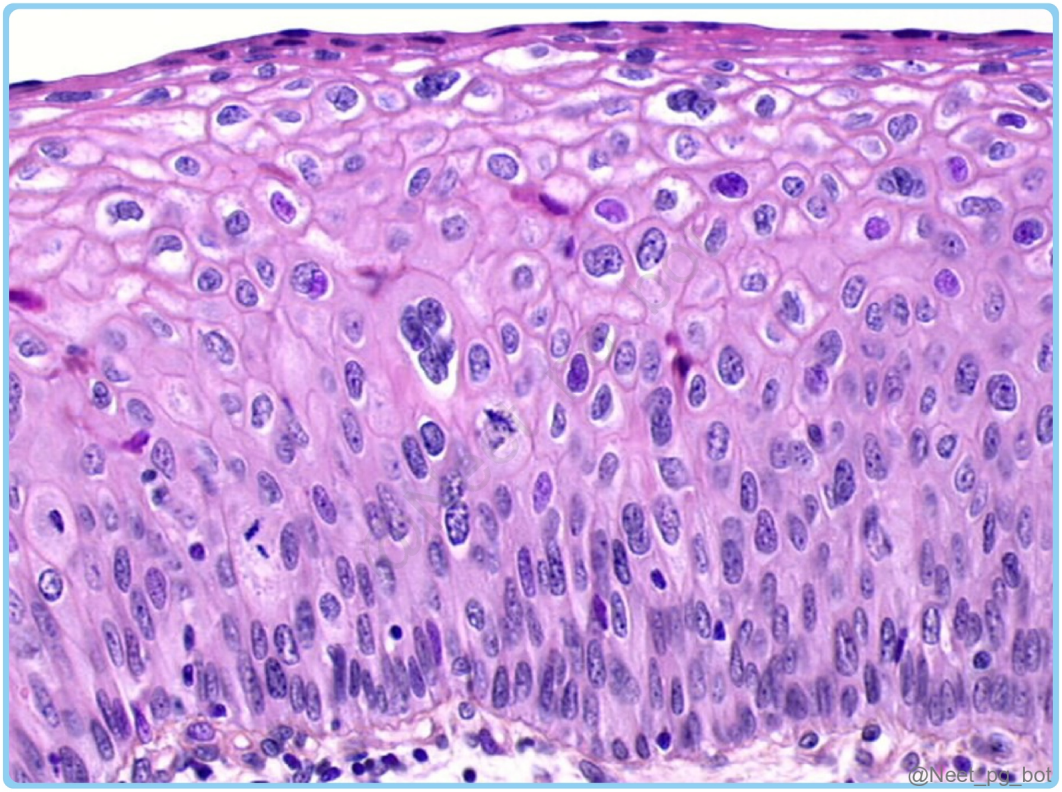
Q10: A 32-year-old woman undergoes a routine gynecological examination. Abnormalities are detected on her pap smear, and colposcopy-guided biopsy reveals dysplastic changes involving two-thirds of the cervical epithelium. What is the most likely diagnosis? {{caption_text}} (Q845613)

A. Cervical intraepithelial neoplasia 1

B. Cervical intraepithelial neoplasia 2

C. Cervical intraepithelial neoplasia 3

D. Invasive cervical carcinoma



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements is true regarding the squamous cell carcinoma of the cervix? HPV types 16 and 18 are the most common HPV types identified in invasive cervical cancer. The most common site of metastasis is the lungs. E6 protein interferes with the activity of the tumor suppressor proteins p53. Squamous cell carcinoma is the most common histologic subtype. (Q845614)

A. 1,2,3,4

B. 1,2,3

C. 1,3,4

D. Only 1

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is most likely associated with basaloid vulvar carcinomas? (Q846624)

A. Not associated with HPV

B. Arise from differentiated vulvar intraepithelial neoplasia

C. Keratinising morphology

D. High-risk HPV

See Answer in Part B → Q12

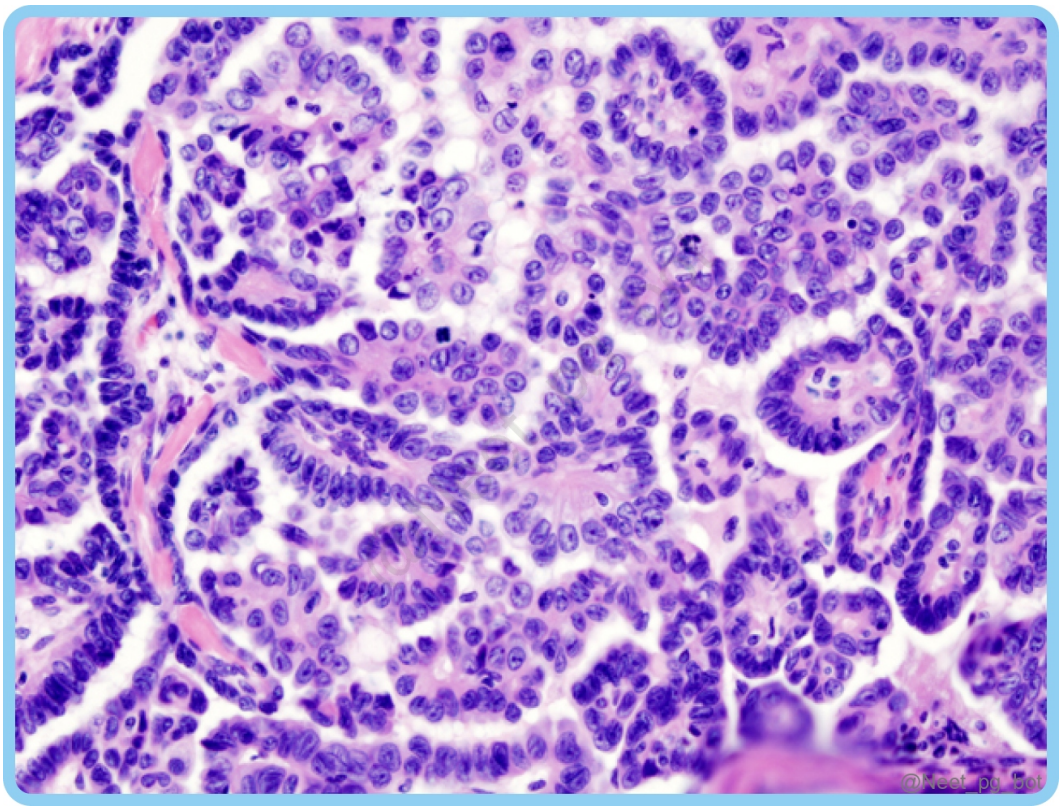
Q1: A 52-year-old woman presents with abdominal bloating, discomfort, and increased abdominal girth. Ascites and a palpable pelvic mass are noted on examination. Histopathological examination shows papillary structures with atypical epithelial cells containing psammoma bodies and elevated CA-125 levels. What is the likely diagnosis? {{caption_text}} (Q845717)

A. Mucinous cystadenocarcinoma

B. Endometrioid carcinoma

C. Serous cystadenocarcinoma

D. Clear cell carcinoma



See Answer in Part B → Q1

@Neet_pg_bot

Q2: What is the extent of nonsquamous growth present in Grade 2 endometrial carcinoma? (Q846626)

A. 5% or less nonsquamous solid growth pattern

B. 6 - 50% nonsquamous solid growth pattern

C. > 50% nonsquamous solid growth pattern

D. >75% nonsquamous solid growth pattern

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 32-year-old woman presents with irregular vaginal bleeding and passage of grape-like clusters at ten weeks of gestation. Ultrasound reveals a heterogeneous pattern with fetal parts. On histopathology, some villi appear enlarged, and there is a presence of fetal tissue admixed with abnormal placental tissue. Which of the following is true regarding this condition? (Q846625)

A. High risk of invasive mole

B. Resulting from androgenetic fertilisation

C. Immunostaining for p57 is negative

D. High risk of malignancy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 29-year-old woman at 11 weeks of gestation presents with vaginal bleeding and passage of grape-like clusters. Ultrasound shows a "snowstorm" appearance without fetal parts. On histopathology, most villi are enlarged with central cistern formation and the absence of fetal tissue. Which of the following is characteristic of this condition? (Q845739)

A. Presence of fetal tissue and partially developed placenta

B. Diploid karyotype, typically 46, XX or 46, XY, with no fetal tissue

C. Triploid karyotype, typically 69, XXX or 69, XXY, with some fetal tissue

D. Normal-sized chorionic villi with no trophoblastic proliferation

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 58-year-old postmenopausal woman presents with progressive abdominal distension, shortness of breath, and pelvic pain. Physical examination reveals ascites and a right-sided pleural effusion. Imaging reveals a solid ovarian mass. A biopsy of the mass shows benign ovarian fibroma. Which of the following is the most likely

diagnosis? (Q845737)

A. Meigs syndrome

B. Pseudo Meigs syndrome

C. Fitz-Hugh-Curtis syndrome

D. Mayer-Rokitansky-Küster-Hauser syndrome

See Answer in Part B → Q5

@Neet_pg_bot

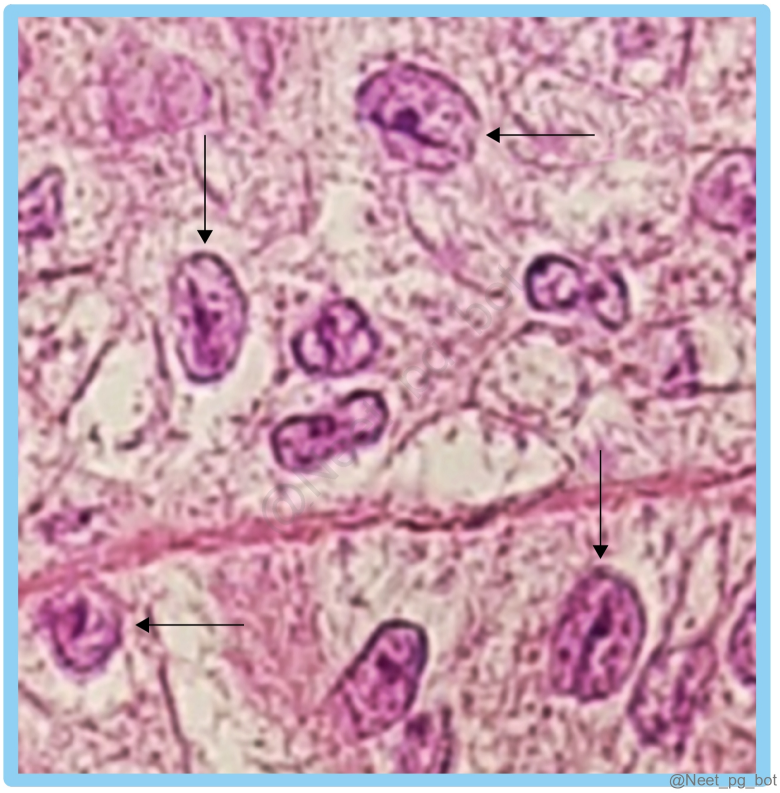
Q6: Which of the following tumours is typically NOT associated with coffee bean nuclei? {{caption_text}} (Q845736)

A. Chondroblastoma

B. Granulosa cell tumour

C. Brenner tumour

D. Yolk sac tumour



See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old postmenopausal woman presents with abnormal uterine bleeding and a pelvic mass. An ultrasound reveals a solid ovarian mass. The mass is surgically removed, and the HPE shows small, follicle-like structures filled with eosinophilic material. Which histological feature is most likely associated with this ovarian tumour? (Q845732)

A. Spindle cells with lipid droplets

B. Call-Exner bodies

C. Reinke crystalloids

D. Signet ring cells

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 19-year-old woman presents with lower abdominal pain and a rapidly enlarging pelvic mass. Imaging reveals a solid and cystic ovarian tumour. A biopsy of the mass shows immature neural elements and other embryonic-like tissues, indicating a high risk of malignancy. What is the most likely diagnosis? (Q845729)

A. Mature teratoma

B. Immature teratoma

C. Carcinoid tumour

D. Monodermal teratoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 28-year-old woman presents with severe vaginal bleeding and lower abdominal pain six months postpartum. USG reveals a heterogeneous uterine mass with haemorrhage and necrosis, raising suspicion of choriocarcinoma. What tumour marker is most likely elevated in her condition? (Q845724)

A. CA-125

B. LDH

C. AFP

D. HCG

See Answer in Part B → Q9

@Neet_pg_bot

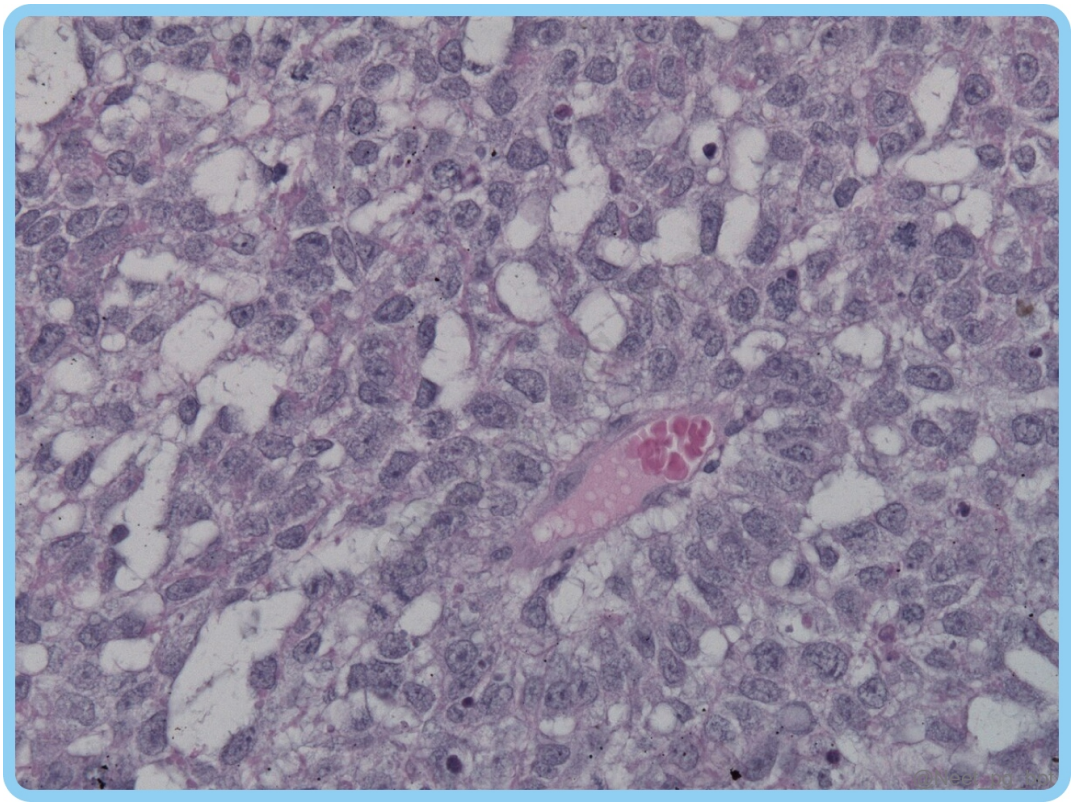
Q10: A 16-year-old female presents with abdominal pain, distension, and a large pelvic mass accompanied by ascites. Elevated serum alpha-fetoprotein levels are detected. Surgical resection of the mass reveals histopathological findings depicted in the image. What is the probable diagnosis? {{caption_text}} (Q845718)

A. Endodermal sinus tumor

B. Dysgerminoma

C. Choriocarcinoma

D. Teratoma



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 34-year-old woman with irregular menstrual cycles and difficulty conceiving undergoes an endometrial biopsy. HPE reveals glands with tall columnar epithelial cells with subnuclear vacuoles. Which phase of the endometrial cycle is most likely being discussed here? (Q845664)

A. Proliferative phase

B. Early secretory phase

C. Late secretory phase

D. Menstrual phase

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Match the following. Tumors Genetic Mutation a) Serous tumors 1) PIK3CA b) Mucinous tumors 2) KRAS proto-oncogene c) Endometrioid carcinomas 3) PTEN d) Clear cell carcinomas 4) BRCA1 and BRCA2 (Q845715)

A. a-4,b-1,c-2,d-3

B. a-4,b-2,c-3,d-1

C. a-3,b-4,c-1,d-2

D. a-2,b-1,c-3,d-4

See Answer in Part B → Q12

@Neet_pg_bot

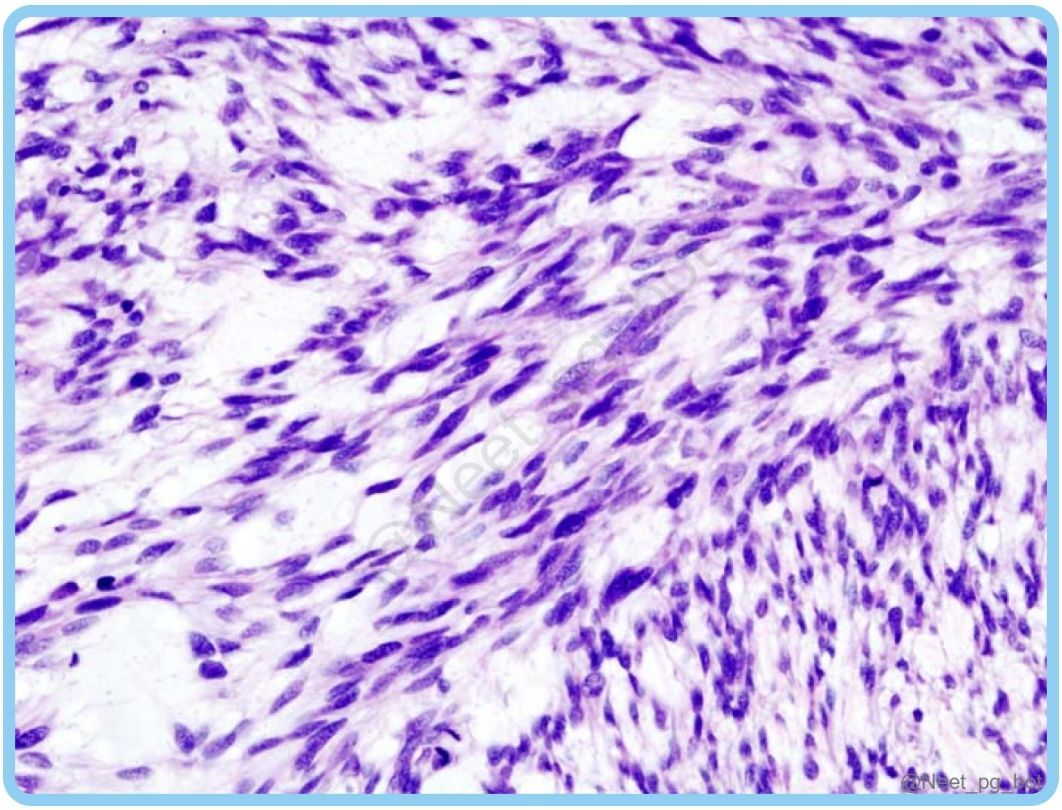
Q13: A 25-year-old woman presents with persistent dull lower abdominal pain and increased urinary frequency. A uterine ultrasound reveals a heterogeneous vascular mass with areas of necrosis. Biopsy results show spindle cells with significant atypia, high mitotic activity, and necrosis. What is the most likely diagnosis? {{caption_text}} (Q845699)

A. Endometriosis

B. Endometrial carcinoma

C. Leiomyoma

D. Leiomyosarcoma



See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 30-year-old pregnant woman at 20 weeks gestation presents with acute onset of severe abdominal pain. On examination, she has a tender, firm uterine mass. Ultrasound shows a fibroid with heterogeneous echotexture and increased vascularity. What type of degeneration is most likely occurring in the fibroid? (Q845698)

A. Hyaline degeneration

B. Calcific degeneration

C. Red degeneration

D. Myxoid degeneration

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 40-year-old woman presents with heavy menstrual bleeding, pelvic discomfort, and increased urinary frequency. Examination reveals an enlarged, irregular uterus, and imaging shows well-defined, solid myometrial masses.Which of the following genetic rearrangements is seen in leiomyomas? (Q845694)

A. MED12

B. KIT

C. p53

D. BRAF

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 55-year-old postmenopausal woman presents with abnormal uterine bleeding and pelvic discomfort. On examination, her uterus is mildly enlarged, and an endometrial biopsy reveals hyperplasia with atypia. Further investigation suggests endometrial carcinoma.Which of the following genes is not responsible for the pathogenesis of Endometrial carcinoma? (Q845691)

A. PTEN

B. KRAS

C. CTNNB-1

D. ETV1

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 49-year-old nulliparous woman with a history of irregular menses and breast cancer treated with tamoxifen presents with vaginal bleeding. Transvaginal ultrasound indicates irregular endometrial thickening, while biopsy confirms complex endometrial hyperplasia with atypia progressing to endometrioid carcinoma. Which of the following is not a risk factor for the above condition? (Q845690)

A. Thin physique

B. Diabetes mellitus

C. Tamoxifen

D. Unopposed estrogenic stimulation of the uterus

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following genetic mutations is associated with Endometrial hyperplasia? (Q845689)

A. BRCA 1 gene

B. PTEN gene

C. TP53 gene

D. BRCA 2 gene

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following statements is NOT true about Adenomyosis? (Q845688)

A. It presents with abnormal uterine bleeding.

B. Ectopic endometrial tissue is found at least 2.5 cm from the endometrial junction.

C. It is seen in pre-menopausal women.

D. Biopsy shows irregular nests of endometrial stroma arranged within the myometrium.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 28-year-old woman with chronic pelvic pain worsened during menstrual periods and accompanied by heavy bleeding, was found to have a 'chocolate' brown cyst on her ovaries during a laparoscopy. What is the most commonly accepted theory for the pathogenesis of this condition? (Q845686)

A. Benign metastasis theory

B. Metaplastic theory

C. Extrauterine stem/progenitor cell theory

D. Regurgitation theory

See Answer in Part B → Q20

Q1: A patient presents with ascites and omental caking. Imaging reveals solid components in an adnexal mass, and there is a long-standing history of symptoms. CA-125 is positive. What is the most probable diagnosis? (Q865380)

A. Serous ovarian tumor

B. Mucinous ovarian tumor

C. Endometroid tumor

D. Granulosa cell tumor

See Answer in Part B → Q1

@Neet_pg_bot

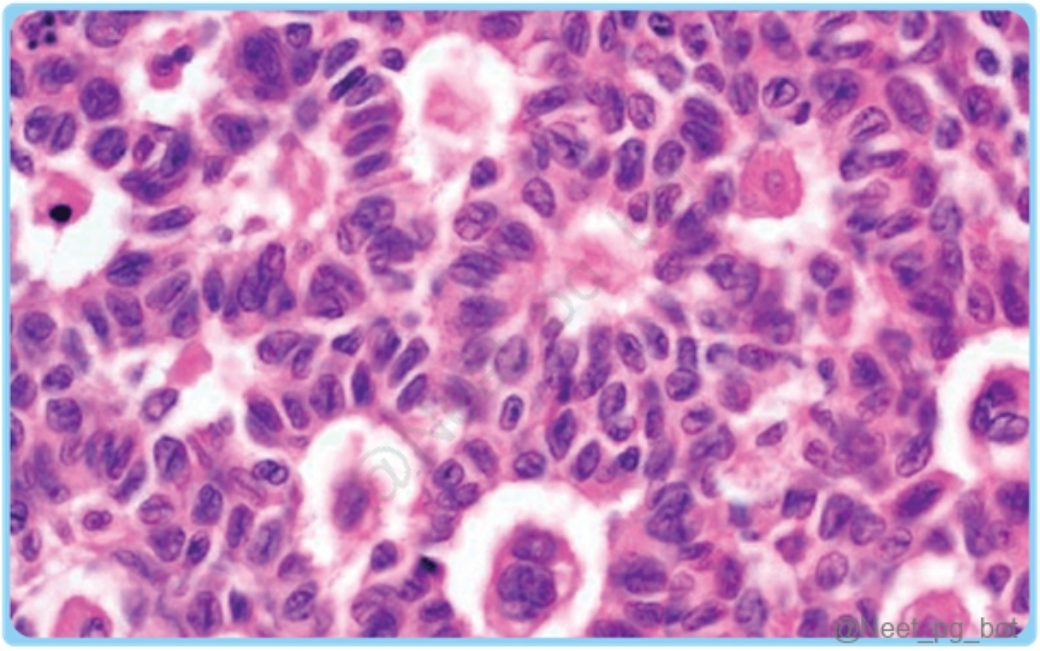
Q2: A histopathological image of an ovarian mass in a lady is shown below. Which of the following statements are true regarding this condition? Sex cord stromal tumor Call-Exner bodies are seen CA125 is high Inhibin is a marker (Q865416)

A. 1, 2, 3

B. 1, 2, 4

C. 2, 4

D. 1, 4



See Answer in Part B → Q2

@Neet_pg_bot

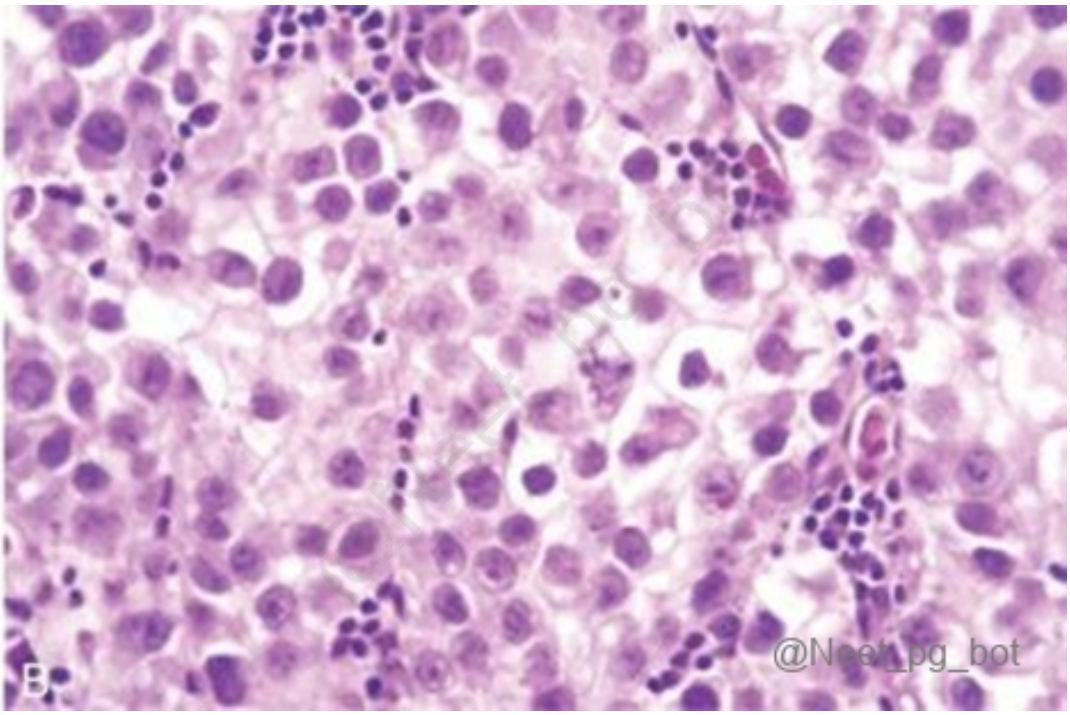
Q3: A 30-year-old man presents with a painless testicular mass. An ultrasound shows a well-circumscribed, homogeneous, non-hemorrhagic testicular tumour. Which of the following is the most likely diagnosis? (Q866364)

A. Yolk sac tumour

B. Choriocarcinoma

C. Teratoma

D. Seminoma



See Answer in Part B → Q3

@Neet_pg_bot

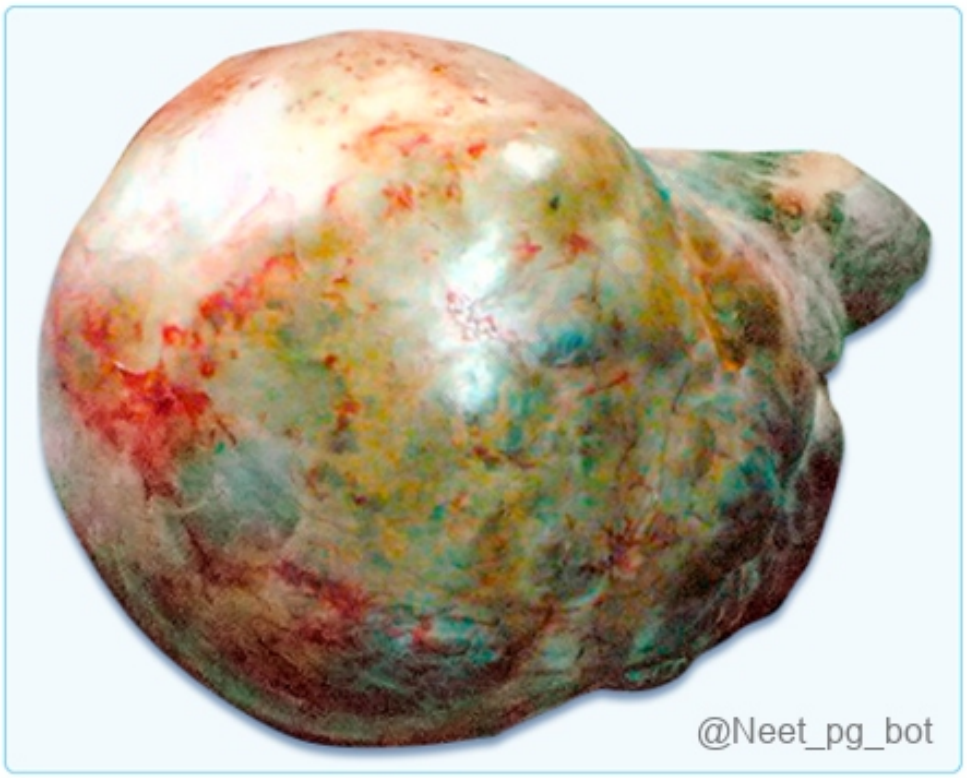
Q4: A patient presents with an ovarian mass that is multiloculated and has a serum CA-125 level >1000 U/mL. What is the most likely diagnosis? (Q866385)

A. Serous cystadenoma

B. Mature teratoma

C. Granulosa cell tumor

D. Serous cystadenocarcinoma



See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the role of inhibin? (Q860564)

A. Stimulates the release of FSH

B. Inhibits the secretion of FSH

C. Inhibition of PRL

D. Stimulation of PRL

See Answer in Part B → Q5

@Neet_pg_bot

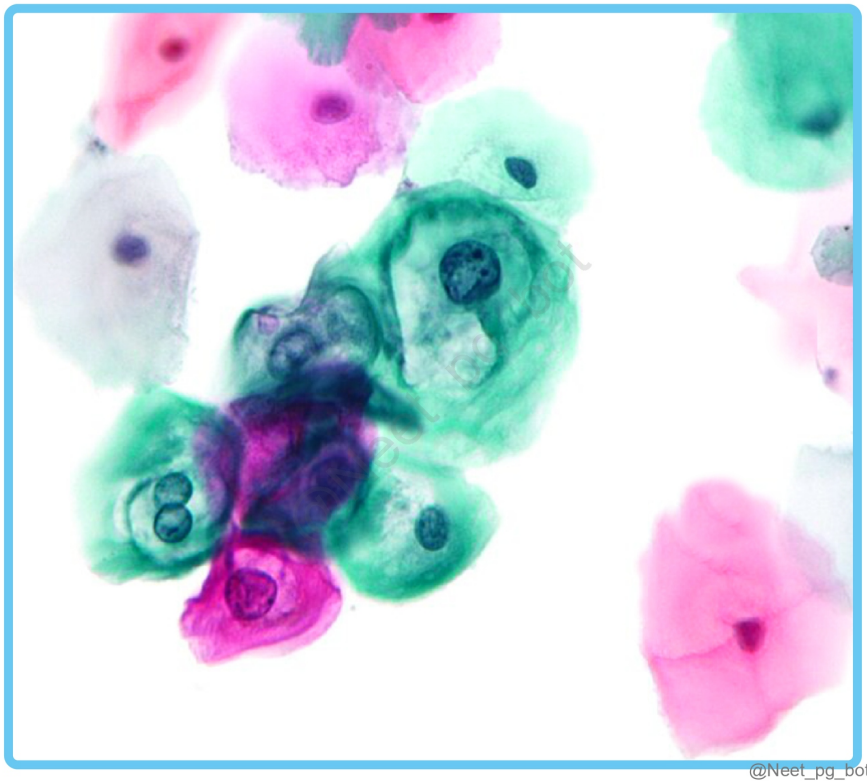
Q6: In the cervical smear below, which of the following stains are used (Q857417)

A. Papanicolaou stain

B. H & E stain

C. Giemsa stain

D. Toluidine blue



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following tumour markers are positive for seminoma? PLAP OCT3/4 NANOG HCG (Q854709)

A. 1 only

B. 1 and 2

C. 1, 2 and 3

D. 1, 2, 3 and 4

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following conditions is NOT caused by high-risk strains of human papillomavirus (HPV)? (Q855950)

A. Cervical cancer

B. Anal cancer

C. Oropharyngeal cancer

D. Laryngeal papillomatosis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: What is the most probable tumour that a 22-year-old woman with a sizable growth in her right ovary, which has been determined to originate from all three germ layers based on histopathology, is experiencing? (Q857106)

A. Dysgerminoma

B. Teratoma

C. Thecoma

D. Theca lutein cyst

See Answer in Part B → Q9

@Neet_pg_bot

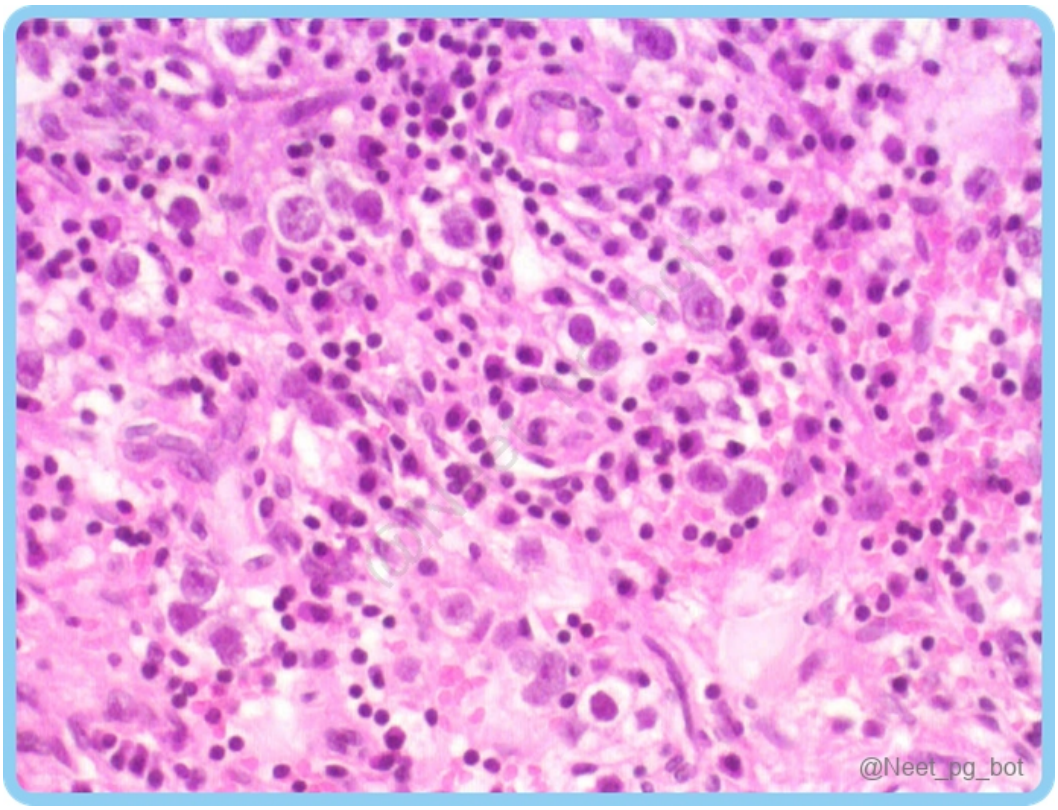
Q10: What is the most likely diagnosis for a 48-year-old patient who came with scrotal swelling, had elevated LDH levels but normal AFP levels on tests for testicular tumours, and exhibited a specific histological picture after orchidectomy? (Q857111)

A. Yolk sac tumor

B. Teratoma

C. Seminoma

D. Embryonal carcinoma



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is not a component of Meigs syndrome? (Q857125)

A. Ascites

B. Right-sided hydrothorax

C. Fibromas of ovary

D. Dysgerminoma of ovary

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following statements is accurate concerning liquid-based cytology? (Q856890)

A. Urine specimen is used

B. Sanger sequencing is used

C. Study of fluid in the tumor microenvironment

D. DNA is collected in microvessels

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is not a constituent of the Papanicolaou stain? (Q856892)

A. Light green SF

B. Orange G

C. Eosin B

D. Hematoxylin

See Answer in Part B → Q13

Q19 (p. 597)	*Q20 (p. 597)*	*Q21 (p. 598)*	*Q22 (p. 599)*		

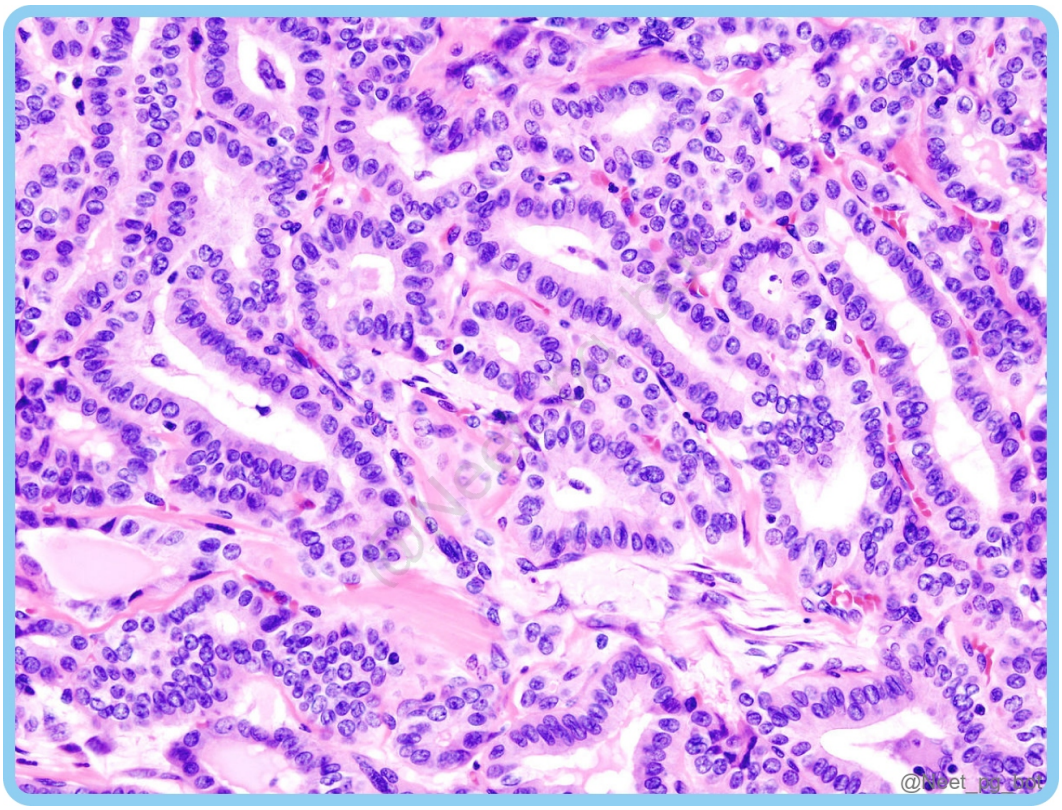
Q1: A 40-year-old patient presents with a nodule in the anterior neck and lymphadenopathy. The tumour is found to have spread to the lymphatics. Histopathological examination shows characteristic findings. What is the most likely diagnosis? (Q845553)

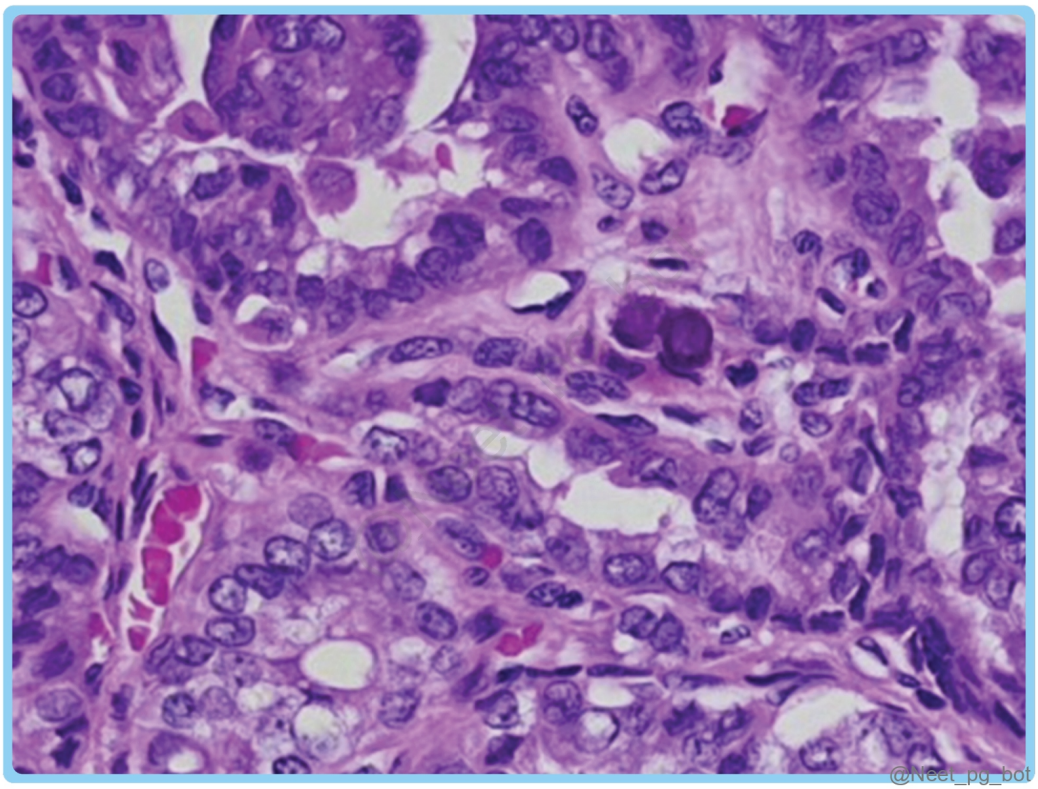
A. Follicular thyroid carcinoma

B. Medullary thyroid carcinoma

C. Papillary thyroid carcinoma

D. Anaplastic thyroid carcinoma





See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old patient is diagnosed with papillary thyroid carcinoma. Which of the following statements about papillary thyroid carcinoma is true? (Q890473)

A. Not associated with radiation exposure

B. Hot nodule on scintigraphy

C. Accounts for 85% of thyroid cancers

D. Has a poor prognosis

See Answer in Part B → Q2

@Neet_pg_bot

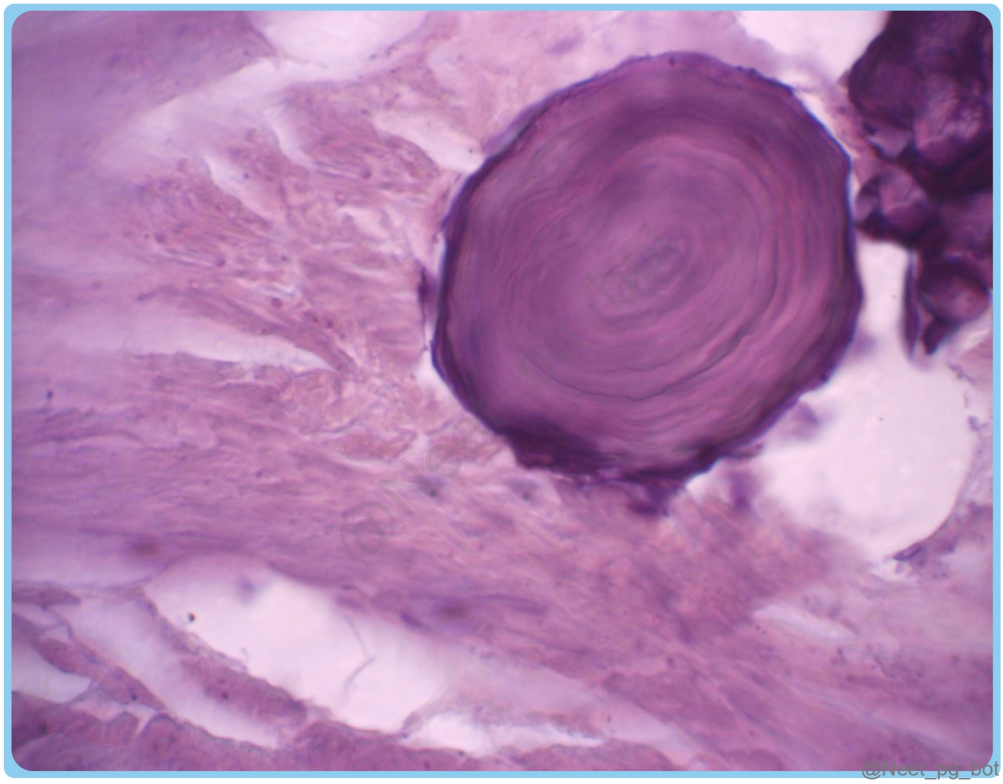
Q3: A 32-year-old woman presents with a midline neck swelling that moves with deglutition and tongue protrusion. The swelling has been present since childhood but has recently increased in size. Surgical excision is performed. Histopathological examination reveals the following findings. What is the most likely diagnosis? (Q890469)

A. Follicular carcinoma

B. Papillary carcinoma

C. Medullary carcinoma

D. Anaplastic carcinoma



See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following correctly represents the most common and least common thyroid carcinomas, respectively? (Q890467)

A. Papillary carcinoma - Anaplastic carcinoma

B. Follicular carcinoma - Medullary carcinoma

C. Medullary carcinoma - Papillary carcinoma

D. Anaplastic carcinoma - Papillary carcinoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is the correct statement regarding a solitary thyroid nodule? (Q890465)

A. Most often malignant

B. Incidence decreases with age

C. Rare in the general population

D. Higher risk of malignancy than multiple nodules

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old woman presents with painful enlargement of the thyroid following an upper respiratory infection. Laboratory tests show ↑ T3/T4, ↓ TSH, and low radioactive iodine uptake. What is the most likely diagnosis? (Q890464)

A. Hashimoto thyroiditis

B. Graves disease

C. Subacute granulomatous thyroiditis

D. Riedel thyroiditis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is the most common cause of hypothyroidism in iodine-sufficient areas? (Q890463)

A. Hashimoto thyroiditis

B. Wolff-Chaikoff effect

C. Pituitary failure

D. Thyroid agenesis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following histopathological features is not typically seen in Hashimoto thyroiditis? (Q890447)

A. Lymphoid follicles with germinal centres

B. Hürthle (oncocytic) cell change

C. Fibrosis extending beyond the thyroid capsule

D. Dense mononuclear inflammatory infiltrate

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following statements regarding hyperthyroidism is correct? (Q890446)

A. Graves' disease is the most common cause of hyperthyroidism.

B. Serum TSH levels are increased in primary hyperthyroidism.

C. Osteoporosis is not a complication

D. Constipation is a typical feature of hyperthyroidism.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old patient presents with a painless lump on the front of the neck, bone pain, fatigue, and episodes of flushed skin. Genetic studies reveal a mutation in the RET gene. Which type of amyloid is typically deposited in this condition? (Q845555)

A. A-β

B. A-CAL

C. A-L

D. A-TTR

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is not a common feature of follicular carcinoma of thyroid? (Q845554)

A. Second most common thyroid malignancy

B. Has a Hurthle cell variant

C. Commonly spreads by lymphatic route

D. FNAC is not helpful in diagnosis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which system is widely used for reporting thyroid cytopathology? (Q845542)

A. TIRADS

B. Gleason System

C. Bethesda System

D. Duke Classification

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Match each type of thyroid tumour with its most commonly associated risk factor: Thyroid Carcinoma Risk Factors: 1. Papillary thyroid carcinoma A. Iodine

deficiency 2. Follicular thyroid carcinoma B. RET proto-oncogene mutations 3. Medullary thyroid carcinoma C. Radiation exposure 4. Anaplastic thyroid carcinoma D. History of a well-differentiated follicular neoplasm (Q845552)

A. 1-C, 2-A, 3-B, 4-D

B. 1-B, 2-C, 3-D, 4-A

C. 1-A, 2-D, 3-C, 4-B

D. 1-D, 2-B, 3-A, 4-C

See Answer in Part B → Q13

@Neet_pg_bot

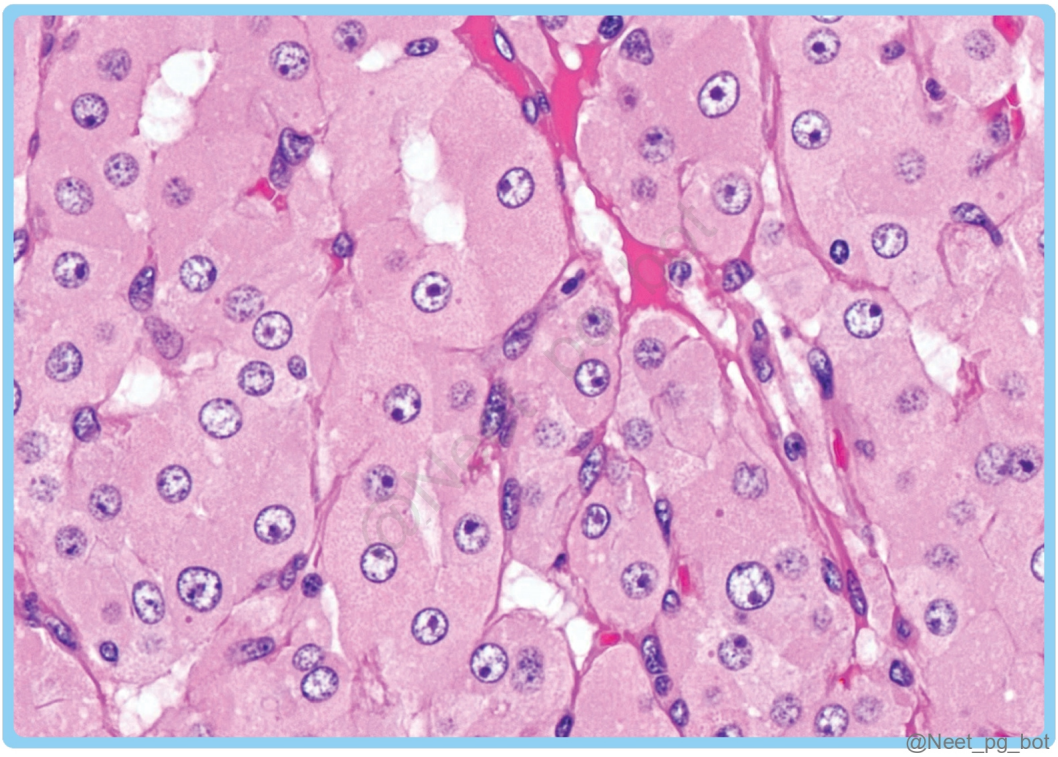
Q14: A 55-year-old patient presents with a solitary thyroid nodule. The patient also reports difficulty swallowing, with no complaints of weight loss, fatigue, or heat intolerance. An excisional biopsy reveals >75% of the following characteristic cells. Which genetic mutation is most commonly associated with this type of thyroid tumour? {{caption_text}} (Q845551)

A. BRAF

B. GNAS

C. RAS

D. PTEN



See Answer in Part B → Q14

@Neet_pg_bot

Q15: What is the finding in the histopathological examination of a biopsy specimen from a patient with De Quervain Thyroiditis? (Q845550)

A. Extensive stromal fibrosis extending beyond the thyroid capsule

B. Follicular hyperplasia with scalloping colloid

C. Mononuclear infiltration with well-developed germinal centres

D. Mixed cellular infiltration with occasional multinucleated giant cells

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a feature of subacute lymphocytic thyroiditis? (Q845549)

A. Also called postpartum thyroiditis

B. Usually presents as a painful enlargement of the thyroid

C. Self-limiting condition

D. Lymphocytic inflammation in the thyroid

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following best describes the gross morphology of Riedel's thyroiditis? (Q845548)

A. Localised nodule within the gland

B. Diffusely enlarged thyroid gland

C. Mobile and well-circumcised mass

D. Stony and hard consistency

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 28-year-old woman comes to the office due to progressively worsening eye irritation and double vision over the last two months. She also reports unintentional weight loss, mood swings, diarrhoea, and palpitations. Physical examination shows tachycardia and bilateral proptosis. What is the pathophysiology causing proptosis? (Q845547)

A. Increased activity of orbital fibroblasts

B. Increased breakdown of hyaluronic acid

C. Increased synthesis of thyroid hormones

D. Increase in sympathetic activity

See Answer in Part B → Q18

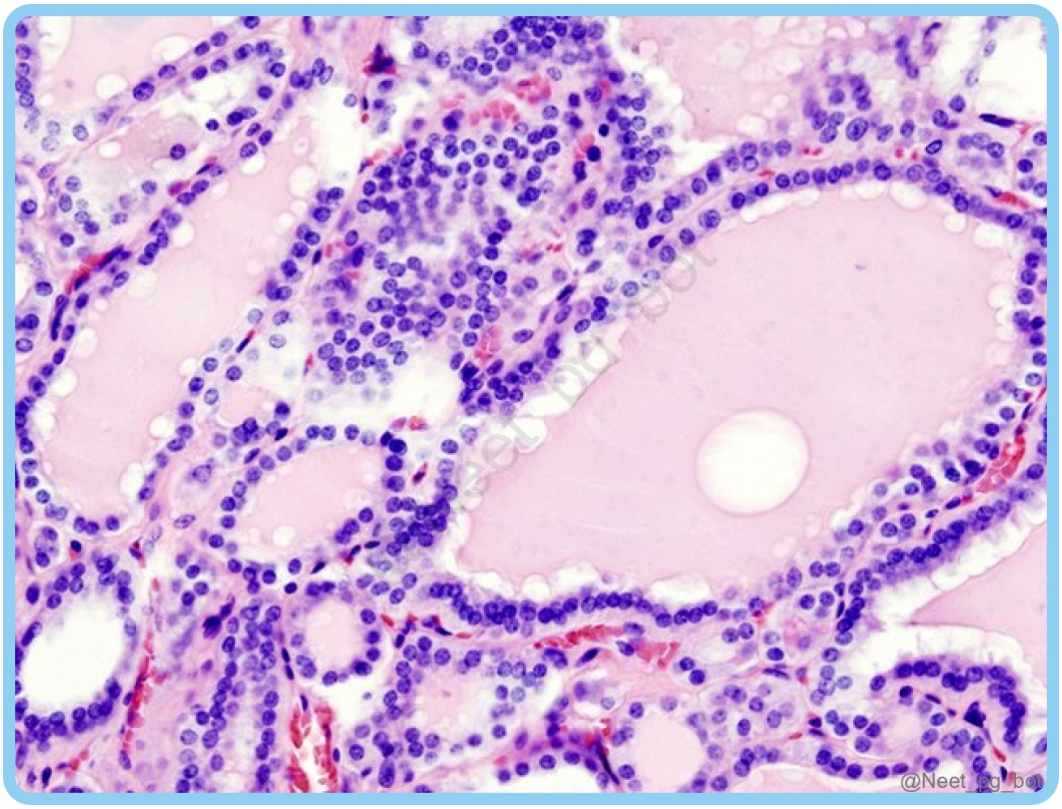
Q19: A 29-year-old lady has been experiencing loss of appetite, profuse sweating, and palpitations for the past three months. Laboratory tests conclude increased T3 and T4 levels with decreased TSH levels. A representative HPE of this condition is shown below. The most common antibodies in this condition target which of the following? {{caption_text}} (Q845546)

A. TSH receptor

B. Thyroid peroxidase

C. Thyroglobulin

D. Dermal fibroblasts



See Answer in Part B → Q19

Q20: Which of the following antibodies are elevated in a patient of Hashimoto's thyroiditis? (Q845545)

A. Thyroid-stimulating immunoglobulins (TSI)

B. Anti-thyroid peroxidase antibodies (Anti-TPO)

C. Anti-thyroid stimulating hormone receptor antibodies (Anti-TSHR)

D. Anti-thyroid hormone antibodies (Anti-T3/T4)

See Answer in Part B → Q20

@Neet_pg_bot

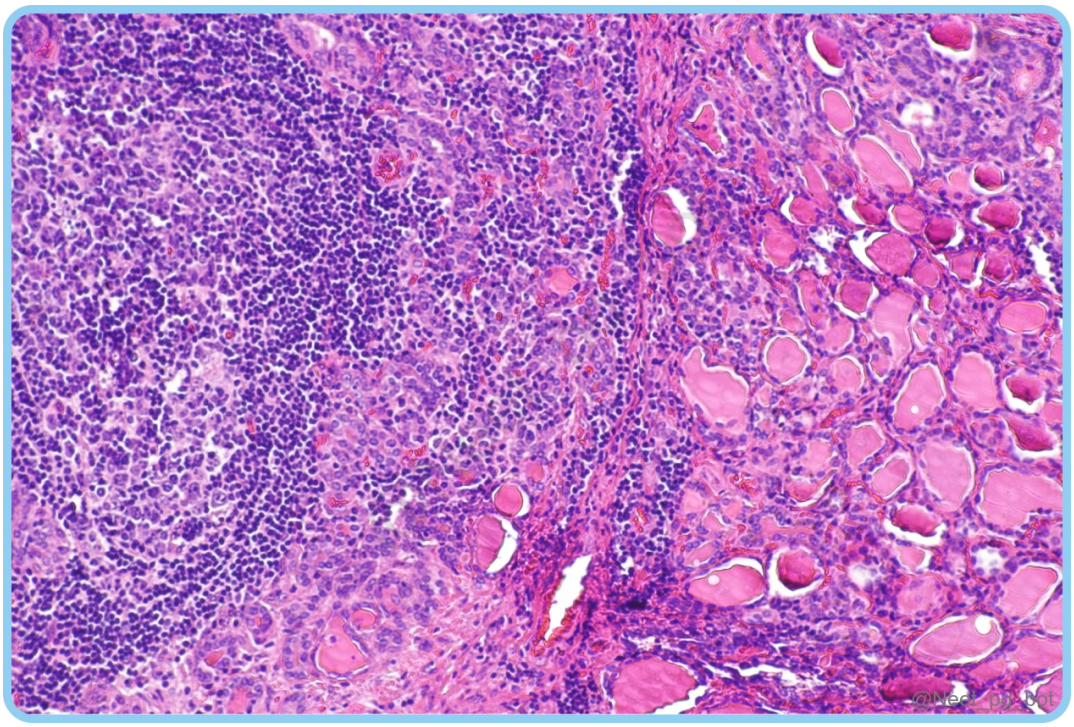
Q21: A 35-year-old female presents with fatigue, weight gain, and cold intolerance. On physical examination, she has diffuse goitre and dry skin. Histopathological examination shows lymphoid infiltration, atrophic thyroid follicles lined in many areas by epithelial cells with abundant eosinophilic, granular cytoplasm as shown below. What is the likely diagnosis? {{caption_text}} (Q845544)

A. Grave’s disease

B. Thyroid nodule

C. Papillary carcinoma

D. Hashimoto thyroiditis



See Answer in Part B → Q21

@Neet_pg_bot

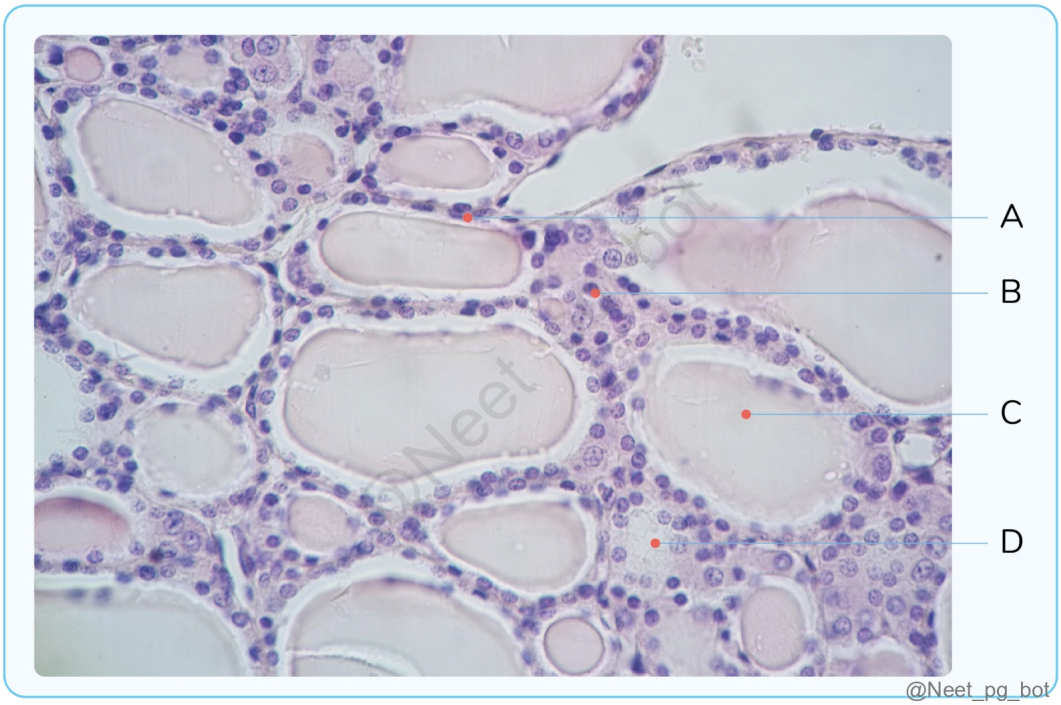
Q22: You are examining a high-resolution microscopic image of thyroid tissue. Which of the following depicts cells responsible for the secretion of calcitonin? {{caption_text}} (Q845543)

A. A

B. B

C. C

D. D



See Answer in Part B → Q22

Q13 (p. 609) *Q14 (p. 610)*

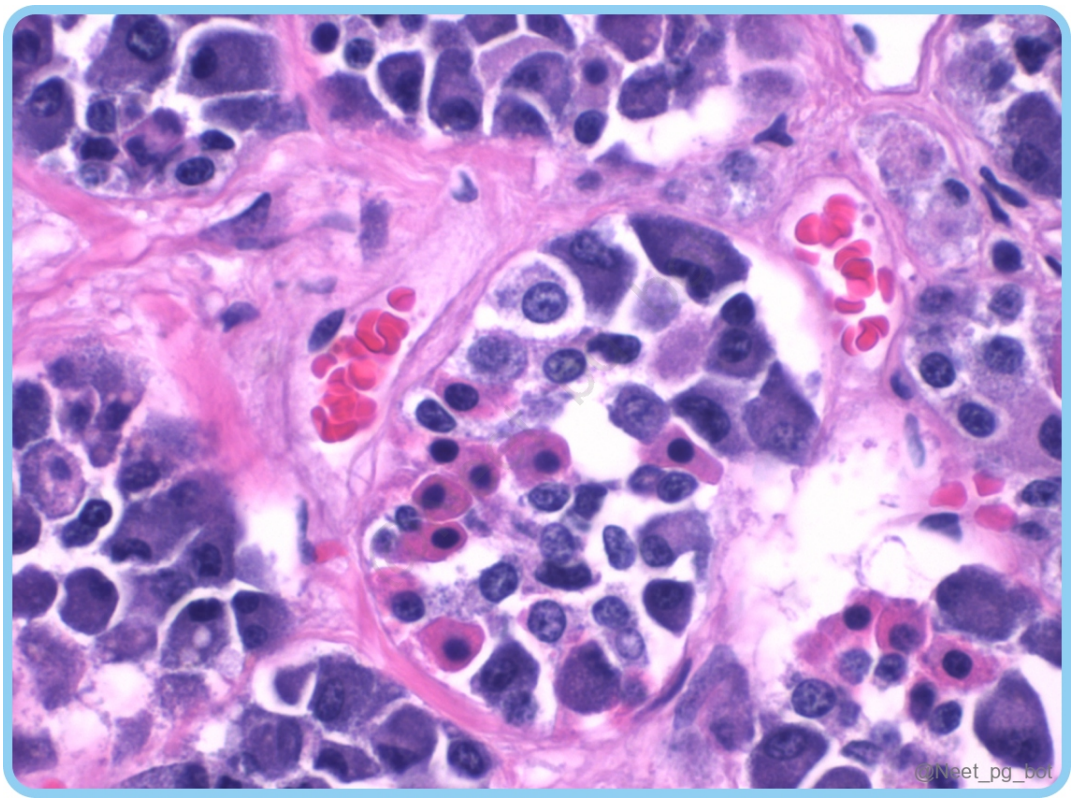
Q1: Which of the following cell types are typically found in the anterior lobe of the pituitary gland, and which are stained pink and purple, respectively? (Q845580)

A. Sommatotrophs and lactotrophs

B. Lactotrophs and thyrotrophs

C. Corticotrophs and gonadotrophs

D. Gonadotrophs and somatotrophs



See Answer in Part B → Q1

@Neet_pg_bot

Q2: Pituitary adenomas are often classified based on the hormones they secrete. Which of the following statements correctly matches the type of pituitary adenoma with its primary hormone secretion and associated syndrome? (Q845581)

A. Prolactinoma – Secretes prolactin – Causes Cushing's disease

B. Somatotroph adenoma – Secretes growth hormone – Causes acromegaly

C. Corticotroph adenoma – Secretes thyroid-stimulating hormone – Causes hyperthyroidism

D. Gonadotroph adenoma – Secretes adrenocorticotropic hormone (ACTH) – Causes Addison's disease

See Answer in Part B → Q2

@Neet_pg_bot

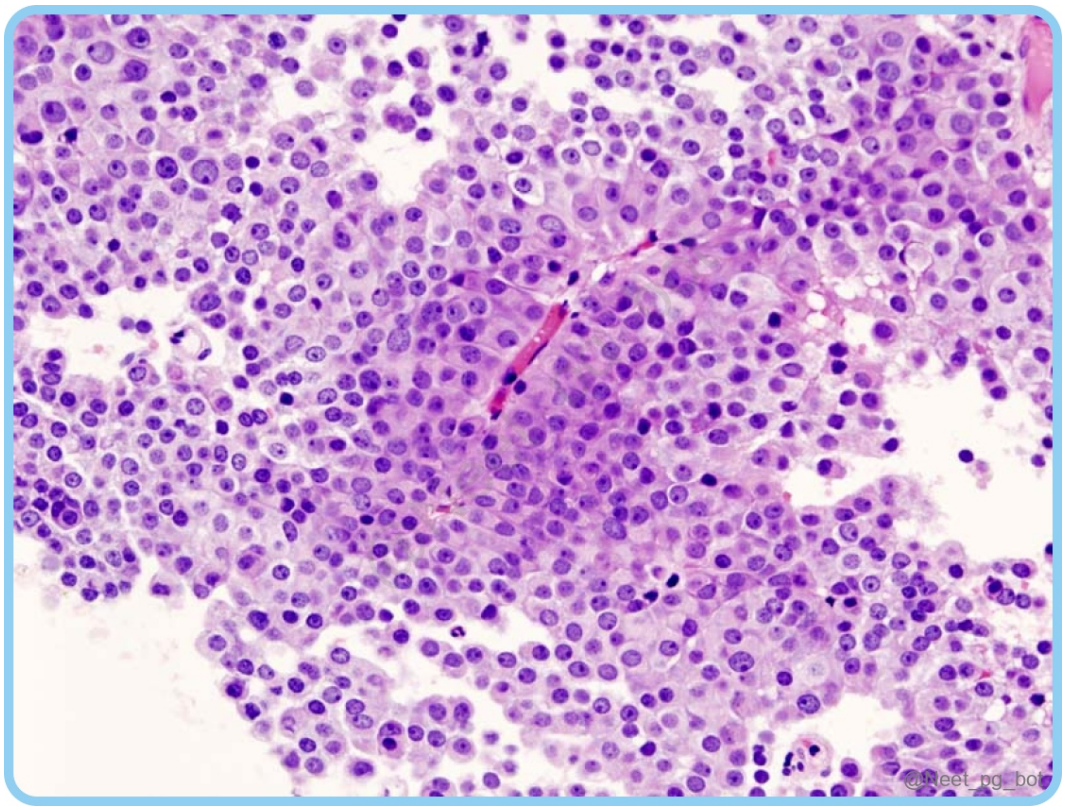
Q3: A pathologist examines a surgically resected pituitary tumour under a microscope. The tumour comprises sheets of monomorphic, round to polygonal cells with central nuclei and sparse to absent reticulin network. What is the most likely diagnosis? (Q845582)

A. Pituitary adenoma

B. Pituitary carcinoma

C. Craniopharyngioma

D. Schwannoma



See Answer in Part B → Q3

@Neet_pg_bot

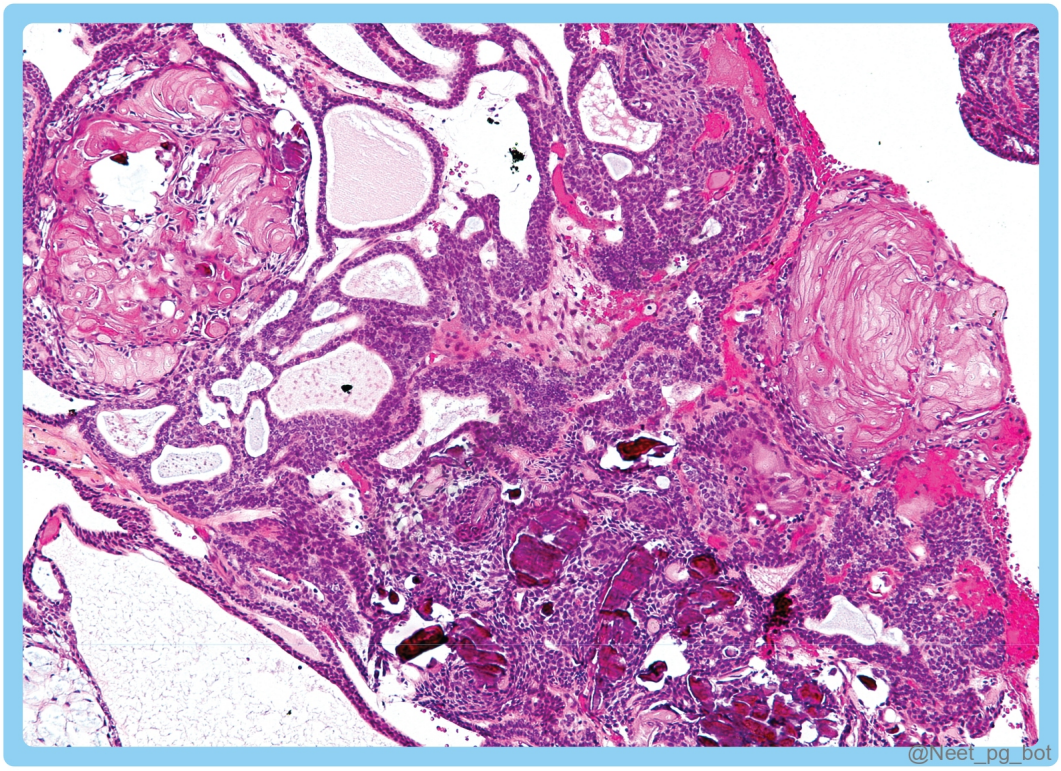
Q4: A 12-year-old child presents with headaches, visual disturbances, and delayed growth. An MRI of the brain reveals a 3 cm cystic mass with calcifications. The growth was found to be encapsulated and multiloculated. What is the most likely diagnosis? (Q845583)

A. Oligodendroglioma

B. Meningioma

C. Craniopharyngioma

D. Pituitary adenoma



See Answer in Part B → Q4

@Neet_pg_bot

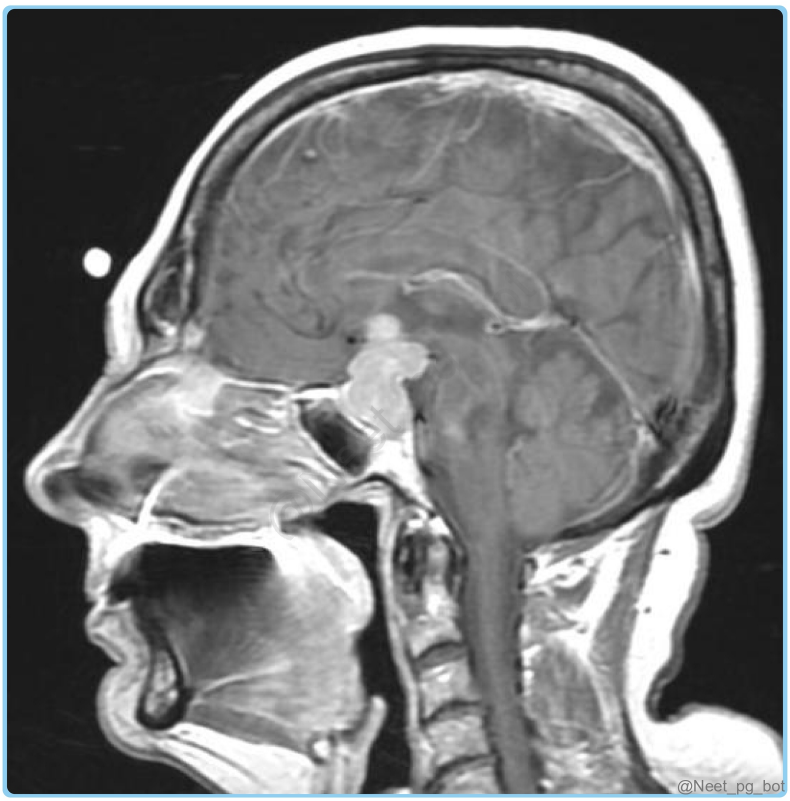
Q5: A 35-year-old male presents with a history of recurrent kidney stones, hypercalcemia, and a recent diagnosis of a pituitary adenoma. Which of the following syndromes is most likely associated with his clinical presentation? (Q845584)

A. MEN 2A syndrome

B. MEN 2B syndrome

C. MEN 4 syndrome

D. MEN 1 syndrome



See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which mutation is associated with pituitary carcinoma? (Q845585)

A. AIP

B. CDKN I B

C. HRAS

D. MEN 1

See Answer in Part B → Q6

@Neet_pg_bot

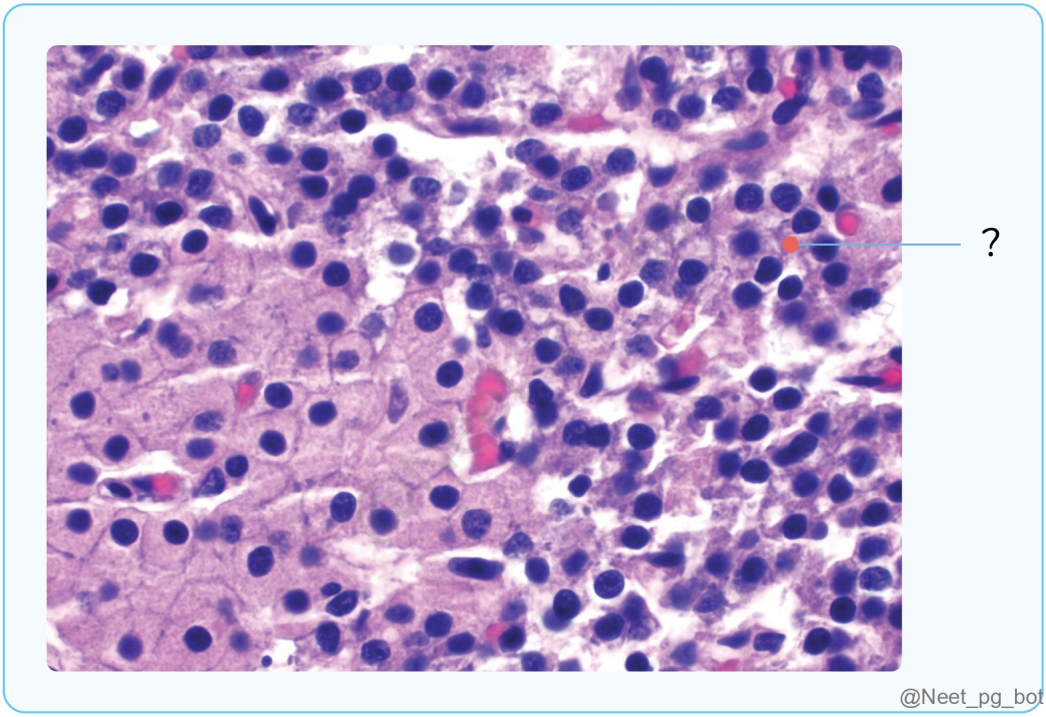
Q7: Identify the marked cells in the histology of the parathyroid below. (Q845586)

A. Oxyphil cells

B. Chief cells

C. Adipocytes

D. Parafollicular cells



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following microscopic features is most indicative of a parathyroid adenoma rather than parathyroid hyperplasia? (Q845587)

A. Diffuse hyperplasia of chief cells throughout the parathyroid gland

B. Stromal fat infiltration within the parathyroid tissue

C. Intranuclear cytoplasmic inclusions within chief cells

D. Difficult to distinguish on microscopy

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following genetic mutations is most commonly associated with pheochromocytoma? (Q845588)

A. Gain of function mutation in n-Myc gene

B. Gain of function mutation in RET gene

C. Loss of function mutation in the RET gene

D. Loss of function mutation in MEN 1 gene

See Answer in Part B → Q9

@Neet_pg_bot

Q10: The 4-year-old kid is brought with complaints of periorbital ecchymosis, miosis, and ptosis. CT scan reveals a tumour on the right kidney with calcifications. A biopsy reveals small, dark blue cells with scanty cytoplasm. Which mutation is most likely connected to this mass? (Q845589)

A. ALK gene mutation

B. RET gene mutation

C. L-MYC gene mutation

D. VHL gene mutation

See Answer in Part B → Q10

@Neet_pg_bot

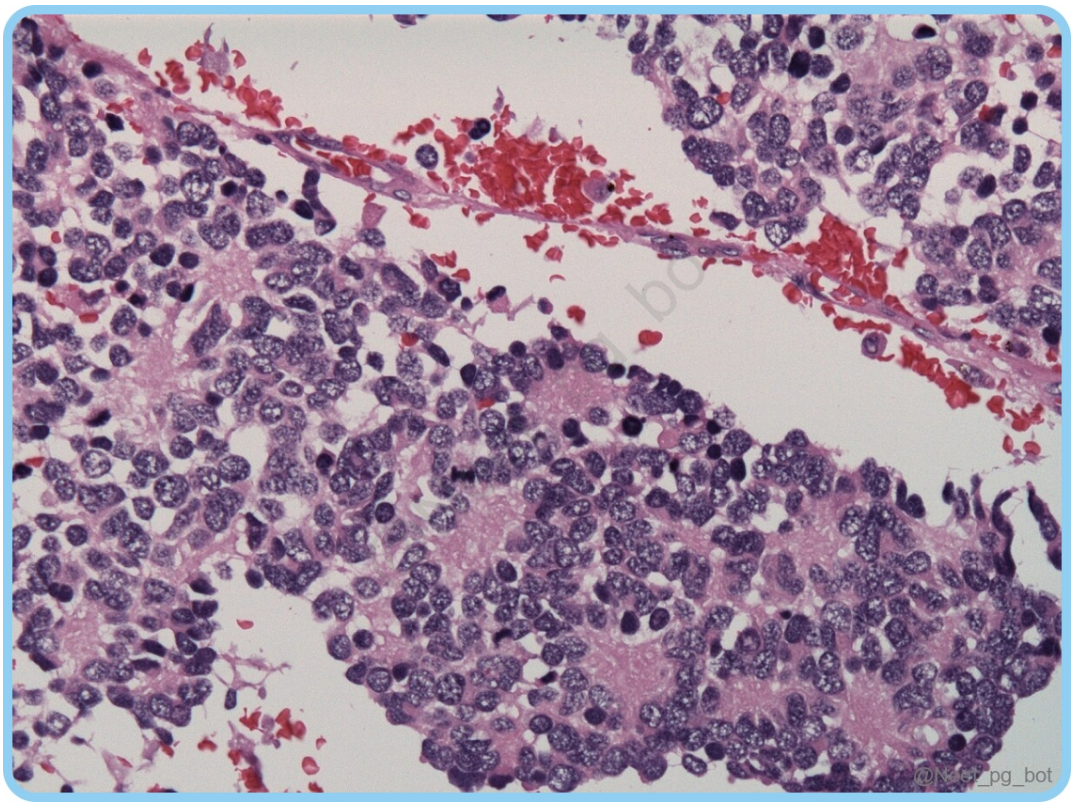
Q11: A 2-year-old boy is brought with complaints of abdominal lump for 2 months. HPE of the mass is shown below. Which of the following conditions is not associated with a similar finding? (Q845590)

A. Neuroblastoma

B. Medulloblastoma

C. Retinoblastoma

D. Primitive neuroectodermal tumors



See Answer in Part B → Q11

@Neet_pg_bot

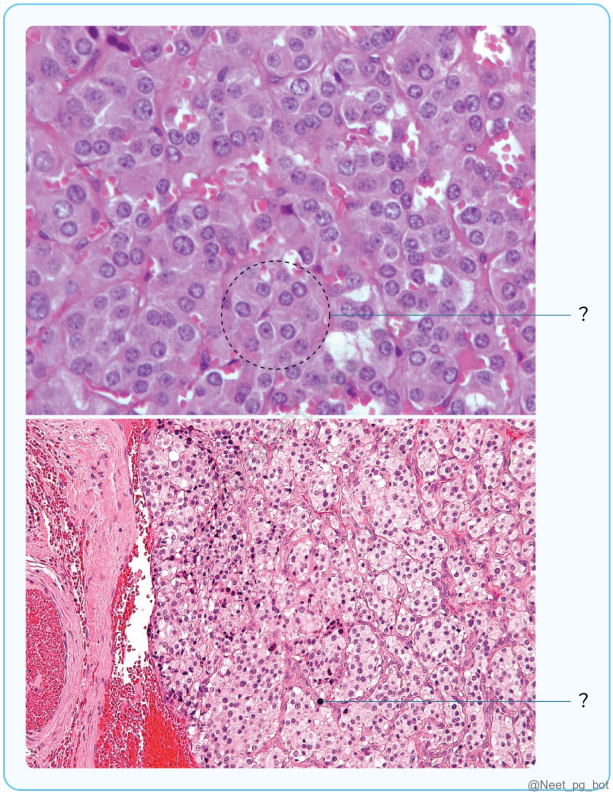
Q12: This histology finding is seen in all these tumors except? (Q845591)

A. Pheochromocytoma

B. Carotid body tumor

C. Neuroblastoma

D. Medullary carcinoma of the thyroid



See Answer in Part B → Q12

@Neet_pg_bot

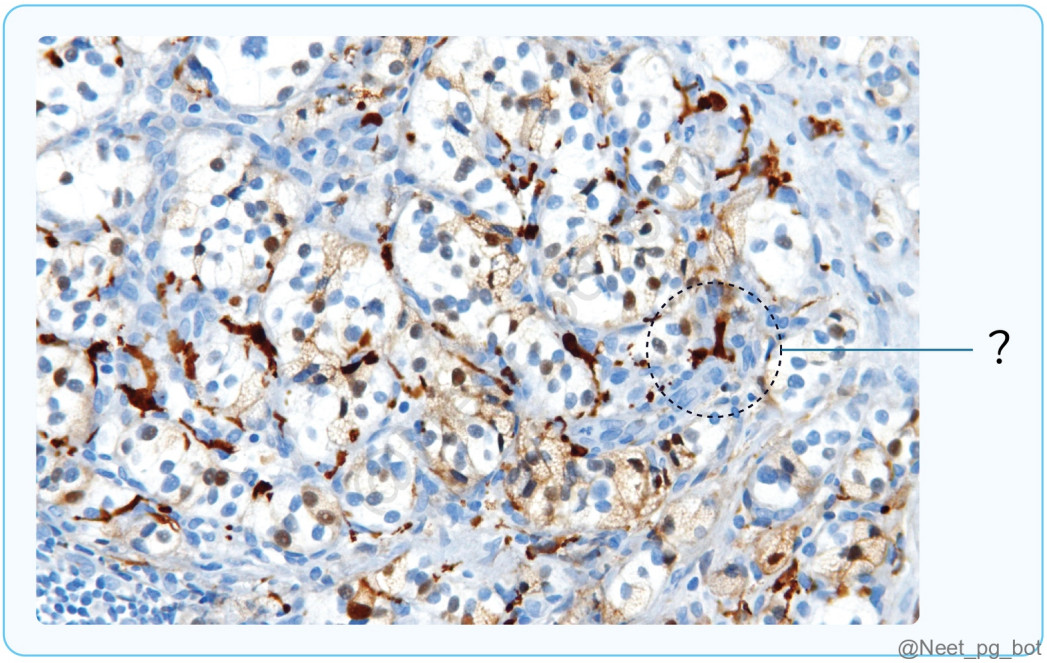
Q13: A 40-year-old woman has been evaluated for intermittent headaches, insomnia, diaphoresis, and unintentional weight loss over the past several months. The patient is found to have a neoplastic mass producing excessive hormones causing symptoms. Histopathology of the same is shown below. These cells marked below stain positive for which of the following immunohistochemical markers? (Q845592)

A. Synaptophysin

B. Chromogranin

C. Neuron-specific enolase

D. S-100



See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 40-year-old woman presents to her primary care physician with a recent diagnosis of medullary thyroid carcinoma (MTC). She reports no significant family history of endocrine disorders. Laboratory investigations show elevated levels of serum calcium and plasma catecholamines and metanephrines. What is the most likely diagnosis in this patient? (Q845593)

A. MEN 1 syndrome

B. MEN 2 A syndrome

C. MEN 2 B syndrome

D. Neurofibromatosis type 1

See Answer in Part B → Q14

@Neet_pg_bot

Q13 (p. 618) *Q14 (p. 619)* *Q15 (p. 619)*

Q1: Mutation in which of the following genes is most commonly associated with medullary thyroid carcinoma? (Q866734)

A. RAS

B. BRAF

C. RET

D. TP53

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient presents with a mass in the front of the neck, along with odynophagia and dyspnea. Histopathology reveals tumour cells positive for TTF-1, synaptophysin, and chromogranin, and there is evidence of amyloid deposition. What is the most likely diagnosis? (Q866374)

A. Papillary thyroid carcinoma

B. Follicular thyroid carcinoma

C. Medullary thyroid carcinoma

D. Anaplastic thyroid carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

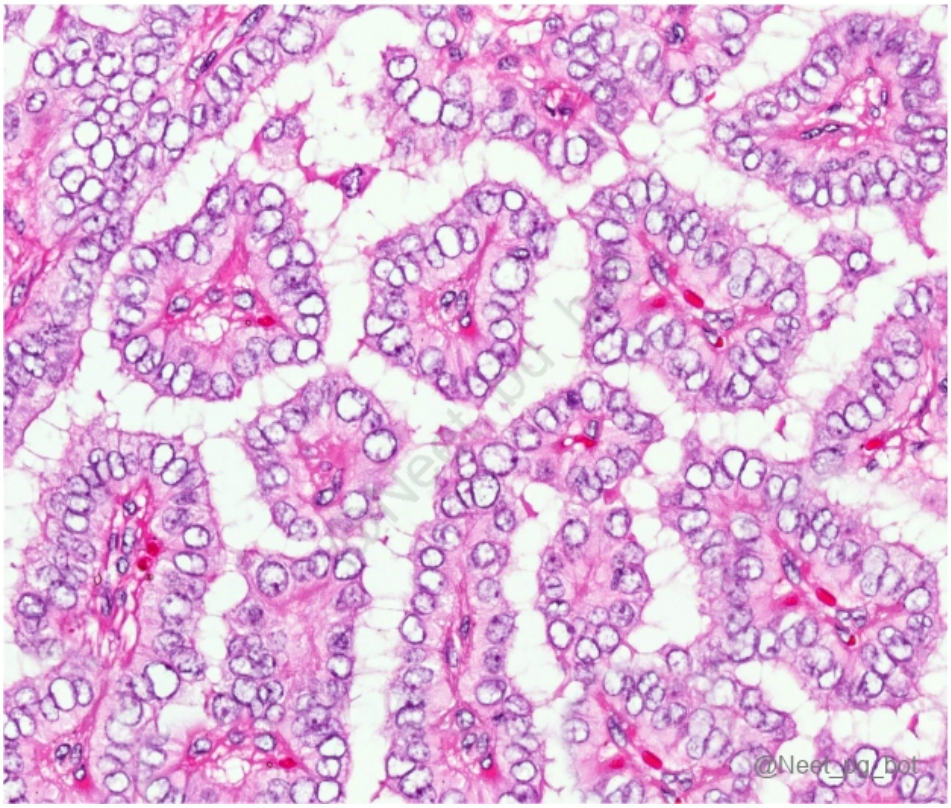
Q3: Identify the gene commonly involved in the carcinoma shown in the image below: (Q843990)

A. RAS

B. PAX8–PPARγ

C. BRAF V600

D. P53



See Answer in Part B → Q3

@Neet_pg_bot

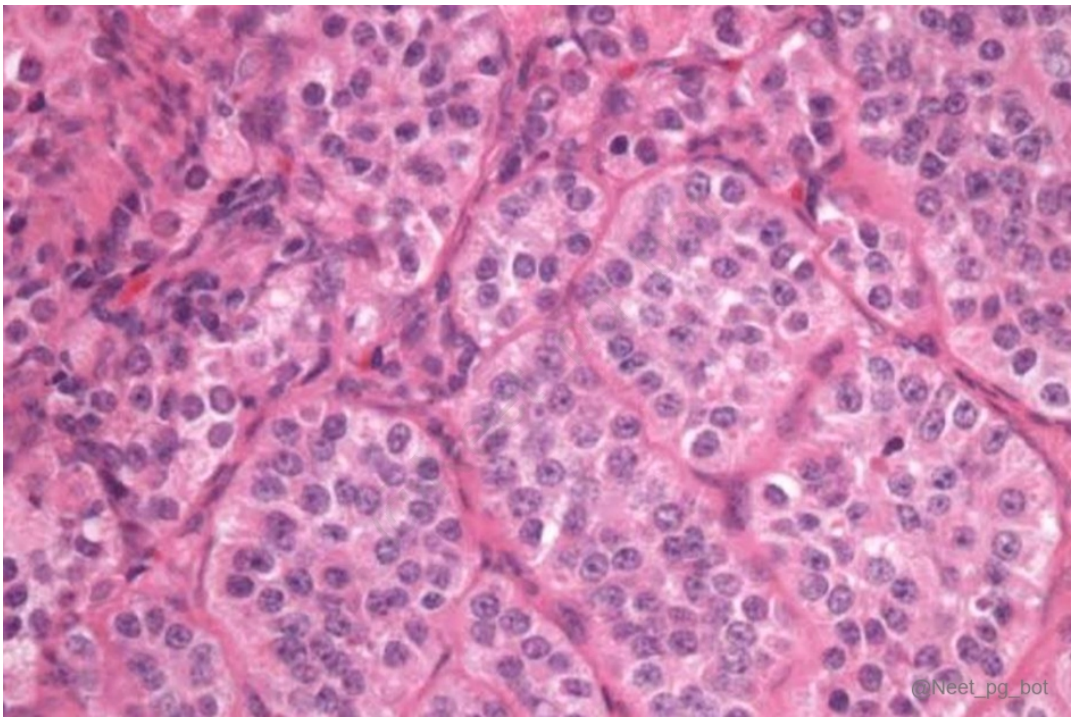
Q4: A patient presents with headaches, palpitations, and hypertension. On laboratory examination, urine VMA is positive. His biopsy findings are given below. Which of the following is a correct statement? (Q844236)

A. Mostly malignant

B. Mostly in children

C. Mostly bilateral

D. Associated with MEN2A



See Answer in Part B → Q4

@Neet_pg_bot

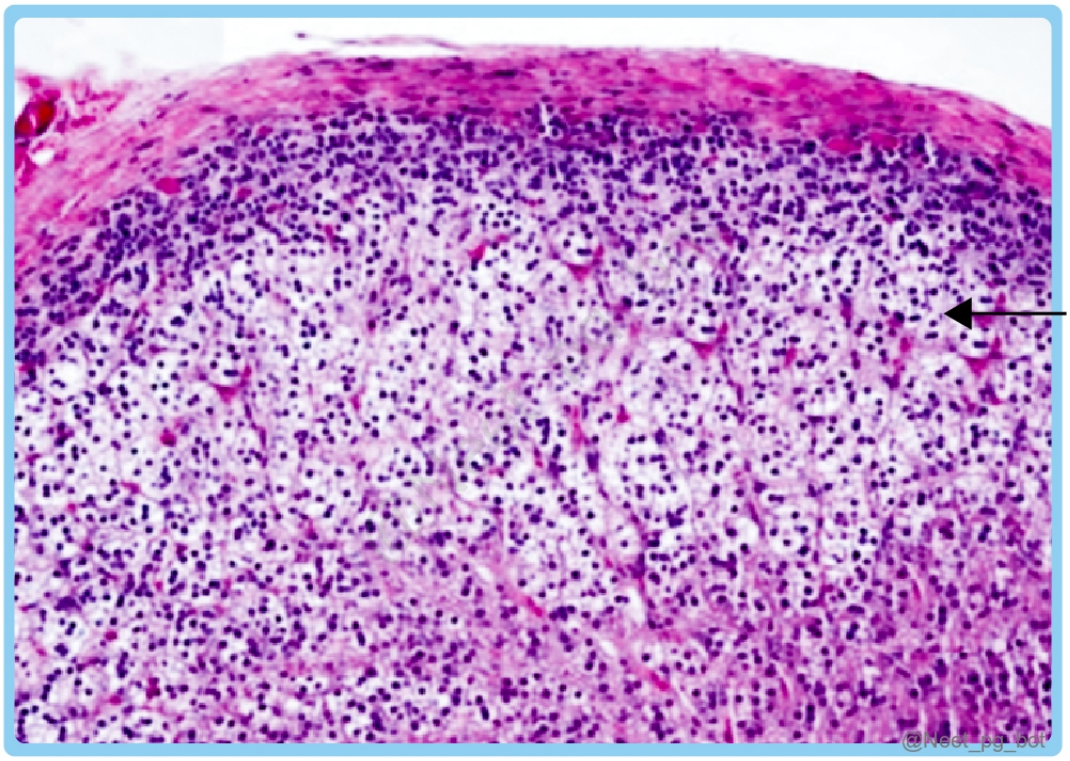
Q5: Which hormone is secreted by the structure marked with an arrow? (Q860565)

A. Glucocorticoid

B. DHEA

C. Androgens

D. Mineralocorticoid



See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is a new intranuclear immunohistochemistry marker for neuroendocrine tumors? (Q840013)

A. Synaptophysin

B. Chromogranin

C. INSM1

D. NCAM1/ CD56

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient presents with neck swelling with compression of the trachea and esophagus. Histopathological assessment shows cell nest and pink extracellular

amyloid stroma. What is the origin of the tumor? (Q840079)

A. Parafollicular C cells

B. Hurthle cell

C. Follicular cells

D. Askanazy cells

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 26-year-old female patient presents with a palpable thyroid nodule and occasional neck discomfort. She has no history of radiation exposure to the neck. On physical examination, a solitary, firm, non-tender thyroid nodule is noted. Ultrasound reveals a hypoechoic nodule with microcalcifications. Fine-needle aspiration biopsy is performed, and histological analysis reveals characteristic nuclear changes. What is the most common thyroid cancer in this patient? (Q820517)

A. Papillary carcinoma

B. Follicular carcinoma

C. Medullary carcinoma

D. Anaplastic carcinoma

See Answer in Part B → Q8

@Neet_pg_bot

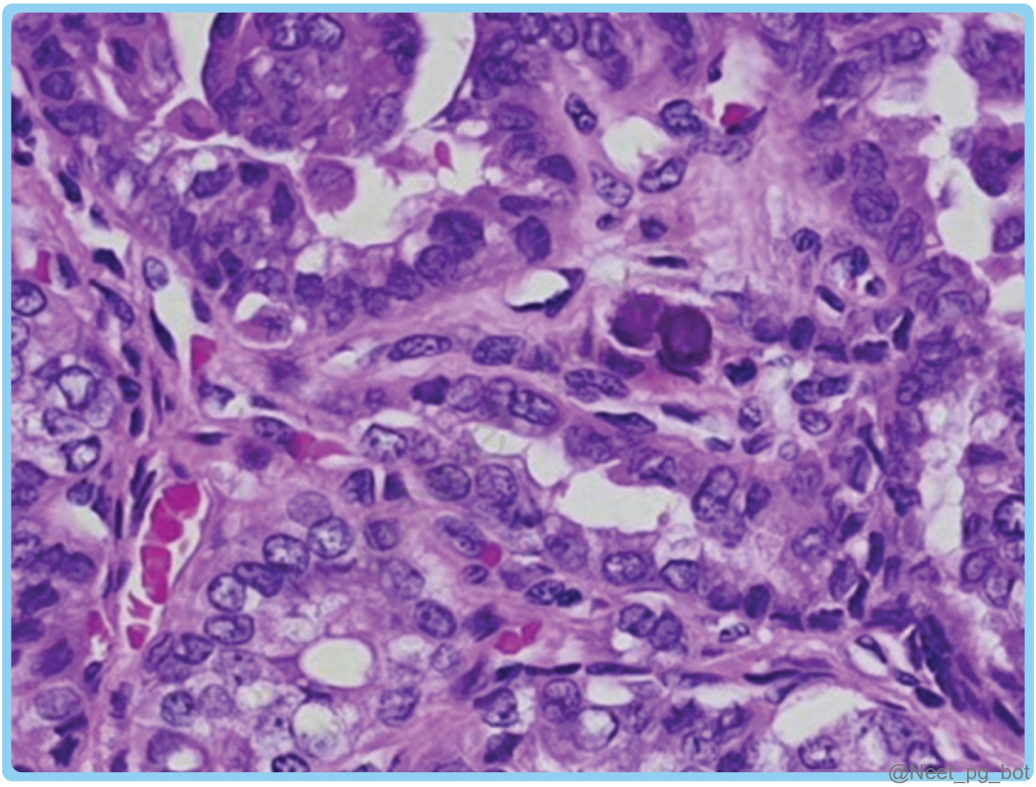
Q9: A 19-year-old female presents with a neck swelling that shifts during swallowing. Ultrasound reveals a 2 cm x 2 cm mass in the left lobe of the thyroid, reaching the strap muscles. Histopathology shows findings as shown in the image. What is the most probable diagnosis? (Q855119)

A. Medullary CA thyroid

B. Follicular CA thyroid

C. Thyroglossal cyst

D. Papillary CA thyroid



See Answer in Part B → Q9

@Neet_pg_bot

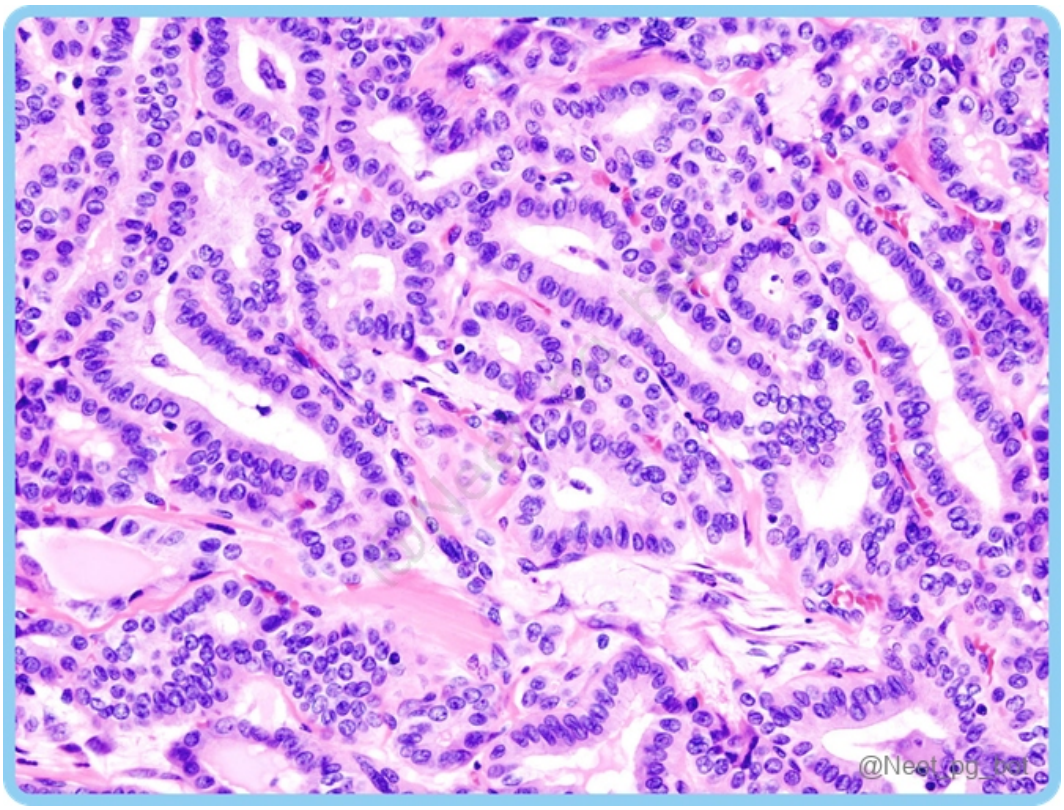
Q10: What is the likely diagnosis for a patient who presents with a swelling in the midline of the neck, based on the biopsy findings, which reveal orphan Annie's eye nuclei as depicted in the image provided? (Q857571)

A. Follicular carcinoma

B. Papillary carcinoma

C. Toxic nodular goiter

D. Medullary carcinoma



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient presented to the OPD with long hands and feet and a protruding lower jaw. Which of the following genes is most likely implicated in this scenario? (Q856900)

A. GATA1

B. PIT1

C. TPIT

D. SF1

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the minimum biopsy specimen requirement for an adequate sample in the case of a thyroid biopsy? (Q856910)

A. 15 follicular cell clusters containing 10-12 cells

B. 10 follicular cell clusters containing 6-8 cells

C. 3 follicular cell clusters containing 10-15 cells

D. 6 follicular cell clusters containing 10-15 cells

See Answer in Part B → Q12

@Neet_pg_bot

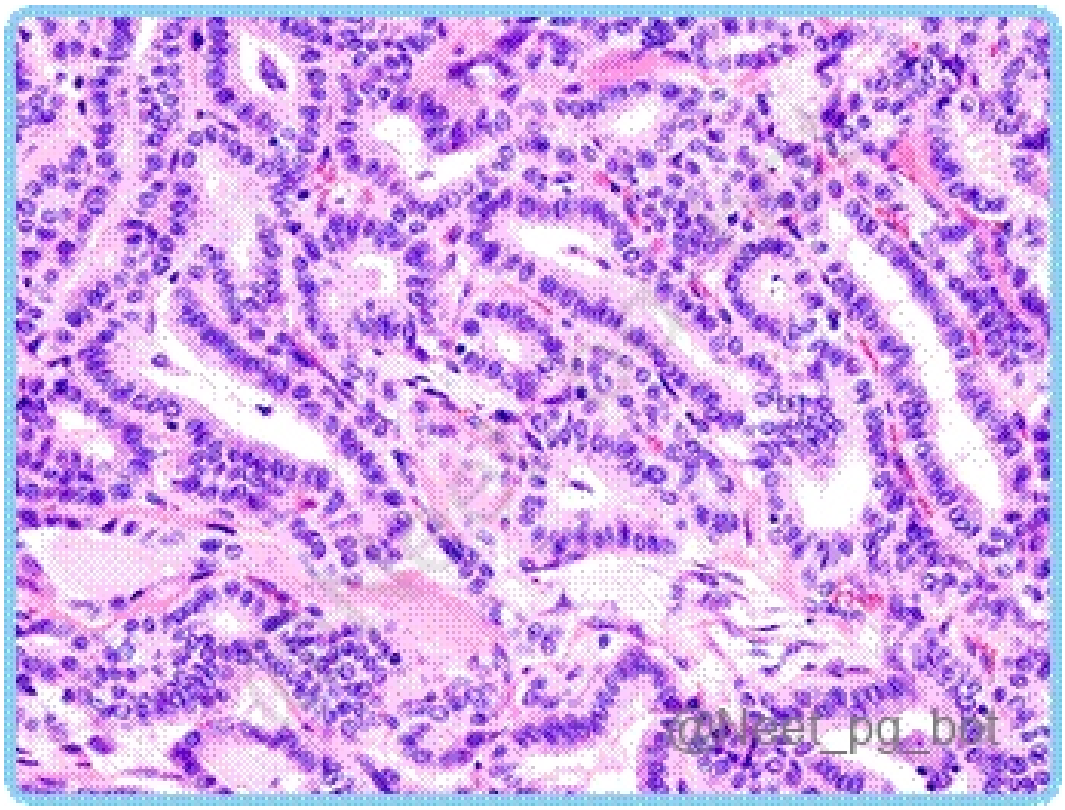
Q13: A patient presents with a midline swelling in the neck. A biopsy reveals Orphan Annie's eye nuclei, as shown in the image below. What is the diagnosis? (Q854832)

A. Follicular carcinoma

B. Papillary carcinoma

C. Toxic nodular goitre

D. Medullary carcinoma



See Answer in Part B → Q13

@Neet_pg_bot

Q14: A middle-aged woman presents with thyroid swelling. Blood tests show elevated TSH levels and the presence of thyroid peroxidase antibodies. Histopathological examination revealed the presence of Hurthle cells. What is the most likely diagnosis? (Q854852)

A. Hashimoto thyroiditis

B. Graves' disease

C. Follicular carcinoma of thyroid

D. Medullary carcinoma of thyroid

See Answer in Part B → Q14

@Neet_pg_bot

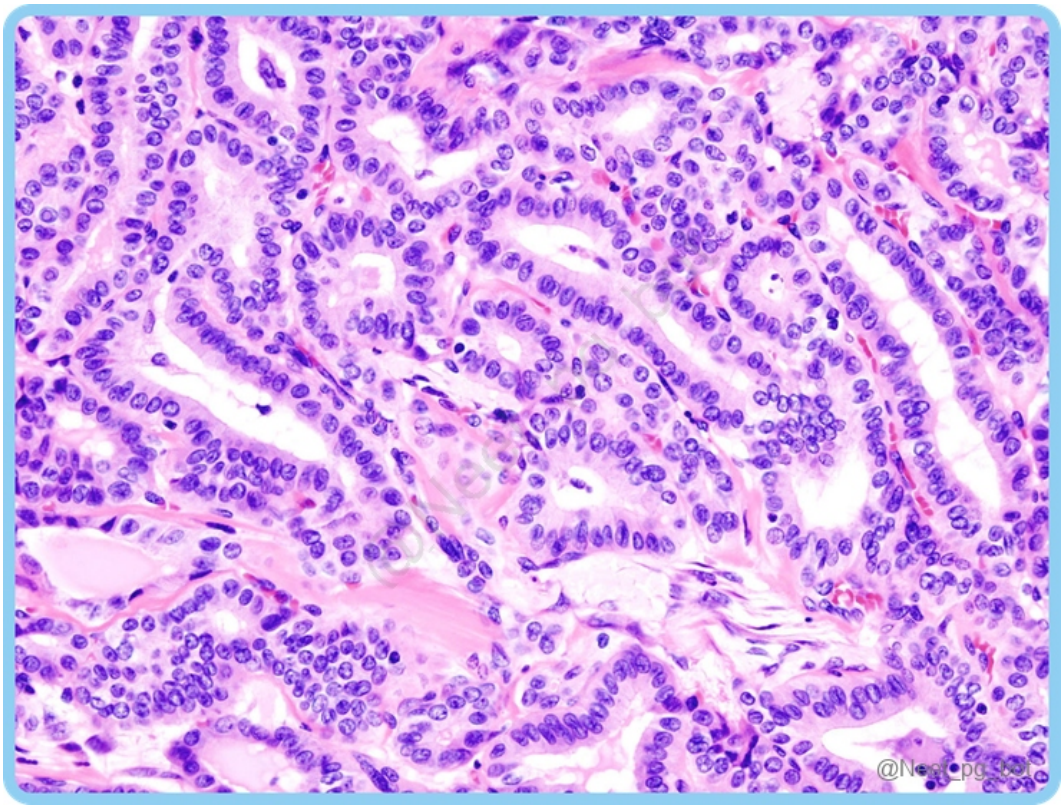
Q15: What is the probable diagnosis for a patient who has swelling in the middle of their neck, along with weight loss, and a thyroid biopsy showing the presence of 'Orphan Annie eye nuclei? (Q859243)

A. Follicular thyroid carcinoma

B. Papillary thyroid carcinoma

C. Anaplastic thyroid carcinoma

D. Medullary thyroid carcinoma



See Answer in Part B → Q15

@Neet_pg_bot

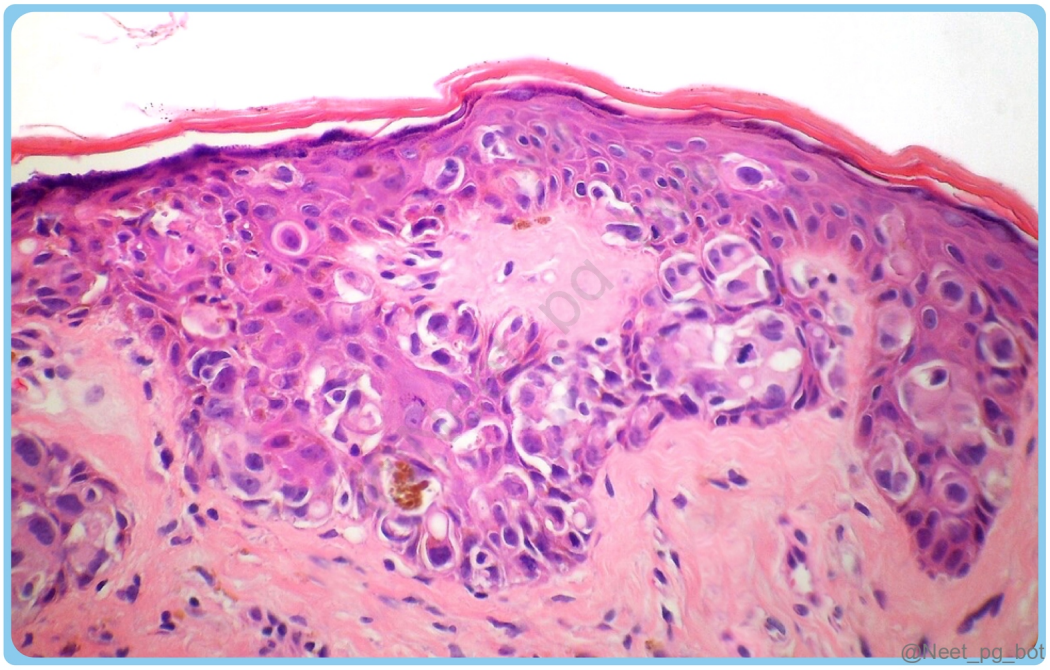
Q2: A 58-year-old woman has a eczematous lesion of the nipple not responding to treatment. Histopathology is shown. What is the most likely diagnosis? (Q890380)

A. Commonly associated with underlying DCIS

B. Malignant cells are present within the nipple epidermis

C. Shows CK7 positivity

D. It commonly presents as a bilateral nipple lesion



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 56-year-old woman presents with persistent unilateral erythematous, scaly crusting of the nipple associated with itching for 3 months. Topical treatment for eczema has not improved the lesion. What is the next step in management? (Q890379)

A. Repeat topical corticosteroids

B. Fine-needle aspiration of the breast mass

C. Nipple biopsy

D. Reassurance and follow-up

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following markers is most useful for distinguishing invasive carcinoma from DCIS? (Q890364)

A. p53

B. p63

C. Cytokeratin 7

D. Estrogen receptor (ER)

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following findings does not indicate a low risk for breast cancer? (Q890362)

A. Cysts with apocrine metaplasia

B. Fibrosis

C. Adenosis

D. Florid hyperplasia

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 52-year-old man presents with a painless swelling of the breast as seen in the image. Which of the following conditions are associated with the development of this condition? Liver cirrhosis Marijuana use Klinefelter syndrome Classical Seminoma (Q890352)

A. 1 and 3 only

B. 1, 2 and 3 only

C. 1, 3 and 4 only

D. 1, 2, 3 and 4

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following conditions is most commonly associated with bloody nipple discharge? (Q890350)

A. Intraductal papilloma

B. Mammary duct ectasia

C. Fibrocystic change

D. Sclerosing adenosis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is a non-proliferative change of the breast? (Q890349)

A. Sclerosing adenosis

B. Radial scar

C. Adenosis

D. Atypical ductal hyperplasia

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not a proliferative breast lesion? (Q890348)

A. Intraductal papilloma

B. Sclerosing adenosis

C. Radial scar

D. Cystic change with apocrine metaplasia

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 36-year-old woman presents with a painful subareolar mass and recurrent nipple discharge. Examination reveals nipple inversion, and histology shows keratinising squamous metaplasia of lactiferous ducts with keratin plugging. Which of the following is the most important risk factor for this condition? (Q890347)

A. Cigarette smoking

B. Alcohol

C. Nulliparity

D. Family history of breast carcinoma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following conditions involves the large ducts of the breast? Mammary duct ectasia Large duct papilloma Paget disease of the nipple Atypical lobular hyperplasia Sclerosing adenosis (Q890346)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 2, 3, 4

D. 2, 4, 5

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following conditions does not arise from the terminal duct lobular unit? (Q890345)

A. DCIS

B. Sclerosing adenosis

C. Intraductal papilloma

D. Mammary duct ectasia

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 24-year-old with a 2-month-old infant presents to the OPD with pain in her left breast. The baby is exclusively breastfed. On examination, the nipple is tender and erythematous with a fluctuant mass beneath the areola. Which of the following is the most common cause of this condition? (Q846611)

A. Pseudomonas aeruginosa

B. Staphylococcus aureus

C. Streptococcus sp.

D. Listeria monocytogenes

See Answer in Part B → Q13

@Neet_pg_bot

Q14: The terminal duct lobular unit (TDLU) is the functional unit of the breast. Which of the following is not a part of the TDLU? (Q845782)

A. Intralobular terminal duct

B. Extralobular terminal duct

C. Lactiferous duct

D. Ductules

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements about phyllodes tumors of the breast is incorrect? (Q845804)

A. They originate in the connective tissue of the breast

B. Often present as rapidly growing breast masses

C. They vary in size from a few centimeters to massive lesions

D. These lesions are always benign

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a feature of complex fibroadenoma? (Q845803)

A. Cysts larger than 0.3cm

B. Sclerosing adenosis

C. Nodules of proliferating stroma forming bulbous protrusions

D. Papillary apocrine change

See Answer in Part B → Q16

@Neet_pg_bot

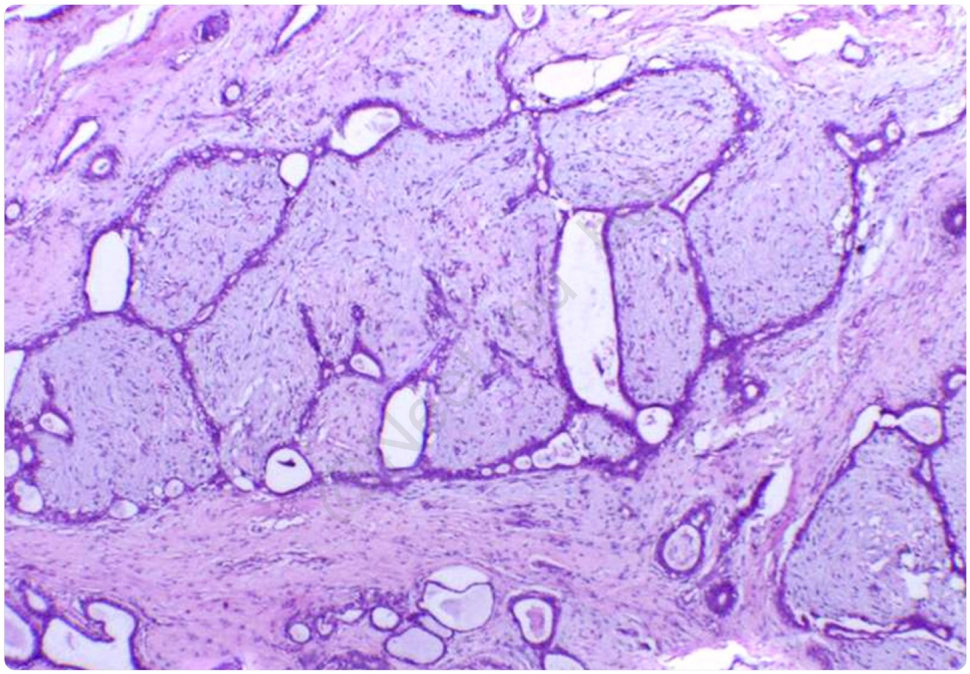
Q17: A 34-year-old woman comes to the clinic due to a mass in her right breast. A 2-cm nodule is noted on breast examination, and the patient is referred for biopsy. Histologic evaluation of the tissue specimen is shown in the image below. What is the most likely diagnosis? (Q845802)

A. Ductal Carcinoma In Situ

B. Intracanalicular Fibroadenoma

C. Sclerosing adenosis

D. Pericanalicular Fibroadenoma



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 38-year-old woman presents with cyclical breast pain, most severe in the week before her period. She also notices her breasts feeling lumpy and swollen around the time of her period, which subsides later. She denies any fever, nipple discharge, or lumps. What is the most likely finding seen in this pathology? (Q845801)

A. Peau d'orange appearance of the skin

B. Nipple retraction and bloody discharge

C. Blue dome of Bloodgood cyst

D. Eczematous changes of the nipple and areola

See Answer in Part B → Q18

@Neet_pg_bot

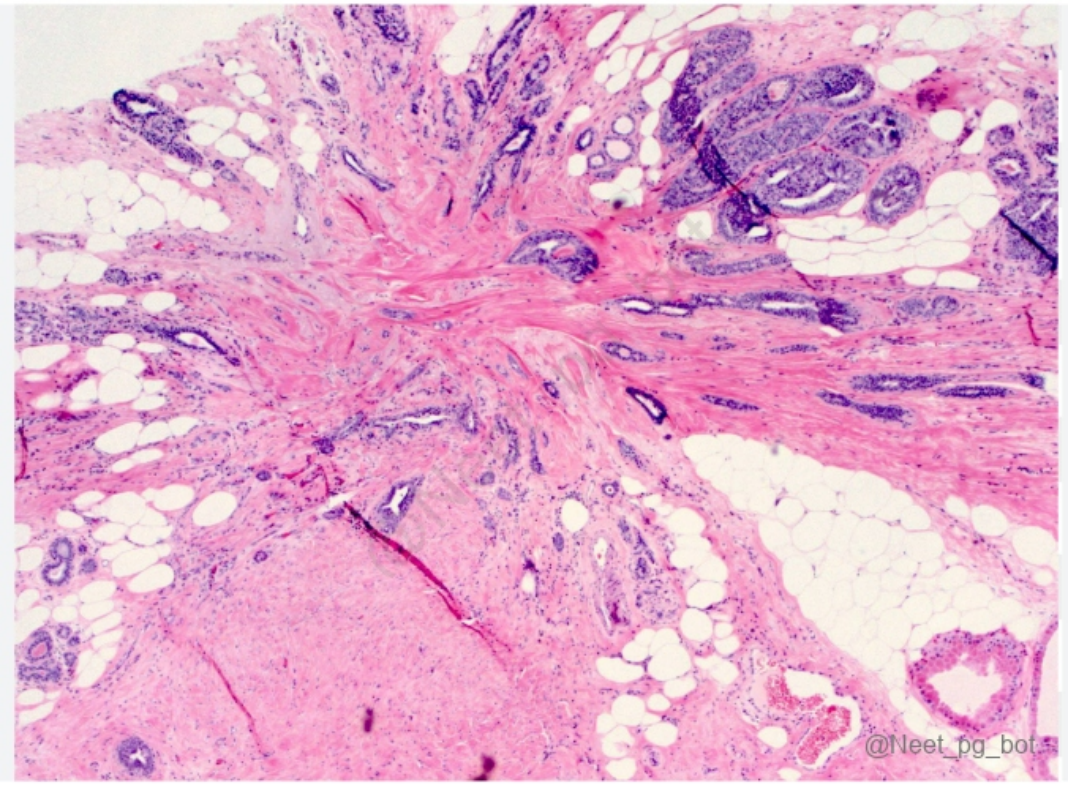
Q19: A 38-year-old woman presents with a firm, irregular mass that has been slowly increasing in size over the past few months. Histopathological examination shows the following, what is the most likely diagnosis? (Q845798)

A. Sclerosing adenosis

B. Radial scar

C. Papilloma

D. Paget’s disease



See Answer in Part B → Q19

@Neet_pg_bot

Q20: What is the absolute risk of a fibrocystic lesion of the breast converting to malignancy? (Q845797)

A. <1%

B. 3%

C. 5-7%

D. 13-17%

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Match the following Category Diseases/disorders 1. Non-proliferative breast changes a) Sclerosing adenosis 2. Proliferative diseases without atypia b) Mild

hyperplasia 3. Proliferative breast diseases with atypia c) Precancerous condition 4. Carcinoma in situ d) Atypical ductal hyperplasia (Q845795)

A. 1- b, 2-d, 3-c, 4-a

B. 1- b, 2-a, 3-d, 4-c

C. 1- d, 2-a, 3-b, 4-c

D. 1- d, 2-c, 3-a, 4-b

See Answer in Part B → Q21

@Neet_pg_bot

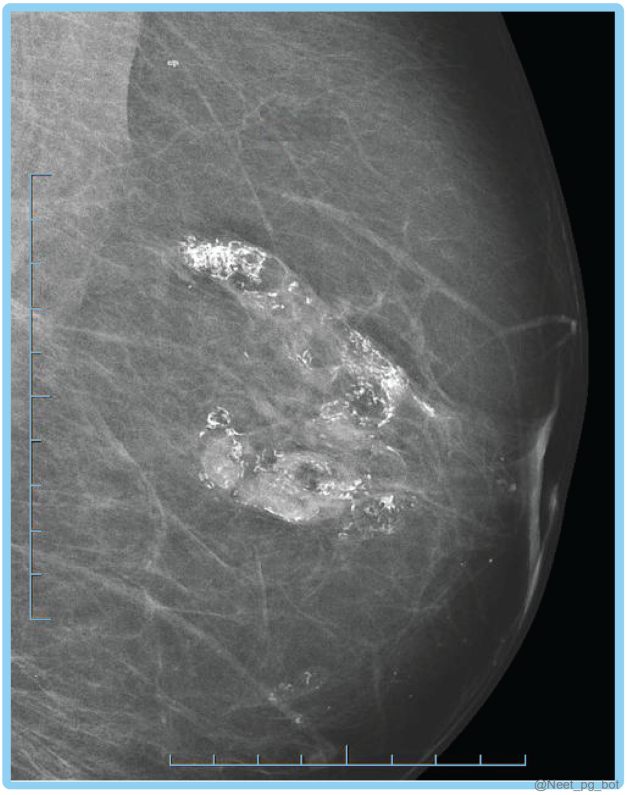
Q22: A 38-year-old woman presents with a firm, immobile mass in her right breast for the past few days. 2 weeks ago, she bruised her breast while exercising. A mammogram reveals scattered punctate calcifications within the lump. What is the most likely diagnosis? (Q845794)

A. Mastitis

B. Breast abscess

C. Fat Necrosis

D. Inflammatory Breast Cancer



See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following conditions is most likely to cause a sticky, green, or black discharge from the nipple? (Q845793)

A. Duct Papilloma

B. Paget's Disease

C. Duct Ectasia

D. Breast Cancer

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following statements regarding Zuska's disease is incorrect? (Q845789)

A. There is squamous metaplasia of the lactiferous duct

B. Characterized by the formation of keratin plug

C. Presents as subareolar abscess

D. Alcohol is a major risk factor

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 48-year-old woman presents with pain in her left breast and associated nipple discharge for the past few weeks. She denies any fever, chills, or recent lactation. On examination, a small ovoid, well-defined subareolar mass is felt. What is the most likely diagnosis? (Q845788)

A. Acute mastitis

B. Duct ectasia

C. Ductal carcinoma in situ

D. Fibroadenoma

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 24-year-old with a 2-month-old infant presents to the OPD with pain in her left breast. The baby is exclusively breastfed. On examination, the nipple is tender and erythematous with a fluctuant mass beneath the areola. Which of the following is the most common cause of this condition? (Q845786)

A. Pseudomonas aeruginosa

B. Staphylococcus aureus

C. Streptococcus sp.

D. Listeria monocytogenes

See Answer in Part B → Q26

Q25 (p. 652)

Q1: A 52-year-old woman presents with a painless palpable breast mass detected during self-examination. Imaging and biopsy confirm carcinoma of the breast. Which of the following is the most common location for breast carcinoma? (Q890381)

A. Upper outer quadrant

B. Upper inner quadrant

C. Lower outer quadrant

D. Lower inner quadrant

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following cancers are commonly associated with the BRCA2 mutation? Male breast cancer Ovarian carcinoma Pancreatic carcinoma Prostate carcinoma Colorectal carcinoma (Q890407)

A. 1, 2, 3, 4

B. 1, 2, 5

C. 1, 2, 4, 5

D. 2, 3, 5

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is the most common stromal malignancy of the breast? (Q890406)

A. Fibrosarcoma

B. Angiosarcoma

C. Liposarcoma

D. Leiomyosarcoma

See Answer in Part B → Q3

@Neet_pg_bot

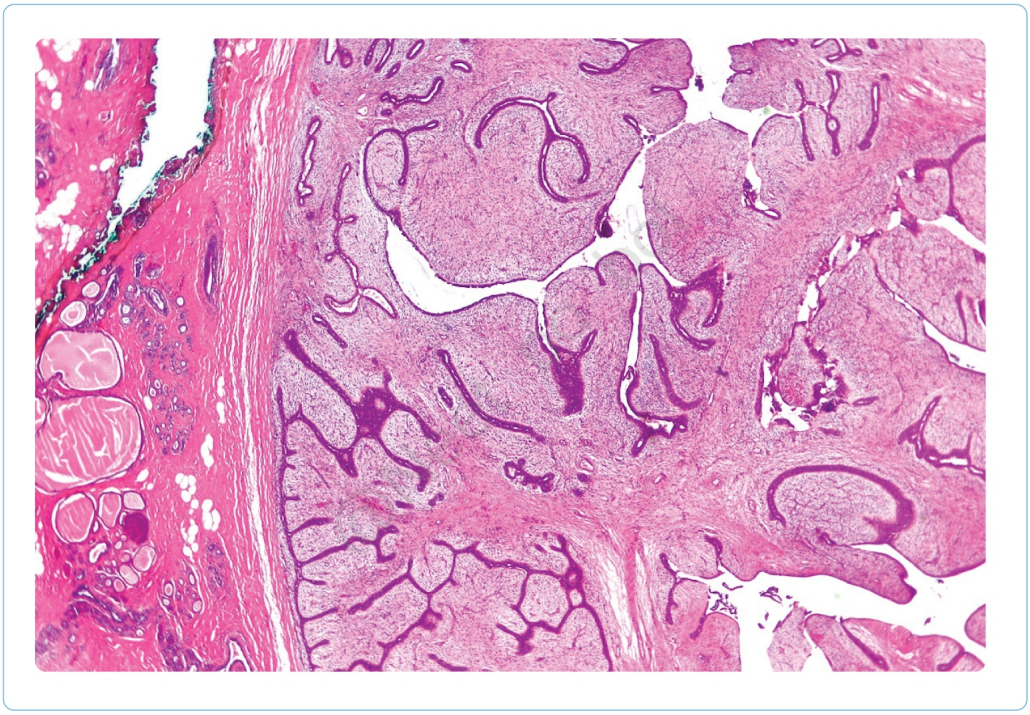
Q4: 60-year-old woman presents with a rapidly enlarging breast mass. Histology shows findings as shown. Which of the following statements regarding the most probable condition is incorrect? (Q890404)

A. Most tumours are benign

B. Metastases contain only the stromal component

C. Arises from the intralobular stroma

D. Local recurrence is rare



@Neet_pg_bot

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 55-year-old woman is diagnosed with invasive breast carcinoma. Several tumour characteristics are evaluated to determine prognosis and guide therapy. Which of the following is considered a good prognostic marker in breast cancer? (Q890402)

A. HER2 overexpression

B. ER positivity

C. Presence of BRCA mutation

D. Basal-type breast cancer

See Answer in Part B → Q5

@Neet_pg_bot

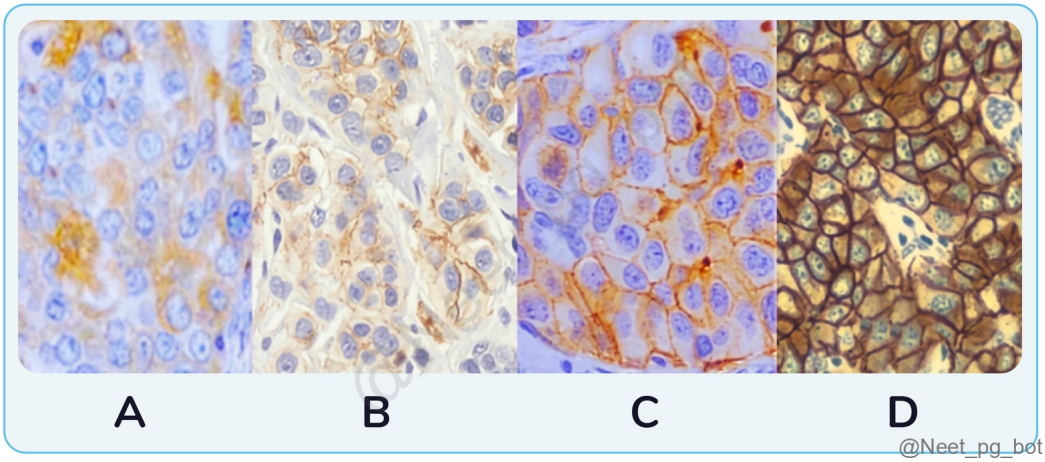
Q6: Which of the following IHC requires confirmation with fluorescence in situ hybridisation (FISH) for HER2 gene amplification? (Q890397)

A. D

B. C

C. B

D. A



See Answer in Part B → Q6

@Neet_pg_bot

Q7: A breast carcinoma is classified as T4d in the TNM staging system. Which of the following features is not characteristic of this stage? (Q890396)

A. Diffuse breast erythema and oedema

B. Peau d’orange appearance of the skin

C. Tumour emboli within dermal lymphatic vessels

D. Prominent neutrophilic inflammatory infiltrate in the dermis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the most common clinical presentation of occult breast carcinoma? (Q890395)

A. Palpable breast lump with nipple retraction

B. Axillary lymphadenopathy due to metastatic carcinoma

C. Bloody nipple discharge

D. Diffuse breast skin thickening resembling peau d'orange

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A breast tumour shows strong ER positivity, PR positivity, HER2 negativity, and a low Ki-67 proliferation index. Which of the following histologic types of breast carcinoma is not associated with this subtype? (Q890394)

A. Tubular carcinoma

B. Papillary carcinoma

C. Mucinous carcinoma

D. Secretory carcinoma

See Answer in Part B → Q9

@Neet_pg_bot

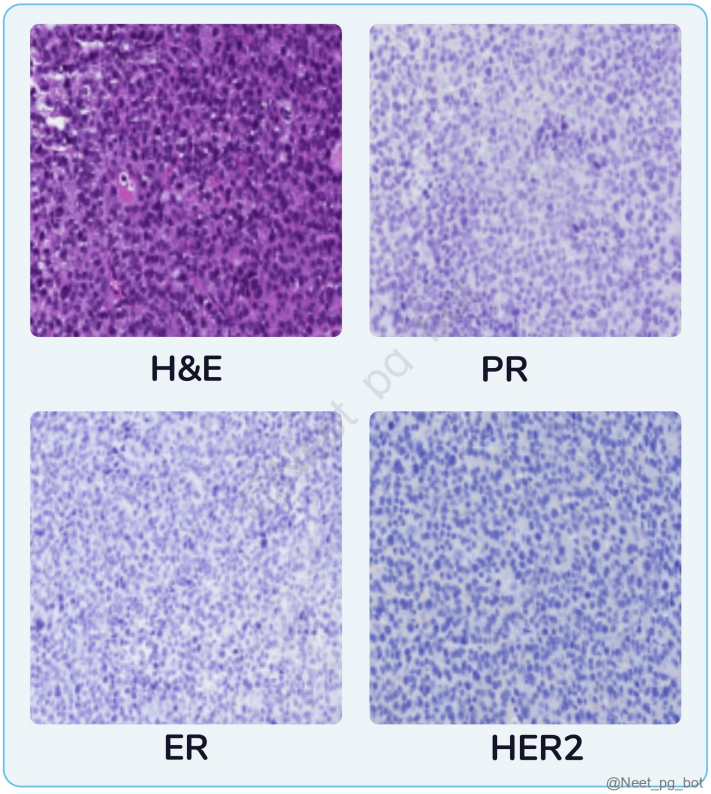
Q10: A 50-year-old woman is diagnosed with an aggressive breast carcinoma. Immunohistochemistry shows findings as shown. Which of the following histologic types of breast carcinoma is not associated with this subtype? (Q890386)

A. Medullary carcinoma

B. Metaplastic carcinoma

C. Adenoid cystic carcinoma

D. Mucinous carcinoma



See Answer in Part B → Q10

@Neet_pg_bot

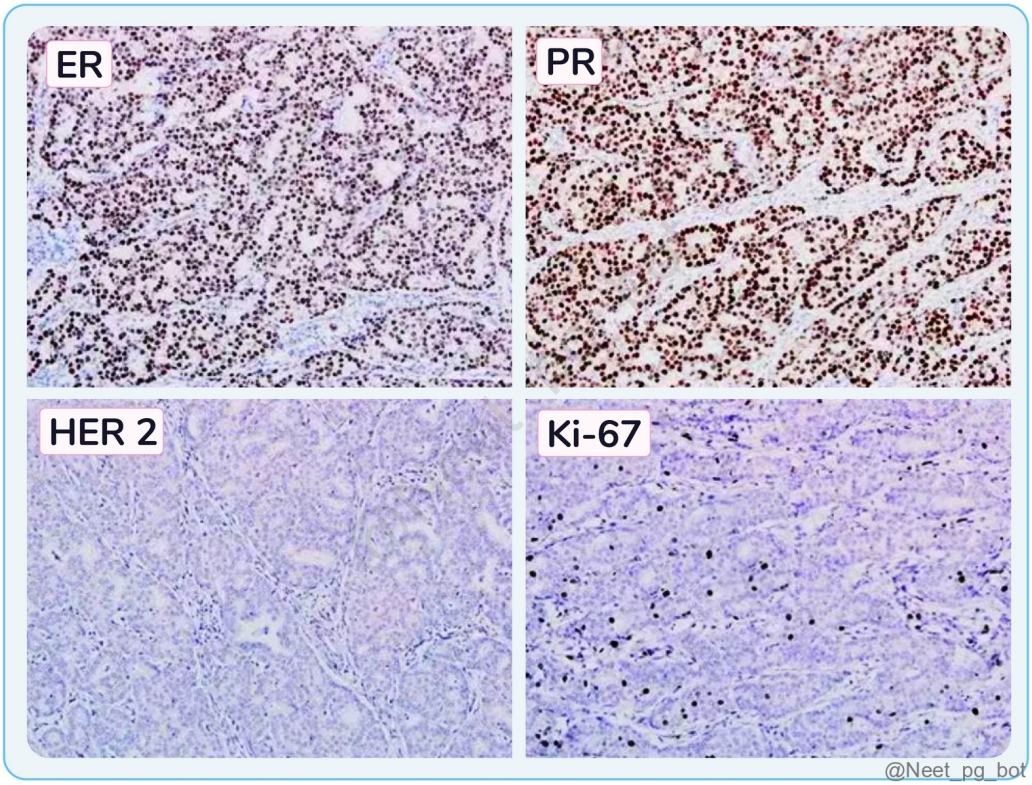
Q11: A 54-year-old woman undergoes a biopsy for a breast mass. Immunohistochemistry shows findings as shown. Which of the following is not a feature of the most probable molecular subtype? (Q890384)

A. Well differentiated

B. Strong luminal gene expression

C. Best prognosis

D. 1q loss



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 48-year-old woman is diagnosed with an aggressive breast carcinoma. Molecular testing reveals a mutation in the TP53 gene, which is the most common genetic alteration seen in this tumor subtype. Which of the following types of breast carcinoma is most likely present? (Q890383)

A. Luminal A breast carcinoma

B. Luminal B breast carcinoma

C. HER2-enriched carcinoma

D. Triple-negative breast carcinoma

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 38-year-old woman with a strong family history of early-onset breast and ovarian cancer undergoes genetic testing. Which of the following correctly states the chromosomal locations of BRCA1 and BRCA2? (Q890382)

A. BRCA1 - 17q21; BRCA2 - 13q12.3

B. BRCA1 - 13q12.3; BRCA2 - 17q21

C. BRCA1 - 11p15; BRCA2 - 17p13

D. BRCA1 - 9p21; BRCA2 - 10q23

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 35-year-old woman comes to the clinic presenting with swelling in the upper quadrant of her left breast. She reports changes in the skin and surrounding nipple areola complex as well. All of the following are risk factors for this condition except? (Q845693)

A. Alcohol

B. Early menarche

C. Age

D. Multiparity

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following parameters is not assessed in the Bloom-Richardson scoring system? (Q845723)

A. Nuclear size

B. Tubule formation

C. Size of the tumor

D. Mitotic count

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A biopsy taken from a patient's breast lump is subjected to histopathological examination. Upon staining, it is found to be a luminal breast carcinoma with a high proliferative rate. Overexpression of which of the following cellular proteins has led to this interpretation? (Q845721)

A. Alpha catenin

B. Arp-2/3

C. Ki-67

D. Vimentin

See Answer in Part B → Q16

@Neet_pg_bot

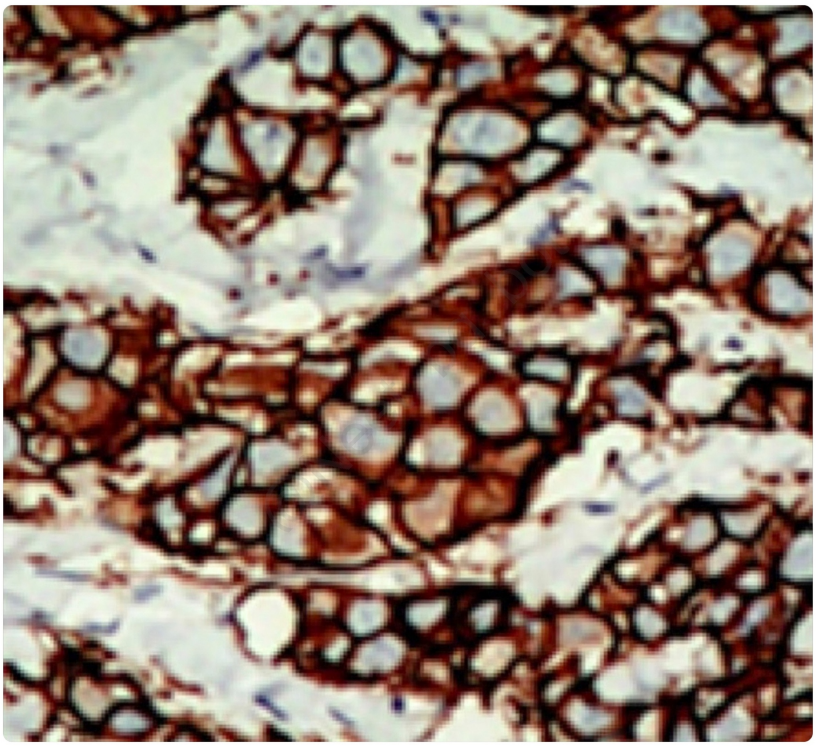
Q17: A patient with a lump in her left breast is subjected to a biopsy. Subsequent immunohistochemistry was done and the image is given below. After an MDT discussion, a decision was made to prescribe Trastuzumab as the appropriate management for this patient. What would have been the diagnosis based on the above clinical scenario? (Q845716)

A. Apocrine carcinoma

B. Medullary carcinoma

C. Tubular carcinoma

D. Papillary carcinoma



See Answer in Part B → Q17

@Neet_pg_bot

Q18: You are provided with results of receptor status from the biopsy obtained from a patient's breast lump. You realize that her molecular subtype carries a low proliferative rate and a better prognosis. Which of the following will not be the likely histological subtype in this patient? (Q845714)

A. Tubular carcinoma

B. Medullary carcinoma

C. Papillary carcinoma

D. Mucinous carcinoma

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Consider the following statements about Paget's disease of the breast? 1. It is an in-situ cancer. 2. Presence of Paget cells is needed for diagnosis. 3. Underlying carcinoma is usually LCIS. 4. Immunostaining is positive for carcinoembryonic antigen (CEA). Which of the above are true statements? (Q845712)

A. 1,3, and 4

B. 1,2, and 4

C. 1,2, and 3

D. All of the above

See Answer in Part B → Q19

@Neet_pg_bot

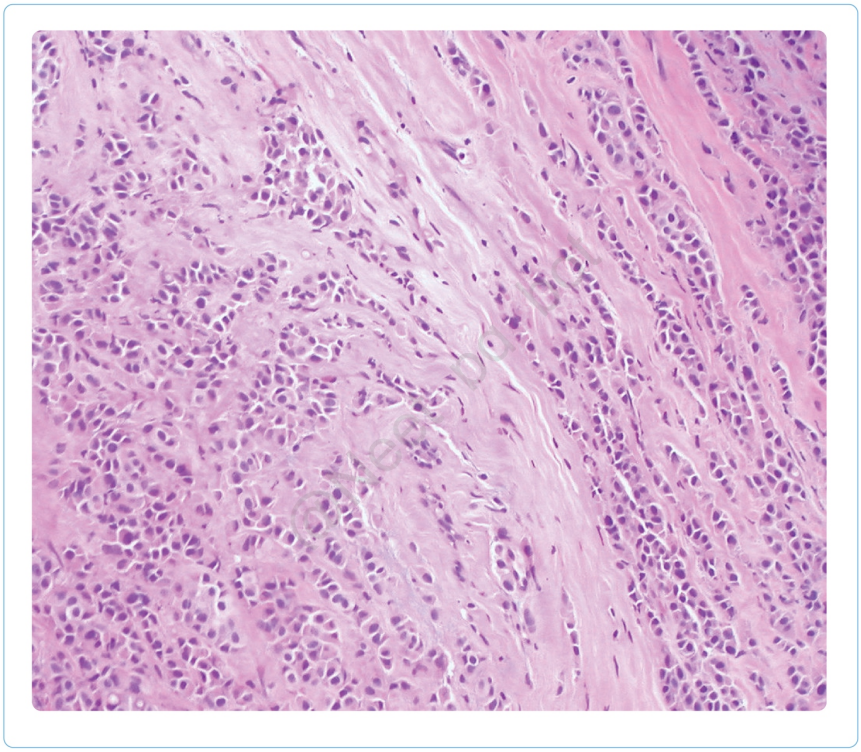
Q20: A 60-year-old woman presents with a newly diagnosed left-sided breast mass on routine mammography. Core needle biopsy shows the following findings. Further molecular study revealed the involvement of the CDH1 gene. Which of the following statements are incorrect concerning this type of breast cancer? 1) Increased E-cadherin expression is observed in tumor cells. 2) Minimal desmoplasia and fibrosis were observed on microscopy. 3) A contralateral breast examination is usually required due to bilateral involvement. 4) It is associated with a poor prognosis compared to other types of breast cancer. 5) Metastatic spread affects leptomeninges and retroperitoneum. (Q845710)

A. 1, 2, 3, 4

B. 1, 2, 3

C. 1, 4

D. 1, 2, 4, 5



@Neet_pg_bot

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following is associated with the worst prognosis? (Q845707)

A. Paget’s disease

B. Metaplastic carcinoma

C. Medullary carcinoma

D. Inflammatory carcinoma

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 50-year-old woman presents with discomfort in her left breast. Mammography reveals a suspicious mass. Ultrasound-guided core needle biopsy is performed. Based

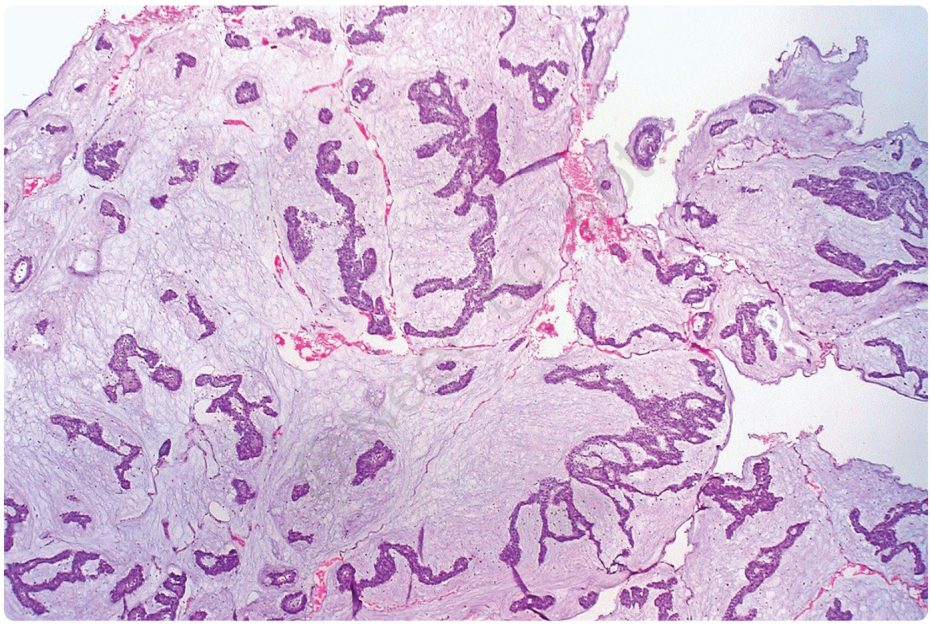
on the histopathological findings, what is the most likely diagnosis? (Q845703)

A. Lobular carcinoma

B. Ductal carcinoma in situ

C. Medullary carcinoma

D. Mucinous carcinoma



@Neet_pg_bot

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 45-year-old woman presented with a palpable breast lump detected during a routine self-examination. A biopsy confirmed the diagnosis of infiltrating ductal carcinoma (IDC). Which of the following is not a subtype of IDC? 1. Tubular carcinoma 2. Medullary carcinoma 3. Colloid carcinoma 4. Lobular carcinoma 5. Papillary carcinoma 6. Apocrine carcinoma 7. Secretory carcinoma 8. Myofibroblastoma 9. Angiosarcoma (Q845701)

A. 3, 4, 8, 9

B. 4, 6, 8

C. 2, 4, 7, 9

D. 4, 8, 9

See Answer in Part B → Q23

@Neet_pg_bot

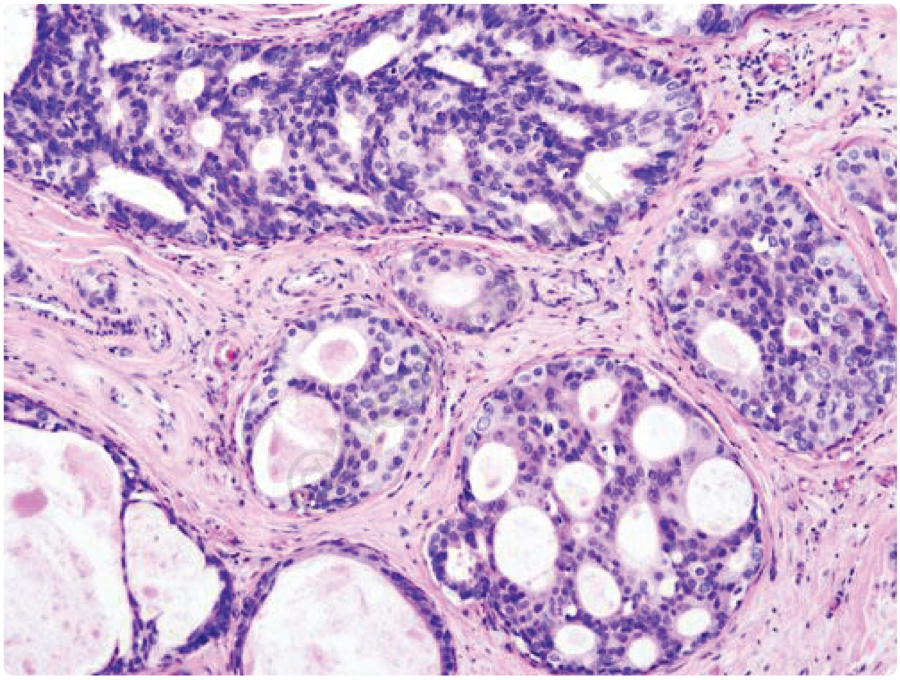
Q24: A 52-year-old woman presents for her routine mammogram, which reveals microcalcifications in the right breast. She has no significant family history of breast cancer and is asymptomatic. A core needle biopsy is performed, and the histopathological image is shown below. Based on histopathology, what is the most likely diagnosis? (Q845697)

A. Invasive Ductal Carcinoma

B. Lobular Carcinoma in Situ

C. Ductal Carcinoma in Situ

D. Fibroadenoma



See Answer in Part B → Q24

@Neet_pg_bot

Q25: Mutations in which of the following genes is not associated with breast cancer? (Q845696)

A. BRCA1

B. STK11

C. CDH1

D. CHEK1

See Answer in Part B → Q25

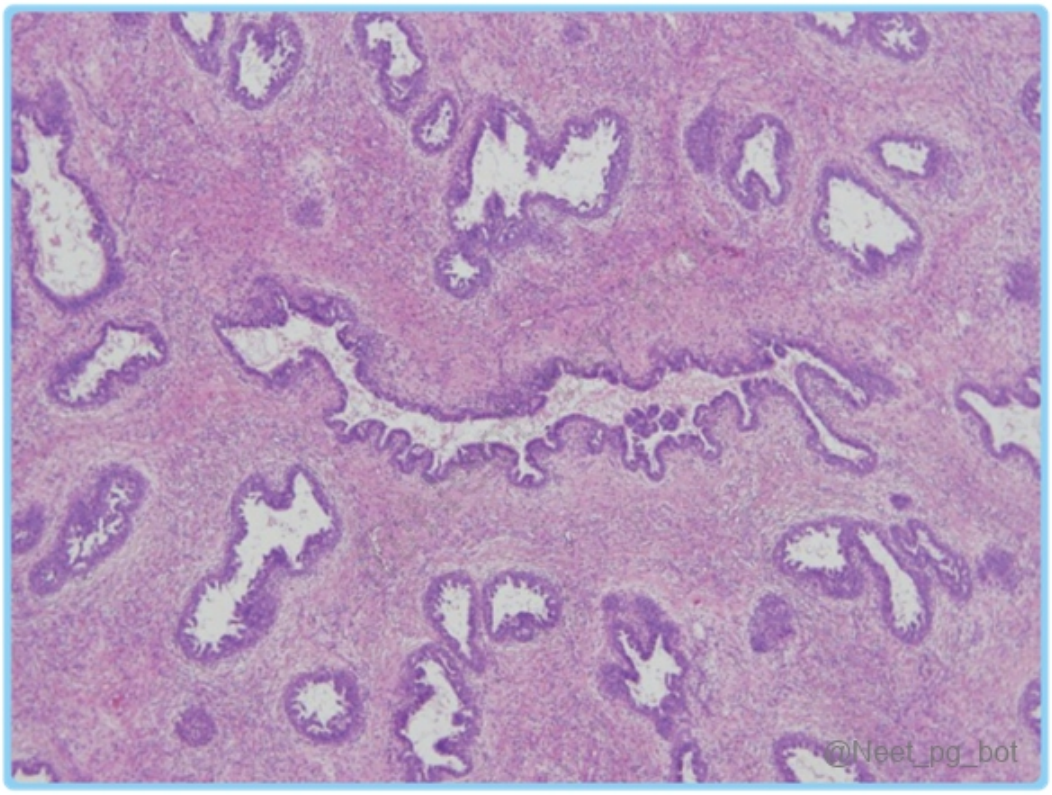
Q1: A 27-year-old woman discovers a well-defined mobile and rubbery breast lump measuring 4x7 cm on self-examination. The lesion is painless and has been stable over several months. What is the most likely diagnosis? (Q860560)

A. Acute mastitis

B. Fibroadenoma

C. Ductal ectasia

D. Sclerosing adenosis



See Answer in Part B → Q1

@Neet_pg_bot

Q2: What does luminal type A tumour refer to? (Q857445)

A. ER+ / HER2 neu- ; mild to moderate proliferation

B. ER+ / HER2 neu+

C. ER- / HER2 neu-

D. ER+ / HER2 neu- ; high proliferation

See Answer in Part B → Q2

@Neet_pg_bot

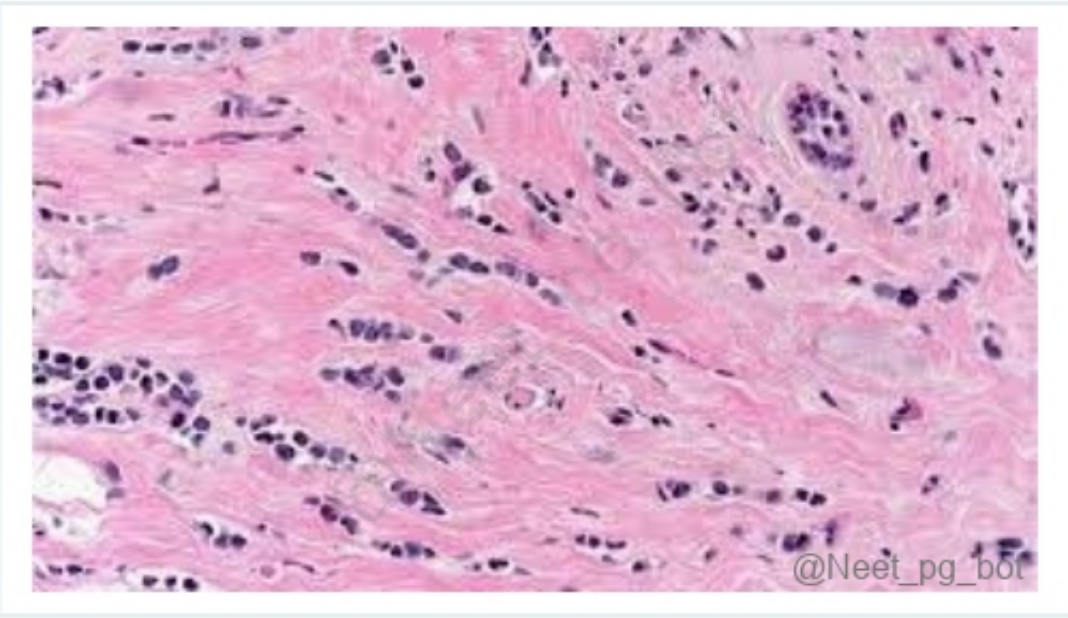
Q3: A woman presents with a firm and irregular lump in the upper outer quadrant of her breast. The histopathological slide of the mass sample is provided. What is the most likely diagnosis? f (Q830822)

A. Phyllodes tumor

B. Inflammatory breast carcinoma

C. Invasive lobular carcinoma

D. Fibroadenoma



See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is NOT a favorable prognostic marker for a middle-aged woman diagnosed with breast carcinoma presenting with a lump in her right breast? (Q793798)

A. Luminal subtype

B. Low Ki67 /MIB 1 index

C. Her2 overexpression

D. Mucinous carcinoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 35-year-old woman presents with a lump in the upper outer quadrant of her breast. Histopathological examination of the mass shows cells in mucin pools and faint nuclei. What is the most likely diagnosis? (Q858517)

A. Colloid carcinoma

B. Papillary carcinoma

C. Medullary carcinoma

D. Lobular carcinoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old female presents with a lump in the upper outer part of her breast. Histopathological analysis of the mass reveals a signet ring appearance. What is the probable diagnosis? (Q857606)

A. Colloid carcinoma

B. Papillary carcinoma

C. Medullary carcinoma

D. Phyllodes tumour

See Answer in Part B → Q6

Q1: Q1. A 40-year-old woman presents with headache and undergoes evaluation for a brain tumor/ cerebellopontine angle. Histopathological examination reveals a tumor composed of Antoni A and Antoni B areas. Which of the following is the most sensitive immunohistochemical marker for this tumor? (Q882188)

A. S-100 protein

B. Glial fibrillary acidic protein (GFAP)

C. Epithelial membrane antigen (EMA)

D. c-KIT

See Answer in Part B → Q1

@Neet_pg_bot

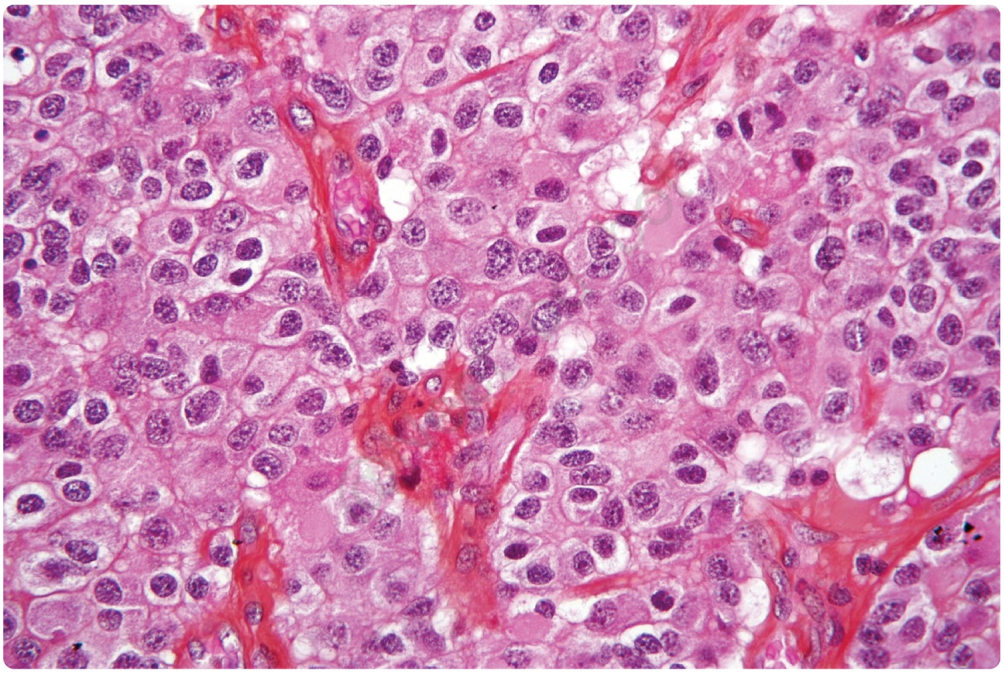
Q2: A 38-year-old woman has a new onset of recurrent seizures. MRI detects a frontal lobe mass. A biopsy of the mass shows cells with a perinuclear halo, as shown in the image. What is the most likely diagnosis? {{caption_text}} (Q845168)

A. Oligodendroglioma

B. Glioblastoma multiforme

C. Meningioma

D. Ependymoma



@Neet_pg_bot

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which genetic mutation is associated with multiple bilateral renal cysts and cerebellar hemangioblastomas and a family history of renal cell carcinoma? (Q845175)

A. VHL gene mutation

B. TSC 1 gene mutation

C. APC gene mutation

D. PTCH gene mutation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is true regarding primary CNS lymphoma? (Q845174)

A. Caused by EB Virus (EBV)

B. Caused by underexpression of PDL1 gene

C. Leptomeningeal spread is common

D. Typically arises from meningeal layers.

See Answer in Part B → Q4

@Neet_pg_bot

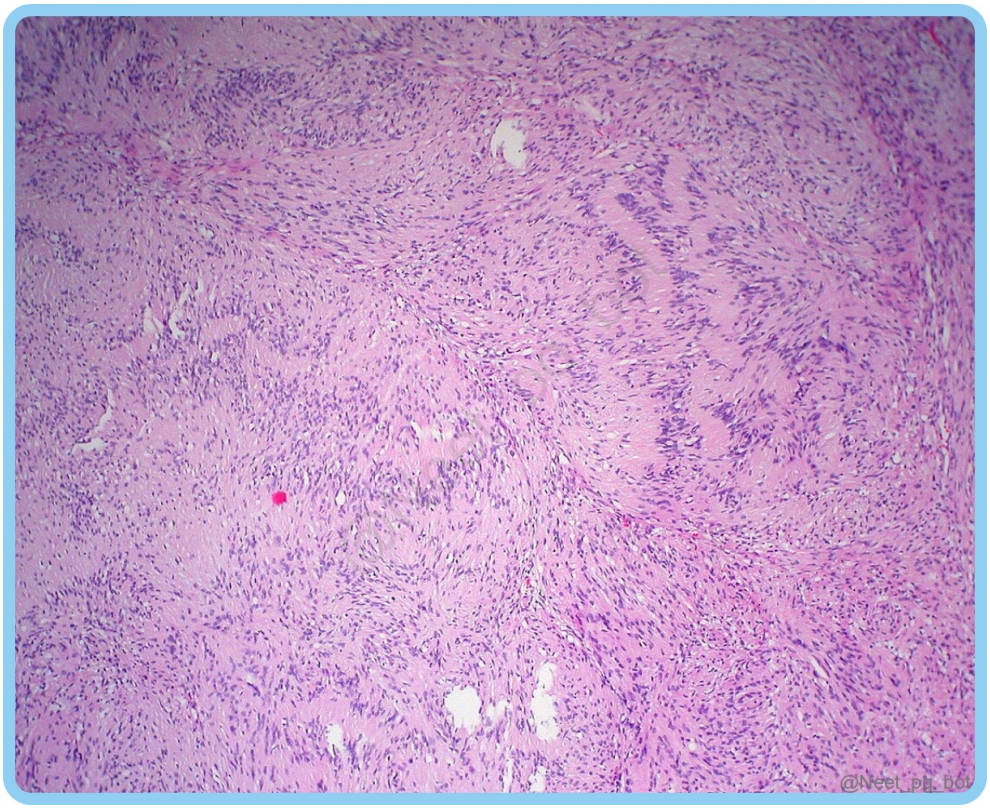
Q5: A 45-year-old woman with right-sided hearing loss, tinnitus, and vertigo has an MRI showing a mass at the right cerebellopontine angle from the vestibulocochlear nerve. Biopsy reveals encapsulated tissue with areas of dense cellularity and loose myxoid regions, as depicted in the image below. Which of the following statements is NOT true regarding this condition? (Q845173)

A. Associated with NF-1 gene mutation

B. Typically exhibit verocay bodies

C. Expresses Merlin

D. Immunoreactivity for S-100



See Answer in Part B → Q5

@Neet_pg_bot

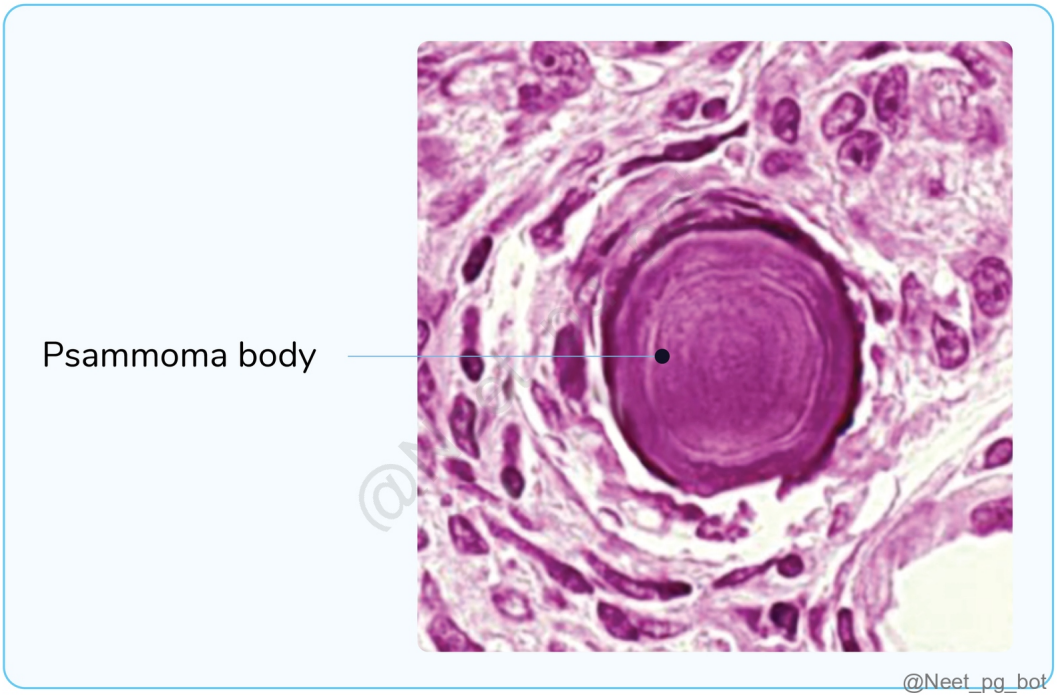
Q6: A 35-year-old female presents with persistent headaches and weakness in her right upper limbs. Imaging reveals a brain tumor that is PR+. Biopsy reveals psammoma bodies with necrosis, cellular atypia, mitosis >4/hpf, and invasion of brain parenchyma. What is the most likely diagnosis? {{caption_text}} (Q845172)

A. Typical meningioma

B. Atypical meningioma

C. Anaplastic meningioma

D. Papillary meningioma



See Answer in Part B → Q6

@Neet_pg_bot

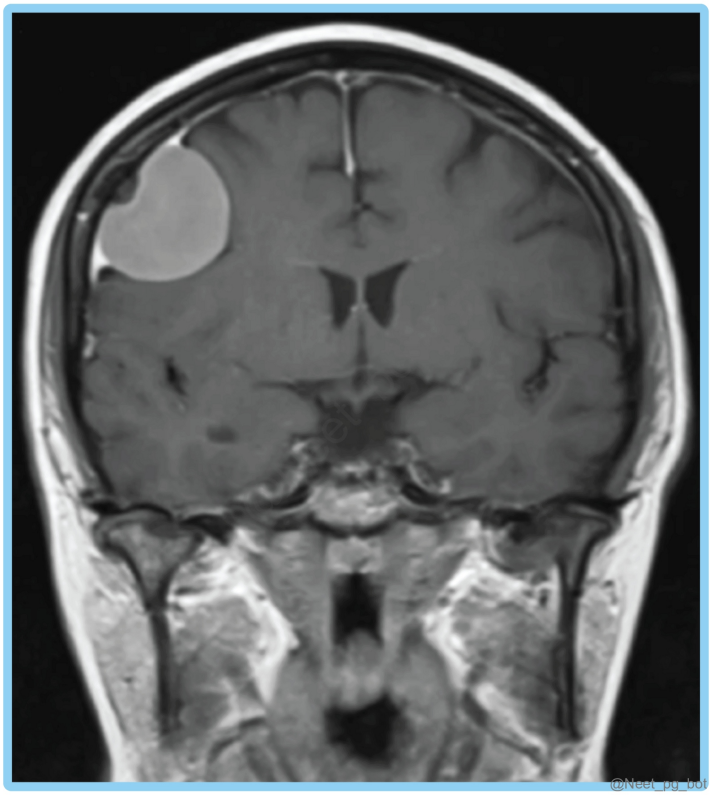
Q7: A 28-year-old gravid woman comes to the ODP due to a severe headache that started during her pregnancy. Investigations reveal the following. Which of the following statements is not true for the above condition? {{caption_text}} (Q845171)

A. Progesterone receptor-positive

B. Risk factors include exposure to radiation

C. Associated with NF2 gene mutation

D. HPE shows perivascular pseudorosettes



See Answer in Part B → Q7

@Neet_pg_bot

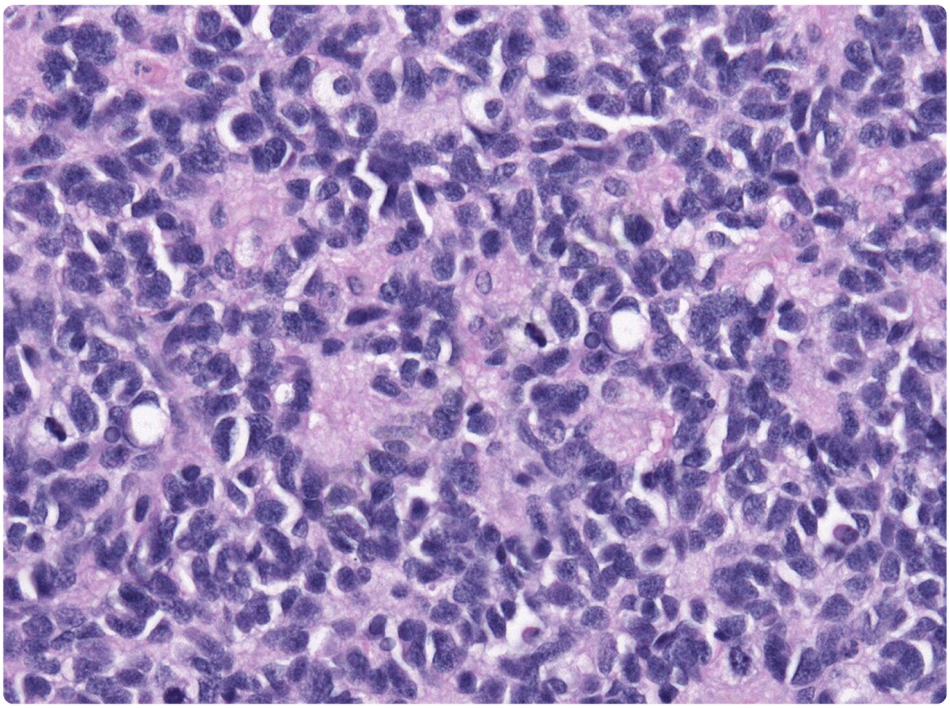
Q8: A 7-year-old boy presents with a history of persistent morning headaches, vomiting, and difficulty with coordination for the past two months. MRI shows a mass in the cerebellum, and HPE shows Homer Wright's rosette. What is the most common route of metastasis? {{caption_text}} (Q845170)

A. Lymphatics

B. Hematogenous

C. Drop metastasis

D. All of the above



@Neet_pg_bot

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 28-year-old man comes to the OPD due to a severe headache and blurring of vision. MRI indicates an intraventricular mass in the posterior fossa obstructing the CSF flow. Following surgical resection, which histopathological finding is most probable on examination? (Q845169)

A. Perivascular pseudorosette

B. Perinuclear halo

C. Psammoma bodies

D. Homer Wright rosettes

See Answer in Part B → Q9

@Neet_pg_bot

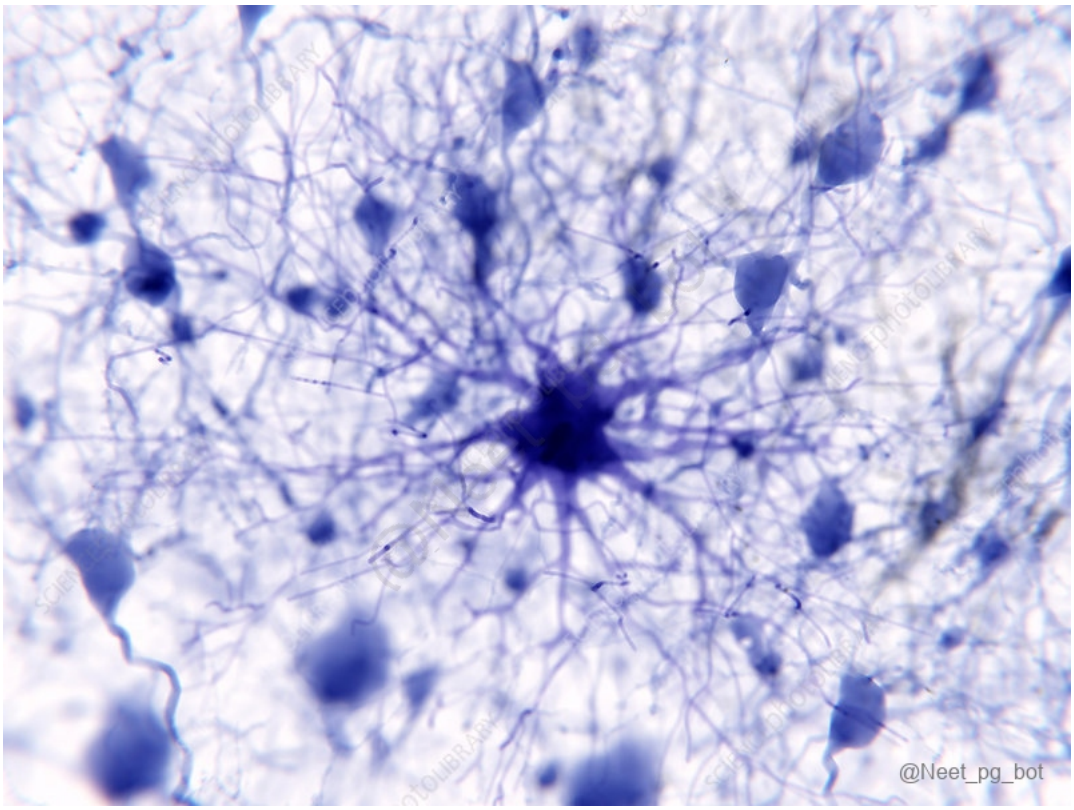
Q10: Identify the following CNS cells and match them with their specific roles: 1.Fibrous astrocytes A.It is found primarily in white matter and maintains the blood-brain barrier Star-shaped cells Functions: Formation of Blood Brain Barrier (BBB) Involved in repair mechanism IHC stain: Glial Fibrillary Acidic Protein (GFAP) marker 2. Oligodendrocyte B. Line the brain's ventricles and assist in producing cerebrospinal fluid (CSF). Function: Formation of myelin in CNS Perinuclear halo Special stain for Myelin: Luxol fast blue 3. Ependymal cell C. Produce myelin sheath for fast impulse conduction in the CNS. Present in ventricles of the brain Helps in formation of Cerebrospinal fluid (CSF) 4. Protoplasmic astrocytes D. Phagocytize pathogens in CNS and are physiologically and embryologically unrelated to other neural cell types. Location: Found in the grey matter. Help maintain the appropriate concentration of neurotransmitters. 5.Microglia E. They are found in the grey matter and help maintain the appropriate concentration of neurotransmitters. Phagocytize pathogens in the CNS. Origin: Physiologically and embryologically unrelated to other neural cell types (Q845147)

A. 1- A, 2-B, 3-C, 4-D, 5-E

B. 1- A, 2-C, 3-B, 4-E, 5-D

C. 1- B, 2-C, 3-A, 4-E, 5-D

D. 1- E, 2-C, 3-A, 4-B, 5-D



@Neet_pg_bot

Q11: A 10-year-old child presents with a history of headaches and balance difficulties over the past few months. Histopathological examination of the biopsy shows bipolar cells with long, thin hairlike processes, dense fibrillary meshwork, and characteristic eosinophilic corkscrew-shaped inclusions. Which inclusion bodies are involved in this type of tumor? (Q845167)

A. Rosenthal fibers

B. Glomeruloid bodies

C. Negri bodies

D. Lewy bodies

See Answer in Part B → Q11

@Neet_pg_bot

Q12: According to the Anne Mayo grading system, what grade would be assigned to the tumor showing hypercellularity, nuclear atypia, and mitotic activity but no evidence of microvascular proliferation or necrosis? (Q845166)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old patient presents with new-onset headaches, seizures, and progressive unilateral weakness. Brain MRI reveals a cerebral mass with irregular borders and heterogeneous contrast enhancement. Biopsy shows GFAP-positive glial cells. What is the possible diagnosis? (Q845165)

A. Astrocytoma

B. Neurocytoma

C. Medulloblastoma

D. Meningioma

See Answer in Part B → Q13

@Neet_pg_bot

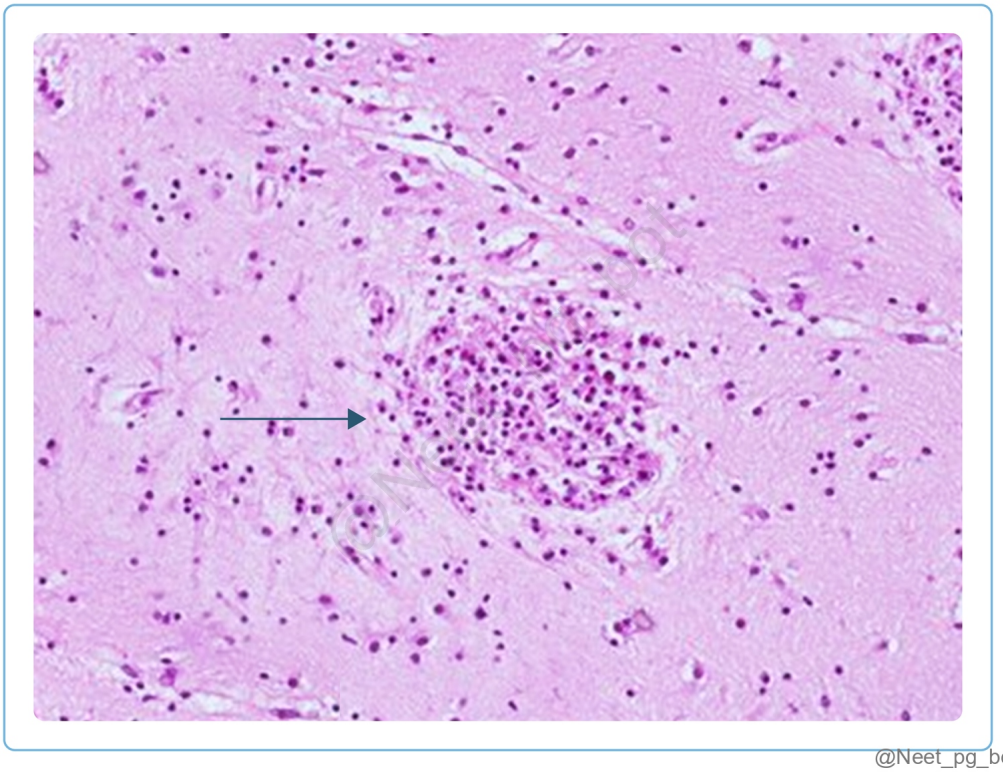
Q14: Match the following: 1. Neuronophagia a) 2. Rabies b) 3. Microglial nodules c) 4. Globoid bodies d) (Q845164)

A. 1-b,2-c,3-a,4-d

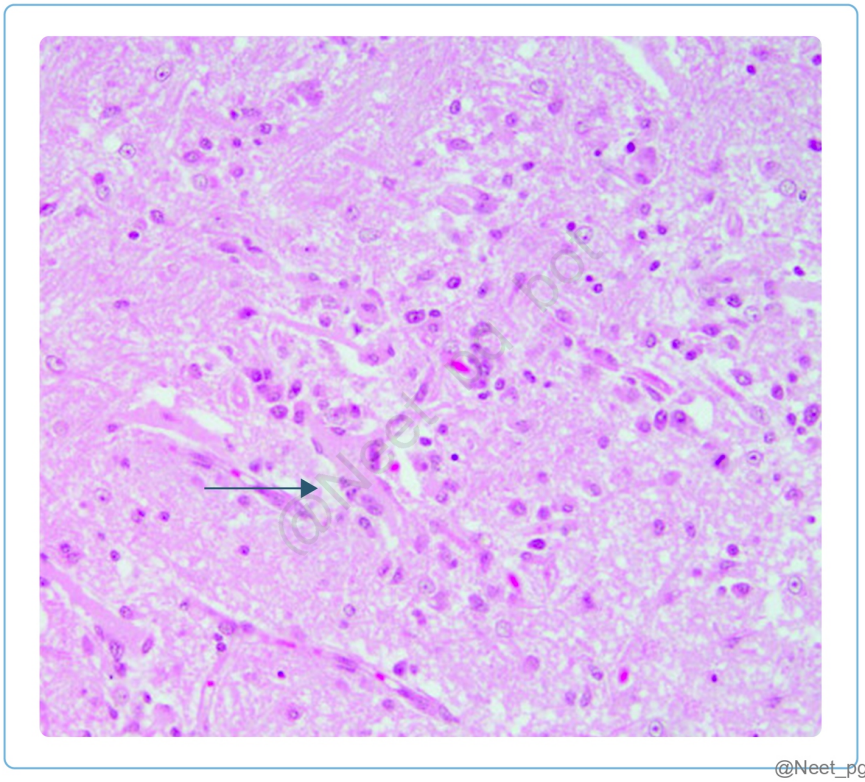
B. 1-a,2-c,3-b,4-d

C. 1-a,2-b,3-d,4-c

D. 1-b,2-d,3-a,4-c



@Neet_pg_bot



@Neet_pg_bot

Q15: Which of the following features are not seen in Alzheimer's Disease? (Q845163)

A. Bunina bodies

B. Neuritic plaques

C. Neurofibrillary tangles

D. Hirano bodies

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following statements about Alzheimer's Disease is/are correct? 1) Due to the mutation of the APP gene on Chromosome 21 2) Alpha and Gama secretase pathways are involved 3) APOE2 is a risk factor 4) Affects the frontal, parietal, and temporal lobes. (Q845162)

A. 2,3

B. 2,4

C. 1,3

D. 1,4

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 65-year-old male presents with a 6-month history of resting tremor in his right hand, which improves with movement. He reports increasing slowness in daily activities and stiffness, particularly in the morning. He has had occasional falls due to unsteadiness while walking. Physical examination reveals a shuffling gait and cogwheel rigidity. All of the following are true statements regarding this condition except? (Q845161)

A. A key pathological feature in the substantia nigra neurons is observed.

B. This condition can occur due to mitochondrial dysfunction.

C. Mutations in LRRK2 are the most common cause of autosomal dominant disease.

D. Homozygous mutation of glucocerebrosidase is an important risk factor for this condition.

See Answer in Part B → Q17

@Neet_pg_bot

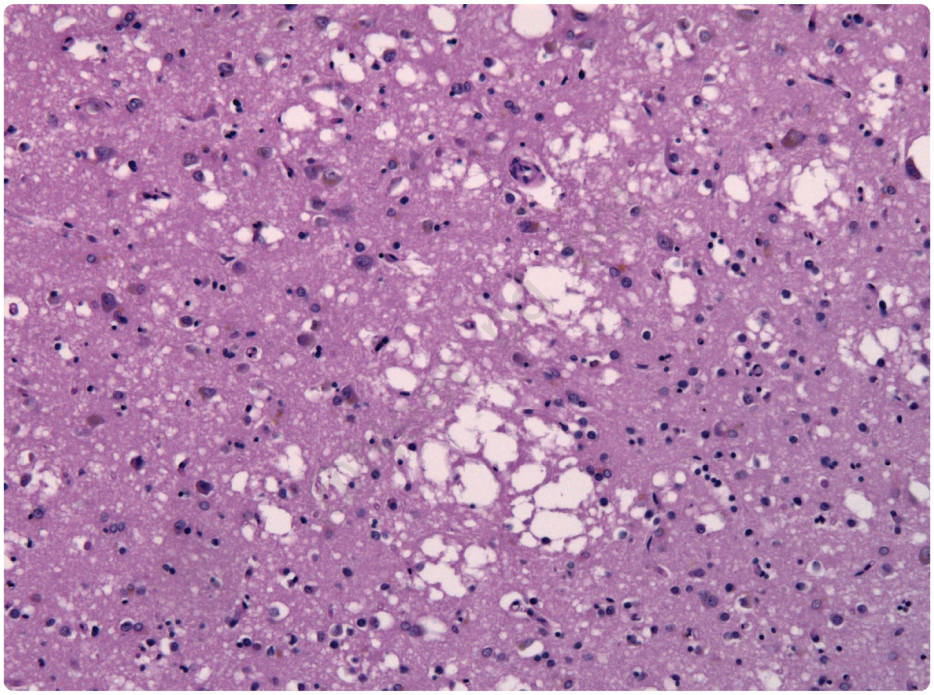
Q18: A 55-year-old male presented with behavioral changes and involuntary movements over the past several weeks. Neurological examination revealed ataxia and myoclonus. He passed away after 4 months, and biopsy findings of the brain tissue are shown below. Based on these findings, which of the following statements is false regarding this condition? Proteinaceous particles with single-stranded RNA cause it. It results from the misfolding of PrPsc to PrPc. Spongiform transformation is a characteristic histopathological feature It is associated with a good prognosis if diagnosed early. Familial forms are associated with specific genetic mutations. (Q845160)

A. 1, 2 and 4

B. 1, and 4

C. 2 and 4

D. 3, 4 and 5



@Neet_pg_bot

Q1: A 40-year-old female presents with frequent headaches. The investigation reveals raised intracranial pressure and the presence of a dural-based tumour. Which of the following histological findings correlates with the diagnosis? (Q858139)

A. Fried-egg appearance

B. Flexner-Wintersteiner rosettes

C. Psammoma bodies with whorling of tumor cells

D. Homer-Wright rosettes

See Answer in Part B → Q1

@Neet_pg_bot

Q2: What is the most common cause of berry aneurysm? (Q859895)

A. Endothelial injury of the vessel due to hypertension

B. Muscle intimal elastic lamina layer defect

C. Muscle and adventitial layer defect

D. Adventitia defect

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Tau protein inclusions are involved in: (Q859856)

A. Alzheimer’s disease

B. Huntington's disease

C. Amyotrophic lateral sclerosis

D. CNS lymphoma

See Answer in Part B → Q3

@Neet_pg_bot

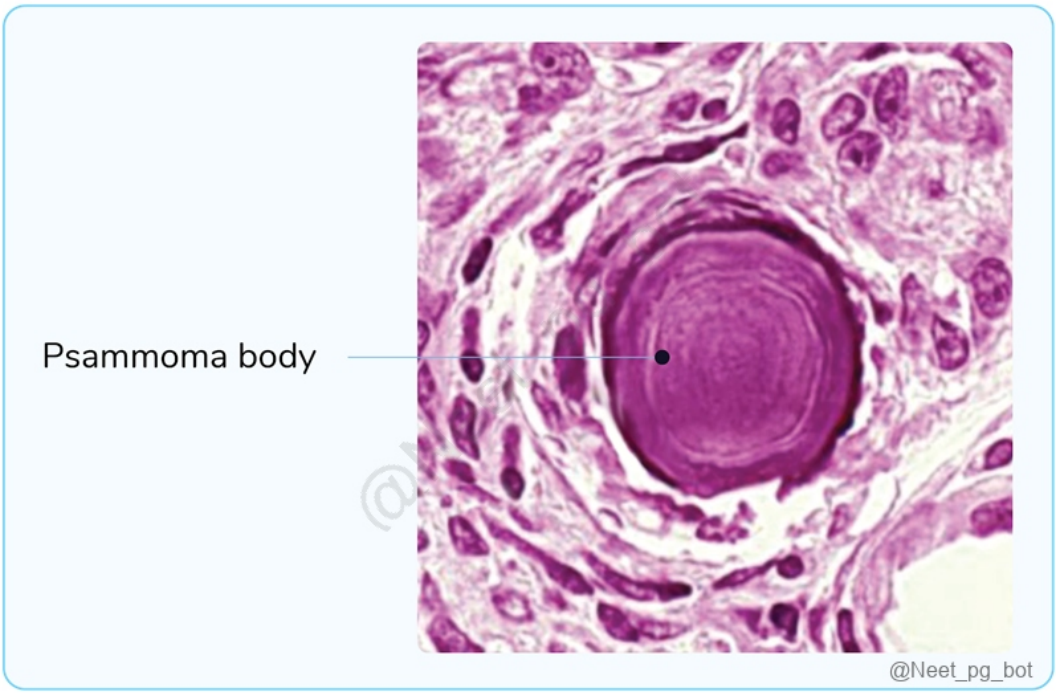
Q4: A 40-year-old female presents with the development of seizures, for which a CT-guided biopsy was done. The histopathological image showed the presence of psammoma bodies. What is the most likely diagnosis? (Q859262)

A. Astrocytoma

B. Medulloblastoma

C. Meningioma

D. Ependymoma



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 24-year-old patient presented with swelling in the wrist joint. Histopathological examination of the swelling revealed spindle cells with palisading of the nuclei and Verocay bodies. Which of the following is the most likely condition? (Q854862)

A. Schwannoma

B. Neurofibroma

C. Neuroma

D. Glioma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: All of the following conditions are related to the same core pathology, except: (Q856486)

A. Parkinson’s disease

B. Alzheimer’s disease

C. Lewy body dementia

D. Multisystem atrophy

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the most common cause of berry aneurysm? (Q857610)

A. Endothelial injury of the vessel due to hypertension

B. Muscle intimal elastic lamina layer defect

C. Muscle and adventitial layer defect

D. Adventitia defect

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A mutation in the SOD1 gene is most commonly associated with which of the following conditions? (Q866751)

A. Huntington's disease

B. Multiple sclerosis

C. Amyotrophic lateral sclerosis (ALS)

D. Parkinson's disease

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old patient presents with severe headaches, seizures, and progressive neurological deficits. Imaging reveals a large mass with areas of necrosis and irregular borders in the brain. The biopsy confirms the diagnosis of a malignant tumor. Which of the following options represents the most common type of brain tumor in adults? (Q820559)

A. Medulloblastoma

B. Meningioma

C. Retinoblastoma

D. Glioblastoma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 70-year-old patient presents with progressive memory loss, cognitive decline, and behavioral changes. Imaging reveals characteristic amyloid plaques and neurofibrillary tangles in the brain. On further investigation, the accumulation of a specific protein is found to be a hallmark of this disease. What is the protein responsible for the amyloidosis seen in Alzheimer's disease? (Q820521)

A. Amyloid beta protein

B. ATTR

C. Amyloid beta 2 protein

D. Acal

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is the disorder associated with hexanucleotide repeat? (Q860225)

A. Fragile X syndrome

B. Huntington disease

C. Myotonic dystrophy

D. Frontotemporal dementia

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 5-year-old child presents with a lesion in the right eye. Histopathology reveals the presence of Flexner-Wintersteiner rosettes. What is the likely diagnosis? (Q860515)

A. Retinoblastoma

B. Optic nerve glioma

C. Rhabdomyosarcoma

D. Ocular melanoma

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is a marker of Alzheimer's disease? (Q844213)

A. Synuclein

B. Aβ 40 and 42

C. Polyglutamine

D. FUS

See Answer in Part B → Q13

@Neet_pg_bot

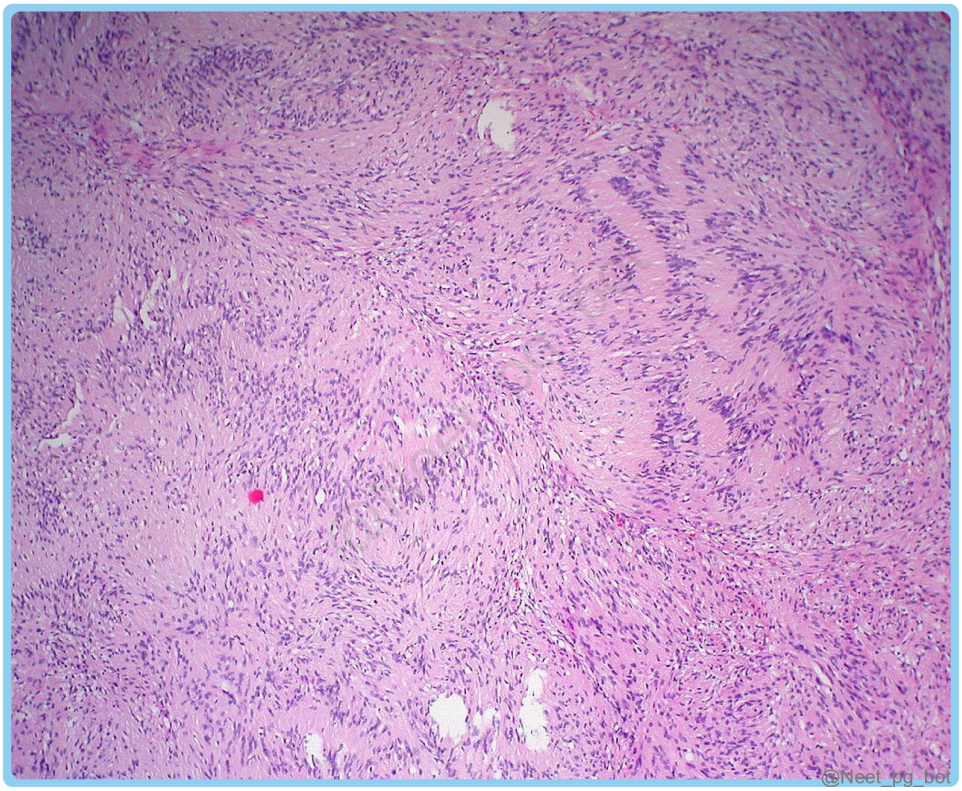
Q14: A patient presents with a hand lesion, and the histopathology of the lesion is provided. Which of the following statements is incorrect? (Q853372)

A. It originates from the peripheral nerve

B. Verrocay bodies are seen in light microscopy

C. Associated with neurofibromatosis

D. It is malignant and often metastasizes



See Answer in Part B → Q14

@Neet_pg_bot

Q15: A child presents with visual disturbances and delayed growth. Imaging reveals a suprasellar mass, and histopathology shows the presence of "wet keratin" (compact, eosinophilic anucleate keratin). What is the most likely diagnosis? (Q866366)

A. Craniopharyngioma

B. Medulloblastoma

C. Glioma

D. Pituitary adenoma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: In the WHO grading of astrocytoma, which grade does glioblastoma fall under? (Q793781)

A. I

B. II

C. III

D. IV

See Answer in Part B → Q16

@Neet_pg_bot

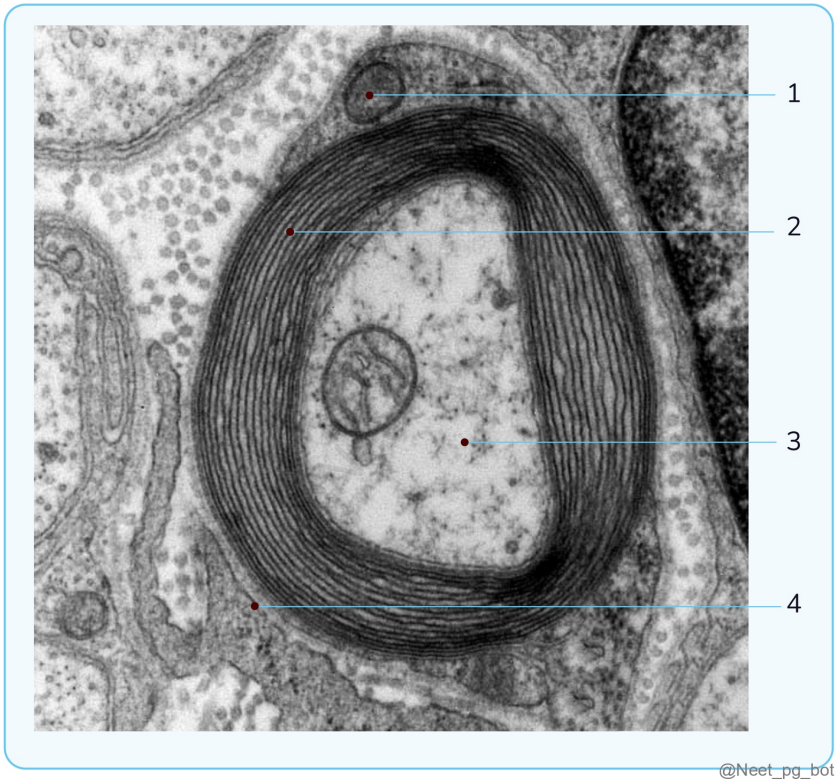
Q17: An electron microscopic picture of a cut section of a nerve fibre is given. Identify the area that will be affected by the most common variant of Guillain-Barre syndrome. (Q855395)

A. 1

B. 2

C. 3

D. 4



See Answer in Part B → Q17

Q1: A child presents with skin eruptions upon exposure to sunlight and is diagnosed with a DNA repair defect. Which type of repair defect is most likely responsible? (Q844175)

A. Nucleotide excision repair defect

B. Base excision repair defect

C. Mismatch repair defect

D. Recombination repair defect

See Answer in Part B → Q1

@Neet_pg_bot

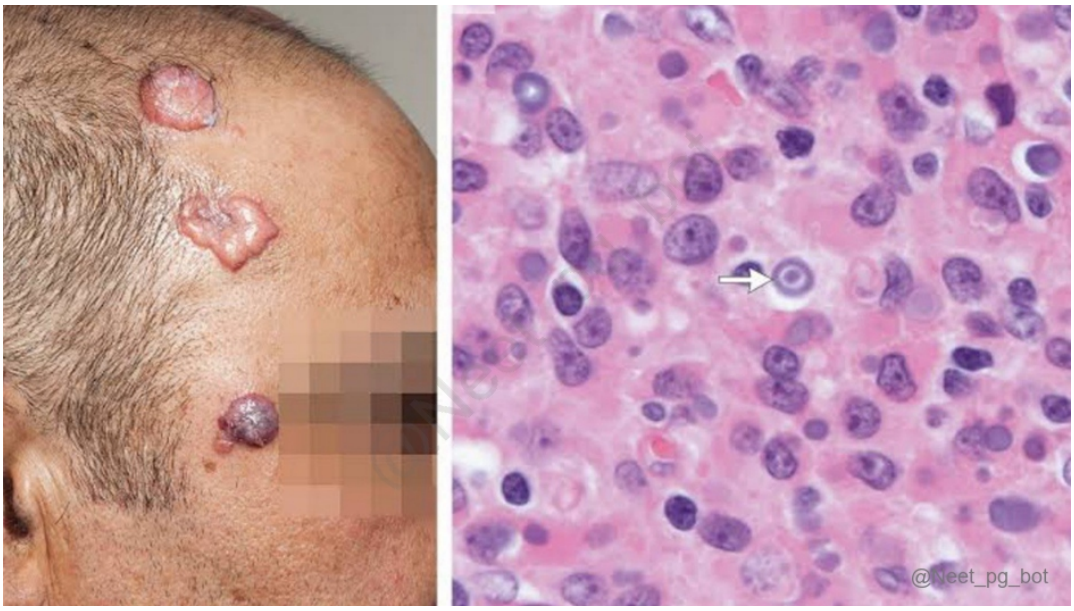
Q2: Identify the diagnosis based on the image provided: (Q844180)

A. Tuberculosis (TB)

B. Malakoplakia

C. Pyoderma gangrenosum

D. Squamous cell carcinoma (SCC)



See Answer in Part B → Q2

@Neet_pg_bot

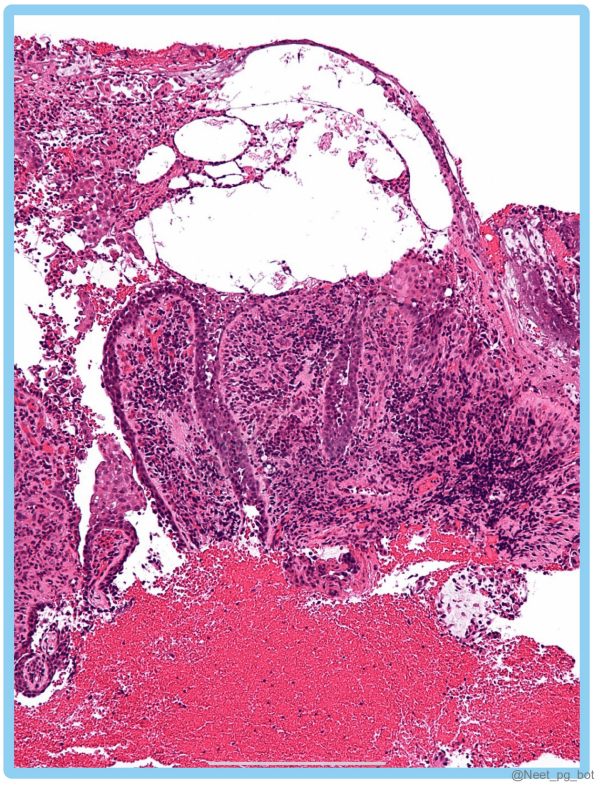
Q3: Identify the given condition. (Q856687)

A. Pemphigus Vulgaris

B. Leprosy

C. Mycosis fungoides

D. Visceral leishmaniasis



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 5-year-old child who presented with proptosis of one of the eyes was found to have a desmin-positive tumour. What is the probable diagnosis? (Q856705)

A. Ewing’s sarcoma

B. Embryonal rhabdomyosarcoma

C. Leukaemia

D. Retinoblastoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A patient underwent surgery for lipoma 5 weeks ago and now presents with a scar at the incision site, which is limited to the original wound boundaries. What is the most likely diagnosis? (Q857162)

A. Keloid

B. Exuberant granulation

C. Hypertrophic scar

D. Granulation tissue

See Answer in Part B → Q5

@Neet_pg_bot

Q6: An 8-year-old boy presents with progressive muscle weakness and walking difficulties. On examination, pseudohypertrophy of the calf muscles was noted. Which of the following is true regarding this condition? (Q858113)

A. Abnormal collagen

B. Absent dystrophin

C. Expansions of CAG triplet repeats

D. Defective fibrillin

See Answer in Part B → Q6

@Neet_pg_bot

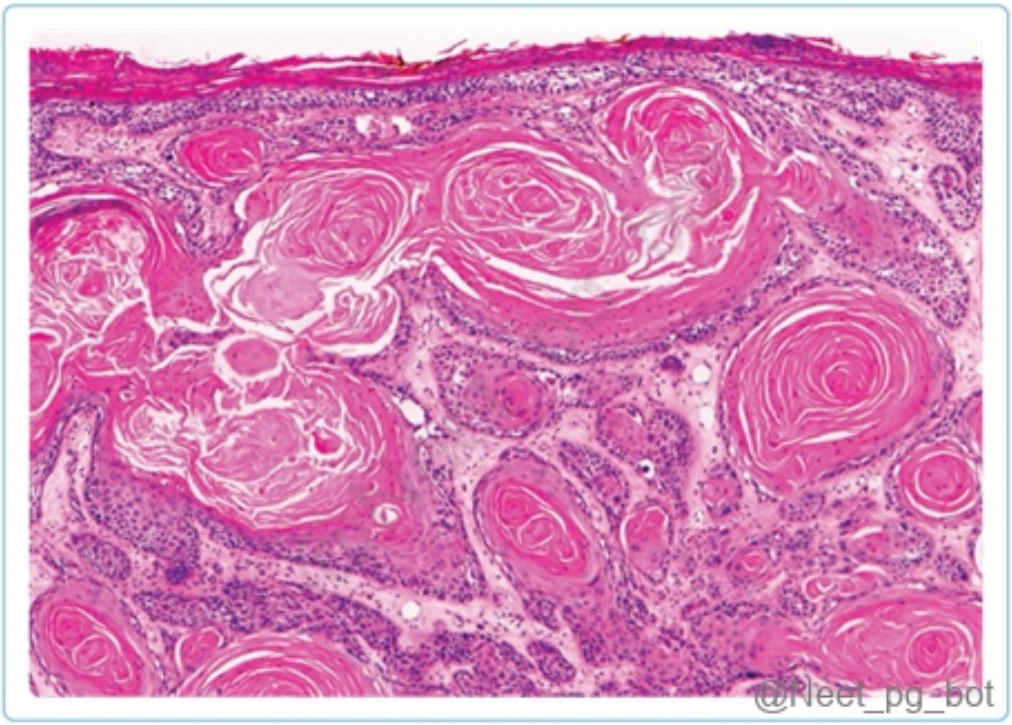
Q7: A farmer has a lesion on the shoulder. What is the most likely diagnosis based on the histopathological image of the lesion given below? (Q860532)

A. SCC

B. BCC

C. Molluscum contagiosum

D. Verrucous carcinoma



See Answer in Part B → Q7

@Neet_pg_bot

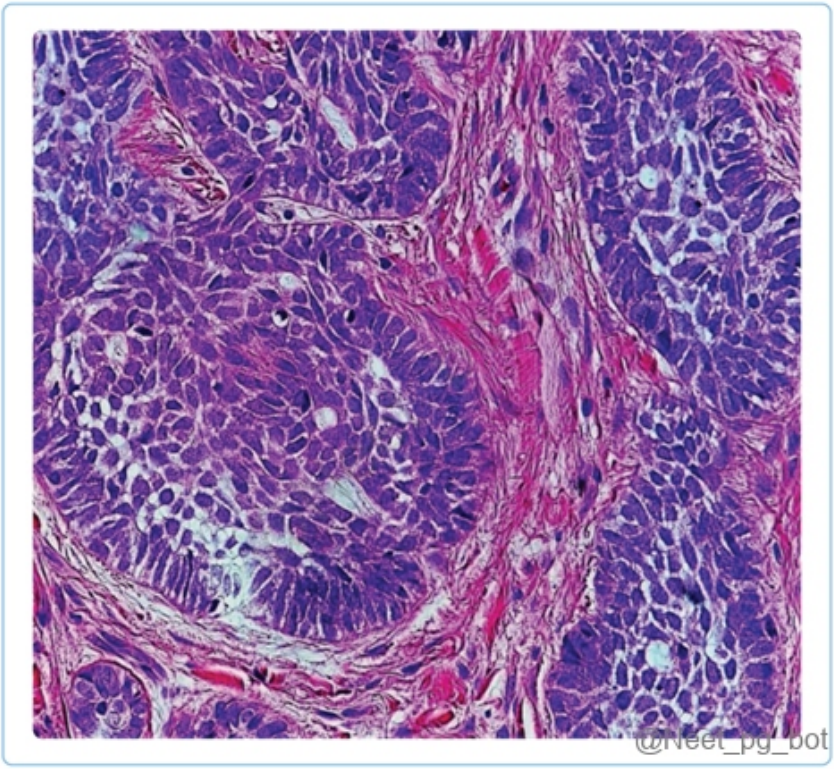
Q8: Identify the histopathological image. (Q860535)

A. Basal cell carcinoma

B. Squamous cell carcinoma

C. Adenocarcinoma

D. Malignant melanoma



See Answer in Part B → Q8

Q1: What is the most common reason for an elevated reticulocyte count among the conditions? (Q846639)

A. Aplastic anemia

B. Hemolytic anemia

C. Megaloblastic anemia

D. Myelophthisic anemia

See Answer in Part B → Q1

@Neet_pg_bot

Q2: What is the most likely interpretation if Hemoglobin is 9 g/dL, MCV is 104 fL, MCH is 22 pg, and MCHC is 31 g/dL? (Q846648)

A. Microcytic Hypochromic Anaemia

B. Normocytic Normochromic Anaemia

C. Macrocytic Hypochromic Anaemia

D. Microcytic Normochromic Anaemia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: What is the Mean Corpuscular Hemoglobin Concentration (MCHC) using Hemoglobin (Hb) level is 15 g/dL and Hematocrit (Hct) is 45%? (Q846647)

A. 33.3 g/dL

B. 34.0 g/dL

C. 32.0 g/dL

D. 30.0 g/dL

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old male patient presents for a routine check-up. His laboratory results show that his Hemoglobin (Hb) level is 14 g/dL, and his RBC count is 4.7 million cells/μL. Using these values, calculate the Mean Corpuscular Hemoglobin (MCH). (Q846646)

A. 29.8 pg

B. 29.0 pg

C. 30.0 pg

D. 28.5 pg

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Calculate MCV in a patient where RBC count is 4.5 million cells per microliter (cells/μL), Hb 9gm/dl and Hematocrit is 30% (Q846645)

A. 65.7 fL

B. 66.7 fL

C. 67.7 fL

D. 68.7 fL

See Answer in Part B → Q5

@Neet_pg_bot

Q6: RBC indices Definitions 1. MCV a) Indicates the variation in the size of red blood cells. 2. MCH b) Reflects the average volume of a red blood cell. 3. MCHC c) Measures the average amount of haemoglobin in a single red blood cell. 4. RDW d) Represents the amount of haemoglobin per unit volume of red blood cells. (Q846644)

A. 1-b, 2-c, 3-d, 4-a

B. 1-c, 2-a, 3-b, 4-d

C. 1-d, 2-a, 3-c, 4-b

D. 1-b, 2-d, 3-c, 4-a

See Answer in Part B → Q6

@Neet_pg_bot

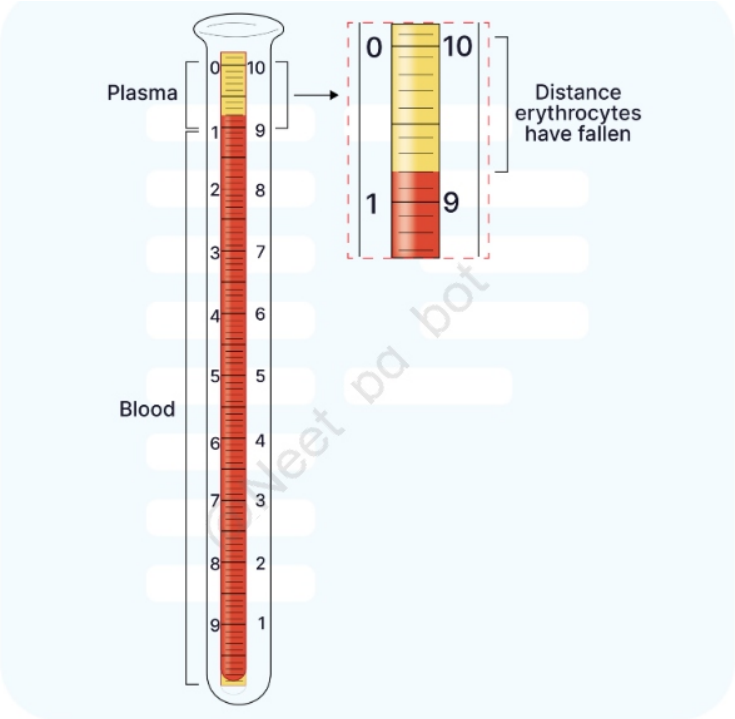
Q7: A 5-year-old child presented with a fever and his blood sample was taken to measure ESR using the Wintrobe tube. What are the advantages of the instrument (A) over instrument (B)? (Q846643)

A. The test is more sensitive

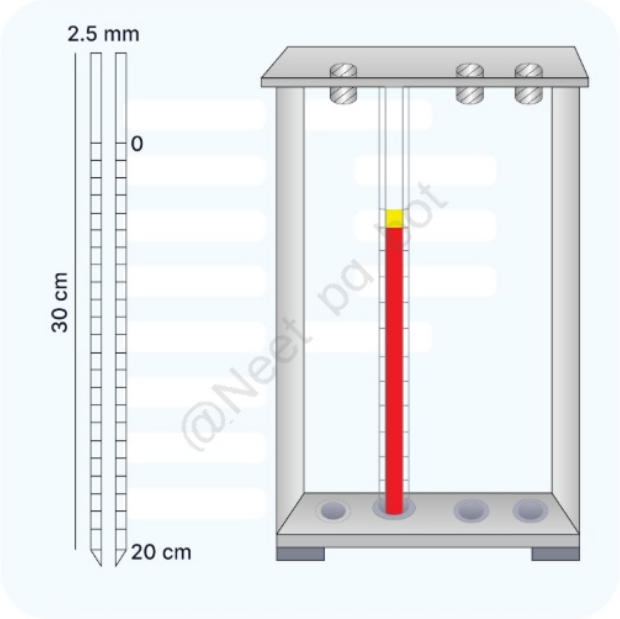
B. Does not need anticoagulant

C. Useful for estimation of both PCV and ESR

D. More volume of the tube



A



B

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which statement accurately describes ESR (Erythrocyte Sedimentation Rate)? (Q846642)

A. Non-specific marker of inflammation

B. Proportion of red blood cells in the total blood volume

C. Reflects the oxygen-carrying capacity of the blood

D. Reported in percentage

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 48-year-old man presents to the clinic with fatigue, palpitations, and shortness of breath. Examination reveals pallor. Using the following values, calculate the reticulocyte production index: Reticulocyte count: 5% Hemoglobin: 9 g/dL Hematocrit: 28% (Q846641)

A. 1.8

B. 1.5

C. 2.5

D. 2.0

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old man presents to the OPD with fatigue, weakness, and breathlessness. He shows pallor and icterus on examination. Given his hemogram results, reticulocyte count of 5%, haemoglobin of 9 g/dL, and hematocrit of 28%, calculate his corrected reticulocyte count. (Q846640)

A. 4.0

B. 5.1

C. 4.5

D. 3.0

See Answer in Part B → Q10

@Neet_pg_bot

Q11: At which site does erythropoiesis primarily occur in an adult human? (Q845922)

A. Bone marrow of long bones

B. Bone marrow of all bones

C. Yolk sac

D. Liver

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the approximate maturation time for reticulocytes in the bloodstream to form mature red blood cells? (Q846637)

A. 1-2 days

B. 2-5 days

C. 6-7 days

D. 8-10 days

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the normal range for reticulocyte count in adults? (Q846636)

A. 0.5-2%

B. 2-6%

C. 2-3%

D. 0-0.1%

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 25-year-old woman experiences ongoing fatigue and weakness, appearing pale upon examination. Laboratory investigations reveal low haemoglobin levels, and a peripheral blood smear is ordered. Which stain is most effective for visualising reticulocytes in peripheral blood smears? (Q846635)

A. Prussian Blue

B. New Methylene Blue

C. Periodic acid-Schiff (PAS) stain

D. Wright stain

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which stage of erythropoiesis is characterised by the expulsion of the nucleus, resulting in a smaller, pyknotic cell with increased haemoglobin content? (Q846634)

A. Reticulocyte

B. Normoblast

C. Basophilic erythroblast

D. Proerythroblast

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which condition is NOT typically associated with a dry tap during bone marrow aspiration? (Q846633)

A. Aplastic anaemia

B. Hairy cell leukemia

C. Myelofibrosis

D. Chronic Myeloid Leukemia

See Answer in Part B → Q16

@Neet_pg_bot

Q17: If a person is 45 years old, what would be the expected percentage of cellularity in their bone marrow biopsy? (Q845972)

A. 45%

B. 55%

C. 65%

D. 75%

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 35-year-old man undergoes a bone marrow biopsy, which shows a composition of cells and fat. What is the ratio of hematopoietic cells to fat cells expected in an adult? (Q845971)

A. 1:1

B. 1:3

C. 2:3

D. 3:1

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 56-year-old male presents with pancytopenia and is scheduled for a bone marrow biopsy to determine the underlying cause. What is the most common site for performing a bone marrow biopsy in this patient? (Q845946)

A. Anterior Superior Iliac spine

B. Posterior Superior Iliac spine

C. Proximal femur

D. Proximal tibia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Identify the instrument shown in the image below. (Q845945)

A. Salah needle

B. Klima needle

C. Jamshidi needle

D. Quincke needle

See Answer in Part B → Q20

Q1: A 30-year-old male presents with severe fatigue, shortness of breath, and dark urine after eating fava beans. He has a history of recurrent hemolytic anemia. On examination, he appears pale and jaundiced. Which statement correctly describes the pathogenesis of his condition? (Q845845)

A. Deficiency in an enzyme leads to oxidative stress-induced hemolysis.

B. Excessive production of glutathione leads to the destruction of red blood cells.

C. Decreased levels of reactive oxygen species (ROS) lead to decreased oxidative damage.

D. The severity is not influenced by environmental factors or dietary triggers like fava beans.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which investigation is considered the most definitive for confirming the diagnosis of paroxysmal nocturnal hemoglobinuria (PNH)? (Q890597)

A. Ham’s acid hemolysis test

B. Bone marrow biopsy

C. High-performance liquid chromatography (HPLC)

D. Flow cytometry

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 12-year-old girl presents for a regular health maintenance visit. There are no active complaints, and she has been feeling well. She has no chronic medical conditions and does not take any medications. She has a positive family history of thalassemia. Which of the following best confirms the diagnosis of thalassemia trait? (Q882123)

A. Elevated HbA2

B. Reticulocytosis

C. NESTROFT

D. Peripheral smear

See Answer in Part B → Q3

@Neet_pg_bot

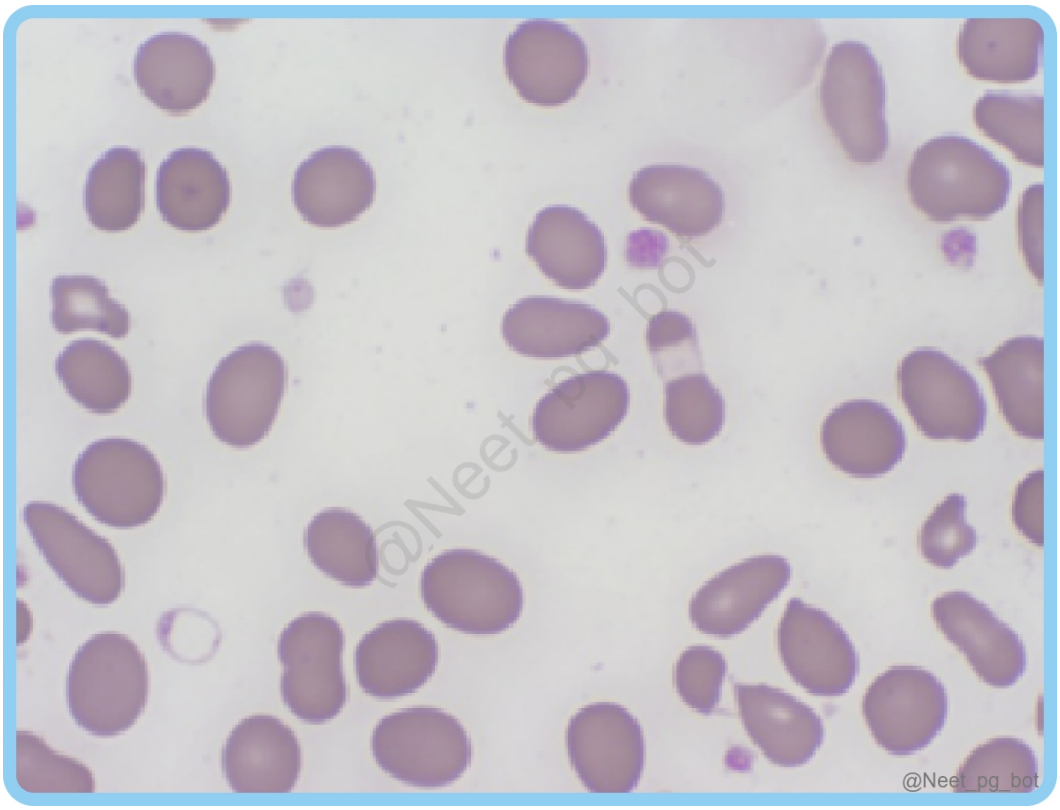
Q4: Match the following histopathological findings with their correct diagnosis: 1. A. Sickle Cell Anemia 2. B. Hereditary Spherocytosis 3. C. G6PD deficiency 4. D. Thalassemia (Q845892)

A. 1-C, 2-D, 3-A, 4-B

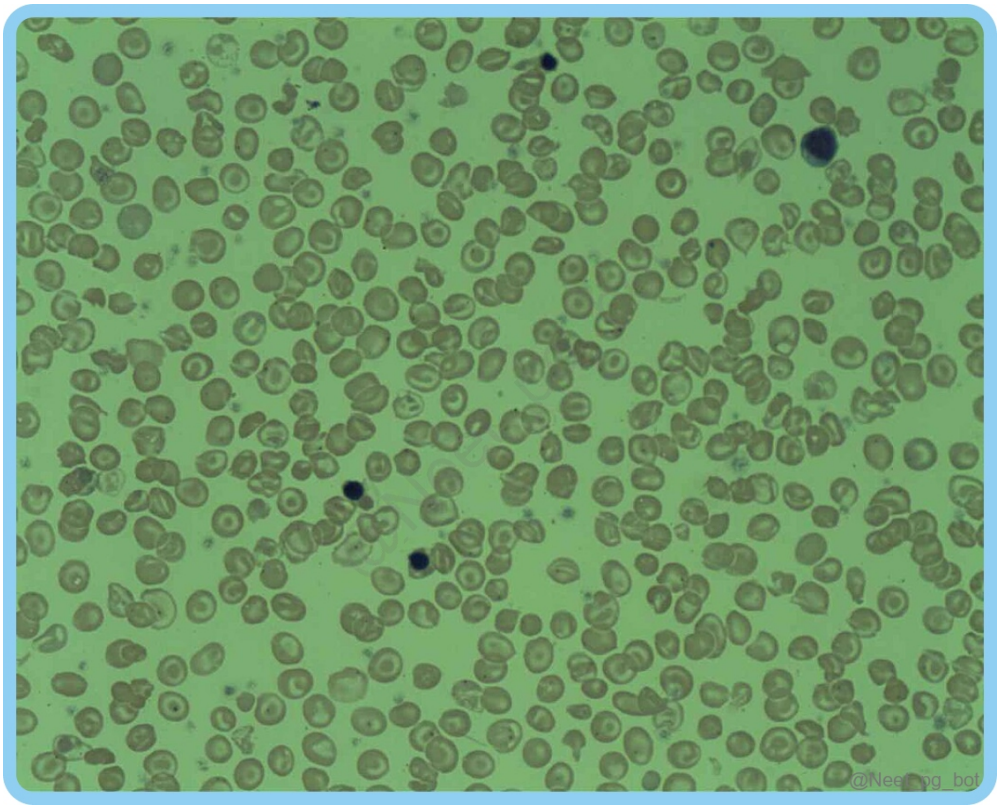
B. 1-D, 2-C, 3-B, 4-A

C. 1-B, 2-A, 3-D, 4-C

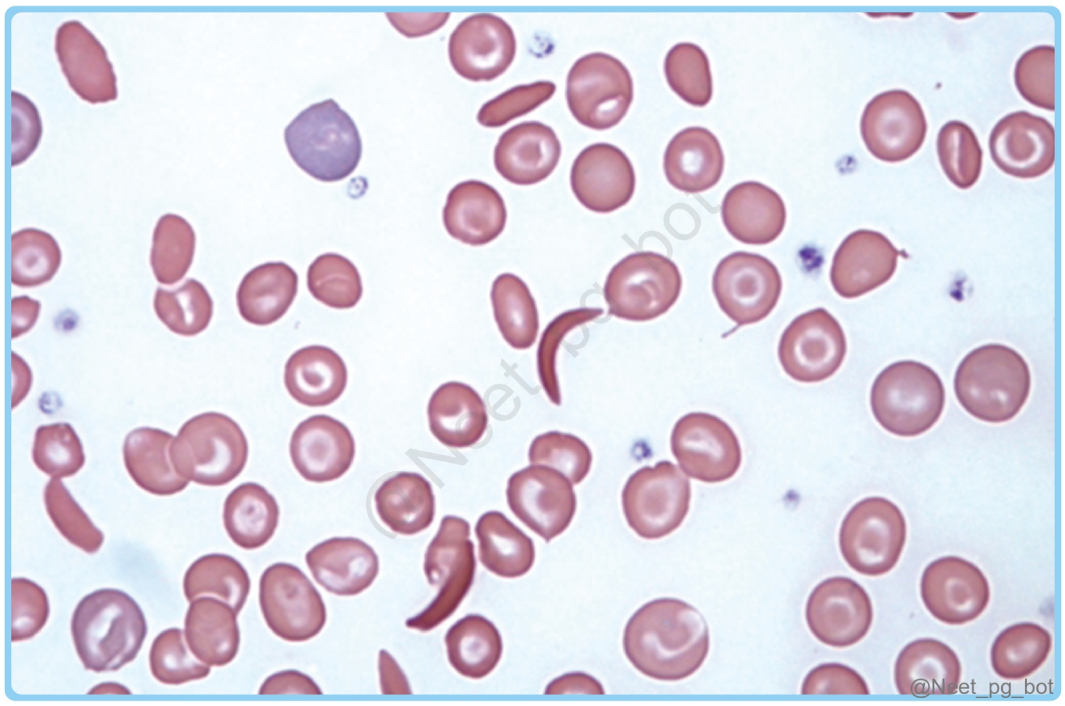
D. 1-A, 2-B, 3-C, 4-D

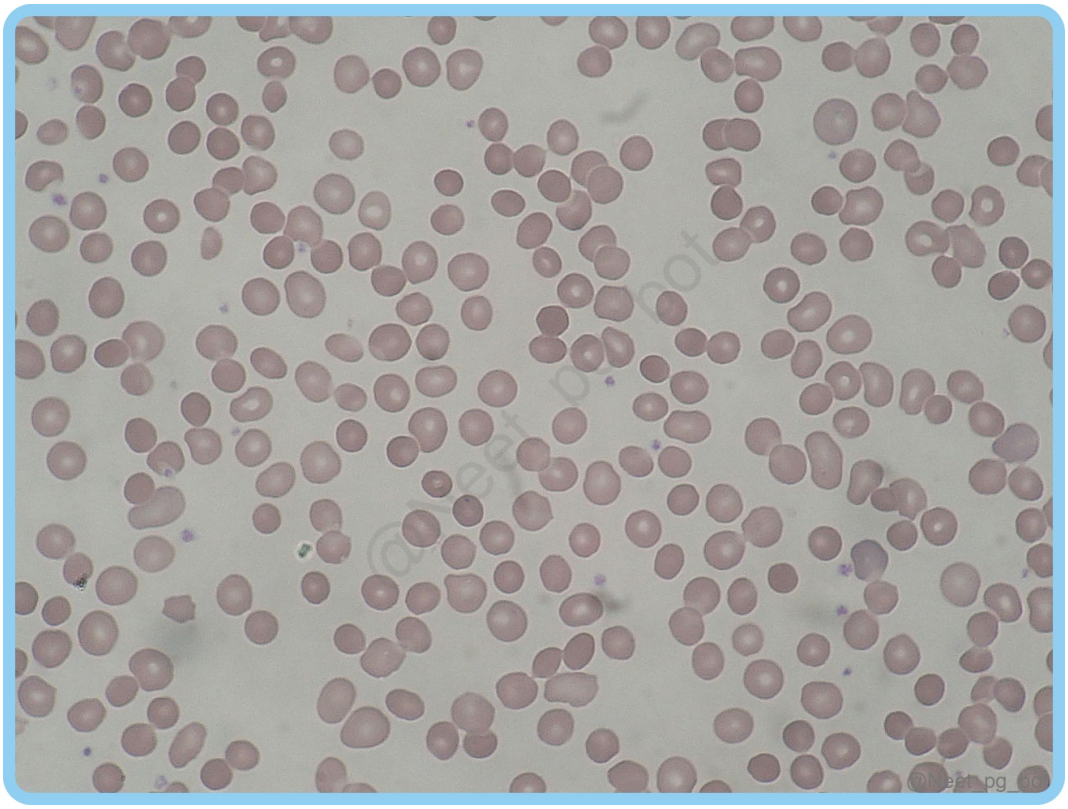


@Neet_pg_bot



@Neet_pg_bot





See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following treatments is commonly used for Paroxysmal Nocturnal Hemoglobinuria? (Q845891)

A. Rituximab

B. Bevacizumab

C. Eculizumab

D. Trastuzumab

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is the most common cause of death in Paroxysmal Nocturnal Hemoglobinuria? (Q845890)

A. Pancytopenia

B. Acute Myeloid Leukemia

C. Hepatic vein thrombosis

D. Myelodysplastic syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following defects is seen in paroxysmal nocturnal hemoglobinuria? (Q845889)

A. Spectrin

B. CD 45 and CD 95

C. G6PD enzyme

D. PIGA gene

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding Paroxysmal Nocturnal Hemoglobinuria (PNH) is true? (Q845888)

A. Causes extravascular hemolysis

B. Splenectomy would be beneficial

C. Causes hemolysis only at night

D. Acquired intracorpuscular defect

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old male presents to the emergency department with symptoms of acute hemolytic anemia. A methemoglobin reduction test is performed, revealing a delayed rate of methemoglobin reduction. What is the underlying principle of the above-mentioned screening test used to diagnose G6PD deficiency? (Q845846)

A. Measures the levels of methemoglobin in red blood cells.

B. Evaluates the ability of red blood cells to reduce methemoglobin back to haemoglobin.

C. Detects G6PD activity by measuring the rate of reduction of a fluorescent dye.

D. Measures the actual activity levels of the G6PD enzyme.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following sequences correctly represents the progression of hemoglobin handling in the body during intravascular hemolysis (IVH)? A. Hemoglobin binds to albumin, forming meth albuminemia B. Hemoglobin combines with haptoglobin C. Haptoglobin saturation and hemoglobin binding to hemopexin. D. RBC lysis causes hemoglobin to leak out. (Q845837)

A. D → B → C→ A

B. D → B → A → C

C. D → C → A → B

D. D → C → B → A

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 6-year-old child presents with a history of recurrent episodes of jaundice, fatigue, and abdominal pain. Physical examination reveals splenomegaly. The child's blood work shows the presence of spherocytes on the peripheral blood smear. An osmotic fragility test is performed. Identify the correct statement about this test. (Q845844)

A. It is a diagnostic test.

B. In thalassemia patients, low osmotic fragility leads to a right shift on the graph.

C. In HS patients, high osmotic fragility leads to a right shift on the graph.

D. Normally, RBC lysis begins at 0.7% NaCl.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is not a typical change in blood indices in patients with hereditary spherocytosis? (Q845843)

A. MCV decreases

B. MCHC increases

C. RDW decreases

D. Hemoglobin decreases

See Answer in Part B → Q12

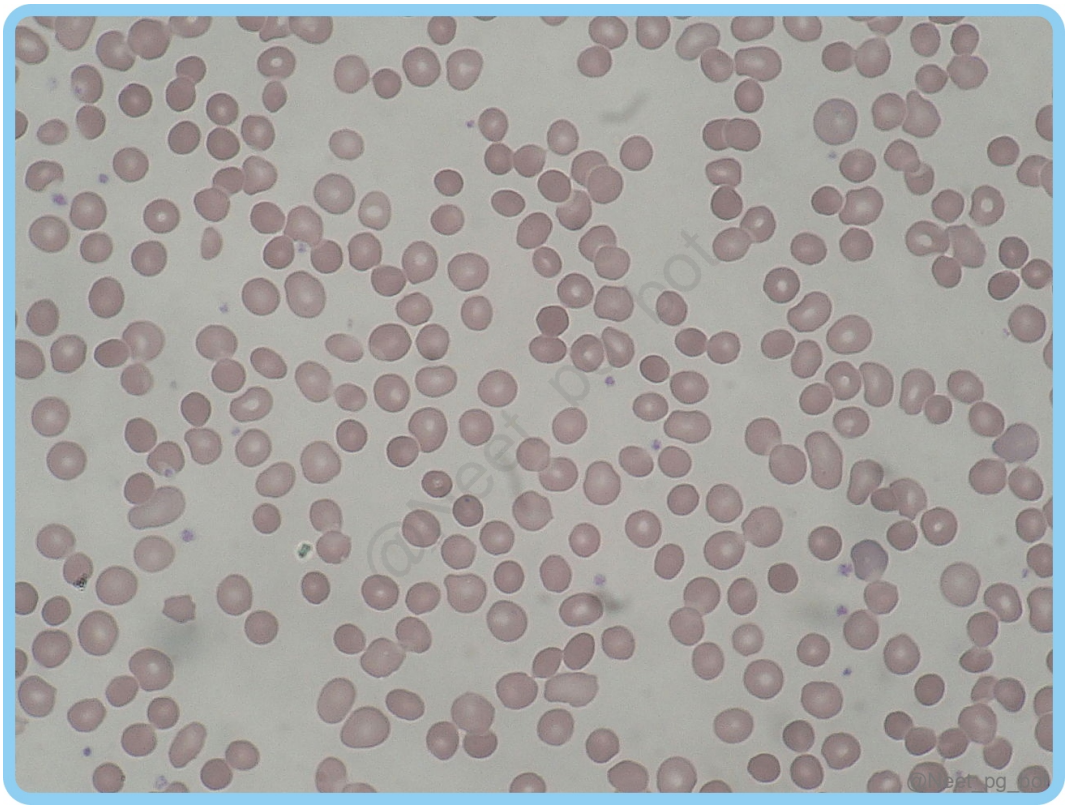
Q13: A 10-year-old child presents with a history of recurrent episodes of jaundice, fatigue, and abdominal pain. Physical examination reveals splenomegaly, and peripheral blood smear shows the following picture. Coomb's test is negative. What is the most likely diagnosis? (Q845842)

A. Hereditary spherocytosis

B. Autoimmune hemolytic anemia

C. Glucose-6-phosphate dehydrogenase (G6PD) deficiency

D. Thalassemia



See Answer in Part B → Q13

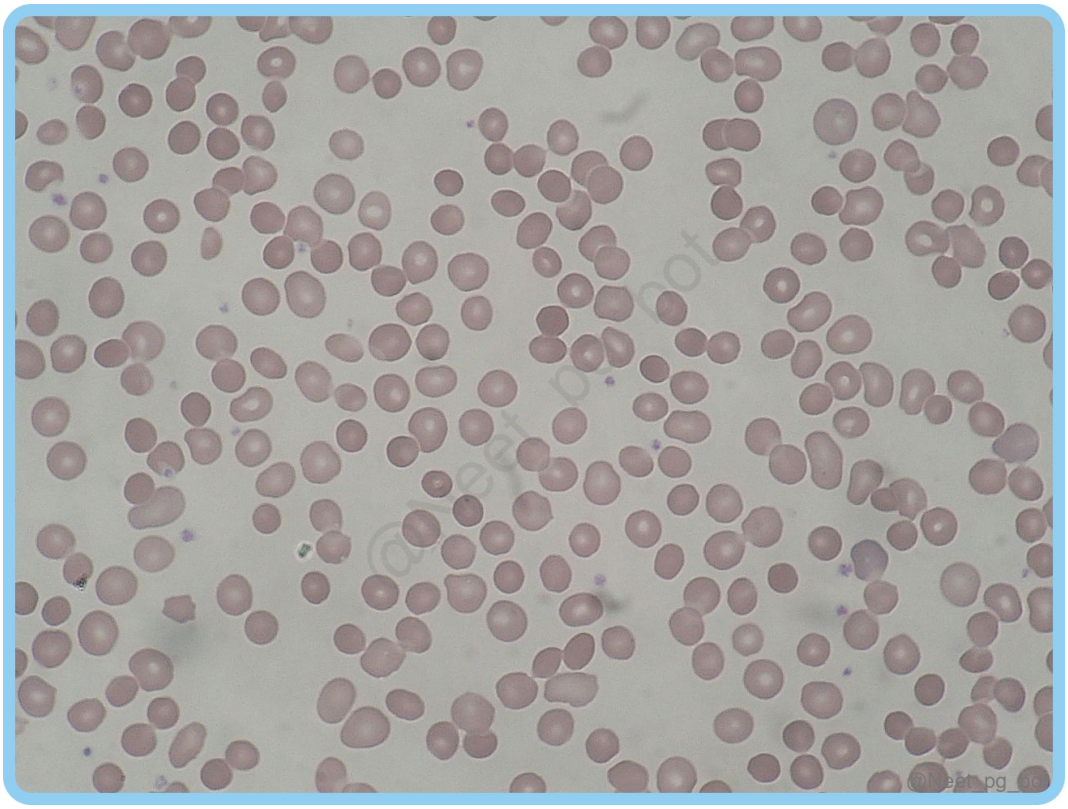
Q14: A 28-year-old male presents with fatigue, jaundice, splenomegaly, and anemia with elevated MCHC. A peripheral smear is done which is shown below. What is the most common protein defect in this condition? (Q845841)

A. Spectrin

B. Band 3 protein

C. Ankyrin

D. Glycophorin A



See Answer in Part B → Q14

@Neet_pg_bot

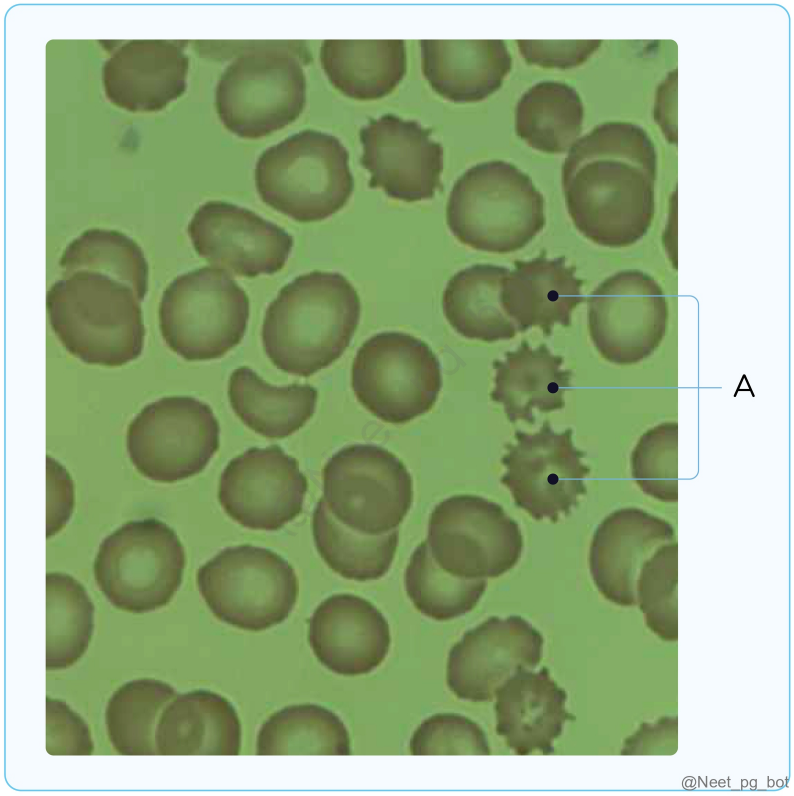
Q15: Examine the provided histopathology image of a blood smear containing two types of abnormal red blood cells. Identify the diseases associated with each cell type. (Q845840)

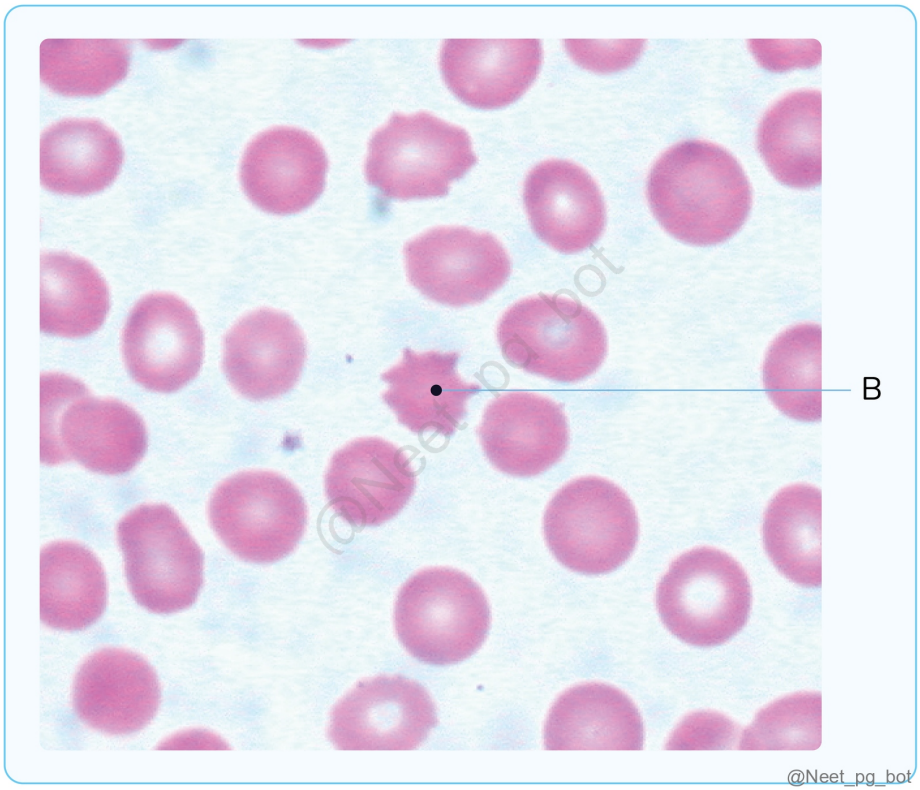
A. a: Pyruvate kinase deficiency, burns, and uremia; b: Abetalipoproteinemia, liver disease, and vitamin E deficiency.

B. a: Abetalipoproteinemia, liver disease, and vitamin E deficiency; b: Pyruvate kinase deficiency, burns, and uremia.

C. a: Abetalipoproteinemia and burns; b: Pyruvate kinase deficiency and uremia.

D. a: Pyruvate kinase deficiency and liver disease; b: Abetalipoproteinemia and vitamin E deficiency.





See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the following causes of hemolysis with their corresponding categories. Categories Causes of hemolysis a. Intracorpuscular defect b. Extracorpuscular defect 1. Hereditary Spherocytosis (HS) 2. G6PD Deficiency 3. Thrombotic Thrombocytopenic Purpura (TTP) 4. Hemoglobin C Disease 5. Hemolytic Uremic Syndrome (HUS) 6. Sickle Cell Anemia (Q845839)

A. 1-a, 2-b, 3-b, 4-a, 5-a, 6-b

B. 1-b, 2-a, 3-b, 4-a, 5-a, 6-a

C. 1-a, 2-a, 3-b, 4-a, 5-b, 6-a

D. 1-a, 2-b, 3-a, 4-b, 5-a, 6-a

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following conditions can cause intravascular hemolysis (IVH)? Select all that apply. a. Paroxysmal Nocturnal Hemoglobinuria (PNH) b. Glucose-6-Phosphate Dehydrogenase (G6PD) deficiency c. Hereditary spherocytosis d. Paroxysmal Cold Hemoglobinuria (PCH) e. Hemolytic Uremic Syndrome (HUS) f. Thrombotic Thrombocytopenic Purpura (TTP) (Q845838)

A. b, c, d, e and f

B. a, b, d, e, and f

C. a, b, c, e, and f

D. a, b, c, d, and f

See Answer in Part B → Q17

Q13 (p. 719)	*Q14 (p. 720)*	*Q15 (p. 721)*	*Q16 (p. 721)*		

Q1: A 1-year-old boy, previously healthy until five months ago, presents with a three-hour history of severe swelling and tenderness of hands and feet. The family history is significant for an older brother who had transfusion-dependent anaemia and died of pneumococcal sepsis at the age of 6. Which haemoglobin molecule composition protected him from developing symptoms until recently? (Q845914)

A. α2γ2

B. α2β2

C. α2δ2

D. α2ε2

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following points best describes the pathogenesis of sickle cell disease (SCD)? Select all that apply. Nonsense point mutation in 6th position of β-globin chain Mutation promotes the polymerization of oxygenated hemoglobin Glutamic acid is changed to valine at the 6th position of β-globin chain Presence of HbF and HbS is protective against SCD. Patients heterozygous for HbS have more severe diseases than homozygous HbS. Individuals with coexistent α-thalassemia have less severe disease. (Q845915)

A. 1, 5, 4, and 6

B. 3, 4, and 6

C. 2, 5, and 6

D. 1, 2, 5, and 6

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following conditions does not lead to sickling of RBCs in patients with sickle cell disease? (Q845917)

A. Dehydration

B. Hypoxia

C. Increased pH

D. Decreased HbF

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 28-year-old man who has received blood transfusions on some occasions and has experienced severe pain in his hands and legs came to follow up. He is currently fine with no complaints and has been receiving treatment that has increased his HbF levels for the past 5 years. Which of the following would be seen in the peripheral smear of this patient? (Q845919)

A. Bite cells

B. Heinz bodies

C. Howell-Jolly bodies

D. Spherocytes

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Match the complications of sickle cell disease (SCD) with their corresponding crises: Complications Crises 1. Acute chest syndrome A. Vaso-occlusive crises 2. Parvovirus B19 infection B. Aplastic crises 3. Splenic enlargement C. Sequestration crisis 4. Splenic fibrosis (Q845921)

A. 1-A, 2-B, 3-C, 4-C

B. 1-A, 2-B, 3-C, 4-A

C. 1-A, 2-A, 3-B, 4-C

D. 1-A, 2-C, 3-B, 4-A

See Answer in Part B → Q5

@Neet_pg_bot

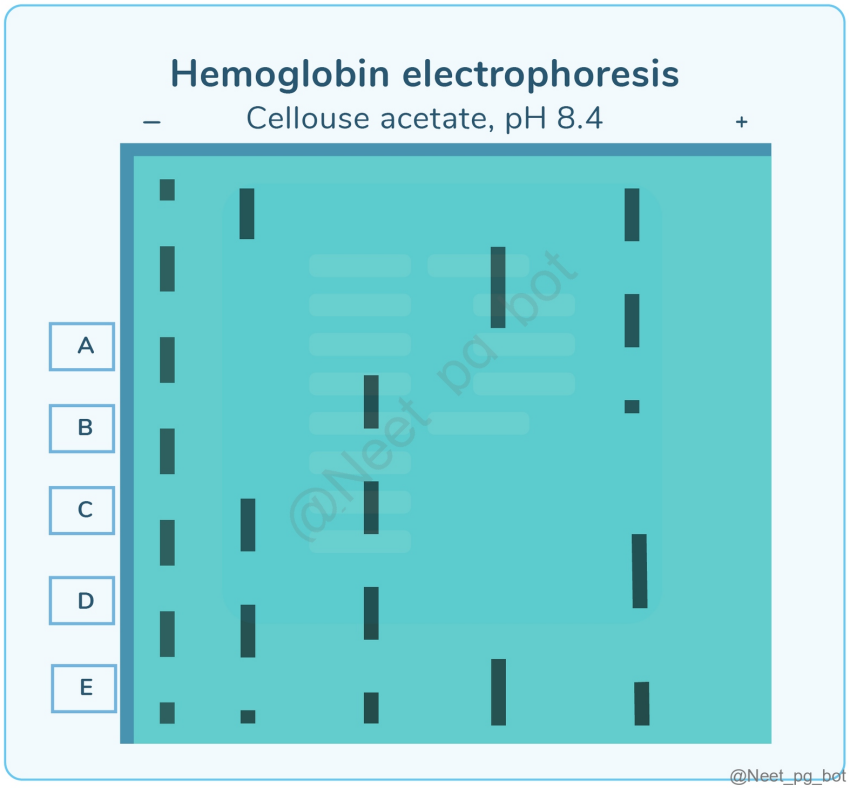
Q6: A 12-year-old girl presents to her primary care physician with complaints of fatigue, pallor, and jaundice. Peripheral smear showed sickling of RBCs. What is the most likely electrophoretic pattern seen in this patient? (Q845923)

A. A

B. B

C. C

D. D



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following statements regarding the different types of thalassemia is correct? Thalassemia major - mutations in both alleles of the HBB gene - impaired production of beta-globin chains. Beta-thalassemia trait - mutations in one allele of the HBB gene - reduced beta-globin chain synthesis. Alpha-thalassemia trait - deletions in one or more alpha-globin genes - decreased production of alpha-globin chains. Thalassemia intermedia - mutations affecting both alpha and beta-globin genes - severe anemia requiring regular blood transfusions (Q845925)

A. 1, 2, and 4

B. 2, 3, and 4

C. 1, 3 and 4

D. 1, 2, and 3

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 25-year-old male presents with fatigue, jaundice, and splenomegaly. Laboratory investigations reveal microcytic hypochromic anemia with increased levels of serum iron and ferritin. Further genetic analysis reveals a mutation in the HBB gene. Upon histopathological examination of the bone marrow, there is evidence of erythroid hyperplasia with ineffective erythropoiesis. Which mutation in the HBB gene is most likely responsible for the patient's presentation? (Q845927)

A. Substitution of cytosine for guanine at position 8 in the promoter region of the HBB gene.

B. Substitution of one nucleotide at position +8 in the coding region of the HBB gene.

C. Splicing mutation resulting in the removal of intervening sequence-IVS1-5 G-> C in the HBB gene.

D. Insertion of a nucleotide at position 54 in the coding region of the HBB gene

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 35-year-old woman with beta-thalassemia major presents to the cardiology clinic with complaints of increasing shortness of breath on exertion and swelling in her ankles. She has been undergoing regular blood transfusions since childhood. She dies after a few days of hospitalization. What is the most common condition leading to her death? (Q845930)

A. Anemia

B. Liver disease

C. Infections

D. Heart failure

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 25-year-old woman presents to the clinic for routine prenatal care. She has no significant past medical history. Her initial lab work reveals a microcytic, hypochromic anemia. Which of the following statements is most accurate in differentiating between iron deficiency anemia (IDA) and beta-thalassemia minor in this patient? (Q845932)

A. RDW is typically elevated in IDA compared to beta-thalassemia minor

B. RDW is typically lower in IDA compared to beta-thalassemia minor

C. Mentzer index is >13 in beta-thalassemia minor

D. RDW is typically normal in both IDA and beta-thalassemia minor

See Answer in Part B → Q10

@Neet_pg_bot

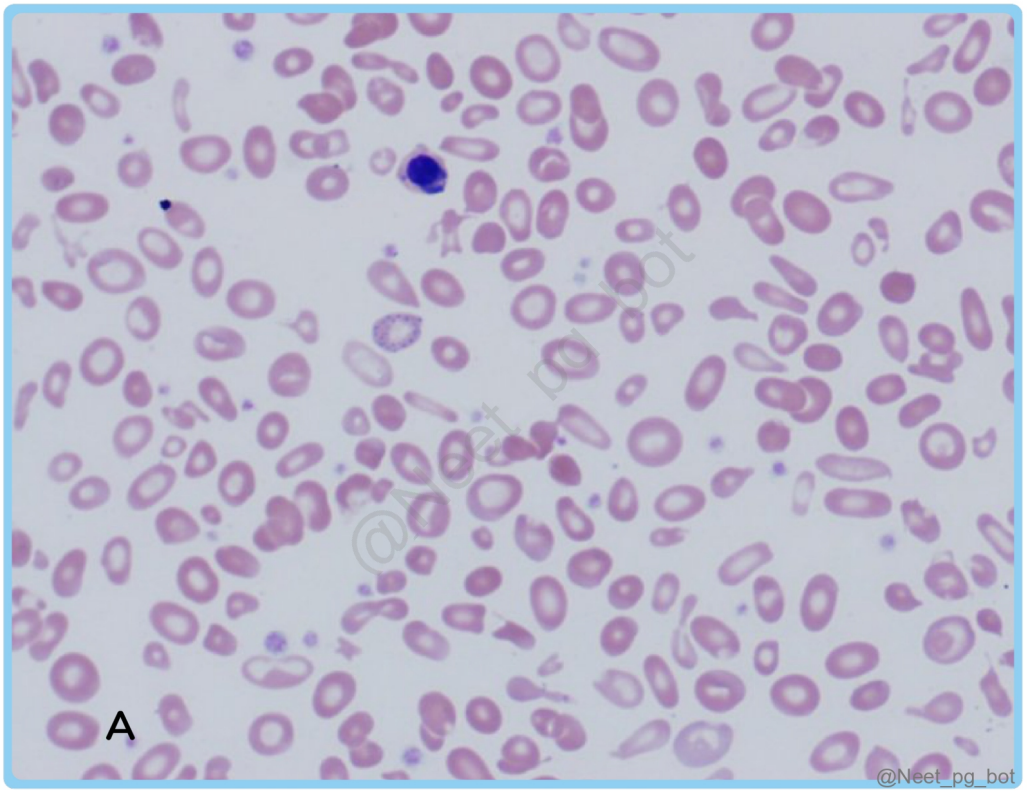
Q11: A hematologist is reviewing the peripheral blood smears of three patients diagnosed with different types of thalassemia. Patient A has severe anemia, target cells, and nucleated red blood cells (NRBCs). Patient B has mild anemia with microcytosis and hypochromia but no NRBCs. Patient C has mild anemia with microcytosis and hypochromia but also shows a small number of NRBCs and some hemoglobin H inclusions. Based on the peripheral smear findings, which of the following correctly matches the patients with their thalassemia types? (Q845933)

A. Patient A: β-thalassemia major, Patient B: β-thalassemia minor, Patient C: α-thalassemia

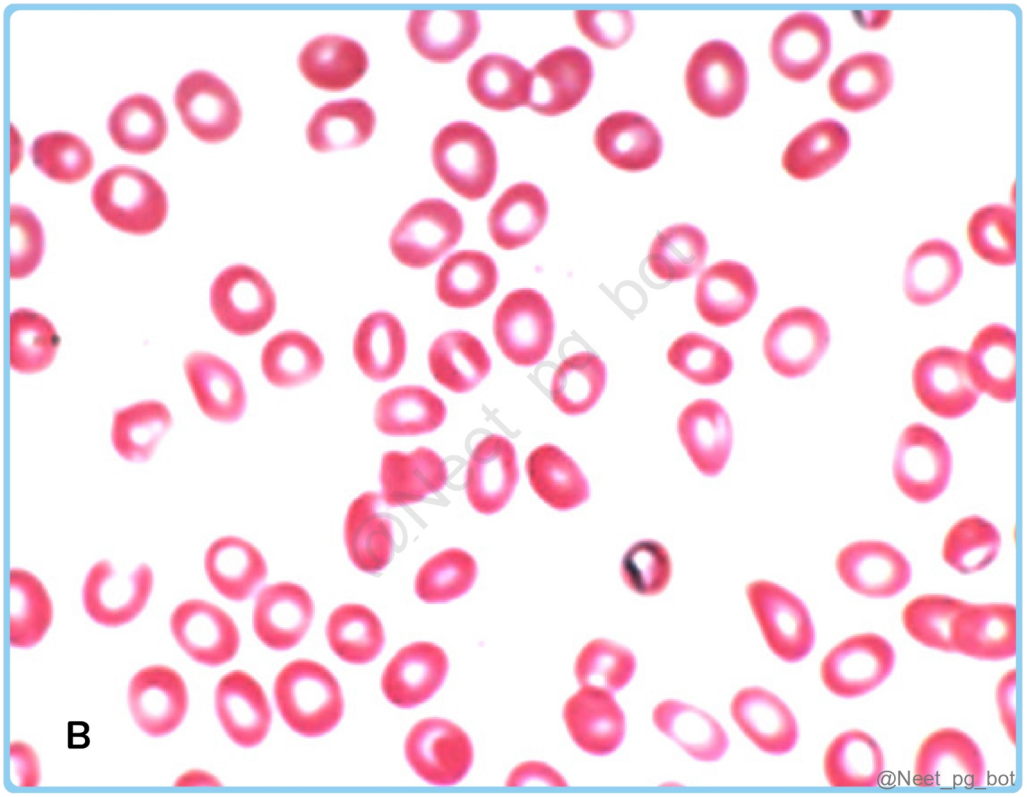
B. Patient A: β-thalassemia minor, Patient B: α-thalassemia, Patient C: β-thalassemia major

C. Patient A: α-thalassemia, Patient B: β-thalassemia minor, Patient C: β-thalassemia major

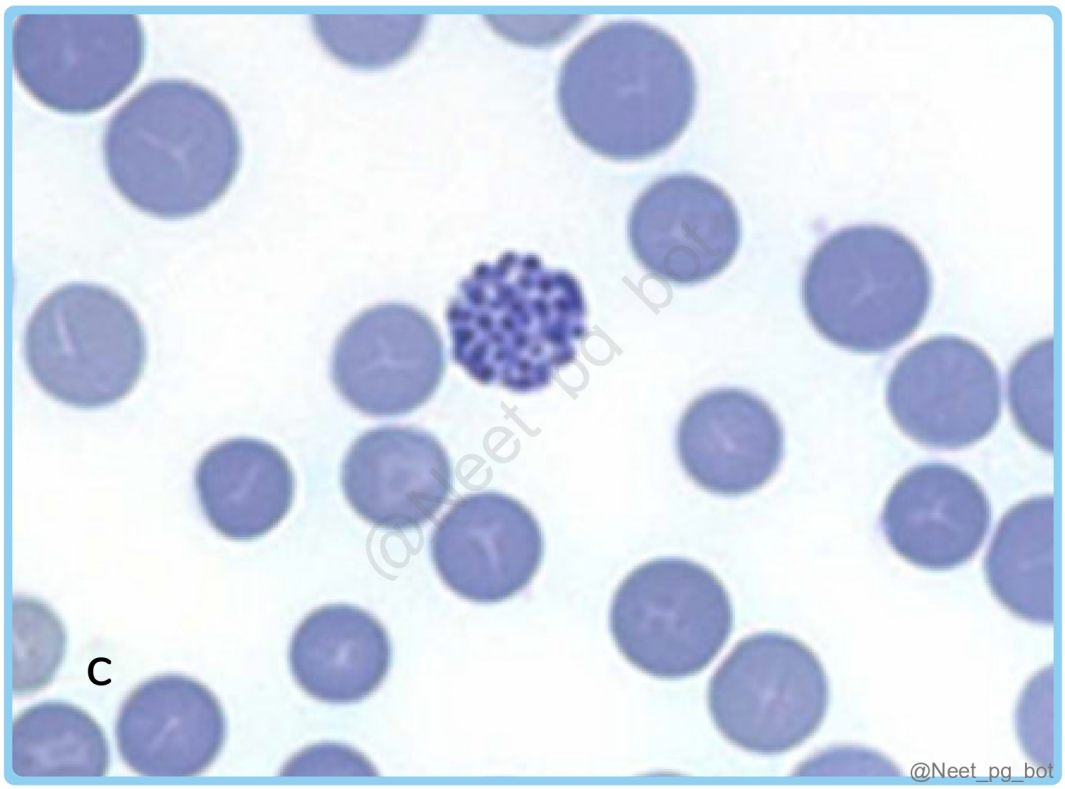
D. Patient A: β-thalassemia major, Patient B: α-thalassemia, Patient C: β-thalassemia minor



A
@Neet_pg_bot



B
@Neet_pg_bot



See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following findings is most consistent with β thalassemia major when compared to β thalassemia minor? (Q845934)

A. Decrease in HbA, slight increase in HbA2, and normal HbF; HPLC: HbA2: 6%, HbF: 2%

B. Decrease in HbA, increase in HbA2, and marked increase in HbF; HPLC: HbA2: 6%, HbF: 90%

C. Absent HbA, slight increase in HbA2, and moderate increase in HbF; HPLC: HbA2: 4%, HbF: 20%

D. Decrease in HbA, normal HbA2, and normal HbF; HPLC: HbA2: 2%, HbF: 2%

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A pregnant woman is a silent carrier for α-thalassemia (α-/αα) and is concerned about the risk of her child inheriting α-thalassemia. Her partner has the

α-thalassemia trait (αα/--). What is the probability that their child will have Hemoglobin H (HbH) disease? (Q845937)

A. 0%

B. 25%

C. 50%

D. 75%

See Answer in Part B → Q13

@Neet_pg_bot

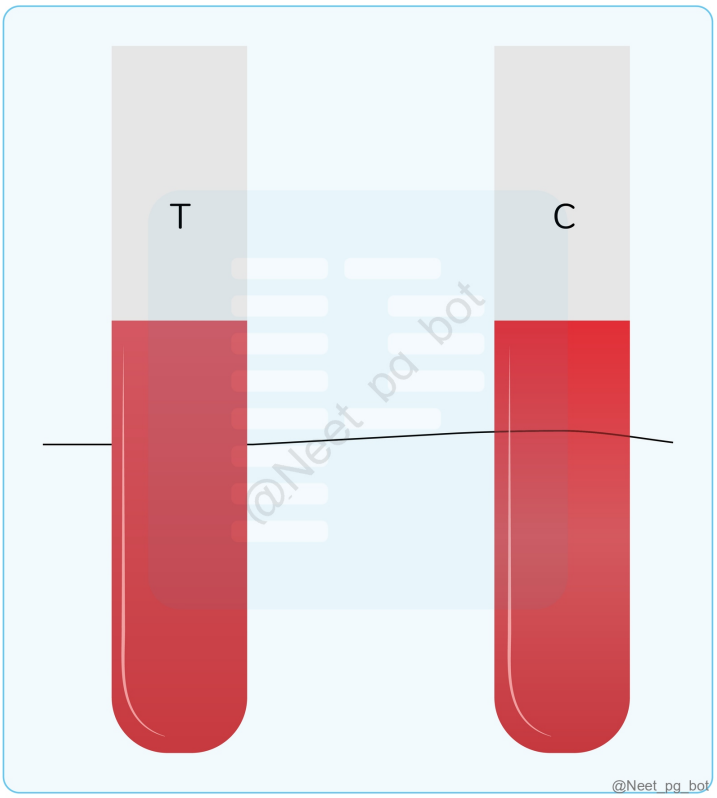
Q14: The medical team, aware of the prevalence of genetic disorders in the village decides to implement a screening process using NESTROFT for beta thalassemia. They plan to test the result by observing the solution turning clear by checking the visibility of a black line behind the test and control tubes. Which of the following on Nestrof test would be indicative of a positive result? (Q845940)

A. Black line visible in both tubes

B. Black line visible in only control tubes

C. Black line not visible in only test tubes

D. No black line visible in any of the tubes



See Answer in Part B → Q14

@Neet_pg_bot

Q15: Match the following diseases with their respective antibodies and target antigens on red blood cells (RBCs): 1. Cold Agglutinin Disease 2. Cold Hemolytic Disease Antibody Target Antigen on RBCs A IgM I antigen B IgG P antigen C IgG I antigen D IgM P antigen Select the correct matching pairs: (Q845943)

A. 1-A, 2-C

B. 1-C, 2-D

C. 1-A, 2-B

D. 1-B, 2-D

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following statements is false regarding warm antibody-mediated autoimmune hemolytic anemia (AIHA)? (Q845944)

A. It is commonly mediated by IgG antibodies active at 37°C.

B. It can be associated with the intake of drugs like alpha-methyldopa and quinine.

C. It typically involves the destruction of red blood cells primarily in the liver.

D. A positive direct Coombs test is often used to confirm the diagnosis.

Q1: Which of the following conditions is least likely to result in iron deficiency anemia? (Q880000)

A. A young 5-year-old suffering from hookworm infection

B. An elderly 60-year-old male diagnosed with carcinoma of the cecum

C. A middle-aged 54-year-old woman who has undergone Billroth II gastrectomy

D. A 25-year-old female consuming a diet predominantly based on maize

See Answer in Part B → Q1

@Neet_pg_bot

Q2: In the human body, where is the majority of biologically active iron located? (Q879988)

A. Hemoglobin

B. Myoglobin

C. Catalase enzymes

D. Ferritin

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient is found to have a mean corpuscular volume (MCV) of 109 fL. Which of the following conditions is least commonly associated with this laboratory finding? (Q879982)

A. Hypothyroidism

B. Vitamin B12 deficiency

C. Orotic aciduria

D. Anemia of chronic disease

See Answer in Part B → Q3

@Neet_pg_bot

Q4: All of the following anemias arise from reduced red cell production, except: (Q879974)

A. Iron deficiency anemia

B. Hereditary spherocytosis

C. Megaloblastic anemia

D. Aplastic anemia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: In individuals living with HIV infection, which hematologic abnormality is observed most commonly? (Q879969)

A. Thrombocytopenia

B. Neutropenia

C. Lymphocytosis

D. Anemia

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What is considered the most significant inflammatory mediator in the pathophysiology of anemia of chronic disease (AOCD)? (Q845881)

A. Interleukin-6

B. Transferrin

C. Interleukin-10

D. Interferon-γ

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 5-year-old child presents to the clinic with symptoms of irritability, abdominal pain, and vomiting. The physician suspects lead poisoning and orders a complete blood count along with a peripheral blood smear. Which of the following findings would most likely be seen on the peripheral blood smear in lead poisoning? (Q845895)

A. Schistocytes

B. Spherocytes

C. Basophilic stippling

D. Bite cells

See Answer in Part B → Q7

@Neet_pg_bot

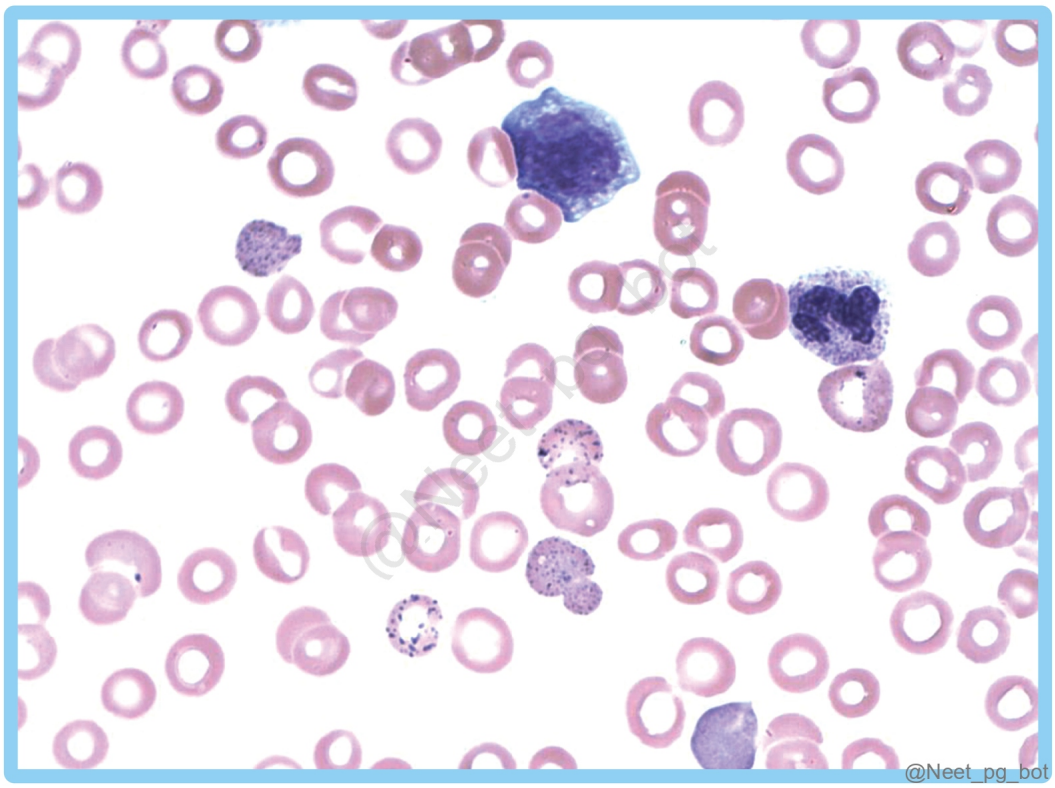
Q8: A peripheral blood smear revealed basophilic granules with Prussian blue stain. Which of the following bone marrow cells are associated with this condition? (Q845894)

A. Sideroblast

B. Siderocyte

C. Reticulocyte

D. Bite cells



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 7-year-old girl presents to the clinic with complaints of fatigue, weakness, and pale skin. Her mother mentions that she has developed cravings for ice (pica). Laboratory tests reveal microcytic anaemia, and her serum ferritin levels are significantly low. Which of the following is the most likely infectious cause of her condition? (Q845887)

A. Giardia lamblia

B. Ancylostoma

C. Diphyllobothrium latum

D. Enterobius vermicularis

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following vitamin deficiencies is most commonly associated with sideroblastic anemia? (Q845886)

A. Vitamin B1 (Thiamine)

B. Vitamin B9 (Folic Acid)

C. Vitamin B6 (Pyridoxine)

D. Vitamin B12 (Cobalamin)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the laboratory findings are suggestive of sideroblastic anemia? Serum Iron Transferrin saturation Serum Ferritin TIBC A. High High High Low B. Low Low Low High C. Low Low High Low D. High Low High Low (Q845885)

A. A

B. B

C. C

D. D

See Answer in Part B → Q11

@Neet_pg_bot

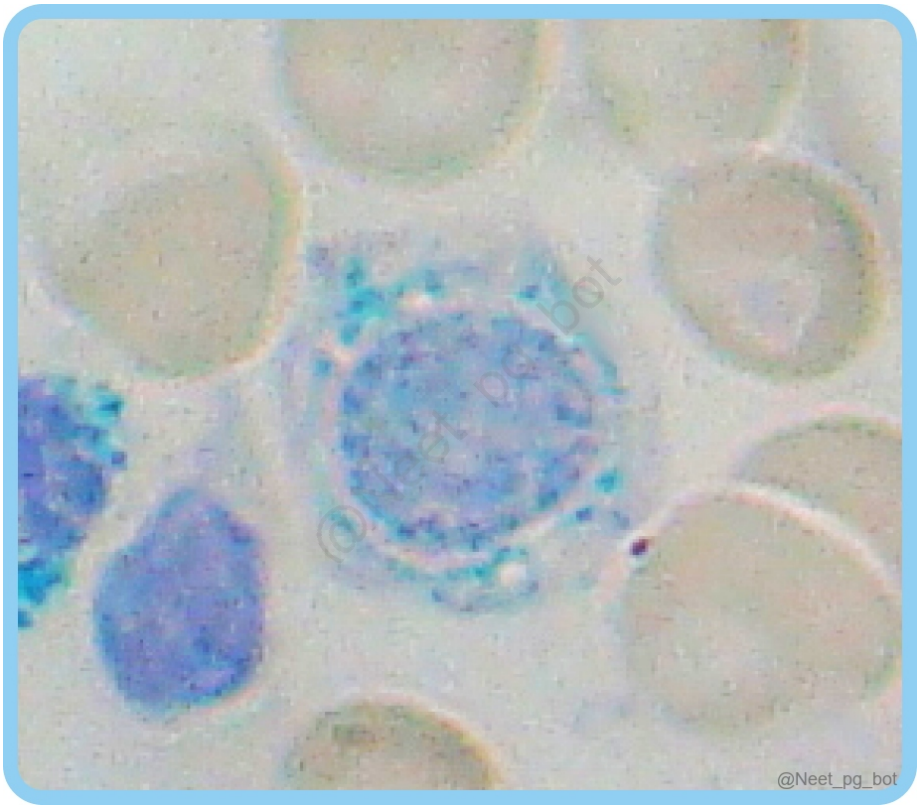
Q12: A 40-year-old female with a history of treatment for latent tuberculosis presents with fatigue. Physical examination reveals pallor and mild jaundice. Bone marrow smear revealed the following findings.which of the following is the most likely diagnosis? Options: (Q845884)

A. Iron deficiency anemia

B. Megaloblastic anemia

C. Sideroblastic anemia

D. Hemolytic anemia



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following new parameters has high specificity for differentiating anemia of chronic disease (ACD) from iron deficiency anemia (IDA)? (Q845883)

A. Serum transferrin receptor (sTfR)/log - ferritin index >1.5

B. Serum transferrin receptor (sTfR)/log - ferritin index <1.5

C. Reduced reticulocyte index

D. Blood film morphology

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 52-year-old female complains of fatigue, joint pain, and stiffness, especially in the mornings. Physical examination reveals swollen and tender joints in her wrists with ulnar deviation at metacarpophalangeal joints. Which of the following lab findings is not associated with this condition? (Q845882)

A. Low serum iron

B. Low transferrin saturation

C. High ferritin

D. High total iron-binding capacity (TIBC)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following investigations is the least helpful in determining the underlying cause of anemia? (Q845864)

A. MCV

B. MCH

C. Peripheral smear

D. Reticulocyte count

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65-year-old female with a history of breast cancer presents with fatigue and pallor. Laboratory results indicate a hemoglobin level of 9.7 g/dL, low serum iron, elevated ferritin, and low total iron-binding capacity (TIBC). All of the following are true regarding this condition except? Anemia is caused by reduced erythroid progenitor proliferation and iron uptake. Causes include chronic infections, autoimmune disorders and lymphoma. Peripheral smear does not show microcytic hypochromic anemia. All the patients benefit from erythropoietin administration. (Q845880)

A. 1, 3, 4

B. 3, 4

C. 4 only

D. 3 only

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following statements correctly describes the principle of Prussian blue stain? (Q845879)

A. Ferrocyanide to ferricyanide

B. Ferrocyanide to ferric ferrocyanide

C. Ferroferric cyanide to ferrocyanide

D. Ferrocyanide to ferrocyanide

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 24-year-old female with severe anemia started on parenteral iron. Which of the following would occur first in this patient as a response to therapy? (Q845878)

A. Increase in serum iron level

B. Erythroid hyperplasia in bone marrow

C. Increase in MCV

D. Increase in reticulocyte count

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 28-year-old female presented with easy fatigability and dyspnea on exertion. She was found to have a hemoglobin of 6 g/dL. What will be most likely finding in the peripheral blood smear of this patient? (Q845877)

A. Macrocytic red cells

B. Cabot ring

C. Hypersegmented neutrophils

D. Microcytic and hypochromic red cells

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 32-year-old female diagnosed with iron deficiency anemia is prescribed oral iron supplements. Foods containing which of the following can she take to increase iron absorption? (Q845876)

A. Ascorbate

B. Oxalate

C. Carbonate

D. Phosphate

See Answer in Part B → Q20

@Neet_pg_bot

Q21: In a patient diagnosed with iron deficiency anemia, the values of all of the following increase except? (Q845875)

A. Total iron binding capacity

B. RBC protoporphyrin

C. Transferrin saturation

D. Transferrin receptor

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 10-year-old girl presented with fatigue, weakness and reduced exercise tolerance. Her mother reports that she has pica, frequently eating chalk and ice and the child also complains of brittle nails and occasional glossitis. Her laboratory results show reduced hemoglobin, MCV 75 fl, MCH 22 pg and RDW 28. What is the most likely diagnosis? (Q845874)

A. Iron deficiency anemia

B. Megaloblastic anemia

C. Sideroblastic anemia

D. Thalassemia major

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 45-year-old male patient was diagnosed with iron deficiency anemia. Which of the following is true about the intracellular regulation of iron in the above condition? IRP- Iron regulatory protein IRE- Iron response elements (Q845873)

A. Ferritin translation is increased by binding IRP to IRE.

B. Ferritin translation is decreased by binding IRP to IRE.

C. Transferrin receptor 1 translation is unaffected by binding IRP to IRE.

D. Transferrin receptor 1 translation is decreased by binding IRP to IRE.

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which transport molecule facilitates the absorption of Fe2+ into enterocytes in the small intestine? (Q845872)

A. Ferroportin

B. Hephaestin

C. DMT-1

D. Hepcidin

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 28-year-old woman presents with fatigue and pallor. Lab tests show hemoglobin of 9 g/dL and MCV of 68 fL. Peripheral smear reveals microcytic and hypochromic red blood cells. Her symptoms and laboratory findings are consistent with iron deficiency anemia. Which of the following statements regarding iron deficiency anemia (IDA) is correct? (Q845871)

A. Serum ferritin levels are elevated.

B. Serum ferritin is the gold standard investigation

C. Decreased serum ferritin levels

D. Serum ferritin levels are not affected.

See Answer in Part B → Q25

@Neet_pg_bot

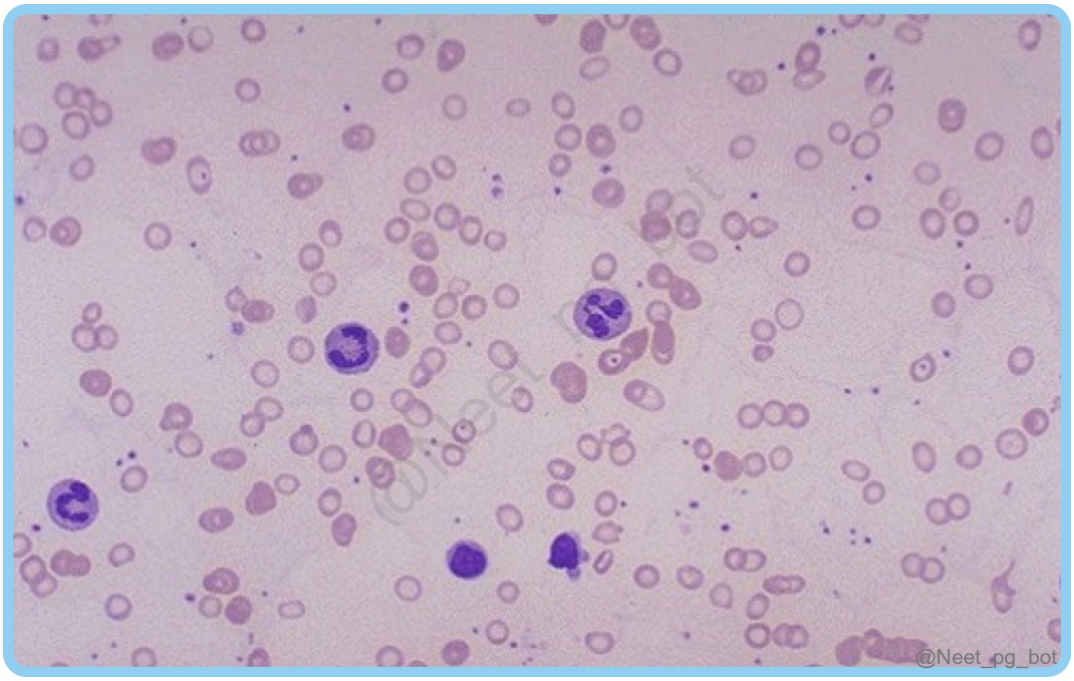
Q26: A 35-year-old woman has been experiencing fatigue, pallor, and shortness of breath for the past six months. Laboratory tests reveal a Hb of 6 gm/dl. Red cell distribution width is increased. Peripheral smear is shown below. Where is the likely site of absorption of the micronutrient deficient in this patient? (Q845870)

A. Jejunum

B. Ileum

C. Duodenum

D. Colon



See Answer in Part B → Q26

@Neet_pg_bot

Q27: All of the following are causes of microcytic hypochromic anemia except? (Q845869)

A. Iron deficiency anemia

B. Sideroblastic anemia

C. Thalassemia

D. Hereditary spherocytosis

Q19 (p. 744)					

Q1: A 72-year-old male complains of increasing tiredness and generalised weakness. On examination, a firm 1-cm nodule is palpated in the prostate gland. Laboratory studies show anemia with a normocytic, normochromic blood picture. Peripheral smear demonstrates occasional myelocytes, tear-drop erythrocytes, and about 2 nucleated red cells per 100 leukocytes. Which diagnosis best explains these findings? (Q880071)

A. Myelodysplastic syndrome

B. Myelophthisic anemia

C. Primary myelofibrosis

D. Myeloproliferative neoplasm

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Myelophthisic anemia typically arises when normal bone marrow is replaced by abnormal tissue. Among the following, which is the leading cause? (Q880070)

A. Granulomatous disorders

B. Secondary deposits from malignant tumours

C. Myeloproliferative disorders

D. Prior exposure to radiation

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following conditions are known to cause pure red cell aplasia? 1. Parvovirus B19 infection 2. Thymoma 3. Chronic neutrophilic leukaemia 4. Diamond–Blackfan anemia 5. Rifampicin use (Q880069)

A. 1, 2

B. 2, 3, 5

C. 1, 4

D. 1, 2, 4

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Aplastic anemia has the potential to evolve into certain hematologic malignancies or disorders over time. Which of the following are known possible transformations? 1. Acute myeloid leukaemia 2. Acute lymphoblastic leukaemia 3. Chronic myeloid leukaemia 4. Chronic lymphocytic leukaemia 5. Myelodysplastic syndrome (Q880036)

A. 2, 3, 4

B. 1, 2

C. 1, 5

D. 1, 3, 5

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following represents the most common known cause of aplastic anemia? (Q880030)

A. Drugs

B. Autoimmune disorders

C. Infections

D. Radiation exposure

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old female with a history of rheumatoid arthritis on long-term therapy presents with dizziness on standing. Clinical examination reveals pallor and koilonychia. Considering the type of anemia associated with chronic inflammatory states, which of the following statements is correct? (Q880025)

A. Both serum iron and tissue iron are within normal limits

B. The anemia may present as normocytic and normochromic

C. Hepcidin production is suppressed

D. Total iron-binding capacity (TIBC) is increased

See Answer in Part B → Q6

@Neet_pg_bot

Q7: With respect to antibodies associated with pernicious anemia, which of the following descriptions is incorrect? (Q880019)

A. Type I antibody can be detected in both serum and gastric secretions

B. Type I antibody interferes with the attachment of vitamin B12 to intrinsic factor

C. Type II antibody blocks the interaction of the intrinsic factor–B12 complex with ileal receptors

D. Type III antibody targets haptocorrin

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old woman who underwent ileal resection for Crohn's disease presents with features of megaloblastic anemia. Which step in vitamin B12 absorption and transport is most likely impaired in her case? (Q880008)

A. Cubilin receptor–mediated uptake

B. Binding of cobalamin to haptocorrin

C. Transport of cobalamin via transcobalamin II

D. Interaction of vitamin B12 with intrinsic factor

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient presents with inflammation of the mouth and tongue. He is a non-vegetarian. As part of the evaluation, a Schilling test was done and found unremarkable. Which of the following investigations could lead to the aetiology behind this presentation? (Q845910)

A. Serum folate levels

B. Peripheral blood smear

C. Anti-IF antibody levels

D. Serum Vitamin B12 levels

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A group of scientists is studying the mechanisms involved in the pathogenesis of megaloblastic Anaemia secondary to vitamin deficiencies. The final study results

demonstrate a "folate trap" as one of the likely pathophysiologic mechanisms of megaloblastic Anaemia. Which of the following is closely associated with the "folate trap"? (Q875986)

A. Normal serum tetrahydrofolate

B. Reduced serum methyltetrahydrofolate

C. Normal serum B12

D. Reduced serum vitamin B12

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements is correct regarding the normal metabolism of vitamin B12? A. Haptocorrin from salivary glands binds to B12 in the stomach. B. It is absorbed in the duodenum with the help of intrinsic factor and transcobalamin II. C. Gastric enzymes play an important role in splitting of haptocorrin-B12 complex. D. It is stored primarily in the liver and has a large reserve capacity. E. It acts as a cofactor for converting homocysteine to methionine and methylmalonyl-CoA to succinyl-CoA. (Q845897)

A. A, B, C, and D

B. A, D, and E

C. A and C

D. C and D

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is true when increased urinary formiminoglutamic acid is detected in a patient to whom histidine is given? (Q845907)

A. Presence of antibodies against intrinsic factor

B. Deficiency of folic acid is present

C. Neurological symptoms are common

D. Presence of worm infestation

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following helps differentiate megaloblastic anaemia caused by vitamin B12 deficiency, not folate? (Q845905)

A. Reduced plasma homocysteine levels

B. Neurological symptoms improve after folate administration

C. Raised urinary methylmalonic acid levels

D. Anaemia doesn’t improve after folate administration

See Answer in Part B → Q13

@Neet_pg_bot

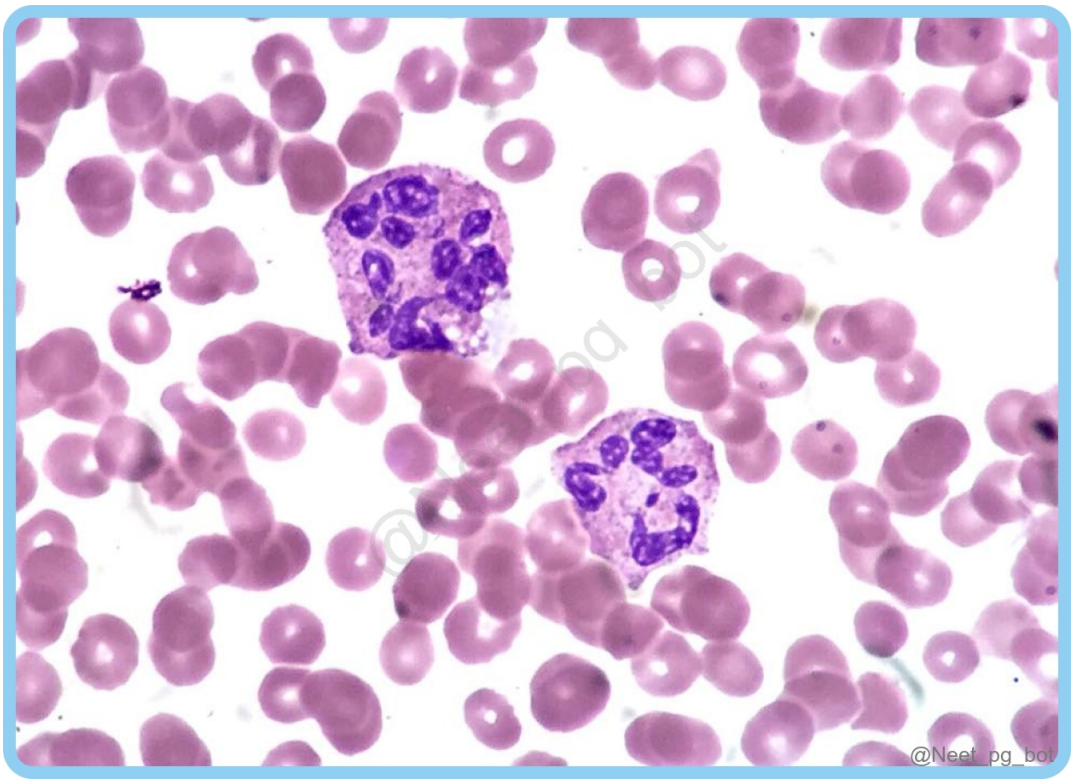
Q14: A patient presents with tiredness and myalgia for the past 3 months. She has hypertension, psoriasis and hyperuricemia, for which she is on multiple medications. A peripheral blood smear is done which is given in the image below. Which of her following medications would have caused these symptoms? (Q845903)

A. Hydrochlorothiazide

B. Adalimumab

C. Methotrexate

D. Colchicine



See Answer in Part B → Q14

@Neet_pg_bot

Q15: All the following findings are seen in vitamin B12 deficiency except? (Q845902)

A. Myeloid/erythroid ratio is 3:1

B. Sieve-like chromatin on bone marrow smear

C. Increased LDH levels

D. Increased bilirubin levels

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a finding on a peripheral blood smear in vitamin B12 deficiency? (Q845901)

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Match the following laboratory findings with the most likely diagnosis. a. Microcytic anaemia, normal homocysteine and methylmalonic acid levels. 1. Vitamin B12 Deficiency b. Macrocytic anaemia, elevated homocysteine and methylmalonic acid levels. 2. Iron Deficiency Anemia (IDA) c. Macrocytic anaemia, elevated homocysteine and normal methylmalonic acid levels. 3. Anaemia of Chronic Disease (ACD) d. Normocytic anaemia, normal homocysteine and methylmalonic acid levels. 4. Folate Deficiency (Q845900)

A. a-2, b-1, c-4, d-3

B. a-1, b-2, c-4, d-3

C. a-2, b-1, c-3, d-4

D. a-3, b-4, c-1, d-2

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 60-year-old female presents with chronic fatigue, shortness of breath, tingling and numbness in her hands and feet, bloating, and epigastric pain after meals. She has a history of occasional heartburn and nausea. On examination, she is pale, has a smooth, enlarged tongue with the following findings on the hand. Lab investigations show haemoglobin to be 9.6 g% and MCV 112. What is the most likely diagnosis? (Q845899)

A. Iron deficiency anaemia

B. Folate deficiency

C. Pernicious anaemia

D. Thalassemia

See Answer in Part B → Q18

@Neet_pg_bot

Q19: All of the following are the causes of anaemia due to vitamin B12 deficiency, except? (Q845898)

A. Pernicious anemia

B. Chronic alcoholism

C. Diphyllobothrium latum infection

D. Gastric resection

See Answer in Part B → Q19

Q1: Caspase-1 is primarily involved in which type of programmed cell death? (Q865391)

A. Apoptosis

B. Pyroptosis

C. Necroptosis

D. Necrosis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 24-year-old male was brought to the emergency department after suffering severe injuries in a motorcycle accident. His blood pressure was 80/60 mm Hg, and he was tachycardic with cold, clammy skin. An ultrasound examination revealed a ruptured spleen. Arterial blood gas analysis was suggestive of metabolic acidosis. Which of the following conditions most likely caused the patient to suffer? (Q857122)

A. Cardiogenic shock

B. Septic shock

C. Hypovolemic shock

D. Neurogenic shock

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is true regarding sirtuins? Increases insulin sensitivity and glucose metabolism Promotes genes that increase longevity They are of 7 types They are one of the types of histone deacetylases (Q855087)

A. 1, 2, 3

B. 1, 2, 3, 4

C. 2, 3

D. 2, 4

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Cell-in-cell appearance is seen in which of the following? (Q855076)

A. Necrosis

B. Apoptosis

C. Necroptosis

D. Entosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Senile atrophy occurs due to which of the following? (Q856024)

A. Denervation

B. Decreased nutrition

C. Decreased workload

D. Reduced blood supply

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which among the following is less related to irreversible cell injury? (Q820573)

A. Blebs formation

B. Karyolysis

C. Amorphous densities

D. Pyknotic nucleus

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is an anti-apoptotic gene? (Q857450)

A. BAK

B. MCL1

C. PUMA

D. BAD

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following diseases is caused by abnormal folding of proteins? (Q857433)

A. Creutzfelt Jakob disease

B. Cirrhosis

C. Nephritic syndrome

D. Sickle cell anemia

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which nuclear change of cell injury is being shown in the image? (Q857432)

A. Pyknosis

B. Karyorrhexis

C. Karyolysis

D. Normal nucleus

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Identify the correct statements regarding amyloidosis. Amyloidosis is called so because it looks like the deposition of starch. Beta-pleated sheets are seen. AL is a type of secondary amyloidosis. It is an extracellular protein. (Q857424)

A. 1, 2 and 3

B. 1, 4

C. 2, 3 and 4

D. 1, 2 and 4

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Apoptotic bodies comprise of? (Q860513)

A. Include cytoplasm + intranuclear material + organelle

B. Cytoplasm + organelle

C. Organelle + intranuclear material

D. Only organelle

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following types of cell death involves activation of caspase enzymes? (Q866340)

A. Necrosis and Apoptosis

B. Apoptosis and Pyroptosis

C. Apoptosis and necroptosis

D. Apoptosis only

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Supravital stains are used in the identification of all except? (Q857588)

A. Reticulocytes

B. Copper in tissue

C. Heinz bodies

D. Ribosomal RNA

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A diabetic male presented with seizures. Radiological examination shows a lesion. Histopathological examination shows liquefactive necrosis. What is the most important mechanism responsible for this? (Q866754)

A. Enzymatic degradation

B. Mechanical

C. Ischemic

D. Pressure

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is pro-apoptotic? (Q866665)

A. Bcl-2

B. Bcl-xL

C. Mcl-1

D. Bax

See Answer in Part B → Q15

@Neet_pg_bot

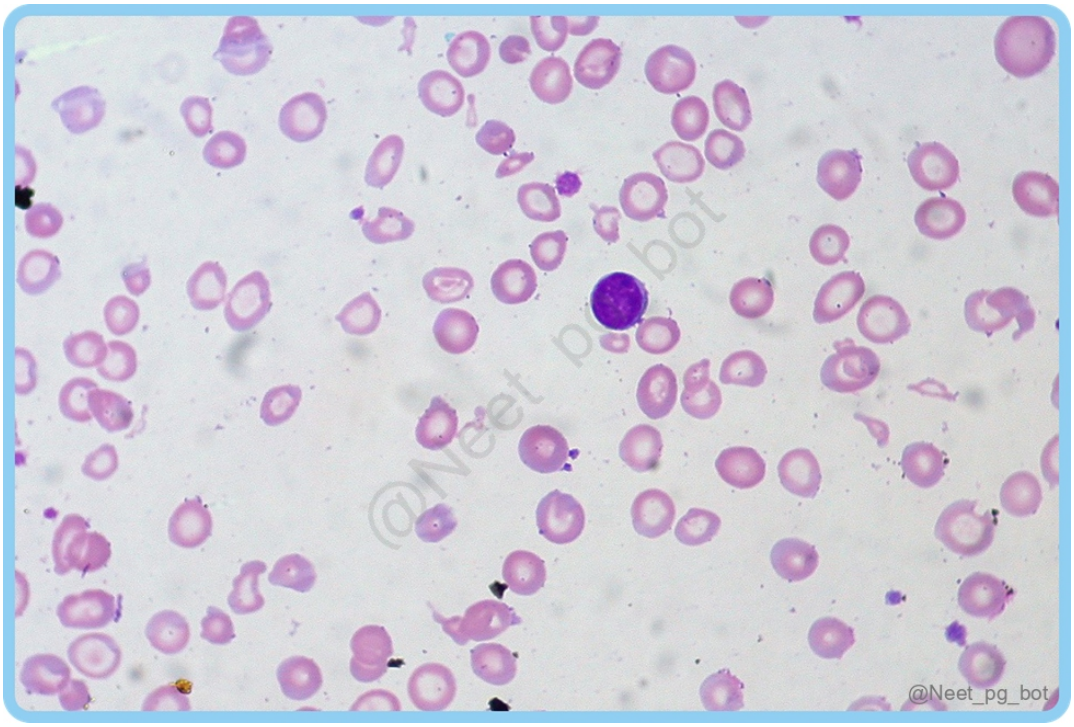
Q16: A female patient presented with fatigue and a history of piles. Routine complete blood count analysis showed a hemoglobin of 8.5 g/dL, an MCV of 65 fL, and an RBC count of 3.2 million and RDW is increased. A peripheral smear is given below. Which of the following is the next best investigation for this patient? (Q855974)

A. HbA2 levels

B. Serum ferritin levels

C. Serum folate levels

D. Serum homocysteine levels



See Answer in Part B → Q16

@Neet_pg_bot

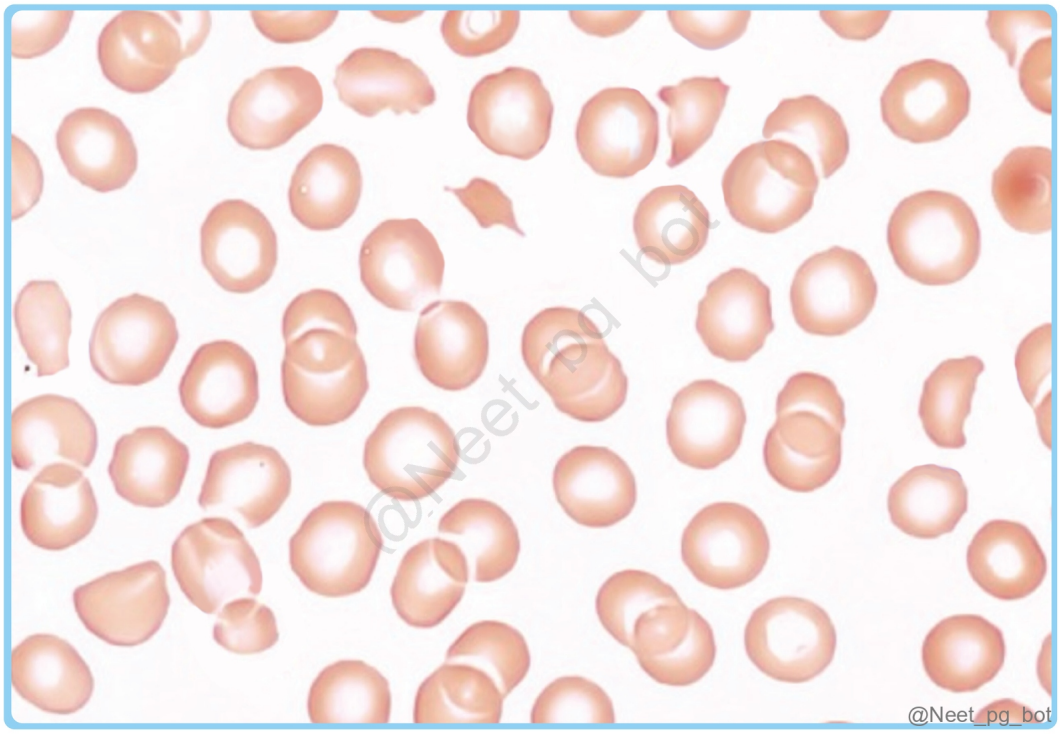
Q17: An elderly patient presents with anemia and hemoglobinuria. Investigations reveal increased bilirubin and lactate dehydrogenase. The peripheral smear image is given below. Which of the following is associated with this? (Q855931)

A. Splenomegaly

B. Mechanical second heart valve

C. Increased HbA2

D. Goitre



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A child presents with recurrent chest infections and abdominal pain. There is a history of delayed growth and bone problems causing facial changes. On examination, he had icterus and mild splenomegaly. Peripheral smear shows following finding. What is the likely diagnosis? (Q855920)

A. Beta thalassemia

B. HbC disease

C. Sickle cell disease

D. Acute coronary disease

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 9-month-old boy presents with progressive pallor and abdominal distention. On examination, hepatosplenomegaly and malar eminence are observed. Laboratory investigations reveal a low hemoglobin level, and the Mentzer index is less than 13. Considering these findings, what is the most likely diagnosis for this patient? (Q859851)

A. Megaloblastic anemia

B. Iron deficiency anaemia

C. Thalassemia

D. Pernicious anemia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 23-year-old male patient presented with a history of fatigue and tiredness. On investigation, he was found to have Hb = 9 g/dl and MCV = 101 FL. A peripheral smear examination showed macrocytic RBC and hypersegmented neutrophils. Which of the following is the most likely etiology? (Q858518)

A. Lead poisoning

B. Iron deficiency anaemia

C. Hemolytic anemia

D. Chronic alcoholism

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 52-year-old male patient comes with complaints of abdominal pain, nausea, and vomiting. A peripheral blood smear reveals macrocytes and hypersegmented neutrophils, and an endoscopy reveals atrophic gastritis. Which of the following conditions is likely to be seen in this patient? (Q854855)

A. Vitamin B12 deficiency

B. Folate deficiency

C. Pyridoxine deficiency

D. Niacin deficiency

See Answer in Part B → Q21

@Neet_pg_bot

Q22: What does the vacutainer tube depicted in the provided image contain? (Q856491)

A. Na-EDTA

B. Trisodium citrate

C. NAF-heparin

D. Clot activator

See Answer in Part B → Q22

@Neet_pg_bot

Q23: The JAK2 mutation is most commonly associated with: (Q856485)

A. Polycythemia vera

B. Essential thrombocytosis

C. Chronic myelogenous leukemia (CML)

D. Primary myelofibrosis (PMF)

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 16-year-old boy presents with jaundice and splenomegaly. His father had a similar illness during adolescence. The MCHC was high. What is the most likely diagnosis? (Q866370)

A. IDA

B. Hereditary spherocytosis

C. Thalassemia major

D. AIHA

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A phlebotomist is asked to collect blood samples for a patient undergoing multiple tests. Which of the following is the correct order of blood collection to avoid contamination of the samples based on the additives in the collection tubes? (Q854685)

A. Light blue → Lavender → Red → Grey

B. Grey → Red → Light blue → Lavender

C. Light blue → Red → Lavender → Grey

D. Red → Lavender → Grey → Light blue

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which of the following causes microcytic anemia? Iron deficiency Thalassemia Lead poisoning Vitamin B12 deficiency (Q879228)

A. 1, 2, 3

B. 1, 2

C. 1, 3

D. 1, 2, 3, 4

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A patient presents with microcytic hypochromic anemia (MCV: 70–79 fL) and a Mentzer index of 11 with increased RBC count. Peripheral blood smear reveals target cells. Which of the following investigations is the most appropriate for establishing the diagnosis? (Q879222)

A. Bone marrow examination

B. Hb electrophoresis

C. Serum ferritin

D. Serum iron and TIBC

See Answer in Part B → Q27

@Neet_pg_bot

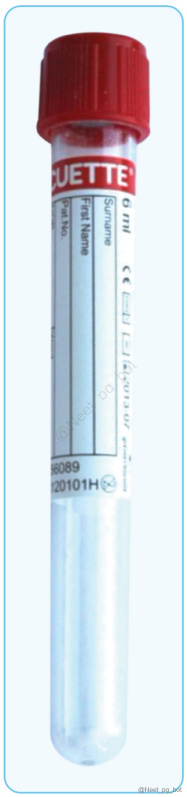
Q28: The vacutainer tube shown in the given image contains the following: (Q855434)

A. EDTA

B. Trisodium citrate

C. NAF - heparin

D. Clot activator



See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following oil red O stain is used? (Q855393)

A. Formalin fixation

B. Frozen section

C. Alcohol fixation

D. Glutaraldehyde fixation

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Which of the following needles is commonly used for bone marrow biopsy? (Q855114)

A. Klima needle

B. Salah needle

C. Jamshidi needle

D. Islam needle

See Answer in Part B → Q30

@Neet_pg_bot

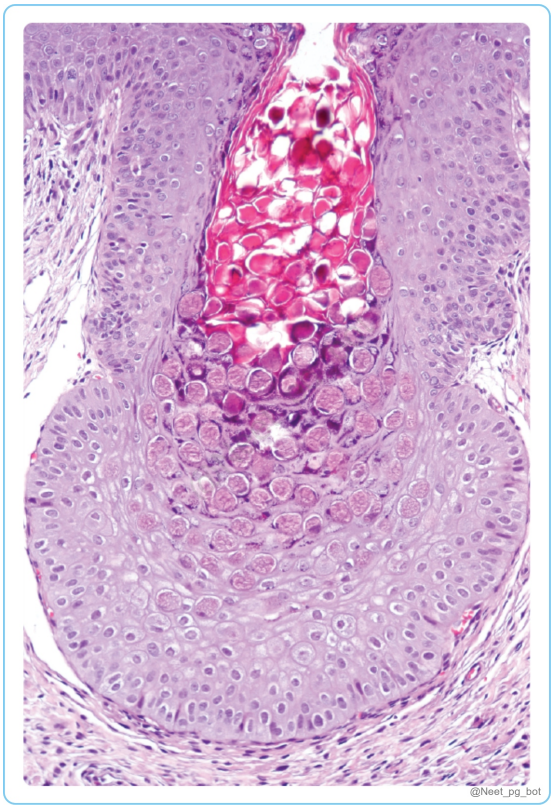
Q31: A child presents with multiple skin lesions over the inner thigh and genital areas. Initially, the lesions started as macules and later developed into nodules. Some of the nodules have a central umbilication. The histology of the lesion is shown below. What would be found on a biopsy? (Q855108)

A. Multinucleate giant cells (Tzanck cells)

B. Donovan bodies

C. Henderson-Patterson bodies

D. Koilocytes



See Answer in Part B → Q31

@Neet_pg_bot

Q32: Pair the stains with their corresponding options Stain Corresponding Option 1. Prussian blue stain a. Iron 2. PAS stain b. Glycogen 3. Congo red stain c. Leprosy 4. Fite-Faraco stain d. Amyloid (Q855085)

A. 1-d, 2-c, 3-b, 4-a

B. 1-c, 2-a, 3-b, 4-d

C. 1-a, 2-b, 3-d, 4-c

D. 1-b, 2-a, 3-c, 4-d

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A woman presents with nodular lesions, 4-6 mm in size, on the inner thighs and peri-anal region. The lesions appear pale, and histopathological examination reveals multiple intracytoplasmic inclusion bodies consistent with Henderson-Patterson bodies. What is the most likely diagnosis? (Q855907)

A. Trichodysplasia spinulosa

B. Condyloma acuminata

C. Molluscum contagiosum

D. Donovanosis

See Answer in Part B → Q33

@Neet_pg_bot

Q34: Which of the following methods is iron in tissues stained? (Q855899)

A. Masson’s trichrome

B. Prussian blue

C. PAS

D. Fite-Faraco

See Answer in Part B → Q34

@Neet_pg_bot

Q35: The following image shows an instrument used to estimate haemoglobin levels. What does it measure? (Q855893)

A. Alkaline hematin

B. Acid hematin

C. Oxyhemoglobin

D. Deoxyhemoglobin

@Neet_pg_bot

See Answer in Part B → Q35

@Neet_pg_bot

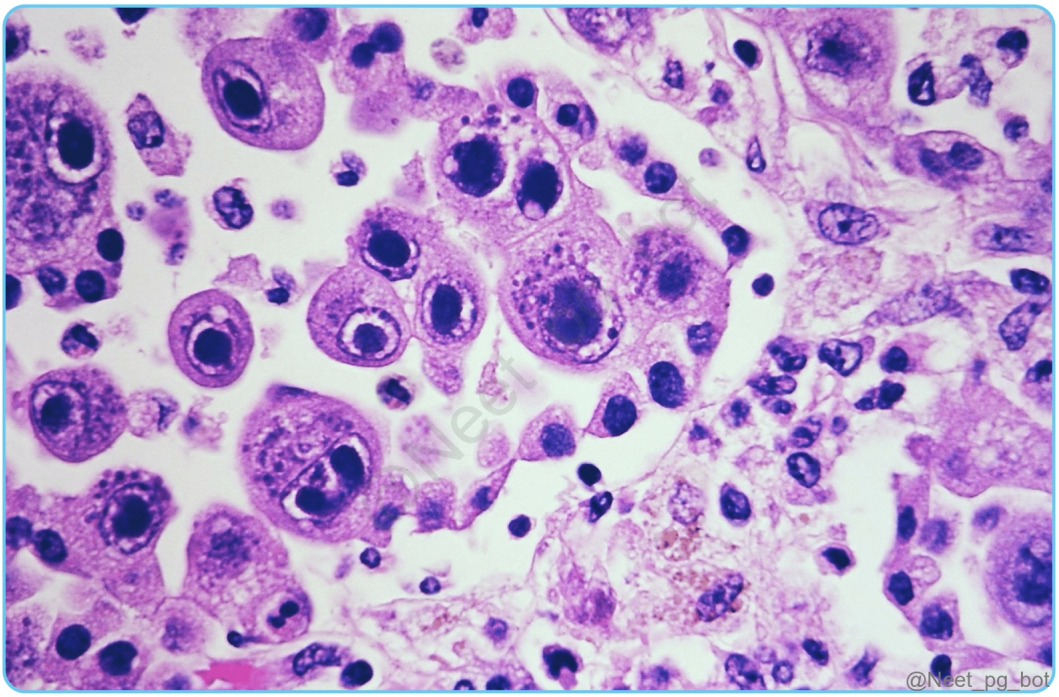
Q36: The given inclusion bodies are characteristic of which of the following organisms? (Q858119)

A. Human papillomavirus

B. Cytomegalovirus

C. Epstein-Barr virus

D. Herpes simplex virus



See Answer in Part B → Q36

@Neet_pg_bot

Q37: A 20-year-old female with easy fatiguability and pallor presented to the OPD. The image of her hand is shown below. What is the most likely diagnosis? (Q856480)

A. Aplastic anemia

B. Vitamin B12 deficiency

C. Iron deficiency anaemia

D. Hypoalbuminemia

See Answer in Part B → Q37

@Neet_pg_bot

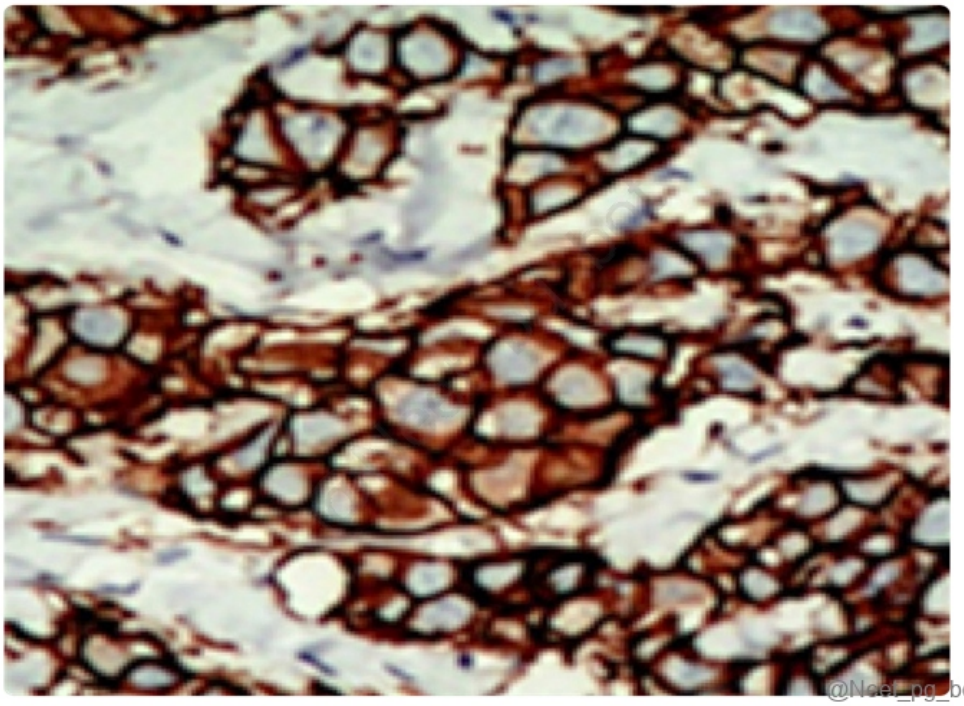
Q38: The image below represents the presence of HER2 neu cells in a patient with breast carcinoma. What agent is used to produce this characteristic discolouration? (Q854670)

A. FITC

B. Phycoerythrin

C. Cyanate dye

D. Diaminobenzidine



See Answer in Part B → Q38

@Neet_pg_bot

Q39: CD markers can be detected by which of the following tests? (Q866390)

A. Cytogenetics

B. Next-generation sequencing

C. Flow cytometry

D. Karyotype

See Answer in Part B → Q39

@Neet_pg_bot

Q40: In Pap smear cytology, which of the following is the most appropriate fixative used to preserve cellular details immediately after smearing? (Q866744)

A. 50% formaldehyde

B. 95% ethanol

C. 70% ethanol

D. 10% buffered formalin

See Answer in Part B → Q40

@Neet_pg_bot

Q41: Which of the following measures is associated with an increased life span? (Q855961)

A. Regular moderate exercise for 30 min

B. Decrease stress

C. Decreasing calorie intake by 30%

D. Pharmacological intervention with proton pump inhibitors

See Answer in Part B → Q41

@Neet_pg_bot

Q42: Choose the correct statement regarding the telomerase theory of ageing: (Q855914)

A. Telomere stability is associated with ageing

B. Abnormal telomerase activation is associated with ageing

C. Decreased telomere length is associated with ageing

D. Increased telomere length is associated with ageing

See Answer in Part B → Q42

@Neet_pg_bot

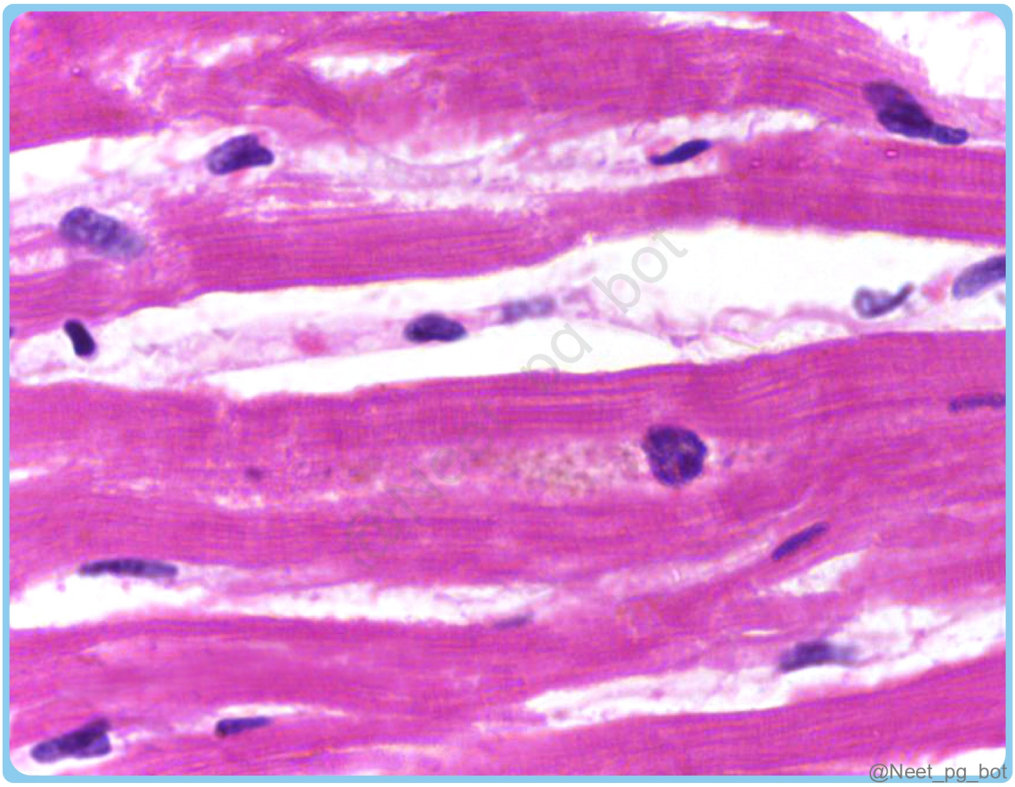
Q43: The body of an 82-year-old man has been seen for a post-mortem to determine the cause of death. You are examining a histopathological slide containing a section of his cardiac tissue where you notice some pigmentation. Which is the substance that is seen in the image given below? (Q859859)

A. Melanin

B. Lipofuscin

C. Hemosiderin

D. Iron



See Answer in Part B → Q43

@Neet_pg_bot

Q44: Among the following, which molecule is required for the presentation of the antigens by the APCs to TH2 cells? (Q859298)

A. NK cells

B. G-protein coupled receptor

C. MHC

D. Lectin receptor

See Answer in Part B → Q44

@Neet_pg_bot

Q45: Which of the following caspases binds to Cyt c and the APAF-1 complex? (Q856488)

A. Caspase 1

B. Caspase 8

C. Caspase 9

D. Caspase 4

See Answer in Part B → Q45

@Neet_pg_bot

Q46: All of the following are crosslinking fixatives except? (Q856893)

A. Glutaraldehyde

B. Formaldehyde

C. Methanol

D. Osmium tetroxide

See Answer in Part B → Q46

@Neet_pg_bot

Q47: A chronic alcoholic patient presented with increasing abdominal girth. On examination, shifting dullness was present, and the liver span was less than 7cm.

Histopathological examination revealed the presence of intracytoplasmic eosinophilic inclusions in hepatocytes. What is the content of these inclusions? (Q856152)

A. Intermediate filaments

B. Actin

C. Microtubules

D. Fibronectin

See Answer in Part B → Q47

@Neet_pg_bot

Q48: A 70-year-old patient presented with cough, fatigue, and weight loss. He was diagnosed with squamous cell carcinoma on bronchoscopy. The resected specimen had a hilar lymph node that was 1 cm in size and showed a black pigment. What is the black pigment likely to be? (Q856097)

A. Anthracotic pigment

B. Melanin

C. Lipochrome

D. Hemosiderin

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A 20-year-old female who is a known case of sickle cell anaemia was rushed to the emergency department with a complaint of extreme pain in the legs and fingers for the past 4 hours. Further examination revealed pain and tenderness in the right upper quadrant, and investigations showed sickle cells on peripheral blood smear and high bilirubin(indirect). What is the diagnosis? (Q860284)

A. IDA

B. Thalassemia

C. Anaemia of chronic disease

D. Sickle cell crisis

See Answer in Part B → Q49

@Neet_pg_bot

Q50: Investigations of a patient being evaluated for leukaemia revealed a WBC count of 450,000/μL, with eosinophilia and basophilia. What is the likely diagnosis in this case? (Q855989)

A. Acute Lymphoblastic Leukemia (ALL)

B. Chronic Myelogenous Leukemia (CML)

C. Chronic Lymphocytic Leukemia (CLL)

D. Acute Myelogenous Leukemia (AML)

See Answer in Part B → Q50

@Neet_pg_bot

Q51: Which of the following is true regarding glucose-6-phosphate dehydrogenase (G6PD) deficiency? (Q856478)

A. Spectrin defect

B. Bite cells are present

C. Cells do not lyse in a hypotonic solution

D. Cells lyse in hypertonic solution

See Answer in Part B → Q51

@Neet_pg_bot

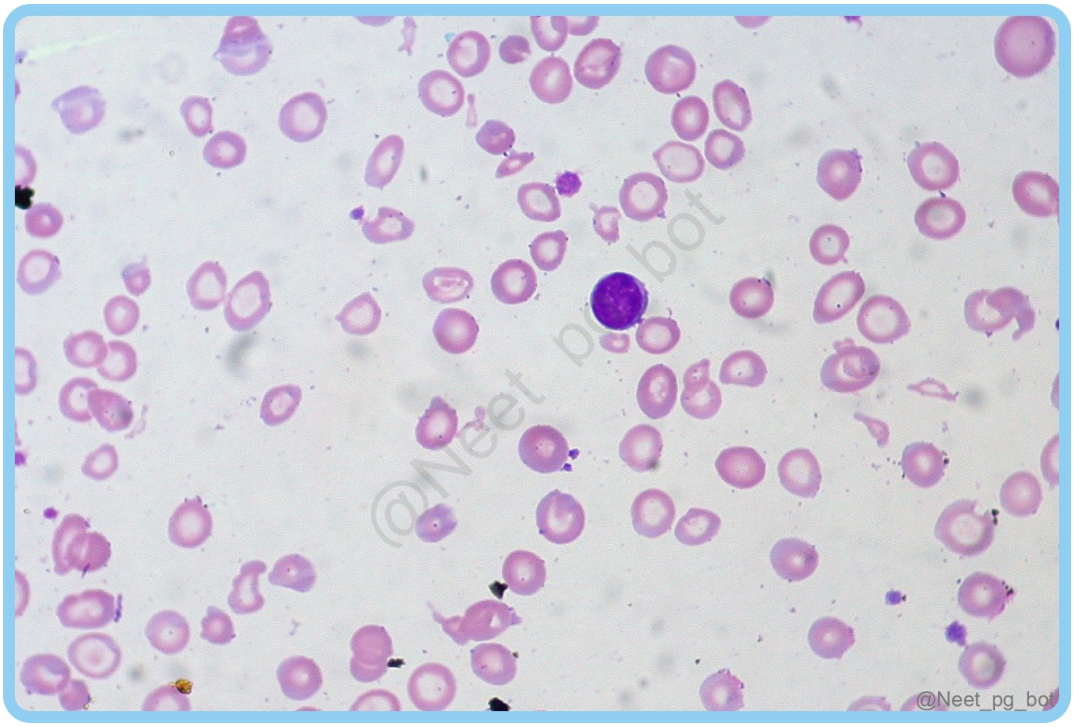
Q52: A 35-year-old woman presents with fatigue. Investigations reveal the following: Hemoglobin (Hb): 5 gm%, low mean corpuscular haemoglobin (MCH), and low mean corpuscular volume (MCV). The peripheral smear shows microcytic hypochromic red blood cells. What is the most likely diagnosis? {{caption_text}} (Q855889)

A. Megaloblastic anaemia

B. Iron deficiency anaemia

C. Thalassemia major

D. Essential thrombocytosis



See Answer in Part B → Q52

@Neet_pg_bot

Q53: Match the following cell types with their associated malignancy: Cell Type Associated Malignancy 1. Popcorn cell a. Acute promyelocytic leukemia 2. Faggot cell b. Lymphocyte-predominant Hodgkin's lymphoma 3. Cerebriform nuclei c. Burkitt lymphoma 4. Starry sky appearance d. Sezary syndrome (Q855885)

A. 1-b, 2-a, 3-d, 4-c

B. 1-a, 2-d, 3-c, 4-b

C. 1-b, 2-c, 3-a, 4-c

D. 1-a, 2-b, 3-d, 4-c

See Answer in Part B → Q53

@Neet_pg_bot

Q54: Which of the following is a feature of hemolytic anaemia? (Q858116)

A. Increased haptoglobin

B. Neutropenia

C. Reticulocytopenia

D. Decreased haptoglobin

See Answer in Part B → Q54

@Neet_pg_bot

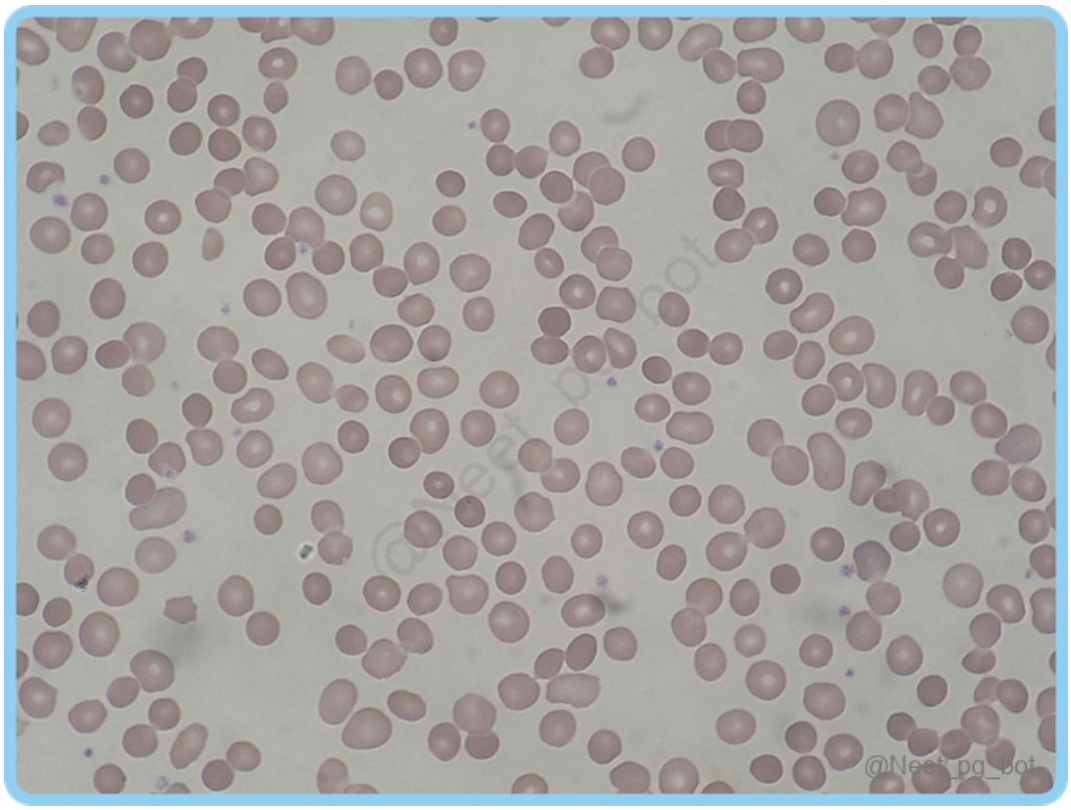
Q55: A child presents with intermittent jaundice and splenomegaly. There is a history of similar complaints in the elder brother. A peripheral smear shows the following findings. Which of the following is the most appropriate diagnostic test for this condition? (Q855398)

A. Osmotic fragility test - Hereditary spherocytosis

B. Coombs test - Autoimmune hemolytic anaemia

C. Genetic testing - G6PD deficiency

D. Flow cytometry - Paroxysmal nocturnal hemoglobinuria



See Answer in Part B → Q55

@Neet_pg_bot

Q56: Serum transferrin saturation level is low. What is the most likely condition? (Q854695)

A. Iron Deficiency Anemia

B. Hemochromatosis

C. Sideroblastic anemia

D. Pernicious anemia

See Answer in Part B → Q56

@Neet_pg_bot

Q57: Which of the following for Sickle cell anaemia is correct? (Q854687)

A. Low mechanical fragility, high osmotic fragility

B. High mechanical fragility, high osmotic fragility

C. Low mechanical fragility, low osmotic fragility

D. High mechanical fragility, low osmotic fragility

See Answer in Part B → Q57

@Neet_pg_bot

Q58: A 45-year-old male patient with a history of chronic inflammatory conditions presents with fatigue, weakness, and pallor. Laboratory investigations reveal microcytic hypochromic anemia. Further evaluation suggests an underlying disorder affecting iron metabolism. Which cytokine is most likely inhibiting the activity of ferroportin in this patient? (Q820595)

A. IL-1

B. IL-6

C. IFN-gamma

D. TNF-Alpha

See Answer in Part B → Q58

@Neet_pg_bot

Q59: A 25-year-old female patient presents to the clinic with complaints of fatigue, weakness, and pale skin. On further investigation, her complete blood count reveals a microcytic anemia. What is the likely diagnosis for this patient? (Q820581)

A. Alcoholism

B. Chronic Kidney disease

C. Hemolytic anemia

D. Iron deficiency anemia

See Answer in Part B → Q59

@Neet_pg_bot

Q60: A patient reports to the outpatient department with complaints of fatigue. Investigation results indicate a Hb of 5.9, increased RDW and TIBC, and low ferritin. What is the most likely diagnosis? (Q860296)

A. Sideroblastic anemia

B. IDA

C. Anaemia of chronic disease

D. Hemolytic anemia

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A 60-year-old woman presents with complaints of fatigue and dyspnea for 2 weeks. On examination, pallor is noted, and haemoglobin is found to be 6 gm/dL. What is the likely finding seen on the peripheral smear? (Q855962)

A. Poikilocytes

B. Microcytic hypochromic cells

C. Macrocytic cells

D. Target cells

See Answer in Part B → Q61

@Neet_pg_bot

Q62: Which of the following cells are located in the centre of the lumen in a venule? (Q860262)

A. Lymphocytes

B. RBCs

C. Neutrophils

D. Platelets

See Answer in Part B → Q62

@Neet_pg_bot

Q63: A 65-year-old patient presents with anaemia. Investigations show low serum iron and ferritin levels, along with increased TIBC. Which of the following is most likely to be present? (Q860216)

A. Iron Deficiency Anemia (IDA)

B. Myelodysplastic Syndrome

C. Aplastic Anemia

D. Anaemia of Chronic Disease

See Answer in Part B → Q63

@Neet_pg_bot

Q64: A 45-year-old patient visits a haematologist with symptoms of weakness and fatigue. Laboratory tests show low haemoglobin, a low reticulocyte count, and normal WBC and platelet counts. The bone marrow analysis reveals a selective reduction in erythroid precursors. What is the likely diagnosis? (Q860156)

A. Aplastic anemia

B. Pure red cell aplasia

C. Iron deficiency anaemia

D. Pernicious anemia

See Answer in Part B → Q64

@Neet_pg_bot

Q65: A patient reports to the outpatient department with complaints of fatigue. Investigation results indicate a Hb of 5.9, increased RDW and TIBC, and low ferritin. What is the most likely diagnosis? (Q860499)

A. Sideroblastic anemia

B. IDA

C. Anaemia of chronic disease

D. Hemolytic anemia

See Answer in Part B → Q65

@Neet_pg_bot

Q66: A 20-year-old female who is a known case of sickle cell anaemia was rushed to the emergency department with a complaint of extreme pain in the legs and fingers for the past 4 hours. Further examination revealed pain and tenderness in the right upper quadrant, and investigations showed sickle cells on peripheral blood smear and high bilirubin(indirect). What is the diagnosis? (Q860485)

A. IDA

B. Thalassemia

C. Anaemia of chronic disease

D. Sickle cell crisis

See Answer in Part B → Q66

@Neet_pg_bot

Q67: Which of the following is not seen after ileal resection? (Q844209)

A. Nuclear cytological asynchrony

B. Neurological manifestations

C. Microcytic hypochromic anemia

D. Reversible dementia

See Answer in Part B → Q67

@Neet_pg_bot

Q68: How is transferrin saturation affected by iron deficiency anemia? (Q844208)

A. Increased

B. Decreased

C. Normal

D. Dynamic

See Answer in Part B → Q68

@Neet_pg_bot

Q69: Which of the following statement is correct regarding Paroxysmal Nocturnal Hemoglobinuria? (Q844193)

A. Sucrose lysis test is used for confirmation

B. Flow cytometry is the best investigation

C. Most common cause of death is heart failure

D. It is an inherited disorder

See Answer in Part B → Q69

@Neet_pg_bot

Q70: In a patient of hereditary spherocytosis, which of the following organisms is likely to attack progenitor cells, resulting in aplastic anemia? (Q844045)

A. CMV

B. EBV

C. Parvovirus B19

D. HSV

See Answer in Part B → Q70

@Neet_pg_bot

Q71: All are hereditary causes of thrombosis except: (Q853369)

A. PNH

B. Protein S deficiency

C. Antithrombin deficiency

D. Homocystinuria

See Answer in Part B → Q71

@Neet_pg_bot

Q72: A patient presents with fever, night sweats, and weight loss for 2 months. On examination, non-tender rubbery nodes are palpable in the supraclavicular and inguinal regions on both sides. A peripheral smear shows the presence of binucleated cells. Which of the following markers will be seen in this condition? CD15 CD30 CD19 CD3 (Q856019)

A. 1, 2, 4

B. 2, 3, 4

C. 2, 3

D. 1, 2

See Answer in Part B → Q72

@Neet_pg_bot

Q73: Which of the following is not true about stem cells? (Q856476)

A. They can differentiate

B. They can replicate

C. They can divide without any regulatory stimulus

D. They can regenerate damaged tissues

See Answer in Part B → Q73

@Neet_pg_bot

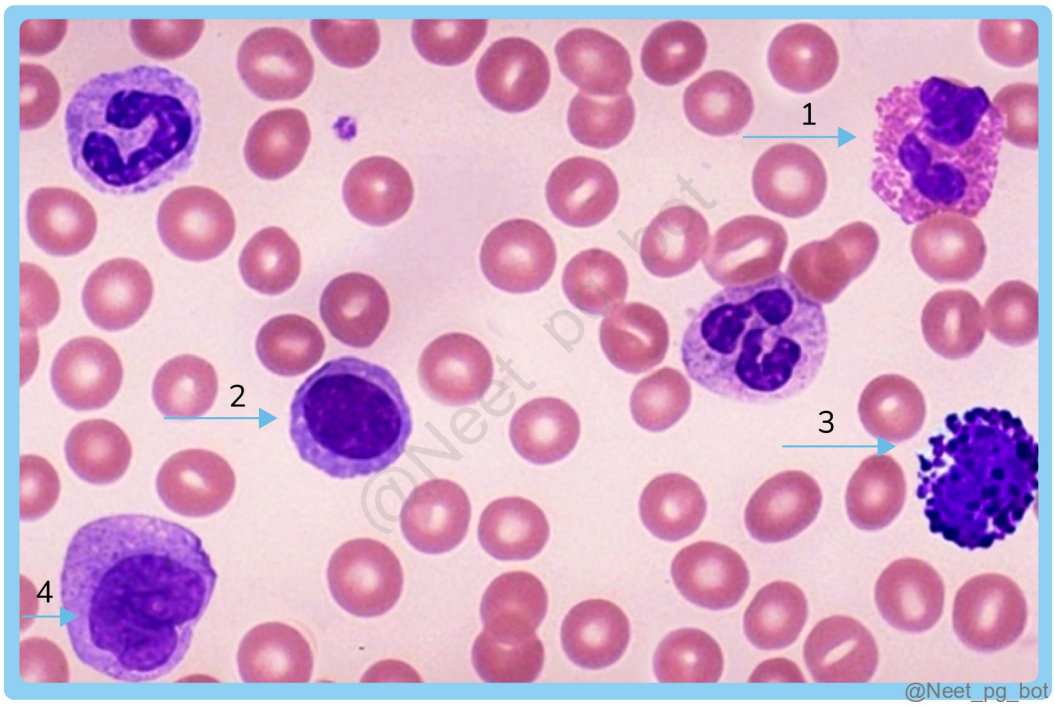
Q74: Identify the cells marked in the given image: (Q856905)

A. Lymphocyte-1, Monocyte-4, Eosinophil-2, Basophil-3

B. Lymphocyte-2, Monocyte-4, Eosinophil-1, Basophil-3

C. Lymphocyte-1, Monocyte-2, Eosinophil-3, Basophil-4

D. Lymphocyte-2, Monocyte-1, Eosinophil-3, Basophil-4



See Answer in Part B → Q74

@Neet_pg_bot

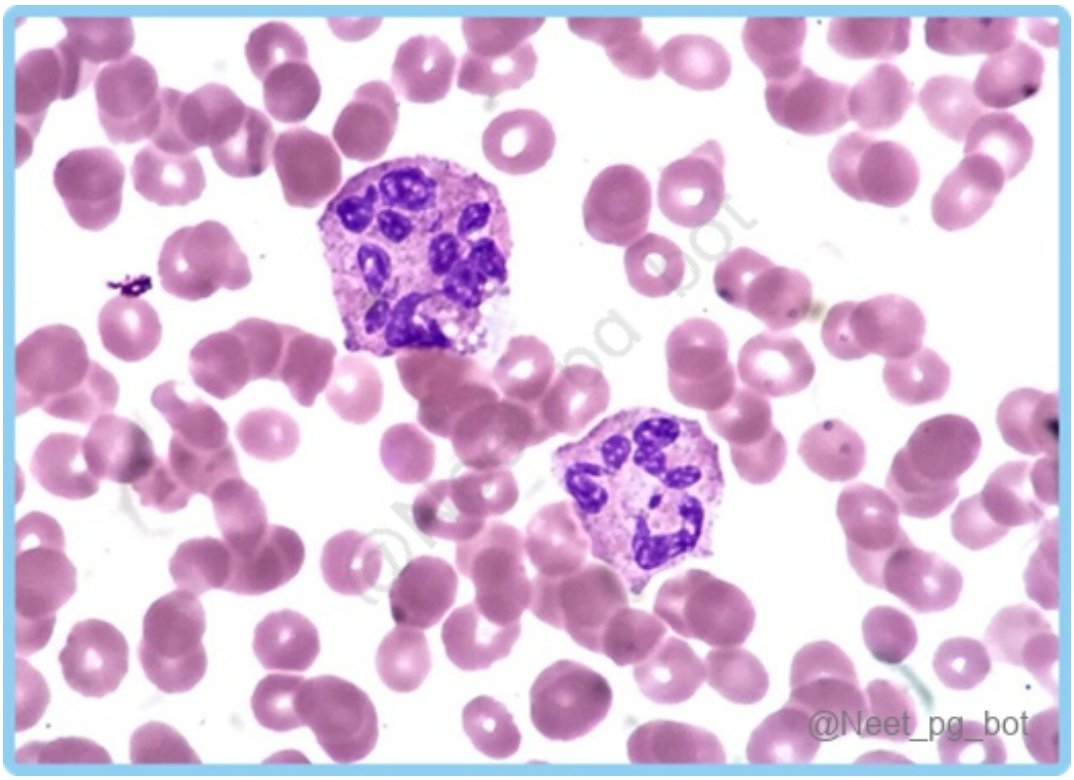
Q75: What is your diagnosis with respect to the findings shown in the peripheral smear: (Q856901)

A. Iron deficiency anaemia

B. Vitamin B12 deficiency

C. Hereditary spherocytosis

D. Acute myeloid leukemia



See Answer in Part B → Q75

@Neet_pg_bot

Q76: Rees and Ecker diluting fluid is used in: (Q856896)

A. Wintrobe tube

B. WBC pipette

C. RBC pipette

D. Hemoglobin pipette

See Answer in Part B → Q76

@Neet_pg_bot

Q77: An 18-year-old male presented to the outpatient department with gum bleeding and fever for the past 2 months. The general examination showed pallor, and the systemic examination was unremarkable. Laboratory examination revealed a Hb level

of 3 g/dl, a TLC of 1500/microL, and a platelet count of 15,000/microL. A peripheral smear shows macrocytes, and the reticulocyte count is 0.5%. A bone marrow examination revealed fatty streaks and absent megakaryocytes with no immature cells. What is the likely diagnosis? (Q856143)

A. Idiopathic acquired aplastic anaemia

B. Paroxysmal nocturnal hemoglobinuria

C. Myelodysplastic syndrome

D. Tuberculosis

See Answer in Part B → Q77

@Neet_pg_bot

Q78: Which of the following is used in treating sideroblastic anaemia? (Q855432)

A. Vitamin B12

B. Vitamin B6

C. Vitamin B1

D. Iron

See Answer in Part B → Q78

@Neet_pg_bot

Q79: Which of the following statements regarding the effect of glucose-6-phosphate dehydrogenase deficiency is correct? Decrease in reduced glutathione Decrease NADPH Decreased lipid peroxidation Decreased RBC membrane damage (Q855416)

A. Only 1 is correct

B. 1 & 2 are correct

C. 2 & 3 are correct

D. 1, 2 & 4 are correct

See Answer in Part B → Q79

@Neet_pg_bot

Q80: A child presented with bilateral proptosis. From the peripheral smear, he was suspected to have chloroma. What is the next investigation of choice? (Q855410)

A. Platelet count

B. WBC count

C. Flow cytometry

D. Bone marrow biopsy

See Answer in Part B → Q80

@Neet_pg_bot

Q81: All of the following are associated with massive splenomegaly, except: (Q855400)

A. Chronic myeloid leukemia

B. Aplastic anemia

C. Hairy cell leukemia

D. Lymphoma

See Answer in Part B → Q81

@Neet_pg_bot

Q82: A 45-year-old male patient was diagnosed with iron deficiency anaemia. Which of the following is true about the intracellular regulation of iron in iron deficiency anaemia? (Q855399)

A. Ferritin translation is increased by binding IRP to IRE

B. Ferritin translation is decreased by binding IRP to IRE

C. Transferrin receptor 1 translation is unaffected by binding IRP to IRE

D. Transferrin receptor 1 translation is decreased by binding IRP to IRE

See Answer in Part B → Q82

@Neet_pg_bot

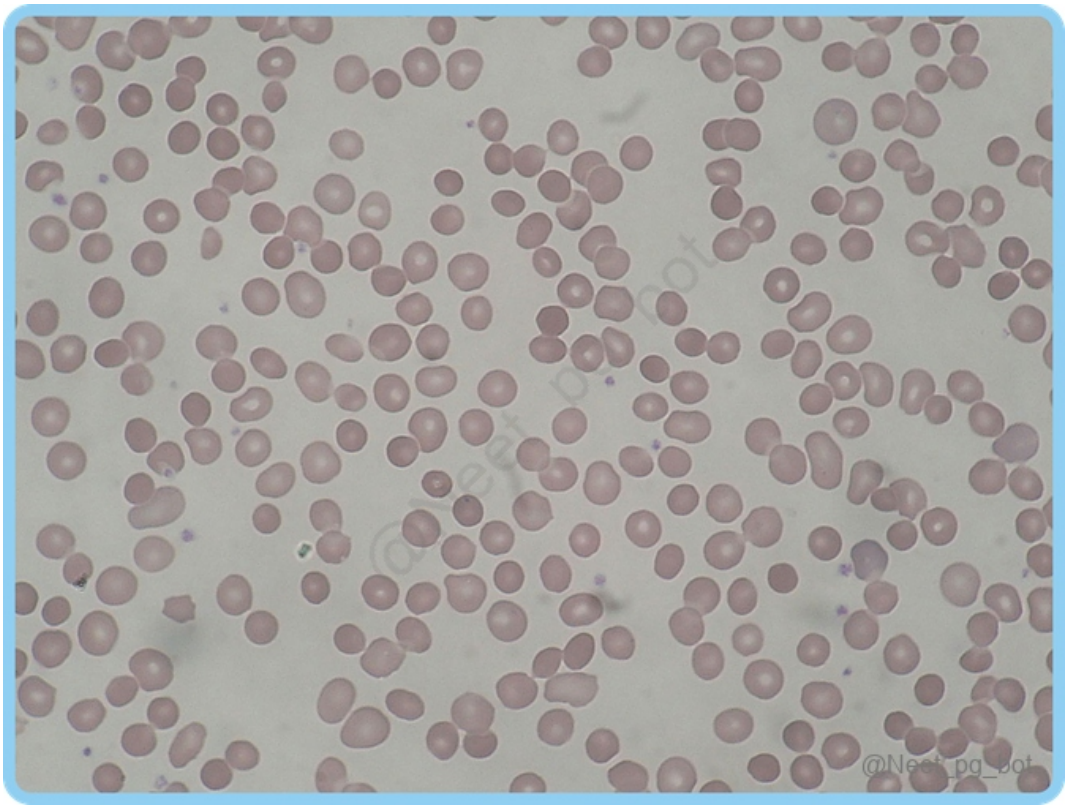
Q83: A 24-year-old male patient presents with anaemia. Both his father and paternal aunt experienced similar illnesses and were effectively treated with splenectomy. The patient's peripheral blood smear resembles the one depicted in the accompanying illustration, showing spherocytes. What other abnormalities can be anticipated? (Q857592)

A. Decreased osmotic fragility

B. Decreased reticulocytes

C. Heinz bodies

D. Howell-Jolly bodies



See Answer in Part B → Q83

@Neet_pg_bot

Q84: What is the most likely diagnosis for an 18-year-old male with gum bleeding, fever for two months, pallor, low haemoglobin (3 gm/dL), low TLC (1500/microL), low platelet count (15000/microL), macrocytes on peripheral smear, 0.5% reticulocyte count, and bone marrow examination showing fatty streaks and a lack of megakaryocytes but no immature cells? (Q857108)

A. Idiopathic acquired aplastic anemia

B. Paroxysmal nocturnal hemoglobinuria

C. Myelodysplastic syndrome

D. Tuberculosis

See Answer in Part B → Q84

@Neet_pg_bot

Q85: A 10-year-old boy presents with fatigue. Investigations reveal the following: Hemoglobin: 9 g/dL MCV: 80 fL MCH: 29 pg Serum ferritin: 185 μg/L TLC: Elevated with predominant lymphocytes and neutrophils. What is the likely diagnosis for this patient? (Q855124)

A. Thalassemia

B. Anemia of chronic disorder

C. Iron deficiency anaemia

D. Sickle cell anemia

See Answer in Part B → Q85

@Neet_pg_bot

Q86: All of the following are seen in the anaemia of chronic disease, except: (Q855067)

A. High serum hepcidin

B. Low serum ferritin

C. Chronic infection

D. Normal iron stores

See Answer in Part B → Q86

@Neet_pg_bot

Q87: A patient is diagnosed with B-cell leukaemia. Which of the following are poor prognostic factors? Hyperdiploidy Age <1 year t(9:22) t(4:11) (Q856031)

A. A, C, D

B. C, D

C. A, B, C, D

D. B, C, D

See Answer in Part B → Q87

@Neet_pg_bot

Q88: Which of the following is true about hereditary spherocytosis? (Q856004)

A. Gallstones develop by 4-5 years of age

B. Splenectomy does not protect against developing gallstones

C. Around 75% of cases show an autosomal dominant pattern

D. High MCH is pathognomonic of HS

See Answer in Part B → Q88

@Neet_pg_bot

Q89: Which of the following is not likely to be seen in a patient with paroxysmal nocturnal hemoglobinuria (PNH)? (Q855389)

A. Aplastic anemia

B. Leukaemia

C. Thrombosis

D. Hemolysis

See Answer in Part B → Q89

@Neet_pg_bot

Q90: Which of the following are features describing necrosis? Cell swelling Disrupted cell membrane Induces inflammation Physiological (Q857443)

A. 1 and 2

B. 1, 2 and 4

C. 1, 2 and 3

D. 1 and 3

See Answer in Part B → Q90

@Neet_pg_bot

Q91: In which of the following conditions is macrocytic anemia seen? (Q793648)

A. Thalassemia

B. Anemia of chronic disease

C. Sideroblastic anemia

D. Liver disease

See Answer in Part B → Q91

@Neet_pg_bot

Q92: Which of the following stains is used for the detection of hemosiderin deposits? (Q793650)

A. Mason-Fontana stain

B. Oil Red O

C. Sudan black

D. Perls Prussian blue

See Answer in Part B → Q92

@Neet_pg_bot

Q93: In iron deficiency anaemia, all of the following are increased except: (Q856136)

A. Transferrin saturation

B. RBC protoporphyrin

C. Total iron binding capacity

D. Ferritin soluble receptors

See Answer in Part B → Q93

@Neet_pg_bot

Q94: A child visited the hospital with her mother with complaints of severe fatigue, lethargy, pallor, and irritation. She has a known case of iron deficiency anemia and is on oral iron supplements. On reviewing the child, the physician in charge plans to start IV iron supplementation. What is the next best test to be done in assessing this child? (Q793752)

A. Blood hemoglobin

B. Total iron binding capacity

C. Serum ferritin

D. Hematocrit

See Answer in Part B → Q94

@Neet_pg_bot

Q95: A software engineer presents to the outpatient department with easy fatiguability. He gives a history of sitting in front of the computer for 12-14 hours. He consumes a lot of junk food with very few fruits and vegetables. Hb is 9 g/dl, and MCV is 80 fl. What is the most likely cause of this patient's anemia? (Q856150)

A. Cyanocobalamin deficiency

B. Iron deficiency

C. Folic acid deficiency

D. Hereditary spherocytosis

See Answer in Part B → Q95

@Neet_pg_bot

Q96: Which of the following is not routinely screened before conducting a blood transfusion? (Q793763)

A. Hepatitis A

B. Hepatitis B

C. Hepatitis C

D. HIV 1 / HIV 2

See Answer in Part B → Q96

@Neet_pg_bot

Q97: Metastatic calcification occurs in all except ? (Q793597)

A. Kidney

B. Fundus of the stomach

C. Pulmonary veins

D. Atheroma

Q13 (p. 801)

Q1: A 45-year-old male complained of fatigue and weakness in daily activities associated with intermittent fever. A blood workup revealed ↑ TLC, ↑ Platelets, and↑ Differential leukocyte count. On further investigations, Chronic Myeloid Leukemia is diagnosed. Which of the following is correct regarding CML? (Q882174)

A. Philadelphia chromosome is present in a minority of cases

B. Tyrosine kinase inhibitors (TKIs) are the drug of choice

C. Most cases present in the blast phase

D. Methotrexate is the drug of choice for AML

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old woman presents with fatigue, night sweats and unintentional weight loss over the past few months. Physical examination reveals palpable lymph nodes and enlarged spleen. Lab tests show significant lymphocytosis (>20,000/μL) with small, mature-appearing lymphocytes. What is true regarding the origin and risk factors of the patient's condition? (Q842739)

A. B cells, no exposure to radiation

B. B-cells, exposure to radiation

C. Myeloid cells; BTK gene mutation

D. Myeloid cells; Philadelphia chromosome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 65-year-old male presents with generalised fatigue and night sweats. Lab tests reveals Hemoglobin (Hb) 12 g/dL Platelet count 150,000/µL Absolute lymphocyte count (ALC) 45,000/µL Total leukocyte count (TLC) 70,000/µL Differential leukocyte count (DLC) 70% lymphocytes, 20% neutrophils, 5% monocytes, and 5% eosinophils Based on these lab findings, what is the most likely diagnosis? (Q842740)

A. ALL

B. AML

C. CML

D. CLL

See Answer in Part B → Q3

@Neet_pg_bot

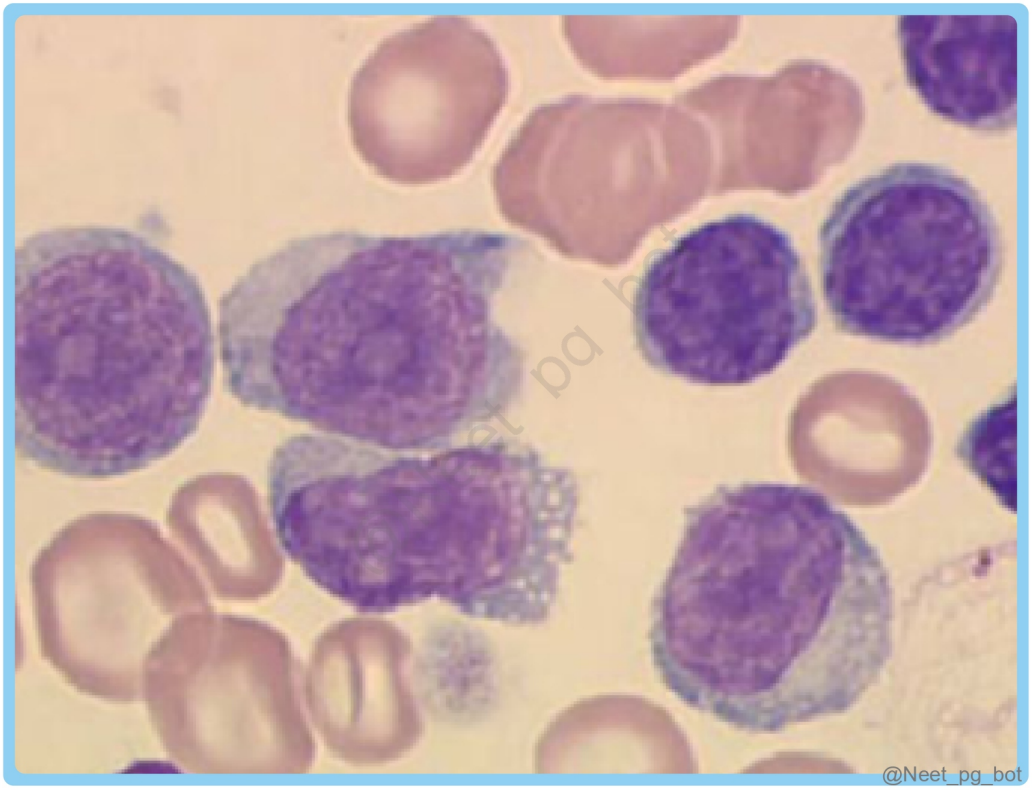
Q4: Match the following peripheral smear images with the respective diagnosis: A. 1. Acute Myeloid Leukemia (AML) B. 2. Chronic Myeloid Leukemia (CML) C. 3. Acute Lymphoblastic Leukemia (ALL) D. 4. Chronic Lymphocytic Leukemia (CLL) (Q842741)

A. 1-B, 2-A, 3-D, 4-C

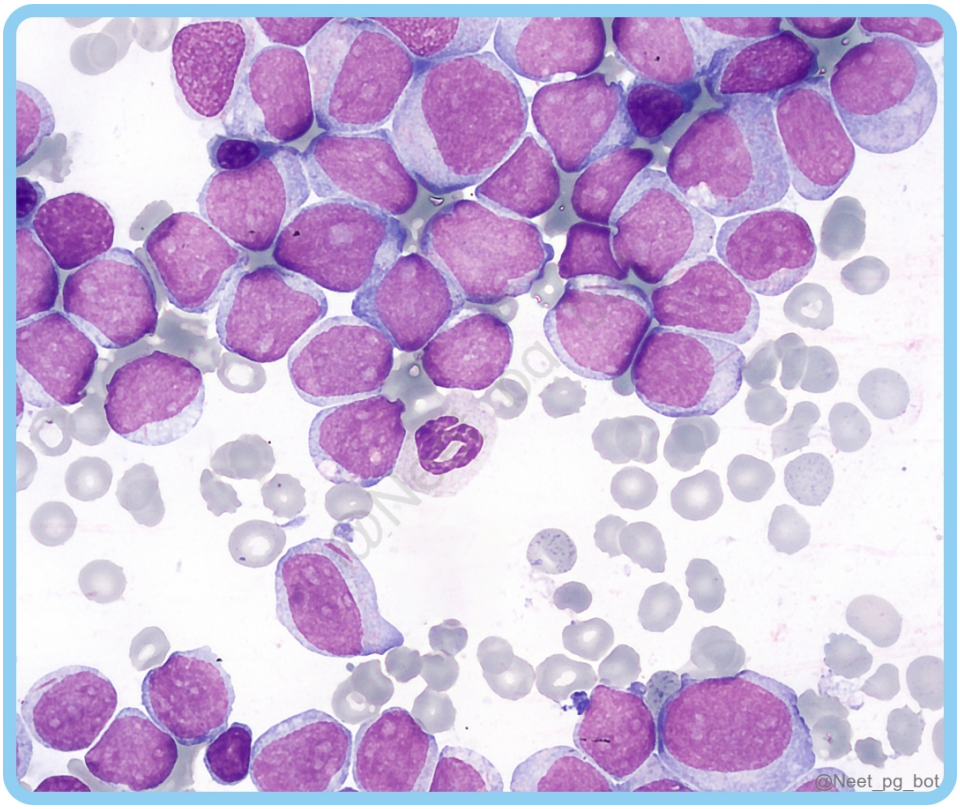
B. 1-B, 2-C, 3-D, 4-A

C. 1-C, 2-D, 3-B, 4-A

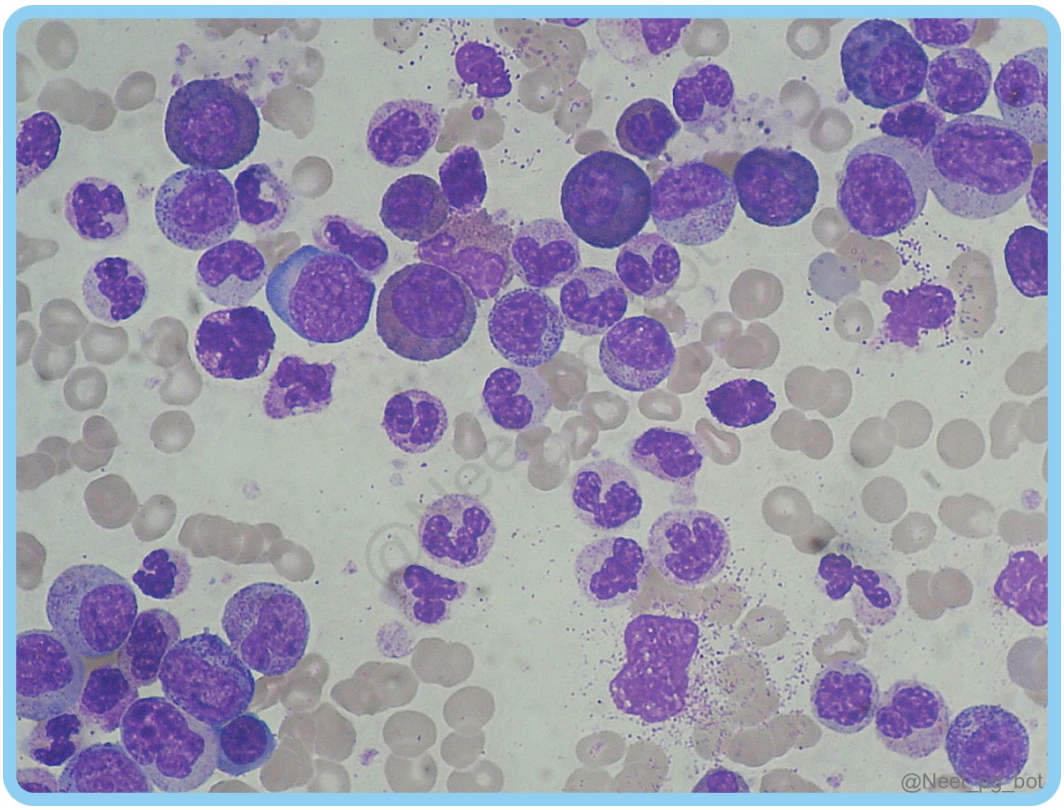
D. 1-D, 2-C, 3-A, 4-B

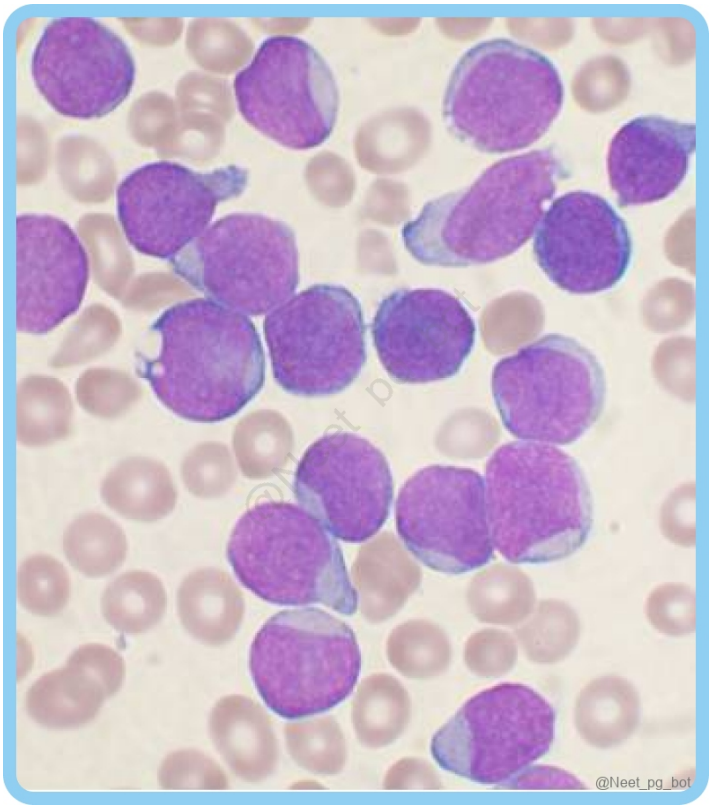


@Neet_pg_bot



@Neet_pg_bot





See Answer in Part B → Q4

@Neet_pg_bot

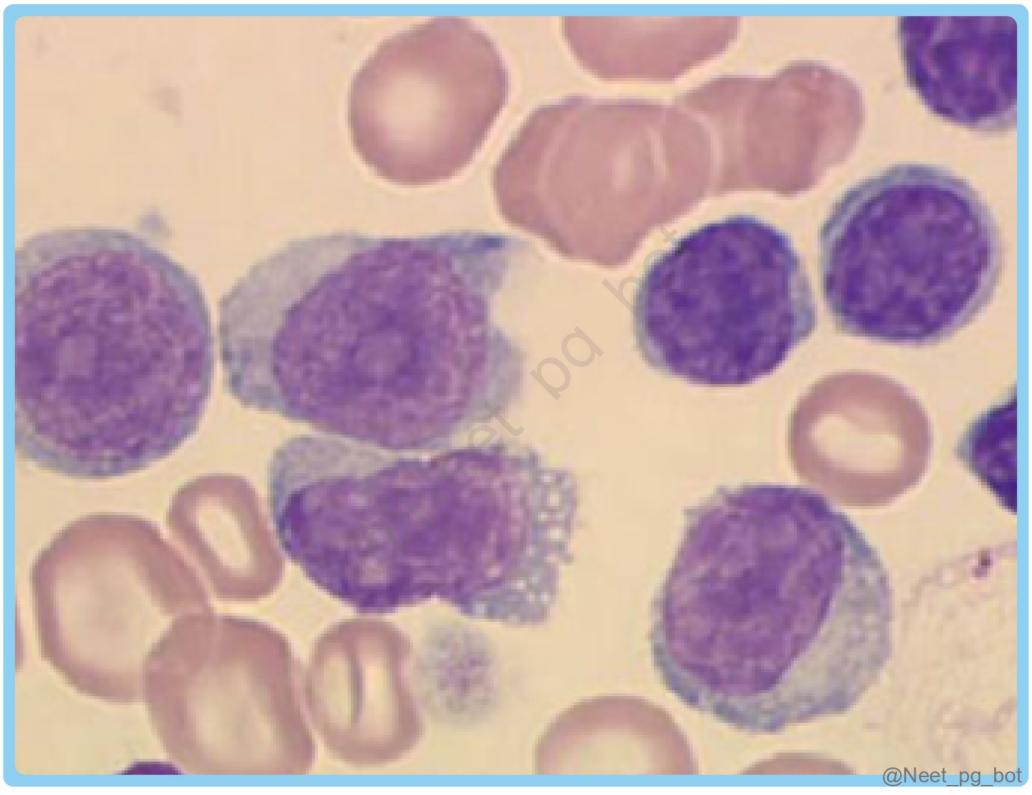
Q5: A 60-year-old man presents with fatigue, night sweats, and unintentional weight loss over the past several months. Examination reveals generalised lymphadenopathy and mild splenomegaly. Peripheral blood smear is shown below. Which of the following is not typically associated with the patient's condition? (Q842742)

A. Autoimmune hemolytic anemia (AIHA)

B. Evan’s syndrome

C. Richter’s syndrome

D. Di Guglielmo Disease



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 52-year-old male presents with complaints of fatigue, abdominal fullness, and night sweats. His complete blood count shows WBC count of 120,000/μL. A peripheral

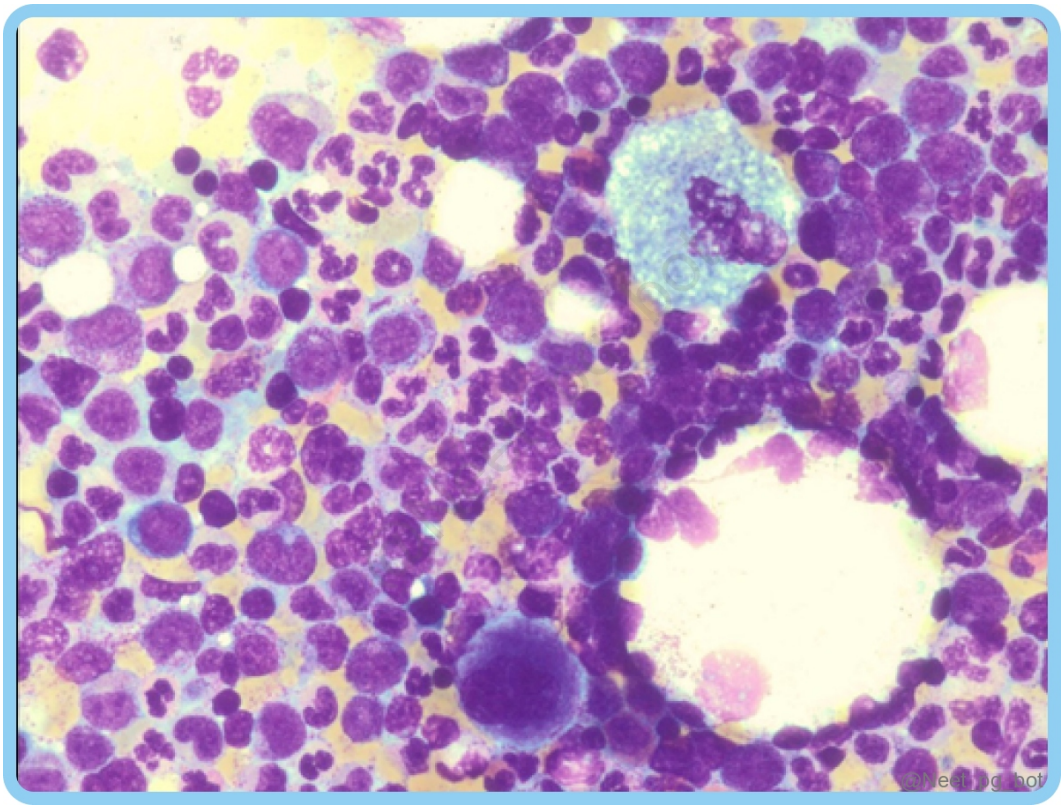
blood smear shows an increased number of granulocytes at different stages of maturation. A bone marrow aspirate is shown below. Which of the following features can be seen in this condition? (Q842743)

A. Diffusely effaced lymph node architecture with proliferation centres

B. Presence of Reed-Sternberg cells

C. Normal marrow cellularity with increased blast cells

D. Hypercellular bone marrow with decreased erythroid precursors



See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 62-year-old woman presents with fatigue, unintentional weight loss, and occasional night sweats over the past few months. On physical examination, cervical lymphadenopathy is noted. A complete blood count reveals leukocytosis with an absolute lymphocyte count of 10,000/mm3. Which of the following flow cytometry marker profiles is most consistent with this form of leukemia? (Q842744)

A. CD5+, CD19+, CD23+, CD10-

B. CD20+, CD79a+, CD5+, CD25-

C. CD3+, CD5+, CD19+, CD20-

D. CD10+, CD19+, CD22+, CD23-

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following are the good prognostic factors of CLL? (Q842745)

A. NOTCH1 mutations

B. CD38+

C. Expression of Zap 70

D. Expression of MiR-15/16

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old man presents with purulent nasal discharge, headache, sore throat, and nonproductive cough. He has maxillary sinus tenderness, pharyngeal erythema, and tender anterior cervical lymphadenopathy. Laboratory results are as follows: Leukocytes 58,000/mm3 Neutrophils 42% Myelocytes 30% Metamyelocytes 8% Band forms 1% Blast cells 1% Eosinophils 6% Basophils 4% The leukocyte alkaline phosphatase score is low. Which of the following is the most likely diagnosis and its appropriate management/drug for treatment? (Q842746)

A. Leukemoid reaction and Amoxicillin

B. CML and Imatinib mesylate

C. ALL and vincristine

D. AML and stem cell transplant

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old man who is a known case of chronic phase CML presents with increasing fatigue, weight loss, and abdominal discomfort. His physical examination reveals splenomegaly. Lab tests show a persistent decline in platelet counts, increased circulating basophils, and a blast count of 12%. What is the most likely explanation for the patient's clinical presentation and laboratory findings? (Q842747)

A. Progression to accelerated phase CML

B. Development of acute lymphoblastic leukemia

C. Entry into the blast crisis phase of CML

D. Development of secondary myelofibrosis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 50-year-old male presents with fatigue, abdominal discomfort, and splenomegaly. Lab tests reveal a markedly elevated WBC count with a left shift and increased myeloid precursor forms on peripheral blood smear. Which of the following statements regarding the leukocyte (neutrophil) alkaline phosphatase (LAP) score in this condition is correct? (Q842748)

A. Normal LAP score

B. Increased due to excessive myeloid cell production

C. Decreased due to cytochemical abnormal WBCs

D. LAP score is relevant only in acute leukemia

See Answer in Part B → Q11

@Neet_pg_bot

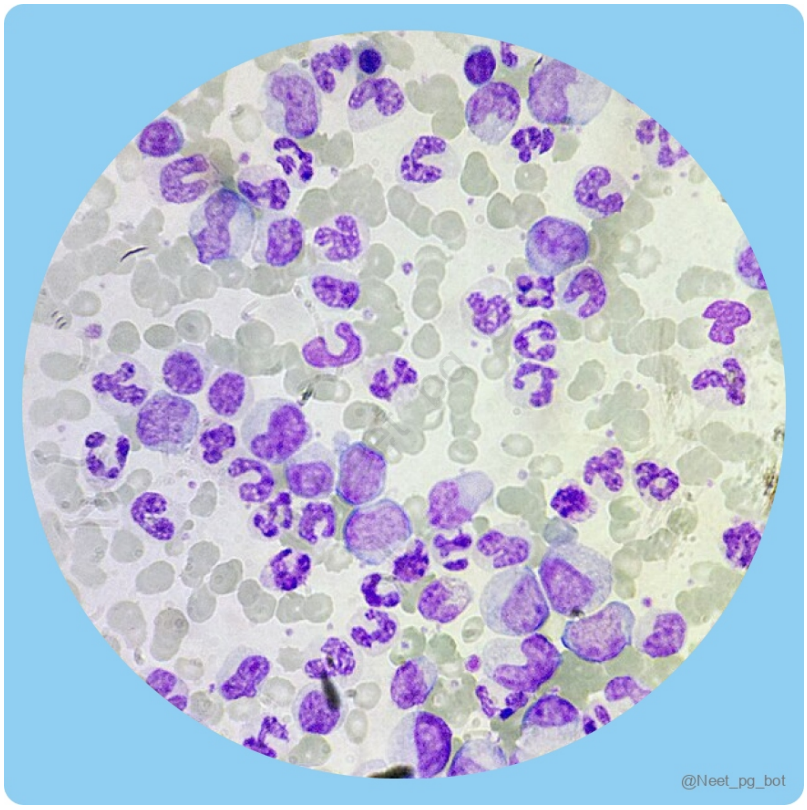
Q12: A 55-year-old patient presents with fatigue, weight loss, and abdominal discomfort. Labs reveal a markedly elevated WBC count with a left shift and increased myeloid precursor forms on peripheral blood smear as shown below. Which of the following is the investigation of choice to confirm the diagnosis? (Q842749)

A. Bone Marrow Aspiration and Biopsy

B. Flow Cytometry Analysis of Peripheral Blood

C. Fluorescent in situ hybridisation (FISH)

D. Serum Lactate Dehydrogenase (LDH) Levels



See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 60-year-old male presents with fatigue and abdominal discomfort. Laboratory investigations reveal a markedly elevated WBC count with a left shift and increased myeloid precursor forms on peripheral blood smear. Which of the following features would help differentiate Chronic Myelogenous Leukemia (CML) from a leukemoid

reaction? (Q842750)

A. Massive splenomegaly

B. High LAP score

C. History of recent antibiotic use

D. Resolution of neutrophilia after treating the underlying cause

See Answer in Part B → Q13

Q13 (p. 811) *Q14 (p. 811)* *Q15 (p. 811)*

Q1: Which of the following images shows the typical features of a plasma cell in a histopathological examination (HPE) of bone marrow? (Q845746)

See Answer in Part B → Q1

@Neet_pg_bot

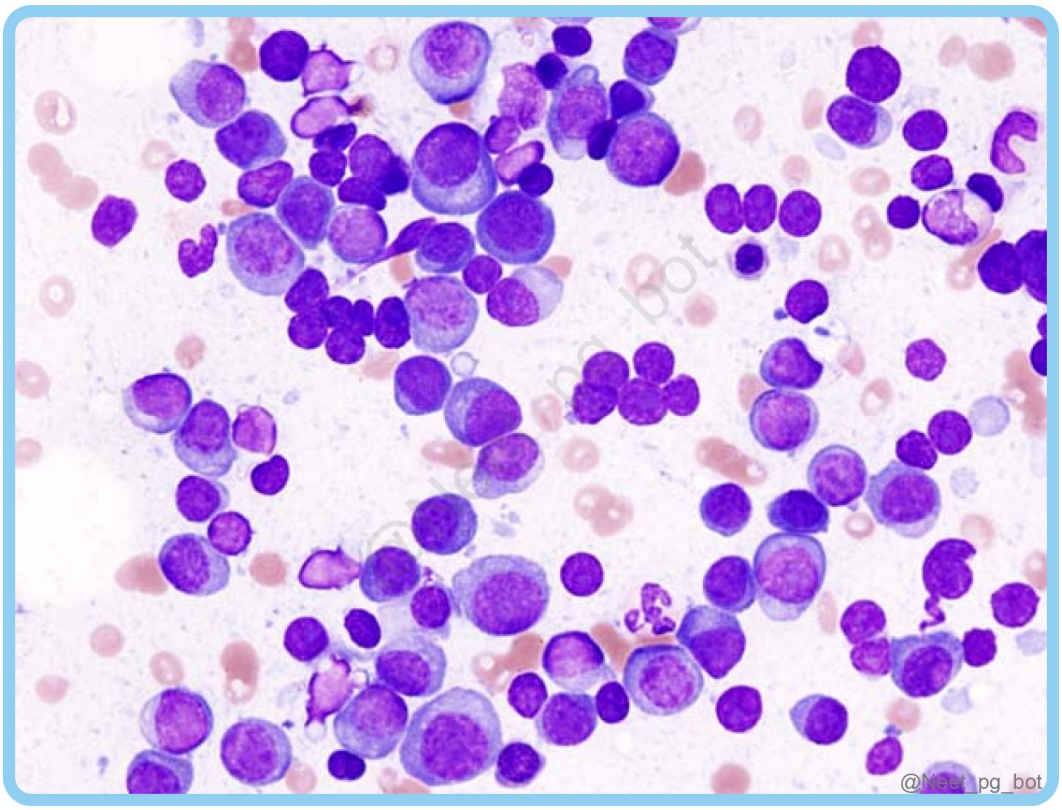
Q2: A 55-year-old woman presents with 6 months of persistent fatigue, lower back pain and recurrent infections. Laboratory tests show hypercalcemia, elevated creatinine, and normocytic anemia. Serum protein electrophoresis indicates a monoclonal spike. Bone marrow biopsy shows atypical plasma cells with eccentric nuclei and perinuclear halos, as shown in the image below. Which of the following cytogenetic abnormalities is not typically associated with this condition? (Q845747)

A. Deletion of chromosome 13q

B. Translocation t(11;14)

C. Trisomy 21

D. Deletion of chromosome 17p



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 68-year-old man presents with complaints of persistent bone pain, particularly in his lower back and ribs, along with fatigue and recurrent infections over the past few months. Further workup demonstrates Bence Jones proteinuria. What temperature does it precipitate at? (Q845748)

A. 100°C

B. 60°C

C. 0°C

D. 30°C

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old woman presents with bone pain, recurrent infections, elevated serum calcium levels, renal dysfunction, and anaemia. Laboratory tests reveal an M spike on serum protein electrophoresis and the presence of Bence Jones proteins in the urine. Based on this presentation, which of the following is not a criterion for a myeloma-defining event in the diagnostic criteria for this condition? (Q845749)

A. Hypercalcemia

B. Anemia

C. Renal failure

D. Bence jones proteinuria

See Answer in Part B → Q4

@Neet_pg_bot

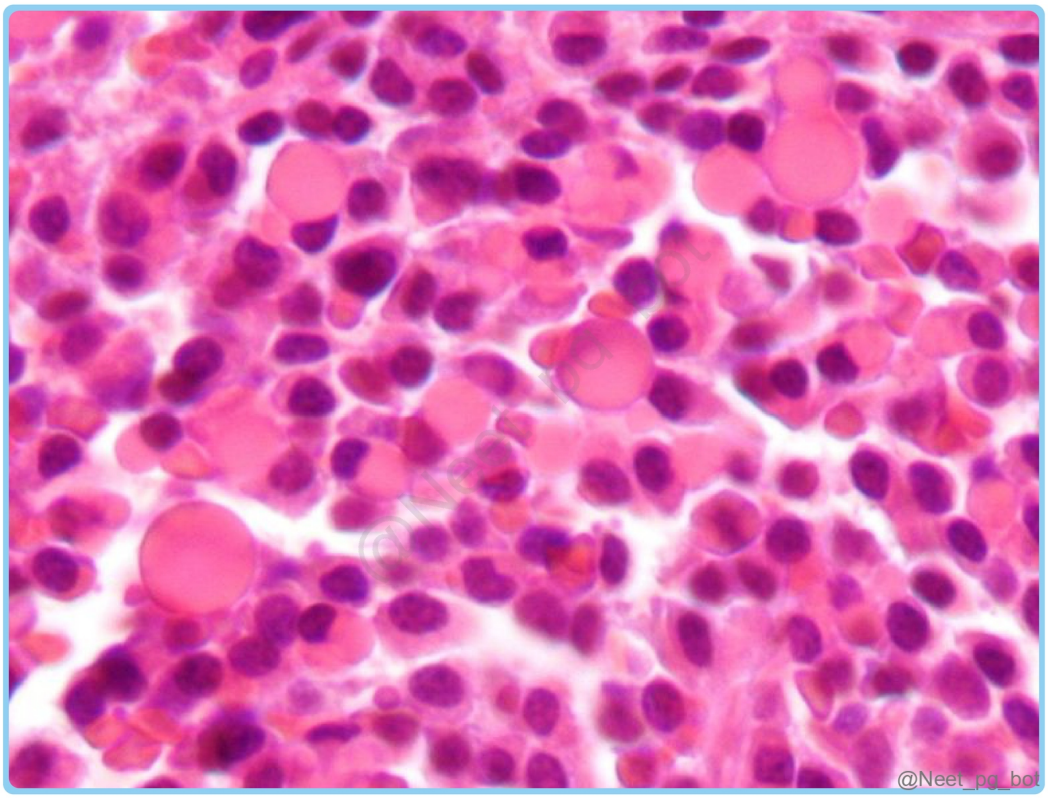
Q5: A 70-year-old woman is being evaluated for monoclonal gammopathy. Bone marrow examination showed abnormal proliferation of plasma cells with evidence of certain microscopic features. Match the following structures with corresponding histopathological images regarding this condition. 1. Flame Cell a) 2. Mott cell b) 3. Russel bodies c) 4. Dutcher bodies d) (Q845750)

A. 1-d; 2-a; 3-c; 4-b

B. 1-d; 2-c; 3-a; 4-b

C. 1-c; 2-d; 3-a; 4-b

D. 1-c; 2-d; 3-b; 4-a



@Neet_pg_bot

Q6: A 65-year-old male presents with fatigue, bone pain, and recurrent infections. Laboratory tests show elevated IL-6 and beta-2 microglobulin levels, while imaging reveals multiple lytic bone lesions. Bone marrow biopsy showed a high percentage of plasma cells, and cytogenetic analysis revealed a deletion of chromosome 17p. Flow cytometry is performed to distinguish abnormal plasma cells from normal ones in this patient. Which marker commonly shows increased expression on plasma cells in multiple myeloma, aiding in this differentiation? (Q845751)

A. CD19

B. CD38

C. CD56

D. CD117

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 68-year-old man presents with fatigue, bone pain, and recurrent infections. Laboratory tests reveal hypercalcemia and increased beta-2 microglobulin; imaging shows multiple lytic bone lesions. Which biochemical test is most commonly used to assess renal function and evaluate kidney damage in patients with multiple myeloma? (Q845752)

A. Serum protein electrophoresis (SPEP)

B. Serum creatinine levels

C. Serum calcium levels

D. Urine protein electrophoresis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 62-year-old male with a routine health check-up is found to have a serum M protein level of 3.5 g/dL and plasma cells making up 25% of the marrow cellularity. He reports no bone pain, normal kidney function, normal calcium levels, and no lytic bone lesions on imaging. What is the most likely diagnosis? (Q845753)

A. Monoclonal Gammopathy of Undetermined Significance (MGUS)

B. Plasma Cell Leukemia

C. Multiple Myeloma

D. Smouldering Myeloma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 70-year-old male presents with blurred vision, dizziness, and epistaxis. Physical examination reveals engorged retinal veins and signs of haemorrhage. Laboratory tests show an elevated serum viscosity. Serum protein electrophoresis reveals a monoclonal IgM spike. What is the most likely cause of the patient's symptoms? (Q845754)

A. Multiple Myeloma

B. Chronic Lymphocytic Leukemia

C. IgA Myeloma

D. Waldenstrom’s Macroglobulinemia

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old male presents with recurrent infections and fatigue. Palatal edema is noted. Laboratory tests show hypogammaglobulinemia and serum protein electrophoresis reveals an absence of normal immunoglobulins but a monoclonal spike in the gamma region. Bone marrow biopsy reveals large lymphoid cells with intracytoplasmic inclusions. Which type of heavy chain disease is most likely causing

the patient's symptoms? (Q845755)

A. Alpha Heavy Chain Disease

B. Gamma Heavy Chain Disease

C. Mu Heavy Chain Disease

D. Delta Heavy Chain Disease

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following represents the normal serum free κ:λ light chain ratio? (Q889647)

A. 0.01 - 0.10

B. 0.26 - 1.65

C. 1.65 - 3.50

D. 3.50 - 5.00

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 67-year-old man presents with back pain and anaemia. Skull radiograph shows multiple punched-out lytic lesions. He is diagnosed with multiple myeloma. Which of the following is the most common location of lytic bone lesions in multiple myeloma? (Q889652)

A. Vertebral column

B. Femur

C. Skull

D. Pelvis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 66-year-old man with multiple myeloma presents with bone pain and hypercalcemia. Imaging shows multiple punched-out lytic lesions. The increased bone resorption in this condition is primarily mediated by which of the following factors produced by neoplastic plasma cells? (Q889654)

A. Interleukin-2

B. MIP-1α

C. Erythropoietin

D. Transforming growth factor-β

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Excessive production of which of the following proteins is most commonly associated with hyperviscosity in multiple myeloma? (Q889661)

A. IgG3

B. IgG

C. IgM

D. IgG2

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which type of multiple myeloma is most commonly associated with a higher risk of renal insufficiency? (Q889663)

A. IgG myeloma

B. IgA myeloma

C. IgD myeloma

D. IgE myeloma

See Answer in Part B → Q15

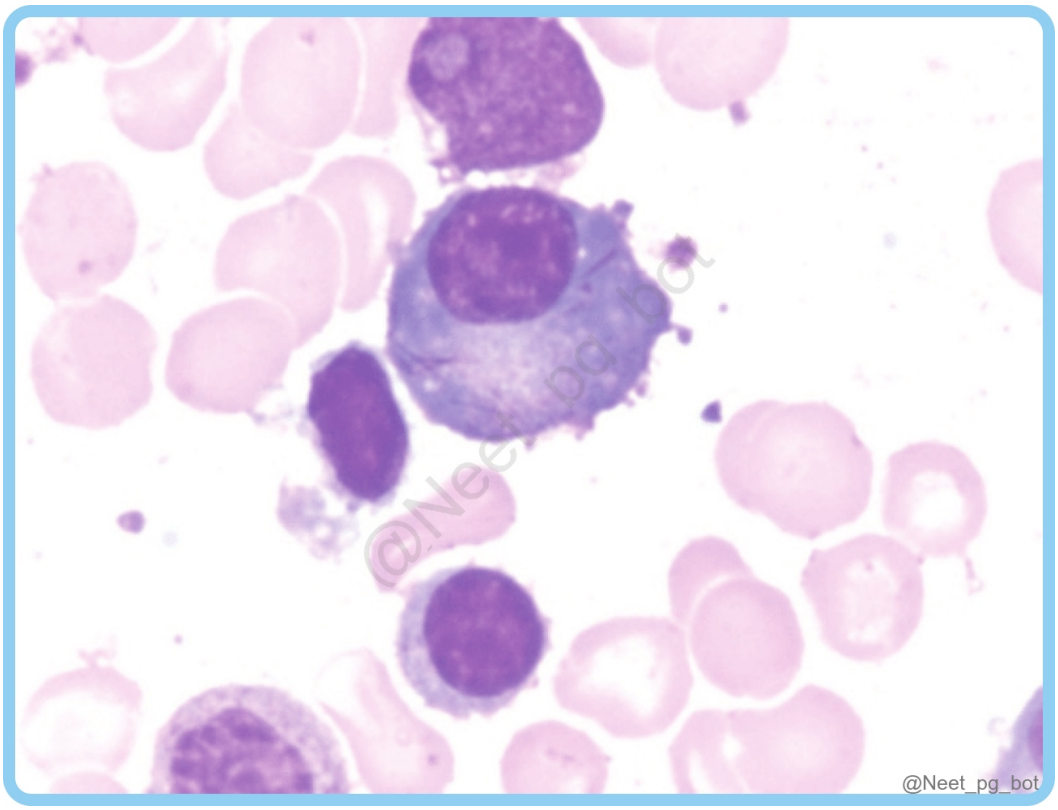
Q1: A 50-year-old man presents with complaints of fatigue, easy bruising, and recurrent nosebleeds over the past month. Laboratory investigations reveal leukopenia and thrombocytopenia. Peripheral blood smear examination demonstrates the presence of cells with Auer rods. In which stage of myelopoiesis are Auer rods typically found? (Q845756)

A. Myeloblast

B. Myelocyte

C. Metamyelocyte

D. Monoblast



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old man presents with complaints of persistent fever, chills, and generalized weakness for the past week. Lab reports revealed leukocytosis with a left shift, and peripheral blood smear examination shows cells with kidney-shaped nuclei and parasites in ring forms inside RBCs. What is the cell called? (Q845757)

A. Monocyte

B. Neutrophil

C. Basophil

D. Eosinophil

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 6-year-old child is brought up due to concerns about persistent fever, fatigue, and frequent infections over the past few weeks. There is generalised lymphadenopathy. Laboratory investigations reveal leukocytosis with lymphoblasts on peripheral smear examination. Which of the following stains are used to visualise lymphoblasts? (Q845758)

A. Periodic Acid Schiff (PAS) stain

B. Myeloperoxidase stain

C. Sudan Black stain

D. Wright stain

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male presents with persistent fatigue, significant weight loss, and night sweats over the past few months. Examination revealed massive splenomegaly. CBC shows elevated white blood cell count. A bone marrow biopsy confirms the diagnosis of CML. Which of the following types of leukocytosis is most commonly associated with this condition? (Q845760)

A. Neutrophilia

B. Eosinophilia

C. Lymphocytosis

D. Basophilia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Match the following cells with their respective images a) Hypersegmented neutrophil 1) b) Hyposegmented neutrophil 2) c) Dohle bodies 3) d) Alder Reilly anomaly 4) (Q845761)

A. a-3, b-4, c-1, d-2

B. a-2, b-1, c-4, d-3

C. a-4, b-3, c-1, d-2

D. a-2, b-3, c-4, d-1

Q6: A 17-year-old boy presented with complaints of a sore throat, fever, and extreme fatigue for the past two weeks. On examination, he has enlarged cervical lymph nodes and an enlarged spleen. A complete blood count reveals lymphocytosis with atypical lymphocytes and is diagnosed as infectious mononucleosis. Which of the following statements is NOT correct? (Q845762)

A. Caused by Epstein-Barr Virus (EBV)

B. The Monospot test is a common diagnostic tool

C. Downey cells are characteristic histopathological features.

D. Also known as Haemophagocytic Lymphohistiocytosis.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 58-year-old patient presents with fatigue, night sweats, and significant weight loss. Physical examination reveals generalized lymphadenopathy and splenomegaly. Blood tests show a markedly elevated white blood cell count. Based on the clinical scenario, which diagnosis is most likely if the bone marrow biopsy reveals over 20% blasts? (Q845763)

A. Chronic Lymphocytic Leukemia (CLL)

B. Acute Myeloid Leukemia (AML)

C. Hodgkin’s Lymphoma (HL)

D. Non-Hodgkin’s Lymphoma (NHL)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old female is undergoing routine blood work. The laboratory technician uses different Vacutainers for various tests. Which Vacutainer colour is used for coagulation studies, such as PT and aPTT? (Q845764)

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following diluting fluids correctly matches its specific use in haematology? (Q845767)

A. Turk's Solution - Platelets

B. Hayem's Solution - WBCs

C. Gower's Solution - RBCs

D. 1% Ammonium Oxalate - WBCs

Q1: As per FAB classification, what percentage of blast cells in bone marrow biopsy is required to diagnose a patient with acute leukaemia? (Q845765)

A. 10

B. 20

C. 25

D. 30

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which is not included in the FAB classification of acute lymphoblastic leukaemia (ALL) L3 subtype? (Q845766)

A. Presence of lymphoblasts with vacuoles and cytoplasmic blebs

B. Expression of surface immunoglobulins

C. Association with Epstein-Barr virus (EBV)

D. t(9;22) Philadelphia chromosome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is not associated with acute lymphoblastic leukaemia (ALL) regarding chromosomes? (Q845768)

A. t(9;22)

B. t(12;21)

C. t(1;19)

D. t(15;17)

See Answer in Part B → Q3

@Neet_pg_bot

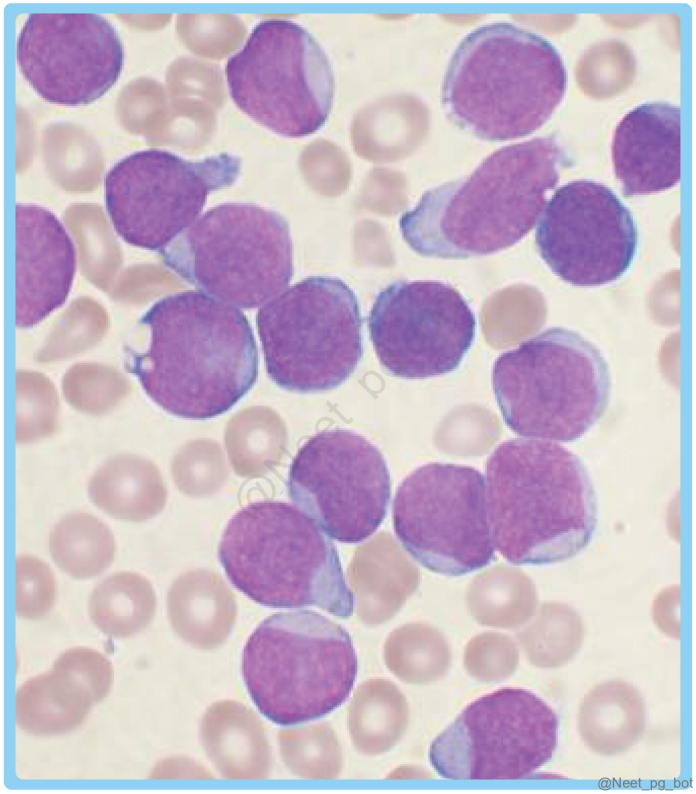
Q4: A 4-year-old male presents with fever, bleeding gums, and fatigue for 5 days. CBC shows Hb of 8g%, TLC 30,000/µL, and platelet count of 40,000/µL. A differential count shows an increased number of immature white blood cells. A bone marrow aspiration is done, as shown below. What is the most likely diagnosis? (Q845769)

A. Chronic myeloid leukaemia.

B. Acute lymphoblastic leukaemia.

C. Acute promyelocytic leukaemia.

D. Aplastic anaemia



See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following markers will be negative on immunophenotyping of a patient with early pre-B acute leukaemia? (Q845770)

A. TdT

B. DR

C. CD19

D. CD10

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following statements is incorrect regarding the prognosis of ALL? Adults have a worse prognosis as compared to children aged 2-9 years. White females have a good survival rate as compared to black males. The Philadelphia chromosome (t(9;22)) is associated with a favourable prognosis. Higher white blood cell counts at diagnosis are associated with a better prognosis. Hypodiploidy in B-ALL is associated with a better prognosis. (Q845771)

A. 3, 4 and 5

B. 2, 3 and 4

C. 1, 4 and 5

D. 4 and 5

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 9-year-old boy presents with fever, fatigue, and worsening shortness of breath. On examination, he has a large anterior mediastinal mass causing respiratory distress . Laboratory findings shows leukocytosis and blasts on peripheral smear. Flow cytometry of blasts reveals the positivity for CD3, CD5, CD7 along with variable expression of CD10. What is the most likely diagnosis? (Q845772)

A. Acute Myeloid Leukemia (AML)

B. T cell Acute Lymphoblastic Leukemia

C. B cell Acute Lymphoblastic Leukemia

D. Chronic Lymphocytic Leukemia (CLL)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding the M4 subtype of AML based on FAB classification is true? (Q845773)

A. It is associated with t(8:21), called AML with maturation.

B. It is associated with t(15:17), called acute promyelocytic leukaemia

C. It is associated with CBF-MYH fusion, called acute myelomonocytic leukaemia

D. It is associated with MPO positivity, called AML without maturation.

See Answer in Part B → Q8

@Neet_pg_bot

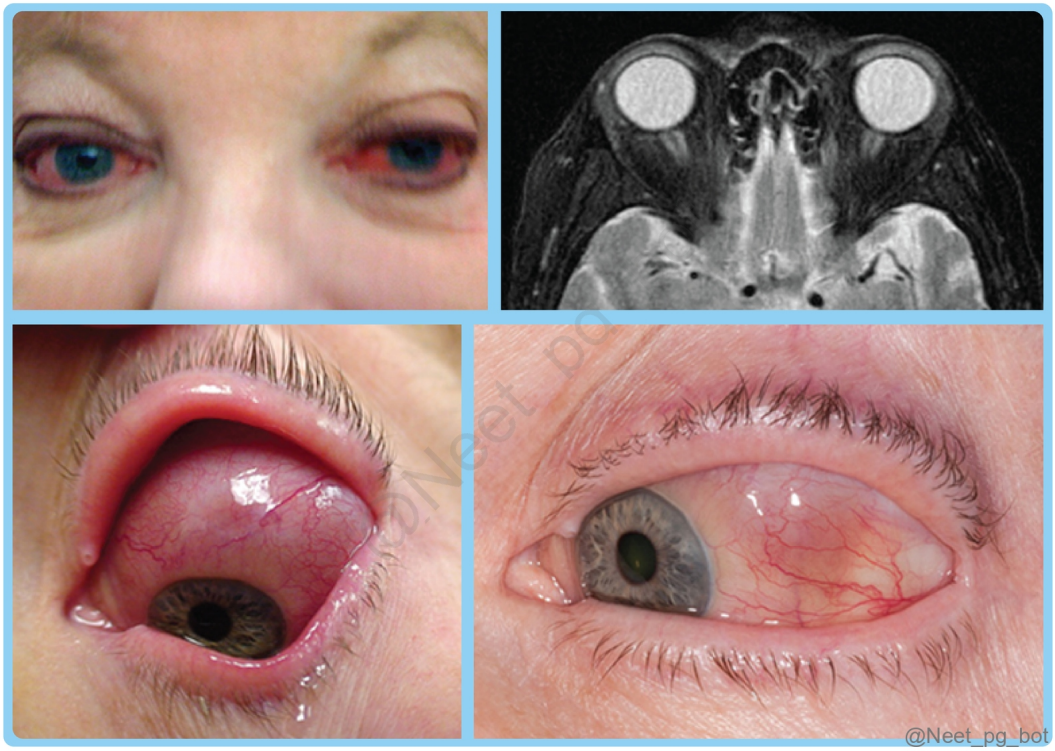
Q9: A 12-year-old boy presents with fatigue, bruising, and intermittent fevers for the past few weeks. Physical examination reveals the following findings. Immunophenotyping of the biopsy specimen shows CD43 and MPO positivity. What is the most likely diagnosis? (Q845774)

A. Acute Lymphoblastic Leukemia (ALL)

B. AML with maturation

C. Acute promyelocytic leukaemia

D. Non-Hodgkin Lymphoma



See Answer in Part B → Q9

@Neet_pg_bot

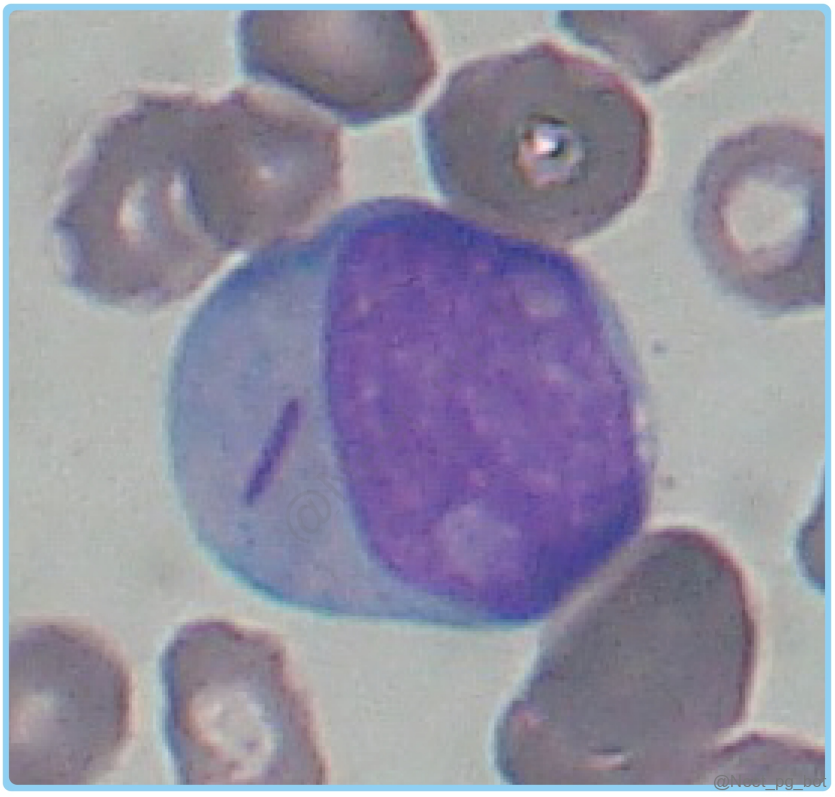
Q10: A 28-year-old female was admitted to the hospital with complaints of frequent nosebleeds, reports of sudden onset chest pain and dyspnea. On examination, she has petechiae and ecchymoses on her skin. Laboratory tests revealed WBC 15,000/µL, haemoglobin 8 g/dL, platelets 20,000/µL and elevated prothrombin time. A peripheral blood smear shows the following findings. Further testing confirms which of the following associated conditions? (Q845775)

A. t(12:21) translocation

B. t(15:17) translocation

C. t(9:22) translocation

D. t(8:21) translocation



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following types of AML, according to the FAB classification, is associated with Down's syndrome? (Q845776)

A. Acute erythroid leukaemia

B. Acute myelomonocytic leukaemia

C. Acute megakaryocytic leukaemia

D. Acute monocytic leukaemia

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is associated with a good prognosis according to WHO classification of AML? (Q845777)

A. AML: Therapy-related

B. AML with MDS-like features

C. AML with recurrent genetic abnormality

D. AML not otherwise specified

See Answer in Part B → Q12

@Neet_pg_bot

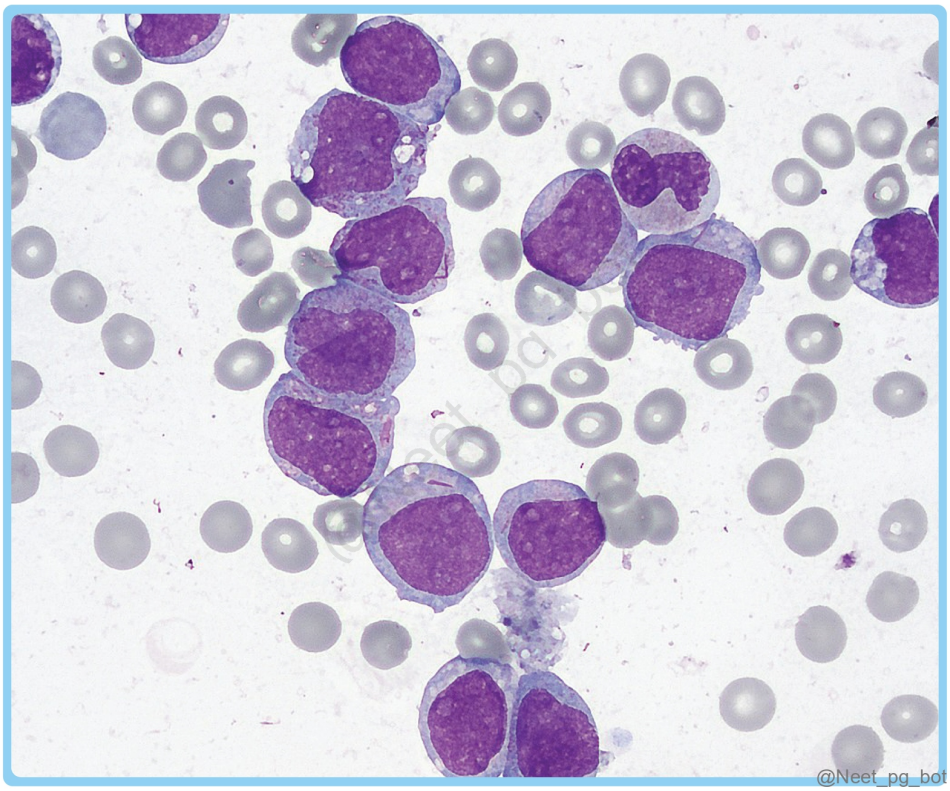
Q13: What is the most likely immunophenotype associated with the condition indicated by the peripheral blood smear shown below? (Q845778)

A. CD13+, CD33+, CD34+, HLA-DR+

B. CD19+, CD20-, CD22+, CD79a-

C. CD3+, CD4+, CD8+, CD5-

D. CD10+, CD19+, CD20+, CD22-



See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 55-year-old female presented with fatigue, easy bruising, and recurrent infections over the past few months. On examination, there is mild splenomegaly, but no lymphadenopathy is noted. Laboratory tests reveal pancytopenia. A peripheral blood smear shows normocytic normochromic red blood cells and bone marrow shows blast count >20%. What is the most likely diagnosis? (Q845779)

A. Aplastic anemia

B. Myelodysplasia

C. Aleukemic leukaemia

D. Myeloproliferative disorder

See Answer in Part B → Q14

Q13 (p. 836) *Q14 (p. 836)*

Q1: A 45-year-old female presents with complaints of occasional headaches and blurred vision. Laboratory tests reveal isolated thrombocytosis without significant leukocytosis or erythrocytosis. Bone marrow biopsy shows increased megakaryocytes. Which of the following types of myeloproliferative neoplasm (MPN) is most likely to be diagnosed based on these findings? (Q845780)

A. Polycythemia Vera (PV)

B. Essential Thrombocytosis (ET)

C. Chronic Myeloid Leukemia (CML)

D. Primary Myelofibrosis (PMF)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 50-year-old male presents with complaints of headaches, dizziness, and pruritus. Physical examination reveals a plethora and splenomegaly. Laboratory tests show elevated hemoglobin and hematocrit levels. Which of the following criteria are consistent with the Polycythemia Vera (PV) diagnosis? (Q845781)

A. Sustained platelet count ≥ 450 x 10^9/L

B. Increased red blood cell mass

C. Presence of JAK2 mutation

D. Presence of CALR or MPL mutation

See Answer in Part B → Q2

@Neet_pg_bot

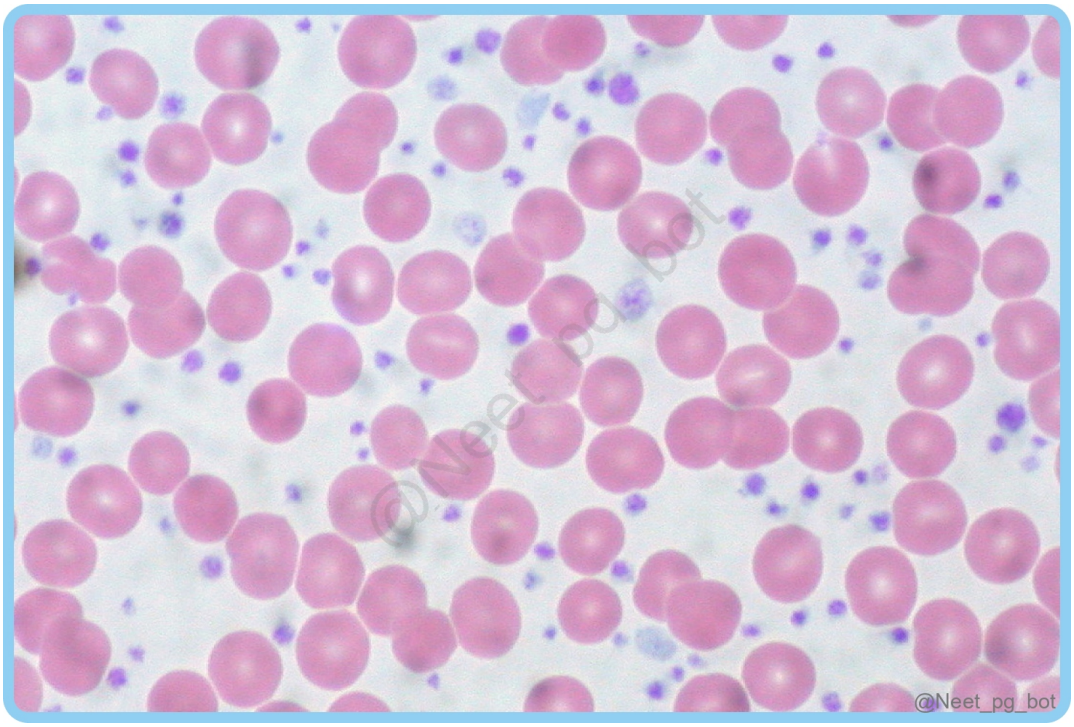
Q3: A 55-year-old female presents to the clinic with complaints of frequent headaches, dizziness, and occasional burning pain in her hands and feet. Examination reveals splenomegaly. Her complete blood count shows a platelet count of 12,00,000/µL. The peripheral blood smear shows marked thrombocytosis with giant platelets. Which of the following is not true regarding this condition? (Q845783)

A. Characterized by the presence of megakaryocytic hyperplasia.

B. Associated with JAK2, CALR, or MPL mutations.

C. Bone marrow biopsy typically shows increased reticulin fibrosis.

D. Increased risk of thrombotic and hemorrhagic events.



See Answer in Part B → Q3

@Neet_pg_bot

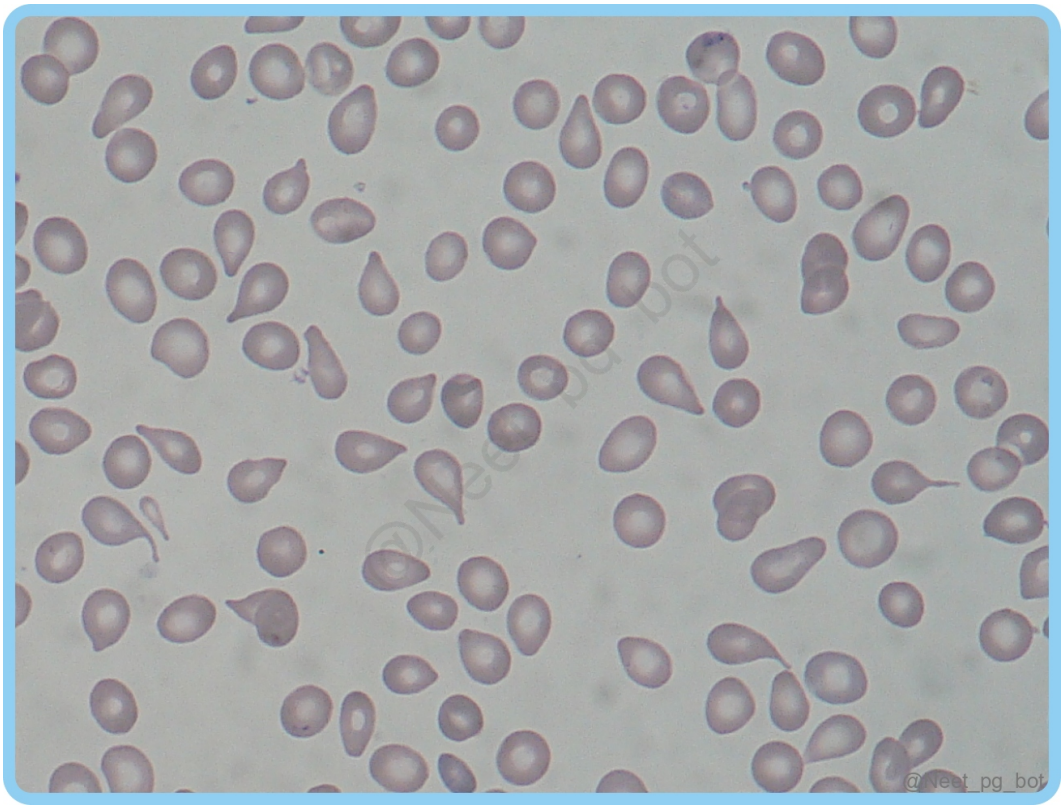
Q4: A 65-year-old man presents with progressive fatigue and significant weight loss for the past six months. Examination reveals a markedly enlarged spleen. Peripheral blood smear shows teardrop-shaped red cells. Bone marrow biopsy confirms the diagnosis of primary myelofibrosis. Which of the following statements regarding the diagnosis is true? 1) It is characterized by extensive marrow fibrosis. 2) Diagnostic criteria include the presence of JAK2, CALR, or MPL mutations. 3) Pathogenesis involves the inappropriate release of fibrogenic factors like PDGF and TGF-β. (Q845784)

A. All statements are true

B. 1,2

C. Only 3

D. 2,3



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old man presents with complaints of increasing fatigue, early satiety, and unintentional weight loss over the past few months. On examination, there is palpable splenomegaly. Laboratory reports reveal pancytopenia with dacrocytes on the peripheral smear. Which of the following is not associated with Myelofibrosis? (Q845785)

A. Dry tap

B. Leukoerythroblastic blood picture

C. Dacrocytes

D. Myeloblasts

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 75-year-old man presents with increasing fatigue, weakness, and easy bruising over the past few months. Labs show pancytopenia. Peripheral blood smear reveals dysplastic differentiation in the erythroid, granulocytic, monocytic, and megakaryocytic lineages. Which condition does this suggest? (Q845787)

A. Hyperlobated megakaryocyte

B. Leukoerythroblastic picture

C. Increased proliferation of RBCs

D. Pawn ball megakaryocyte

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 5-year-old child presents with a skin rash, recurrent ear infections, bone pain, and polyuria. Imaging revealed lytic bone lesions and a biopsy of one of the lesions showed CD1a and S-100 positive Langerhans cells. Which of the following types of Langerhans cell histiocytosis (LCH) is characterized by multifocal uni system involvement? (Q845790)

A. Eosinophilic granuloma

B. Hand-Schüller-Christian disease

C. Letterer-Siwe disease

D. Both A and C

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Pseudo-Gaucher cells are commonly seen in which of the following conditions? (Q889668)

A. Gaucher disease

B. Chronic myeloid leukaemia

C. Hairy cell leukaemia

D. Multiple myeloma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following findings is least likely to be seen in polycythemia vera (PCV)? (Q889669)

A. Low serum erythropoietin

B. Basophilia

C. Budd-chiari syndrome

D. Lymphocytosis

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following conditions is most likely associated with a leucoerythroblastic blood film? (Q889671)

A. Iron deficiency anaemia

B. Vitamin B12 deficiency

C. Primary myelofibrosis

D. Thalassemia

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is not part of the WHO 2022 diagnostic criteria for CMML? (Q889674)

A. Persistent absolute (≥0.5 × 10■/L) and relative (≥10%) peripheral blood monocytosis

B. Blasts constitute <20% in blood and bone marrow

C. Presence of Philadelphia chromosome (BCR::ABL1 fusion)

D. Dysplasia involving ≥1 myeloid lineage

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following findings is not typically present in juvenile myelomonocytic leukaemia (JMML)? (Q889678)

A. Peripheral blood monocytosis ≥1 × 10■/L

B. Blasts <20% in blood and marrow

C. BCR::ABL1 fusion gene

D. Splenomegaly

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following numbered conditions are histiocytic and dendritic cell neoplasms? Langerhans Cell Histiocytosis (LCH) Chronic Lymphocytic Leukaemia (CLL) Rosai-Dorfman Disease (RDD) Juvenile Xanthogranuloma (JXG) Erdheim-Chester Disease (ECD) (Q889681)

A. 1, 3, 4, 5

B. 2, 3, 4

C. 1, 2, 5

D. 2, 4, 5

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following conditions is typically not characterised by pancytopenia? (Q889685)

A. Vitamin B12 deficiency

B. Hairy cell leukaemia

C. Hypocellular myelodysplastic syndrome

D. Immune thrombocytopenic purpura (ITP)

See Answer in Part B → Q14

Q1: A 64-year-old man presents with persistent lymphocytosis on routine blood work. Flow cytometry shows a clonal B-cell population consistent with CLL/SLL. What absolute lymphocyte count (ALC) is required to diagnose CLL rather than SLL? (Q884880)

A. >1,500/mm³

B. >3,000/mm³

C. >5,000/mm³

D. >10,000/mm³

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following genetic alterations represents the central pathogenic event in classic Hodgkin lymphoma? (Q884843)

A. Loss-of-function mutation of IKBα (NFKBIA)

B. Activation of NF-κB

C. Loss-of-function mutation of TNFAIP3 (A20)

D. Copy number gain of the REL proto-oncogene

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient with classic Hodgkin lymphoma undergoes cytogenetic analysis. The Reed-Sternberg cells show a recurrent copy number gain on chromosome 2p, contributing to increased NF-κB activity. Which gene is most likely amplified? (Q884845)

A. TNFAIP3

B. NFKBIA

C. REL

D. PD-L1

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Reed-Sternberg-like cells (RSLC) are seen in which of the following conditions? Infectious mononucleosis Non-Hodgkin lymphoma Solid tumors Classic Hodgkin lymphoma (Q884847)

A. 1, 2 only

B. 1, 2, 3 only

C. 4 only

D. 1, 2, 3, 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 28-year-old man presents with a 3-month history of painless cervical lymphadenopathy. He reports sharp pain in the neck nodes within minutes of drinking small amounts of alcohol, which resolves spontaneously. He also has intermittent low-grade fever and night sweats. Which of the following is the most likely diagnosis? (Q884849)

A. Non-Hodgkin lymphoma

B. Metastatic squamous cell carcinoma

C. Hodgkin lymphoma

D. Tuberculous lymphadenitis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which subtype of Hodgkin lymphoma is associated with biphasic incidence? (Q884854)

A. Nodular sclerosis

B. Mixed cellularity

C. Lymphocyte-rich

D. Nodular lymphocyte predominant

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 65-year-old man presents with fever, weight loss, and generalized lymphadenopathy (Stage III). Lymph node biopsy shows numerous classic Reed–Sternberg cells in a mixed inflammatory background. Which of the following statements regarding this subtype of hodgkin lymphoma is incorrect? (Q884858)

A. It often presents at advanced stage.

B. EBV positivity is seen in approximately 70% of cases.

C. It accounts for about 20–25% of Hodgkin lymphoma cases.

D. It most commonly presents as a mediastinal mass in young females.

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A lymph node biopsy shows a ring of tightly packed small B lymphocytes surrounding a germinal center and displaced outward by it. Which zone is being described? (Q884865)

A. Germinal center

B. Mantle zone

C. Marginal zone

D. Paracortex

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is a T-cell neoplasm? (Q884874)

A. Follicular lymphoma

B. Mantle cell lymphoma

C. Anaplastic large-cell lymphoma

D. Burkitt lymphoma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is the most common site of primary extranodal non-Hodgkin lymphoma? (Q884877)

A. Skin

B. Gastrointestinal tract

C. Central nervous system

D. Bone marrow

See Answer in Part B → Q10

@Neet_pg_bot

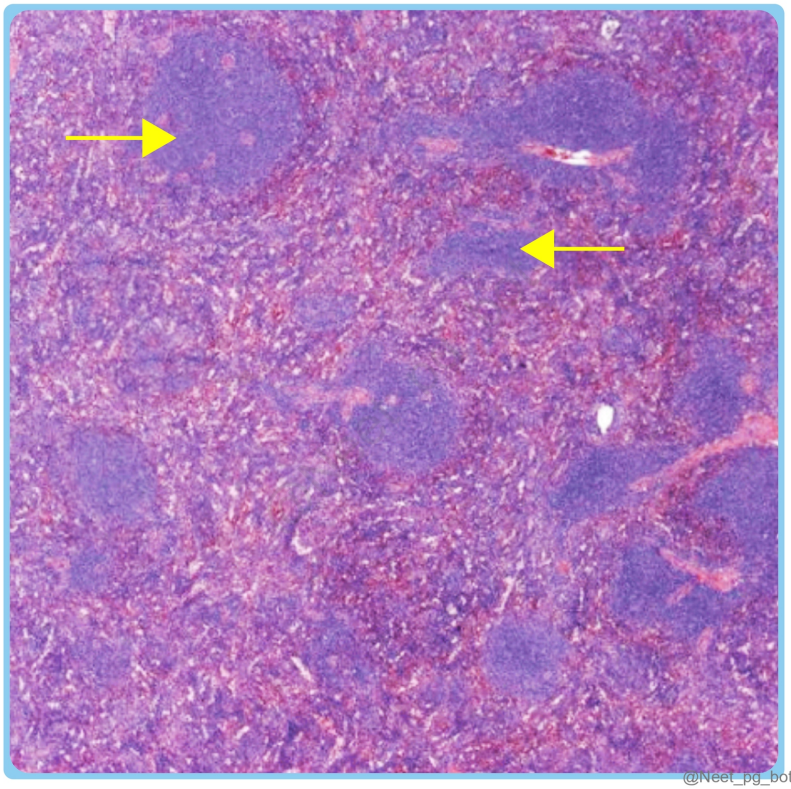
Q11: A 65-year-old man presents with lymphadenopathy and lymphocytosis. Lymph node biopsy & peripheral smear findings are as shown. Which feature is pathognomonic for this condition? (Q884878)

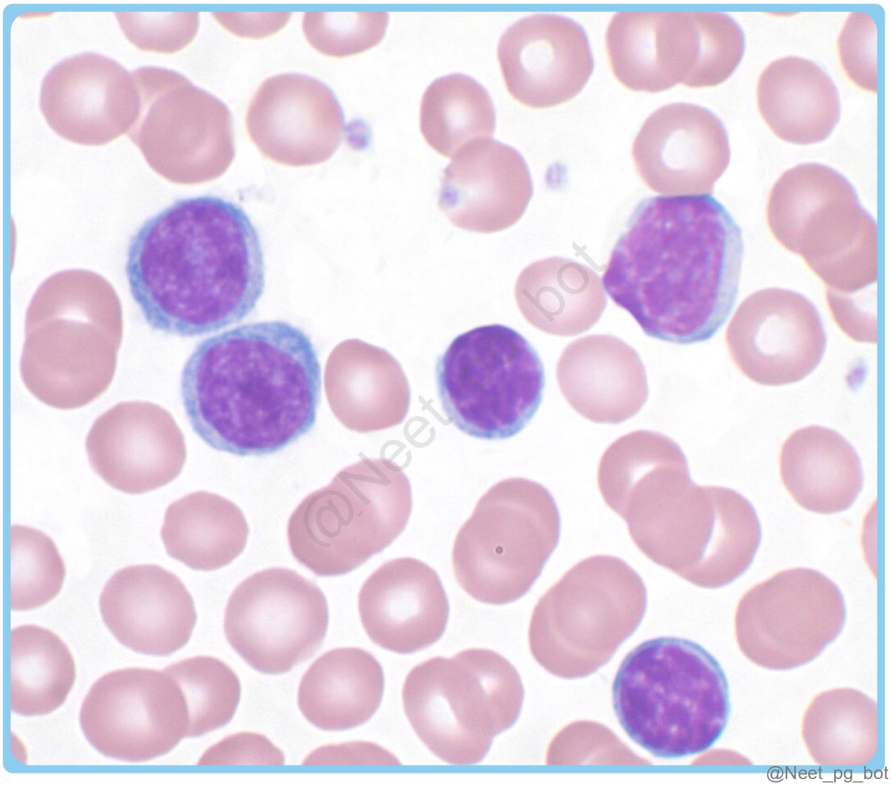
A. Smudge cells

B. Diffuse lymph node effacement

C. Proliferation centres

D. Bone marrow involvement





See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the most common subtype of Hodgkin lymphoma? (Q884841)

A. Lymphocyte-rich

B. Mixed cellularity

C. Nodular sclerosis

D. Lymphocyte-depleted

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements about extranodal marginal zone (MALT) lymphoma is correct? (Q884881)

A. t(11;18) translocation makes it antigen-dependent

B. Spreads systemically early

C. May regress if inciting agent is removed

D. Not associated with chronic inflammation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Marginal zone lymphoma primarily arises from which type of B cell? (Q884882)

A. Naïve B cells

B. Memory B cells

C. Plasma cells

D. Pre-B cells

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Extranodal marginal zone (MALT) lymphoma is commonly associated with which of the following conditions? Sjögren syndrome Hashimoto thyroiditis Helicobacter pylori gastritis (Q884884)

A. 1 and 2 only

B. 2 and 3 only

C. 1 and 3 only

D. 1, 2, and 3

See Answer in Part B → Q15

@Neet_pg_bot

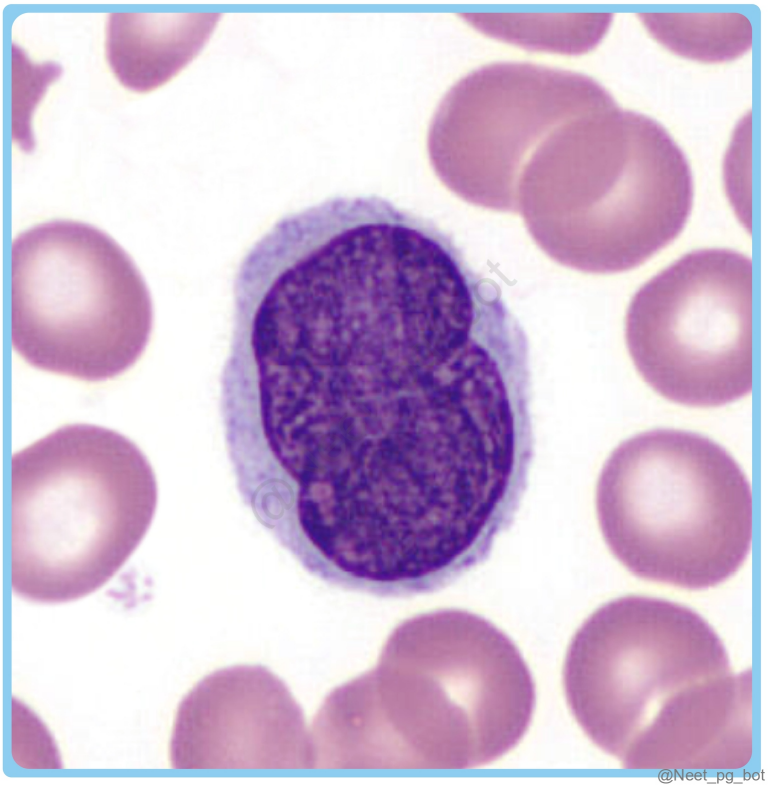
Q16: A 62-year-old man presents with generalized exfoliative erythroderma and intense pruritus. Examination reveals diffuse lymphadenopathy. Peripheral blood smear shows findings as shown. Skin biopsy demonstrates dermal infiltration by atypical CD4■ T cells. What is the most likely diagnosis? (Q884885)

A. Sézary syndrome

B. Mycosis fungoides

C. Peripheral T-cell lymphoma

D. Adult T-cell leukemia/lymphoma



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 60-year-old woman with rheumatoid arthritis presents with recurrent infections. She has splenomegaly and neutropenia. Peripheral smear shows large lymphocytes with azurophilic granules. Cells are CD3■. What is the most likely diagnosis? (Q884888)

A. Chronic lymphocytic leukemia

B. Hairy cell leukemia

C. Large granular lymphocytic leukemia

D. Sézary syndrome

See Answer in Part B → Q17

@Neet_pg_bot

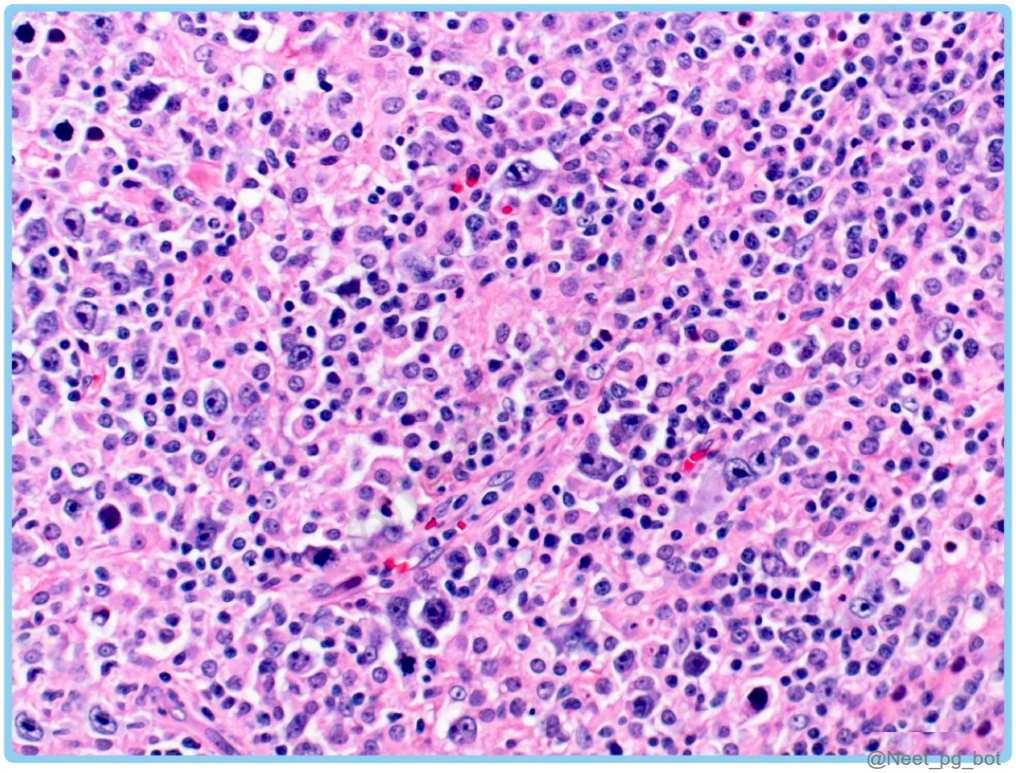
Q18: A 70-year-old man presents with fever, weight loss, and rapidly enlarging lymph nodes. Biopsy shows diffuse sheets of large CD20+ B cells. EBER in situ hybridisation is positive in tumour cells. What is the most likely diagnosis? (Q884909)

A. Epstein-Barr virus-positive diffuse large B-cell lymphoma

B. Classic Hodgkin lymphoma

C. Burkitt lymphoma

D. Angioimmunoblastic T-cell lymphoma



See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 62-year-old man is newly diagnosed with diffuse large B-cell lymphoma. The clinician plans to calculate the International Prognostic Index (IPI) score to assess prognosis. Which of the following are included in the IPI score? Age >60 years Elevated serum lactate dehydrogenase (LDH) Presence of B symptoms ECOG performance status ≥2 More than one extranodal site (Q884910)

A. 1, 2, 3

B. 1, 2, 4, 5

C. 2, 3, 4

D. 1, 3, 5

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 70-year-old man with a 5-year history of chronic lymphocytic leukaemia develops rapidly enlarging lymph nodes, fever, weight loss, and elevated LDH. Lymph node biopsy shows diffuse large B-cell lymphoma. What is the most likely diagnosis? (Q884911)

A. Progressive CLL

B. Richter syndrome

C. Prolymphocytic transformation

D. Hodgkin lymphoma

See Answer in Part B → Q20

@Neet_pg_bot

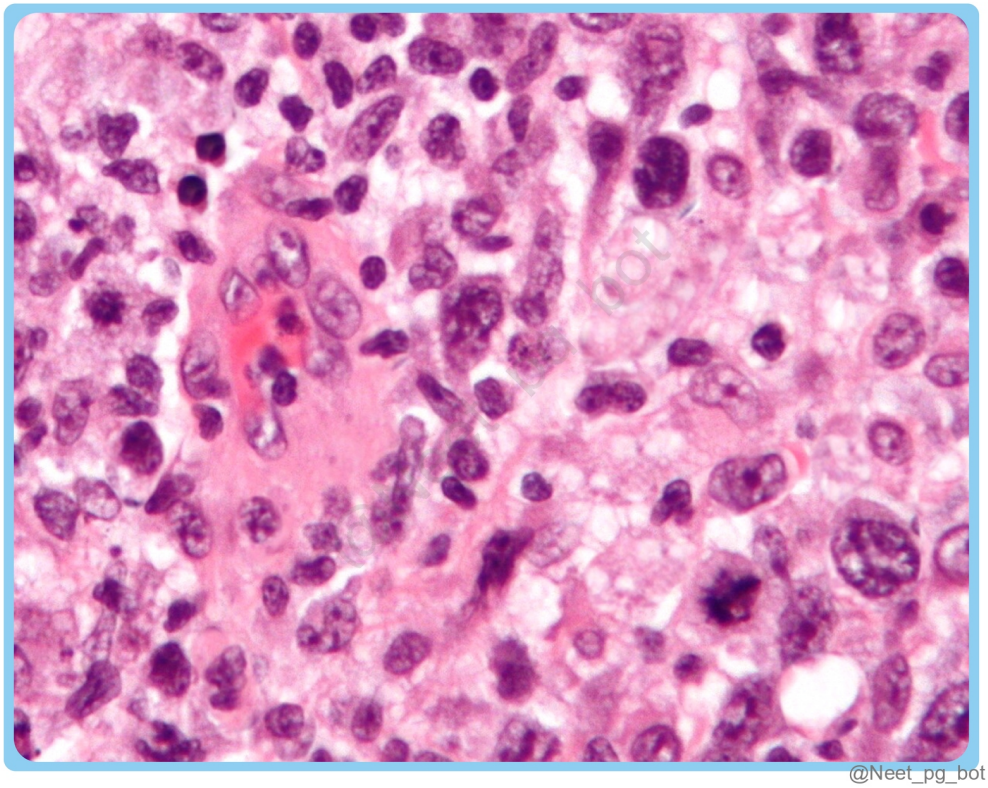
Q21: A 15-year-old boy presents with painless lymphadenopathy. Biopsy shows findings as shown. Tumour cells are CD30 positive and ALK positive. What is the most likely diagnosis? (Q884912)

A. Diffuse large B-cell lymphoma

B. Classical Hodgkin lymphoma

C. Anaplastic large-cell lymphoma

D. Adult T-cell leukaemia/lymphoma



See Answer in Part B → Q21

@Neet_pg_bot

Q22: Match the following lymphomas with their cell of origin. Lymphoma/leukaemia Cell of origin 1. Diffuse large B-cell lymphoma a. Memory B-cell 2. Mantle cell lymphoma b. Germinal/post germinal center B cell 3. Hairy cell lymphoma c. Helper T-cell 4. Mycosis fungoides d. Naive B cell (Q845823)

A. 1-b, 2-a, 3-c, 4-d

B. 1-a, 2-b, 3-d, 4-c

C. 1-d, 2-a, 3-d, 4-c

D. 1-b, 2-d, 3-a, 4-c

See Answer in Part B → Q22

@Neet_pg_bot

Q23: In the WHO classification of Hodgkin lymphoma, which marker is typically expressed in classical Hodgkin lymphoma? (Q845792)

A. CD20

B. CD15

C. CD45

D. BCL-6

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Match the following characteristic cells with their corresponding histopathological variant of Hodgkin lymphoma: Cells A) Popcorn cells B) Lacunar cells C) Mononuclear cells D) Reed-Sternberg cells Histopathology 1. Classical Hodgkin Lymphoma (general type) 2.Mixed Cellularity Classical Hodgkin Lymphoma 3. Nodular Sclerosis Classical Hodgkin Lymphoma 4. Nodular Lymphocyte Predominant Hodgkin Lymphoma (Q845796)

A. A-4, B-3, C-2, D-1

B. A-1, B-4, C-3, D-2

C. A-3, B-2, C-1, D-4

D. A-4, B-1, C-2, D-3

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 28-year-old female presents with painless swelling in her neck and shortness of breath. Imaging studies reveal a large mediastinal mass. A biopsy of the lymph node shows frequent lacunar cells and Reed-Sternberg cells. The RS cells are positive for CD15 and CD30 and usually negative for EBV. Which subtype of Hodgkin's lymphoma is most likely? (Q845799)

A. Nodular Sclerosis Classical Hodgkin Lymphoma

B. Nodular Lymphocyte-Predominant Hodgkin Lymphoma

C. Lymphocyte-Rich Classical Hodgkin Lymphoma

D. Lymphocyte-depleted classical Hodgkin Lymphoma

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 35-year-old male presents with painless swelling of multiple lymph nodes, fever, night sweats, and weight loss. A biopsy of the affected lymph node reveals the presence of Reed-Sternberg cells. Which of the following options regarding Mixed cellularity type Hodgkin's Lymphoma is not true? (Q845800)

A. It is characterised by frequent mononuclear and diagnostic Reed-Sternberg (RS) cells.

B. RS cells in this subtype typically express CD15 and CD30.

C. More than 70% of cases are Epstein-Barr virus (EBV) positive.

D. It is usually associated with a better prognosis than other subtypes of Hodgkin's lymphoma.

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 32-year-old male presents with painless lymphadenopathy in the cervical region. A biopsy reveals the presence of numerous small lymphocytes with scattered large mononuclear Hodgkin and Reed-Sternberg cells, which are CD20 positive and CD15/CD30 negative. Which subtype of Hodgkin's lymphoma is most consistent with these findings? (Q845805)

A. Nodular sclerosis Hodgkin lymphoma

B. Mixed cellularity Hodgkin lymphoma

C. Nodular Lymphocyte-predominant Hodgkin lymphoma

D. Lymphocyte-depleted Hodgkin lymphoma

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 65-year-old male with a history of HIV presents with fever, night sweats, and weight loss. A lymph node biopsy was done. Immunohistochemical staining shows these cells are CD15 and CD30 positive but CD20 negative. He was diagnosed with Lymphocyte-depleted Hodgkin's lymphoma. Which of the following features is characteristic of lymphocyte-depleted Hodgkin's lymphoma? (Q845806)

A. Presence of fibrous bands

B. Abundance of reactive lymphocytes

C. High number of Reed-Sternberg cells

D. Predominance of nodular growth pattern

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 35-year-old male presents with painless enlargement of cervical lymph nodes, accompanied by fever, night sweats, and weight loss. Biopsy reveals large, atypical cells with prominent nucleoli and a mixed inflammatory background. Immunohistochemical staining shows these cells are negative for CD15 and CD30. Which marker is most likely to be positive in these cells? (Q845807)

A. CD20

B. CD3

C. CD15

D. CD30

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 45-year-old male presents with painless swelling of multiple lymph nodes in his neck and groin. He denies experiencing fever, night sweats, or weight loss. Physical examination reveals bilateral cervical and inguinal lymphadenopathy. Based on the Ann Arbor classification, what is this patient's most likely stage of disease? (Q845808)

A. Stage I

B. Stage II

C. Stage III

D. Stage IV

See Answer in Part B → Q30

@Neet_pg_bot

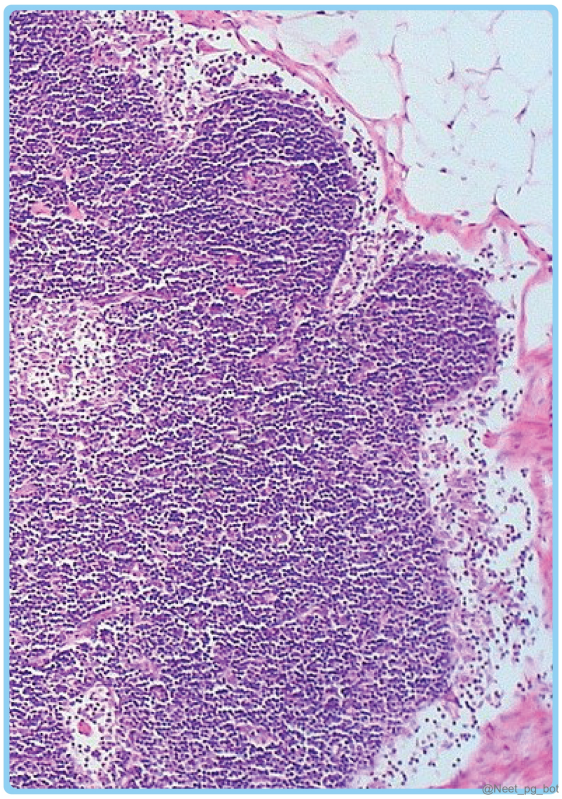
Q31: A 40-year-old male presents with a palpable lump in his right axilla. Physical examination reveals a mobile, non-tender, and rubbery lymph node. FNAC is performed, and the sample is examined under the microscope. Which of the following histological features is characteristic of a normal lymph node? (Q845821)

A. Presence of large pleomorphic cells

B. Disorganized architecture with fibrosis

C. Distorted germinal centres and absence of sinuses

D. Distinct cortex and medulla with germinal centres and sinuses



See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 35-year-old woman came with complaints of chronic fatigue and a palpable nodular mass in her axilla. Further investigations reveal a B-cell neoplasm. Which of the following is the least likely diagnosis? (Q845822)

A. Follicular lymphoma

B. Marginal zone lymphoma

C. Hairy cell leukemia

D. Anaplastic large cell lymphoma

See Answer in Part B → Q32

@Neet_pg_bot

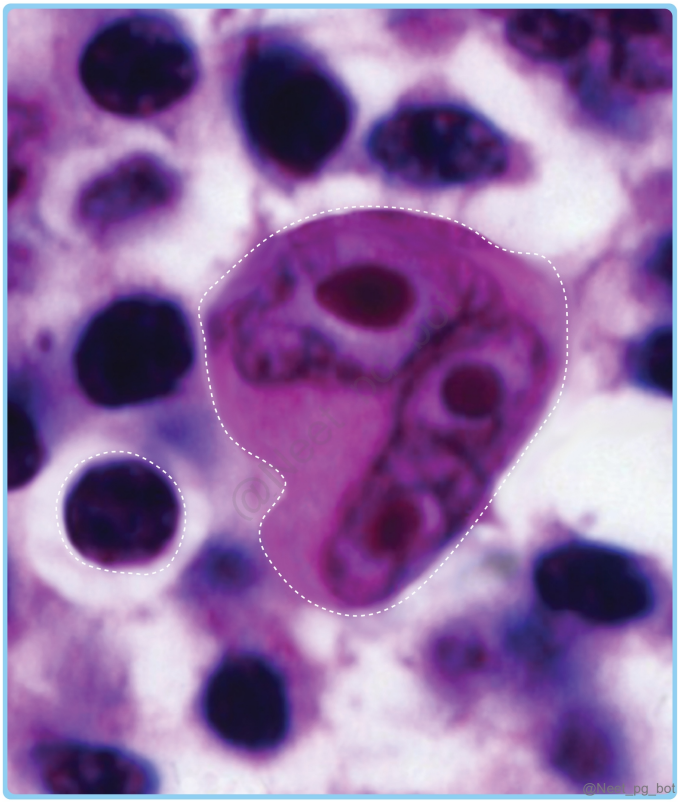
Q33: A 30-year-old female presents with painless swelling of the neck, intermittent fever, night sweats and significant weight loss over the past three months. On examination, enlarged cervical and mediastinal lymph nodes are noted. A biopsy reveals the presence of characteristic cells, as shown in the image below. Which of the following about the described condition is NOT true? (Q845791)

A. More often localised to a single axial group of nodes

B. Typically, it spreads in a contiguous manner.

C. Mesenteric nodes and Waldeyer ring involvement are rare.

D. Extranodal presentation is common.



See Answer in Part B → Q33

@Neet_pg_bot

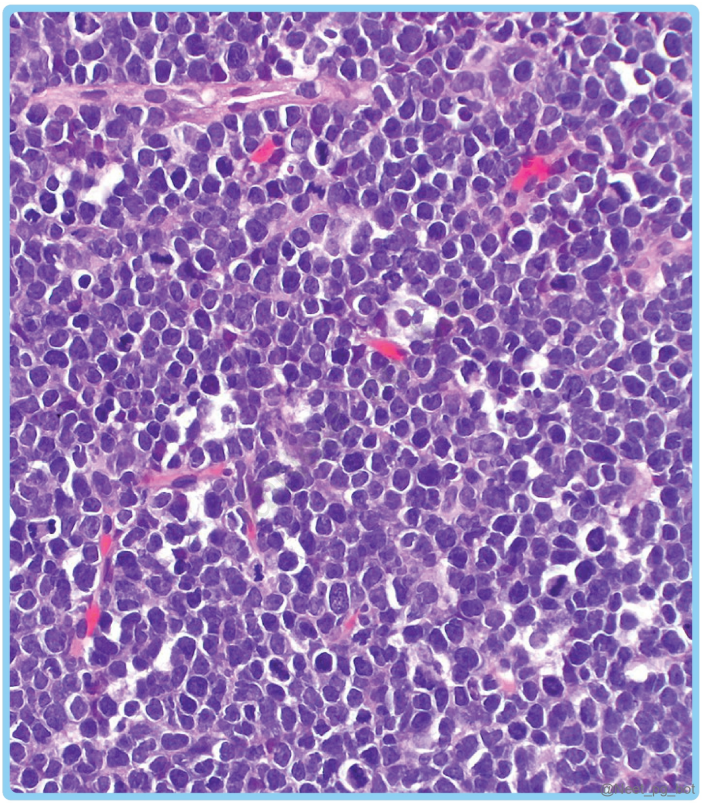
Q34: An 8-year-old boy presents with a large mass over the mandible. On the HPE of the lesion, a 'starry sky pattern' is seen, similar to the image below. This condition is associated with which of the following genetic abnormalities? (Q845824)

A. MYC gene

B. BCL2 gene

C. Cyclin-D1

D. BCL6 gene



See Answer in Part B → Q34

@Neet_pg_bot

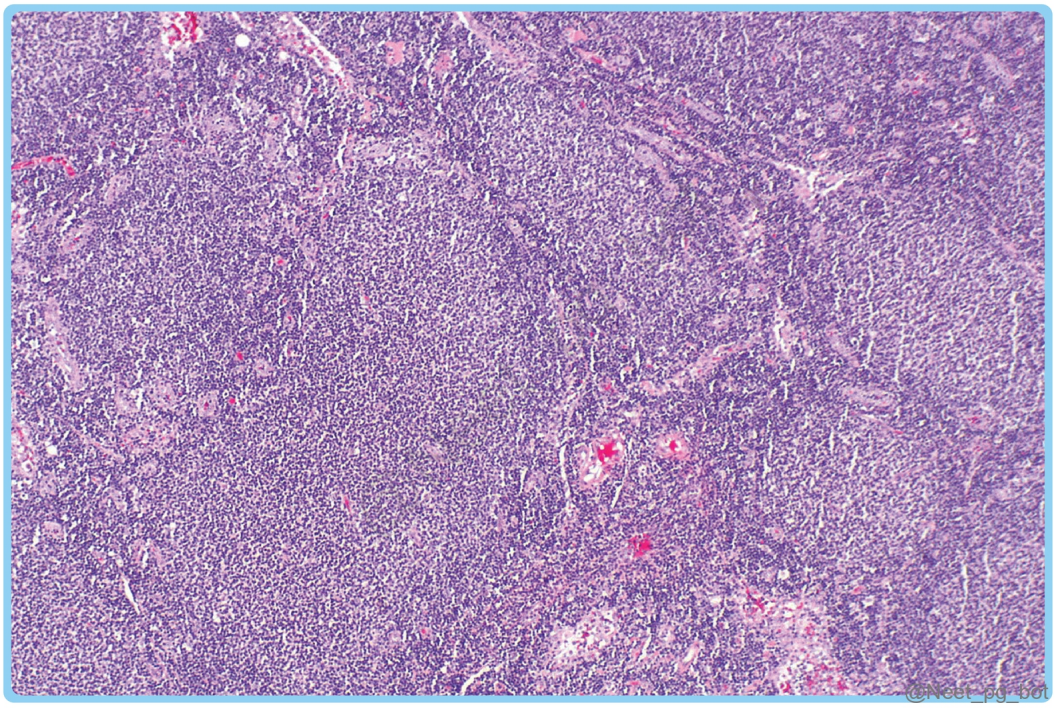
Q35: A 30-year-old man presents to the outpatient department with an axillary mass and complaints of low-grade fever, weight loss, and night sweats for the past 6 months. Histopathological examination (HPE) of a biopsy sample from the mass reveals diffuse follicular growth with centrocytes with cleaved nuclei and centroblasts. Immunohistochemistry shows BCL2 stain positive, CD19, CD20, and CD10 positive, and CD5 negative. What is the most likely diagnosis? (Q845827)

A. Follicular hyperplasia

B. Mantle cell lymphoma

C. Follicular lymphoma

D. Burkitt’s lymphoma



See Answer in Part B → Q35

@Neet_pg_bot

Q36: Match the following neoplasm with its appropriate genetic mutation. Neoplasia Genetic mutation 1. Mantle cell lymphoma A. BCL6 gene 2. Burkitt’s lymphoma B. Cyclin D1 gene 3. Diffuse large B cell lymphoma C. BCL10 / MALT1 4. Marginal zone lymphoma D. MYC gene (Q845828)

A. 1-B, 2-D, 3-A, 4-C

B. 1-B, 2-A ,3-C ,4-D

C. 1-A ,2-C ,3-D,4- B

D. 1-C ,2-D ,3-A ,4- B

See Answer in Part B → Q36

@Neet_pg_bot

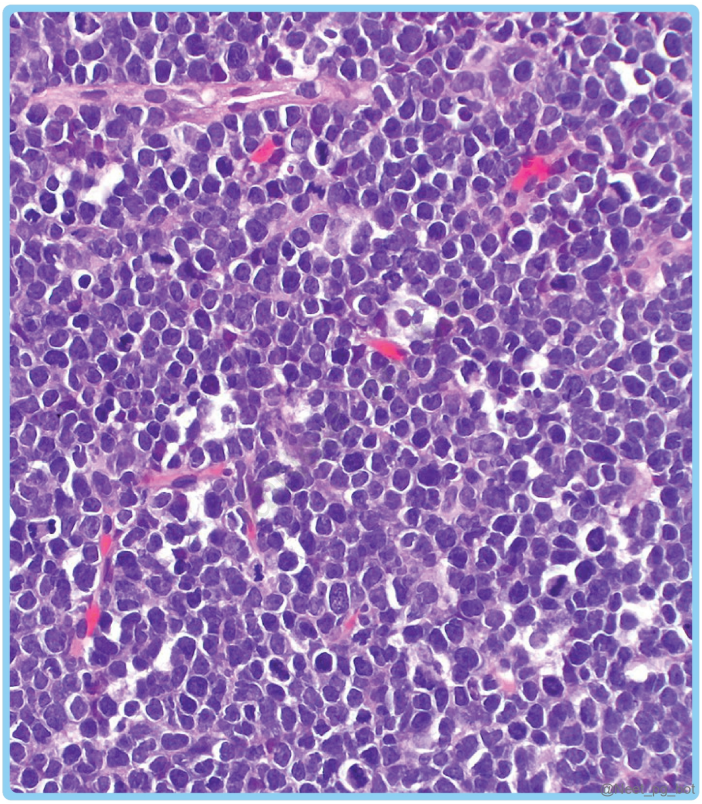
Q37: A 14-year-old boy from Bihar presents with a low-grade fever, weight loss, and abdominal pain for the past 2 months. Investigation reveals a mass involving the ileocecal region, with histopathological examination showing a 'starry sky' appearance, immunohistochemistry positive for CD10, CD19, CD20, and BCL6, and FISH indicating a (8:14) translocation involving the MYC gene. This type of presentation is common in which condition? (Q845829)

A. Endemic Burkitt’s lymphoma

B. Sporadic Burkitt’s lymphoma

C. HIV-associated Burkitt’s lymphoma

D. All of the above



See Answer in Part B → Q37

@Neet_pg_bot

Q38: Which of the following statements correctly differentiates between Primary Effusion Lymphoma (PEL) and Immunodeficiency-associated Large B-cell Lymphoma? (Q845830)

A. PEL presents with lymphomatous masses in solid organs, while Immunodeficiency-associated Large B-cell Lymphoma presents as effusions.

B. PEL is associated with EBV , whereas Immunodeficiency-associated Large B-cell Lymphoma is linked to HHV-8.

C. PEL presents as Effusions and is associated with HHV-8, whereas Immunodeficiency-associated Large B-cell Lymphoma is linked to EBV.

D. Both are predominantly found in immunocompetent individuals without any viral association.

See Answer in Part B → Q38

@Neet_pg_bot

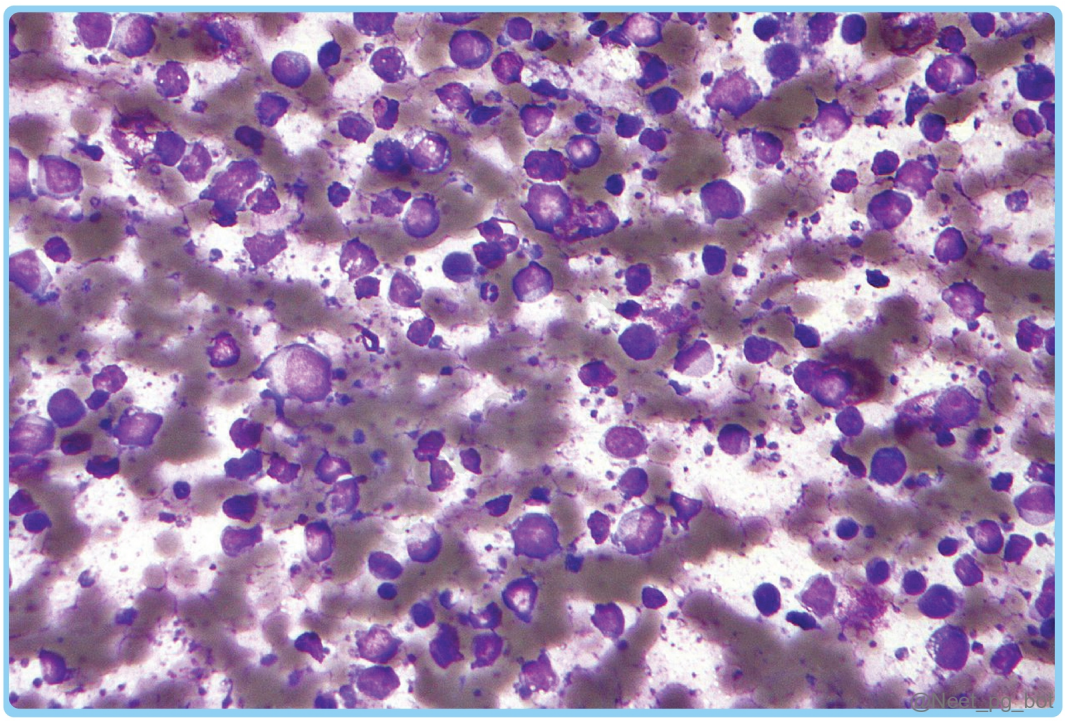
Q39: Match each lymphoma or leukaemia type with its corresponding histopathological finding. Lymphoma/Leukemia Type Histopathological Finding 1.Follicular Lymphoma A) 2. Burkitt's Lymphoma B) 3. Diffuse Large B-Cell Lymphoma (DLBCL) C) 4. Hairy Cell Leukemia D) (Q845833)

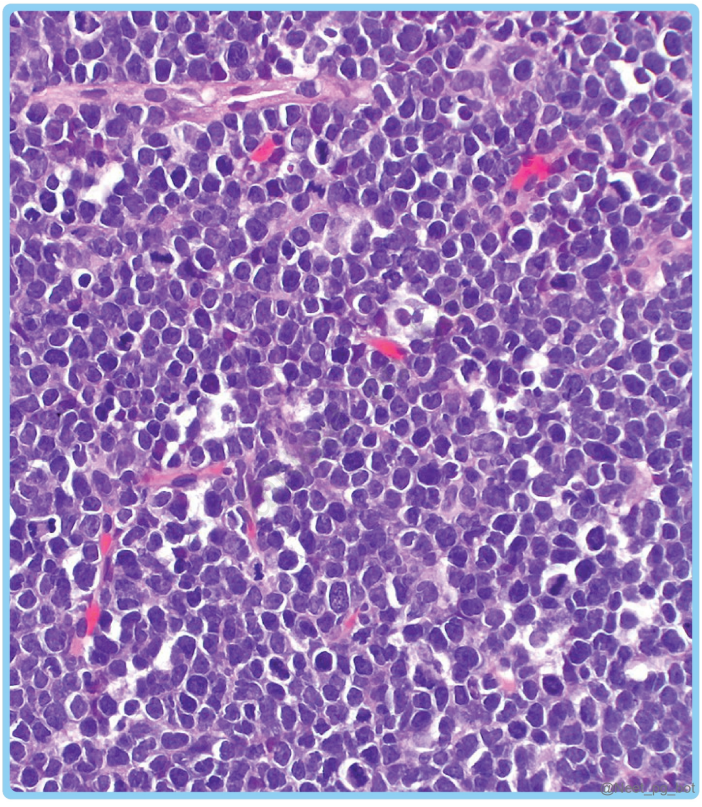
A. 1-C, 2-B, 3-A, 4-D

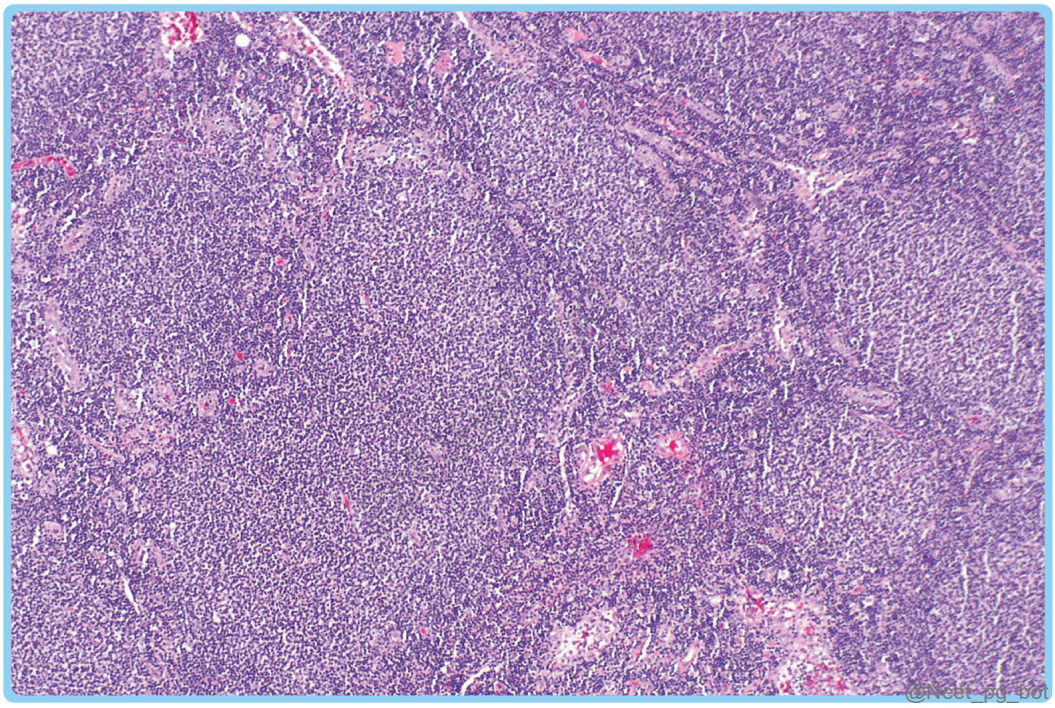
B. 1-B, 2-A, 3-D, 4-C

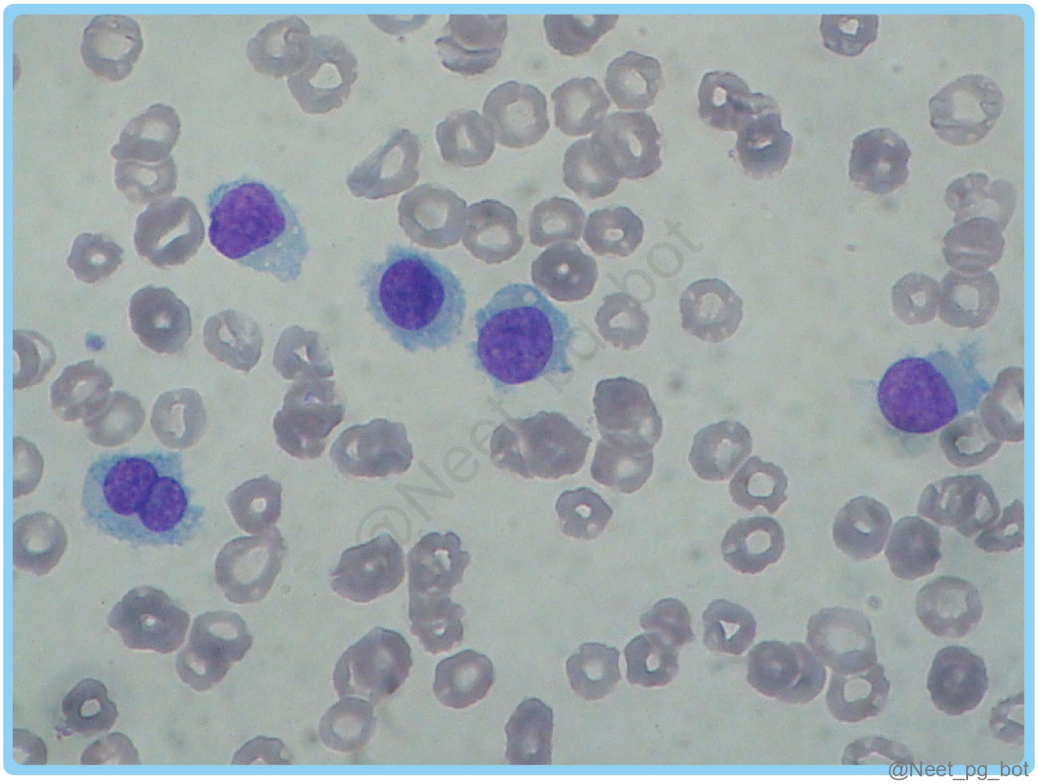
C. 1-D, 2-C, 3-B, 4-A

D. 1-A, 2-D, 3-C, 4-B









See Answer in Part B → Q39

@Neet_pg_bot

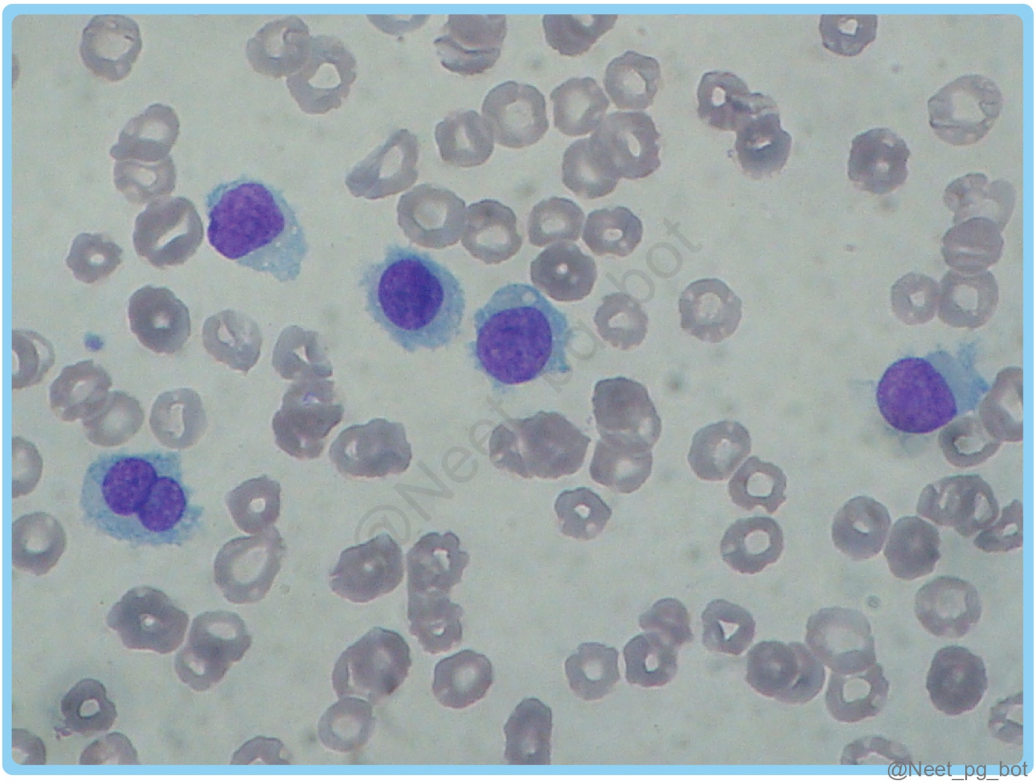
Q40: A 45-year-old male has been complaining of persistent fatigue, recurrent infections, and easy bruising over the past few months. On physical examination, he has a noticeable abdominal mass. A peripheral smear shows the presence of atypical lymphoid cells with cytoplasmic projections, as shown in the image below. Which of the following statements is not true regarding the patient's condition? (Q845834)

A. Associated with the BRAF V600E mutation.

B. Massive splenomegaly is a common clinical feature.

C. The pathogenesis involves the proliferation of immature myeloid cells

D. Typically present with fatigue, infections, and pancytopenia.



See Answer in Part B → Q40

@Neet_pg_bot

Q41: A 55-year-old male presents with persistent fatigue, splenomegaly, and pancytopenia. Peripheral blood smear shows leukocytosis with mature lymphocytes displaying hairy projections. Flow cytometry confirms the presence of CD11c and

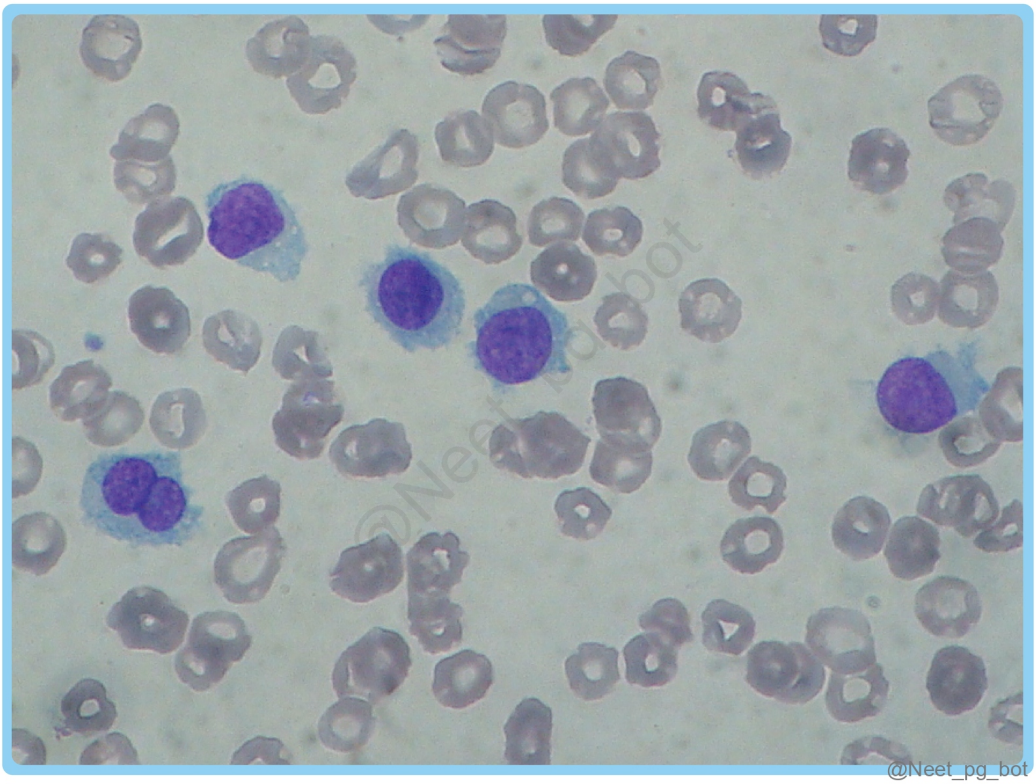
CD25 positive cells. Which of the following is the most specific biomarker commonly useful in the diagnosis of condition? (Q845835)

A. CD 20

B. Annexin V

C. Annexin A1

D. Apolipoprotein A1



See Answer in Part B → Q41

@Neet_pg_bot

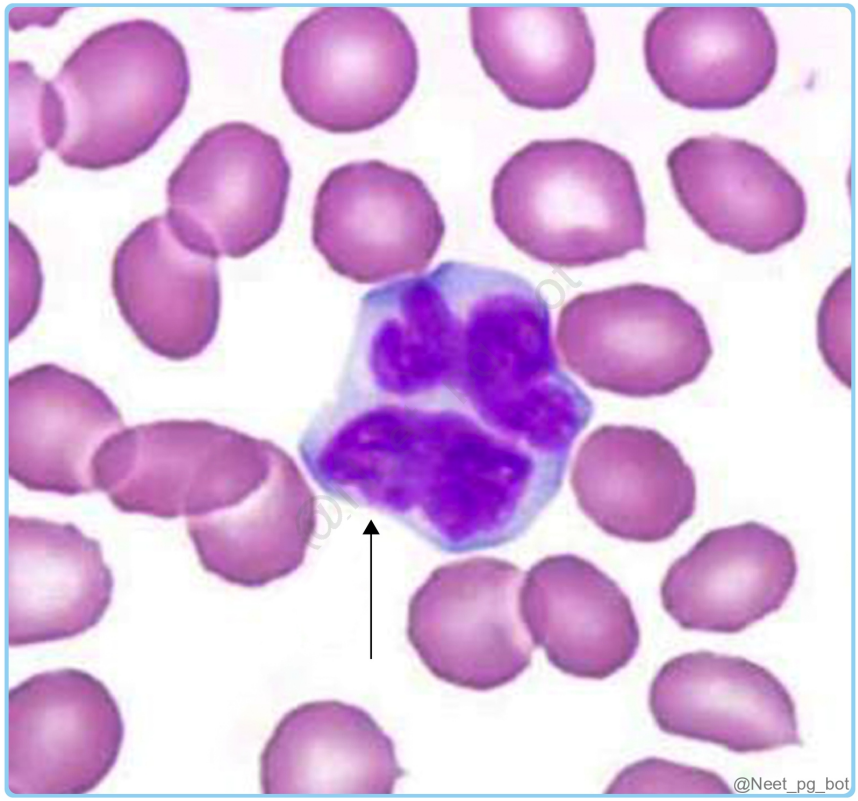
Q42: A 45-year-old male presents with a three-year history of pruritic, erythematous plaques on his trunk and extremities. Physical examination reveals widespread erythematous patches and plaques with a "cerebriform" appearance. Peripheral smear findings reveal the presence of abnormal lymphocytes with convoluted nuclei and abundant cytoplasm. Which of the following is the most likely diagnosis? (Q845836)

A. Mycosis fungoides

B. Adult T-cell leukemia

C. Anaplastic large cell lymphoma

D. Hairy cell leukemia



See Answer in Part B → Q42

Q1: Which of the following is not true about nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL)? (Q856479)

A. EBV negative

B. CD 30 negative

C. CD 20 positive

D. Poor prognosis compared to classical HL

See Answer in Part B → Q1

@Neet_pg_bot

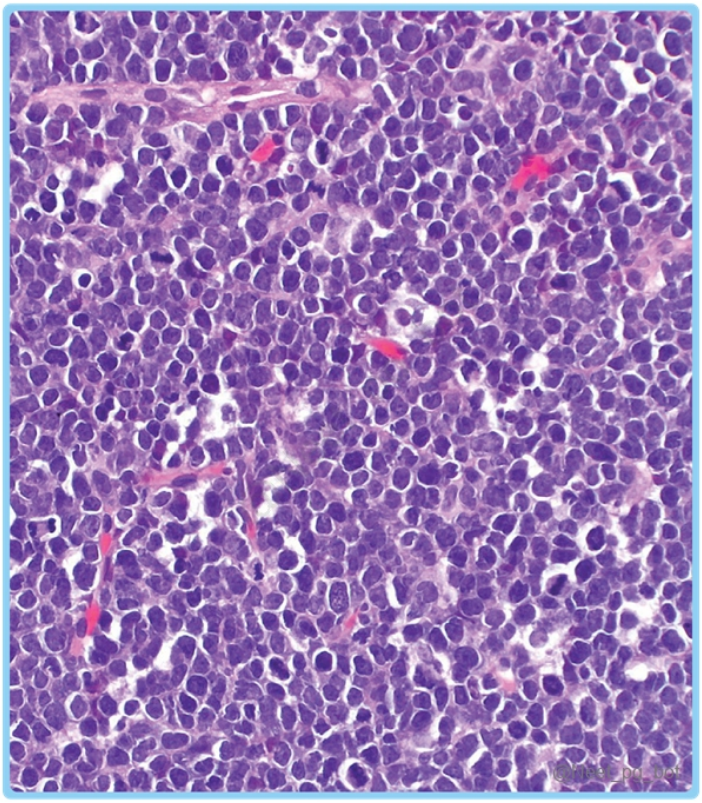
Q2: What is the most likely diagnosis for a 5-year-old boy who has weight loss, fever, and a painless swelling in his jaw area, with anaemia and lymphocytosis revealed by a CBC and biopsy findings shown in the accompanying image?\ (Q857579)

A. Hodgkin’s disease

B. Acute lymphocytic leukemia

C. Chloroma

D. Burkitt’s lymphoma



See Answer in Part B → Q2

@Neet_pg_bot

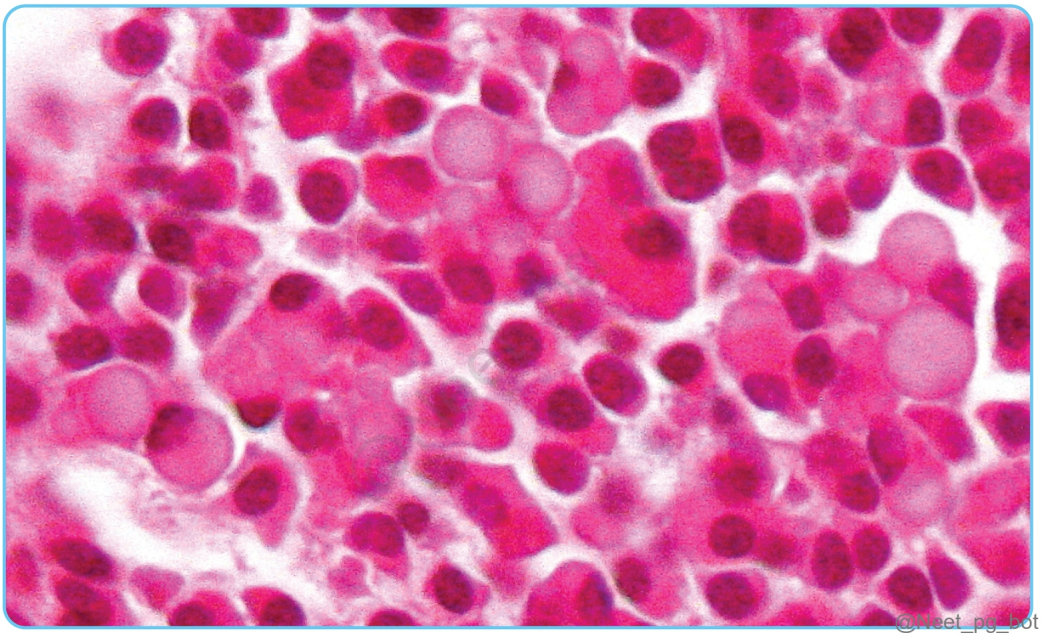
Q3: A 60-year-old male presents with easy fatigability, back pain, and multiple lytic lesions in the skull. The bone marrow biopsy finding is given below. What is the most probable diagnosis? (Q857582)

A. CML (Chronic Myelogenous Leukemia)

B. CLL (Chronic Lymphocytic Leukemia)

C. Multiple Myeloma

D. Hairy Cell Leukemia



See Answer in Part B → Q3

@Neet_pg_bot

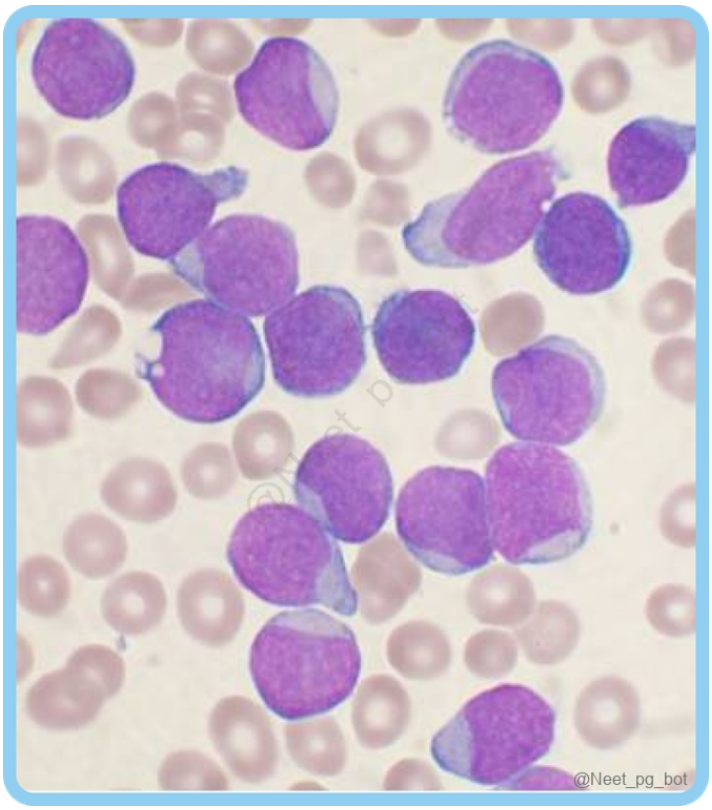
Q4: What is the likely diagnosis for a 10-year-old boy with Down syndrome who presents with a mediastinal mass (SVC-like syndrome), based on the provided bone marrow histology shown below? (Q857605)

A. AML (Acute Myeloid Leukemia)

B. Aplastic anemia

C. ALL (Acute Lymphoblastic Leukemia)

D. Juvenile Myelomonocytic Leukemia (JMML)



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old patient presented with scrotal swelling and ataxia. Which among the following could likely be a cause? (Q856695)

A. Glioblastoma multiforme

B. Hodgkin lymphoma

C. Non-Hodgkin lymphoma

D. Non seminomatous germ cell tumor

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which cell is the origin of chronic lymphocytic leukaemia / small lymphocytic lymphoma? (Q856721)

A. Naive B cells

B. Mature T cells

C. Progenitor T cells

D. Granulocytes

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient with lytic lesions on the skull is suspected of a diagnosis of Langerhans cell histiocytosis. Which of the following is a characteristic finding of electron microscopy? (Q856725)

A. Histiocytes

B. Birbeck granules

C. Eosinophils

D. Giant cells

See Answer in Part B → Q7

@Neet_pg_bot

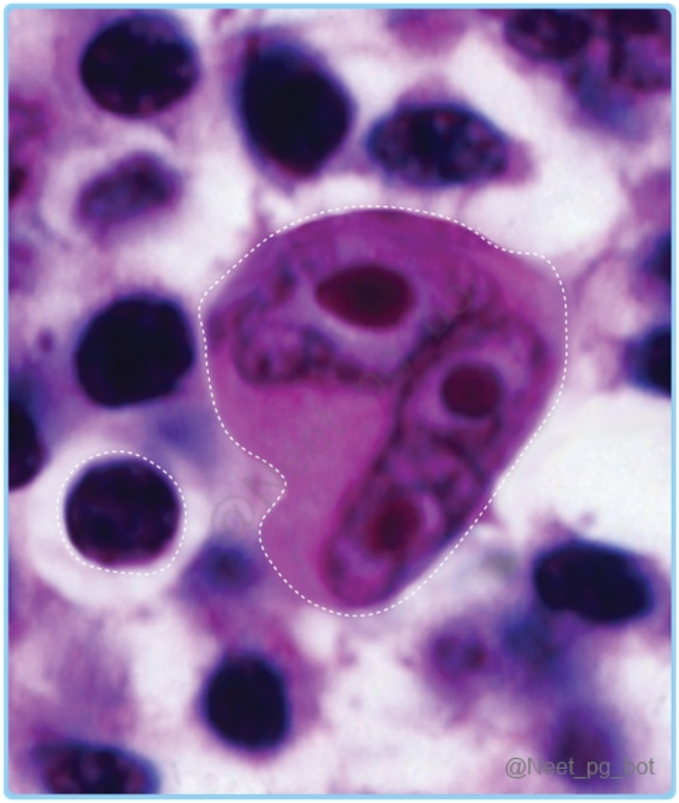
Q8: A 6-year-old boy came with bilateral cervical lymphadenopathy. What is the probable diagnosis, cell, and virus associated with the image given below? RS cell: Reed Stemberg cell HIV: Human immunodeficiency virus CMV: Cytomegalovirus EBV: Epstein–Barr virus (Q856726)

A. Non-Hodgkin’s lymphoma, RS cell, EBV

B. Kaposi sarcoma, Giant cell, HIV

C. Hodgkin’s lymphoma, RS cell, EBV

D. Infectious mononucleosis, RS cell, CMV



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30-year-old male has been complaining of fatigue for the past year. The examination revealed massive splenomegaly. His blood workup shows the presence of anemia, TLC 150,000/microL, and PBS shows 60% neutrophils, 6% basophils, 4% eosinophils, myeloblasts, myelocytes, and metamyelocytes. The myeloid-to-erythroid ratio was 18:1. Which of the following is the most sensitive investigation in this case? (Q856102)

A. Immunophenotyping

B. LAP score

C. FISH and PCR

D. Flow cytometry

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is a poor prognostic marker of multiple myeloma? (Q856140)

A. β-2 microglobulin

B. Calcium levels

C. Serum creatinine

D. Protein levels

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 54-year-old patient presents to the outpatient department with fatigue, tiredness, and cervical lymphadenopathy. The TLC and DLC were normal, with no immature cells. A lymph node biopsy showed diffuse effacement of the lymph node architecture and cells with an indented nucleus and prominent nucleolus that are atypical. CD10 and BCL2 are positive. What is the likely diagnosis? (Q856147)

A. Follicular lymphoma

B. Burkitt lymphoma

C. Mycosis fungoides

D. Chronic myeloid leukaemia

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is a possible explanation for the presence of pancytopenia as indicated by the blood examination results? A. Megaloblastic anemia B. Hairy cell leukemia C. MDS with hypocellular BM D. APML (Q856922)

A. B, D

B. A, B, C

C. B, C, D

D. A, B, D

See Answer in Part B → Q12

@Neet_pg_bot

Q13: 2-year-old with fever, lymphadenopathy and H&E has hallmark cells. The diagnosis of anaplastic large cell lymphoma was made. Most likely translocation? (Q866673)

A. t(8;14)

B. t(8;22)

C. t(2;5)

D. t(14;18)

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Identify the correct statement regarding immune surveillance. (Q856493)

A. Anti-CTLA-4 Ab is a new modality in the treatment of advanced cancers

B. Mutation of tumour suppressor genes decreases antigen toxicity

C. PD1/PDL1 activation leading to tumour suppression

D. Binding of CD28 leads to immune tolerance

See Answer in Part B → Q14

@Neet_pg_bot

Q15: All-trans retinoic acid (ATRA) is used in the treatment of tumours associated with which of the following genetic aberrations? (Q854879)

A. PML-RARA

B. BCR-ABL

C. cMYC

D. RUNX1-ETO

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 70-year-old man has presented with chronic lower back pain, fatigue, and headaches for the last few weeks. On examination, he has pallor and bony tenderness. Lab investigations revealed an increased ESR, and his skull radiograph revealed several punched-out lytic lesions. Which of the following is the best investigation for this patient among the following options? (Q859274)

A. Serum electrophoresis showing IgG

B. Serum levels of CA 15-3

C. Whole-body scan

D. CT head with contrast

See Answer in Part B → Q16

@Neet_pg_bot

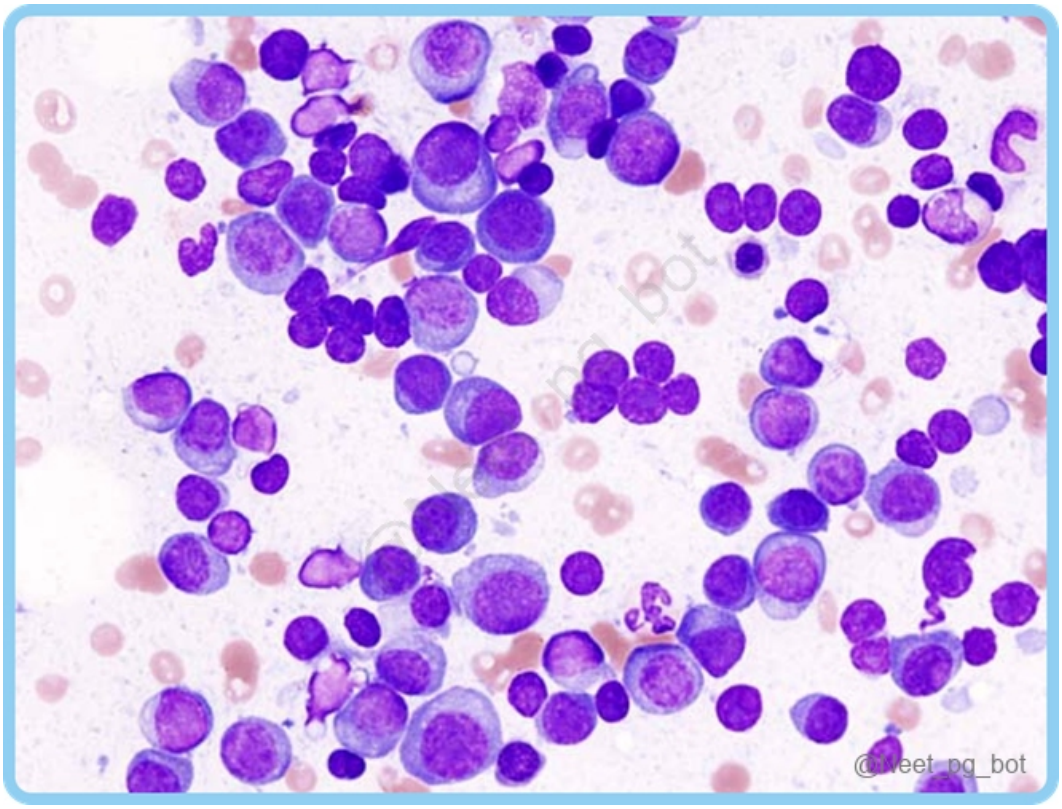
Q17: A 65-year-old male underwent a bone marrow examination, which revealed the presence of the following findings, as shown in the image. What is the likely diagnosis of this patient? (Q859279)

A. Multiple myeloma

B. ALL

C. Tuberculosis

D. Sickle cell disease



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 10-year-old boy with Down syndrome presents with mediastinal mass (presenting as SVC-like syndrome), and Peripheral blood and bone marrow have increased lymphoblasts. What is the probable diagnosis? (Q859296)

A. Acute myeloblastic leukemia

B. Chronic lymphoblastic leukemia

C. Acute lymphoblastic leukemia

D. Chronic myeloid leukemia

See Answer in Part B → Q18

@Neet_pg_bot

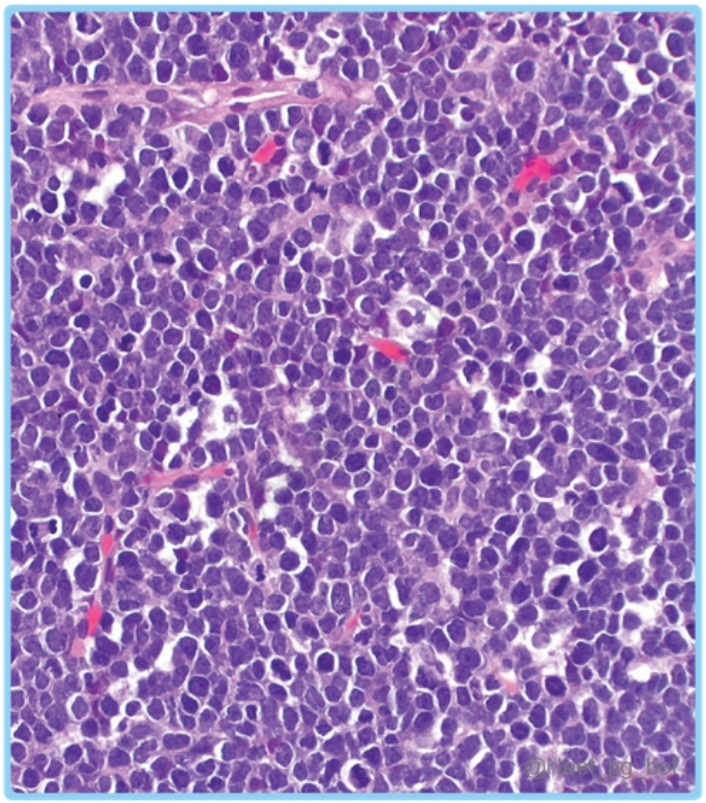
Q19: What is the diagnosis for a 5-year-old boy who has weight loss, fever, and a painless swelling in his jaw area? CBC results indicate anaemia and lymphocytosis. The image below shows biopsy findings from the swelling. (Q859847)

A. Kikuchi disease

B. Infectious mononucleosis

C. Hodgkins lymphoma

D. Burkitt lymphoma



See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 60-year-old male patient presented with anaemia and hepatosplenomegaly. A peripheral smear showed teardrop cells, nucleated RBCs, and giant abnormal platelets. A biopsy showed marrow fibrosis and a few characteristics, as given below.

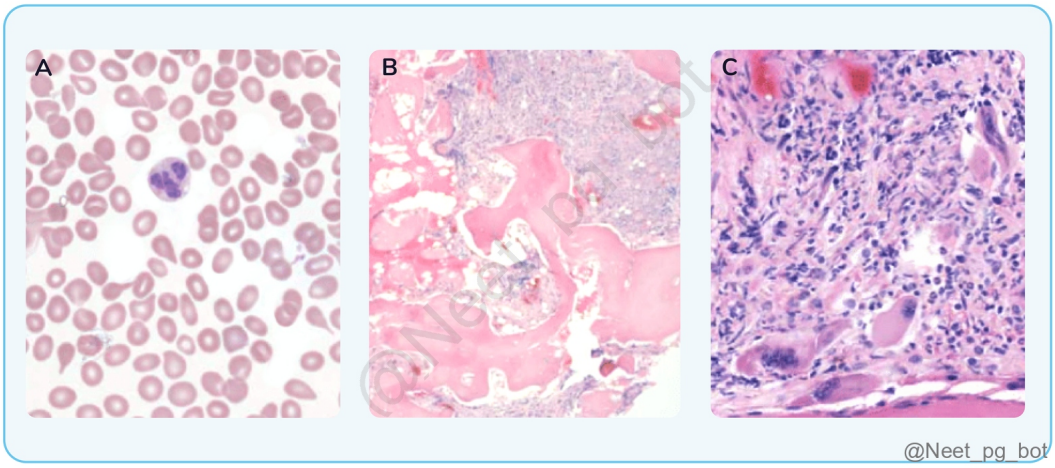
The most likely diagnosis is: (Q859854)

A. Polycythemia vera

B. Essential thrombocythemia

C. Primary myelofibrosis

D. Chronic myeloid leukemia



See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old man presents with nosebleeds, bleeding gums, and multiple ecchymoses. Lab investigations show: Haemoglobin: 8.5 g/dL Platelet count: 12,000 platelets/mm3 Total leucocyte count: 52,000 cells/mm3 with 83% blasts, as seen below. The blasts are CD33 +ve. The most likely diagnosis is: (Q859860)

A. Acute myeloid leukemia

B. Acute lymphoblastic leukemia

C. Chronic lymphocytic leukemia

D. Myelodysplastic syndrome

See Answer in Part B → Q21

@Neet_pg_bot

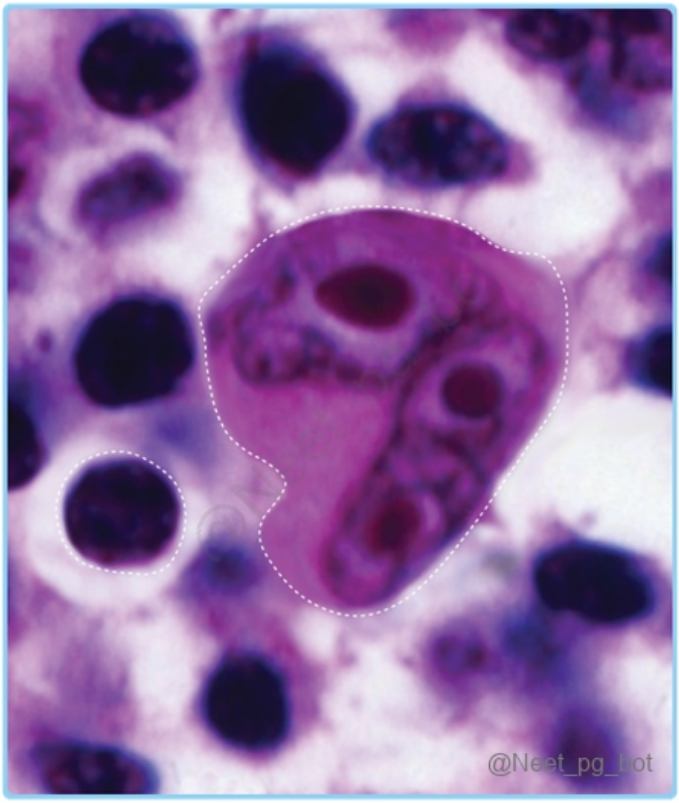
Q22: What is the type of cell from which the cell displayed below originates? (Q859892)

A. NK cells

B. CD4 cells

C. B cells

D. CD8 cells



See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 56-year-old man presents with dragging pain in the abdomen. On examination, there is a massive splenomegaly. A peripheral smear shows leukocytosis with increased myelocytes, metamyelocytes, and basophils. Which of the following translocations is seen in this condition? (Q855983)

A. t(9;22)

B. t(8;21)

C. t(15;17)

D. t(8;14)

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 62-year-old man presents with generalised lymphadenopathy and splenomegaly. Peripheral smear shows small to medium-sized lymphoid cells with irregular nuclear contours. Cytogenetic analysis demonstrates a t(11;14) (q13;q32) translocation. Which of the following markers is most closely associated with the pathogenesis? Cyclin D SOX 11 CD -200 D CD10 (Q879203)

A. 1, 2, 3

B. 1, 2

C. 1, 2, 4

D. 2, 3, 4

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 30-year-old male presents with fatigue for the past year. Examination reveals massive splenomegaly. His blood workup shows the following findings: Anemia Total leukocyte count (TLC): 150,000/microliter Peripheral smear: 60% neutrophils, 6% basophils, 4% eosinophils, myeloblasts, myelocytes, and metamyelocytes Myeloid to erythroid ratio: 18:1 What is the most likely diagnosis? (Q857164)

A. Acute Lymphoblastic Leukemia (ALL)

B. Acute Myeloid Leukemia (AML)

C. Chronic Myelogenous Leukemia (CML)

D. Chronic Lymphocytic Leukemia (CLL)

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 68-year-old man presents with bleeding manifestations. The peripheral smear shows the presence of the cells shown below. Which of the following is the most common chromosomal abnormality seen in this condition? (Q866343)

A. t(8:21)

B. t(15:17)

C. t(14:18)

D. Inv(16)

See Answer in Part B → Q26

@Neet_pg_bot

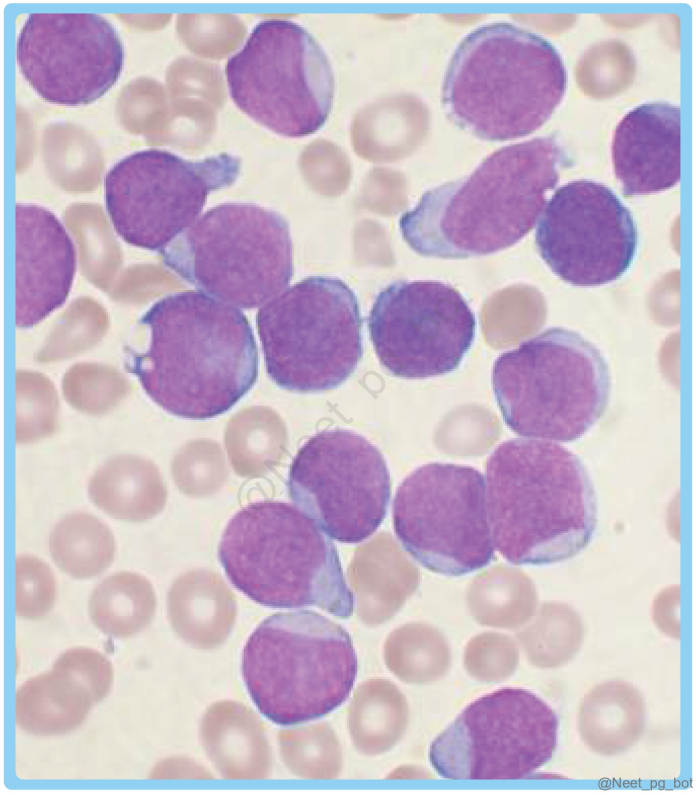
Q27: A young child presents with bleeding gums and bruising for the past two weeks. Bone marrow biopsy and flow cytometry have been performed. What is the diagnosis? (Q853374)

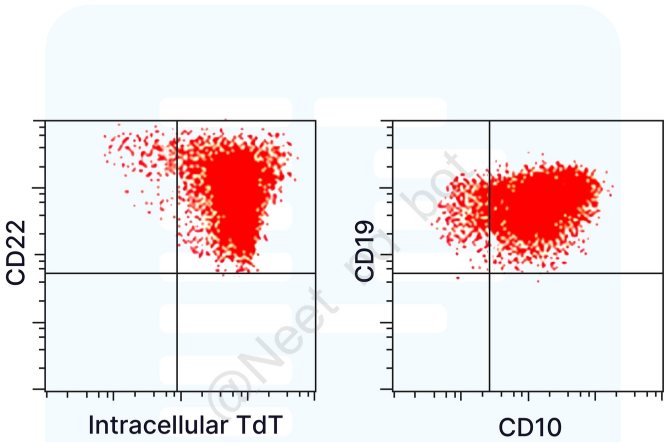
A. Acute myeloid leukemia

B. CLL

C. ALL: B Phenotype

D. ALL: T Phenotype





@Neet_pg_bot

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which gene mutation is most commonly associated with Burkitt's lymphoma? (Q852602)

A. C-myc

B. P-21

C. Rb

D. p53

See Answer in Part B → Q28

@Neet_pg_bot

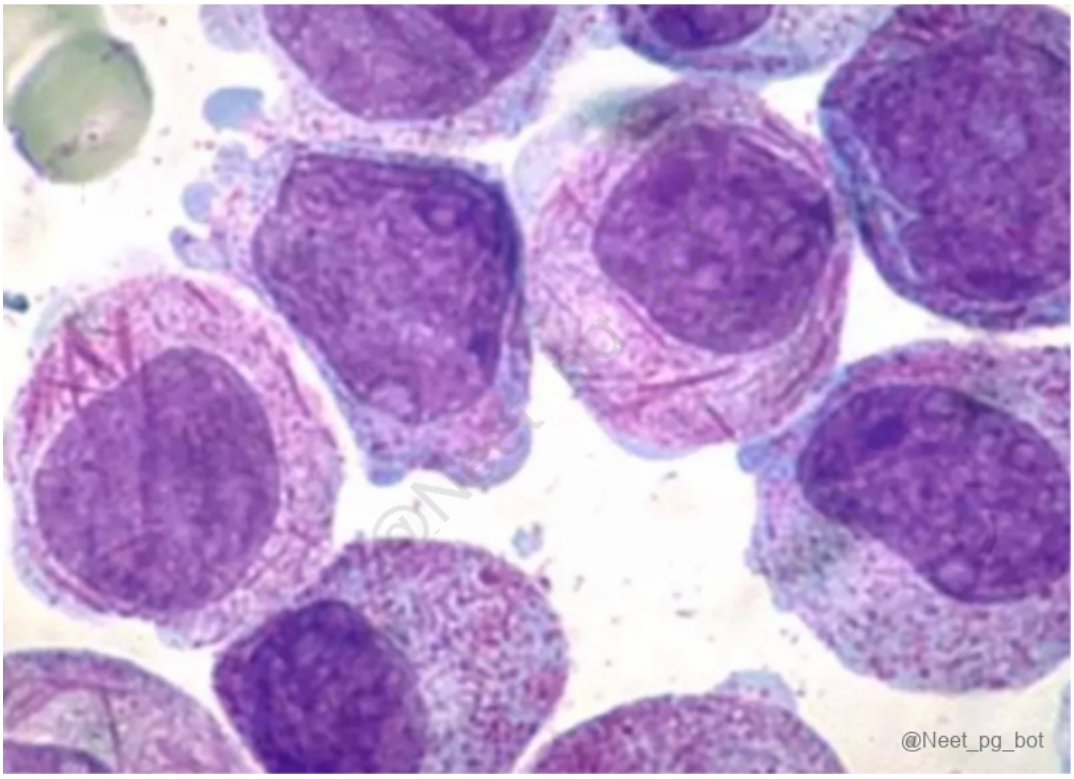
Q29: A 34-year-old female presents with low hemoglobin, platelet count of 25,000/mm 3 , and raised PT and APTT. The peripheral smear image is shown below. Which of the following fusion genes is likely affected? (Q843988)

A. PML-RARA

B. RUNX1-RUNX1T1

C. INV 16

D. IGH-NSD2



See Answer in Part B → Q29

@Neet_pg_bot

Q30: A patient presents with fever, hepatosplenomegaly, abdominal pain, and WBC count > 50,000/mm 3 . Which of the following genetic abnormalities is involved? (Q844072)

A. t(9;22)

B. del(1q)

C. t(15;17)

D. del 3q

See Answer in Part B → Q30

@Neet_pg_bot

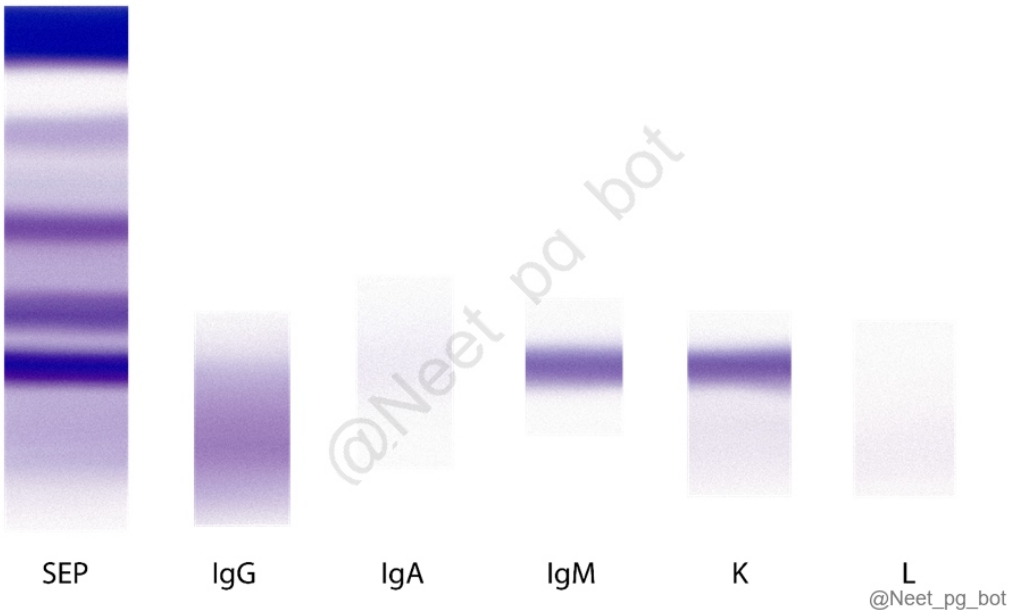
Q31: An elderly patient presents with elevated calcium levels, increased serum creatinine levels, and decreased hemoglobin. Electrophoresis reveals a monoclonal spike. Her immunofixation test findings are given below. Which of the following best describes her condition? (Q844198)

A. Multiple myeloma with increased IgG

B. Multiple myeloma with increased IgM

C. Multiple myeloma with increased IgA

D. Monoclonal gammopathy of unknown significance



See Answer in Part B → Q31

@Neet_pg_bot

Q32: Which of the following is the investigation of choice for CML? (Q860526)

A. LAP score

B. FISH

C. Karyotyping

D. Reciprocal translocation

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Mark the incorrect statement regarding Hodgkin Lymphoma: (Q840028)

A. Reed Sternberg cells are of B-cell origin

B. Waldeyer's ring is involved

C. Nodular sclerosing is the most common subtype and involves mediastinum

D. CD 15, 30 Positivity in Reed Sternberg cells

See Answer in Part B → Q33

@Neet_pg_bot

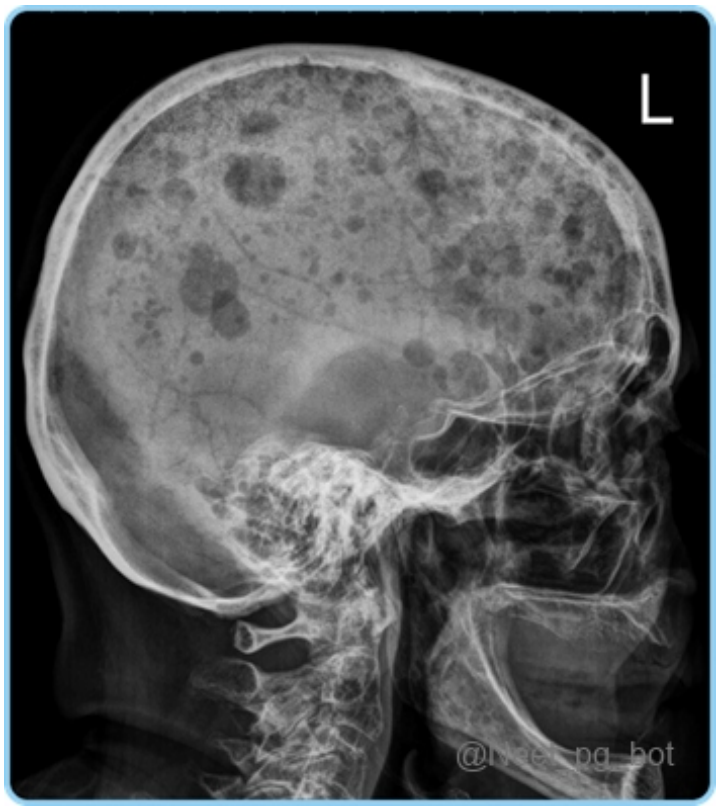
Q34: A patient with elevated calcium and normal alkaline phosphatase undergoes a skull X-ray. What is the likely diagnosis? (Q860163)

A. Grave’s disease

B. Paget’s disease

C. Multiple myeloma

D. CML



See Answer in Part B → Q34

@Neet_pg_bot

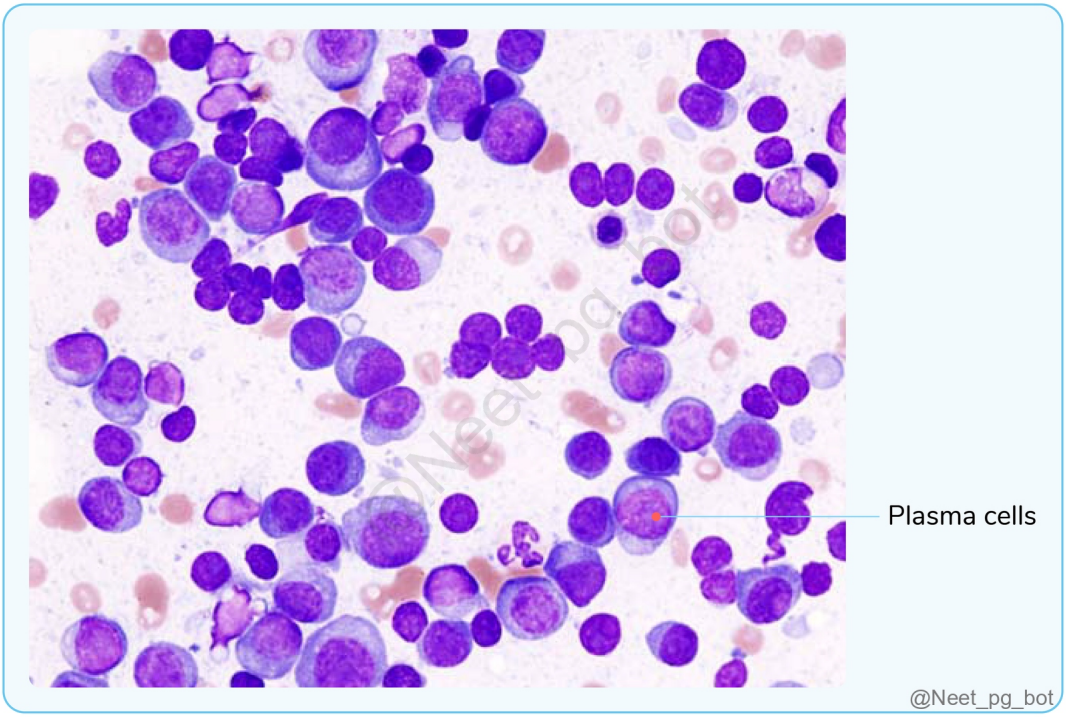
Q35: A 50-year-old male complains of lower back pain with a 1-1.5 mm osteolytic lesion at the T10 vertebra. Histopathological findings are given below. Which of the following options is correct regarding this condition? (Q860232)

A. Presence of Bence-Jones proteinuria

B. Absence of Rouleaux formation

C. Absence of free light chains

D. Decreased Calcium levels in the blood



See Answer in Part B → Q35

@Neet_pg_bot

Q36: Which among the following is associated with Cryoglobulinemia? (Q860258)

A. Hepatitis C infection

B. Ovarian cancer

C. Diabetes

D. Leukaemia

See Answer in Part B → Q36

@Neet_pg_bot

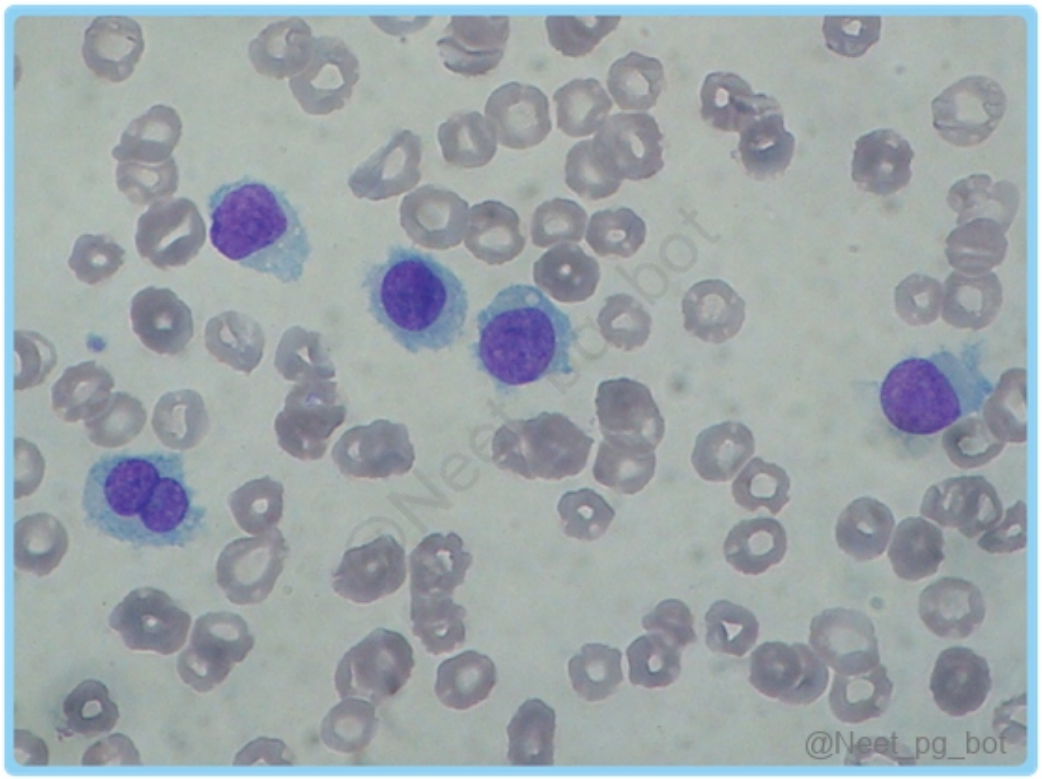
Q37: Which of the following cells is shown in the given image? (Q857427)

A. Hairy cell

B. Gaucher cell

C. Sickle cell

D. Target cell



See Answer in Part B → Q37

@Neet_pg_bot

Q38: A 70 year old male presents with low back ache and progressive pallor. On work up: KFT is deranged, LFT is normal with normal level of albumin and gamma globulin increased disproportionately. X-ray spine shows multiple lytic lesions. Which of the following is the most probable diagnosis? (Q820525)

A. Multiple myeloma

B. MGUS

C. Immunoglobulin light chain amyloidosis (AL)

D. Solitary plasmacytoma.

See Answer in Part B → Q38

@Neet_pg_bot

Q39: A 55-year-old male patient presents with fever, night sweats, and pleural effusion. On further investigation, he is diagnosed with Primary Effusion Lymphoma. What is the most likely causative agent responsible for this condition? (Q820628)

A. HHV-8

B. EBV

C. HPV

D. HIV

See Answer in Part B → Q39

@Neet_pg_bot

Q40: What further test should be conducted for a 60-year-old male patient who has presented with widespread lymph node enlargement, elevated white blood cell count, and smudge cells observed on peripheral smear? (Q854682)

A. Cytogenic study

B. Bone marrow biopsy

C. Flow cytometry from peripheral blood

D. X-ray crystallography

See Answer in Part B → Q40

@Neet_pg_bot

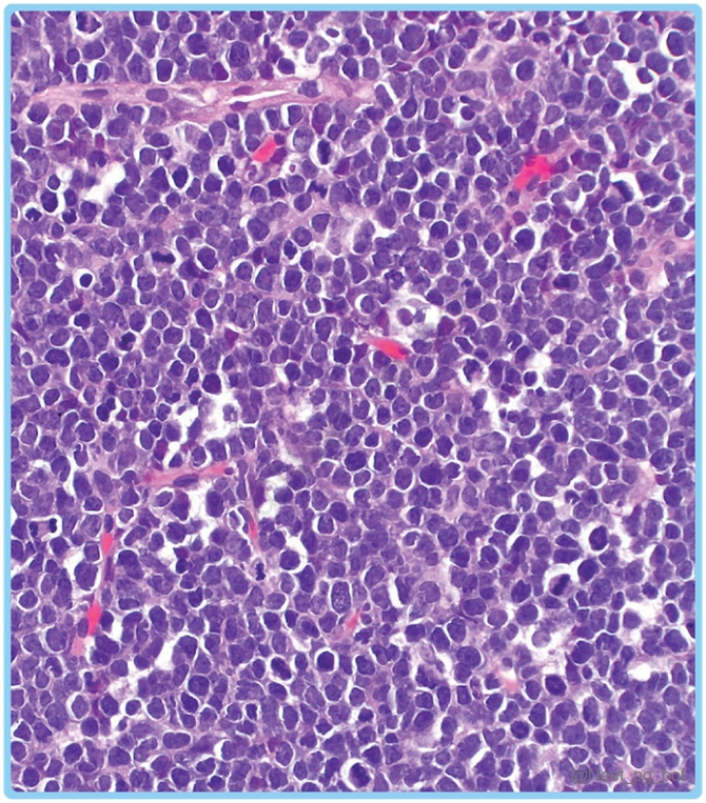
Q41: An African child is found to have a mass in the jaw. A biopsy of the mass was done, and it appears as shown in the image below. The child also has a translocation, t(8;14). What is the probable diagnosis? (Q855405)

A. Acute myeloid leukemia

B. Follicular lymphoma

C. Multiple myeloma

D. Burkitt lymphoma



See Answer in Part B → Q41

@Neet_pg_bot

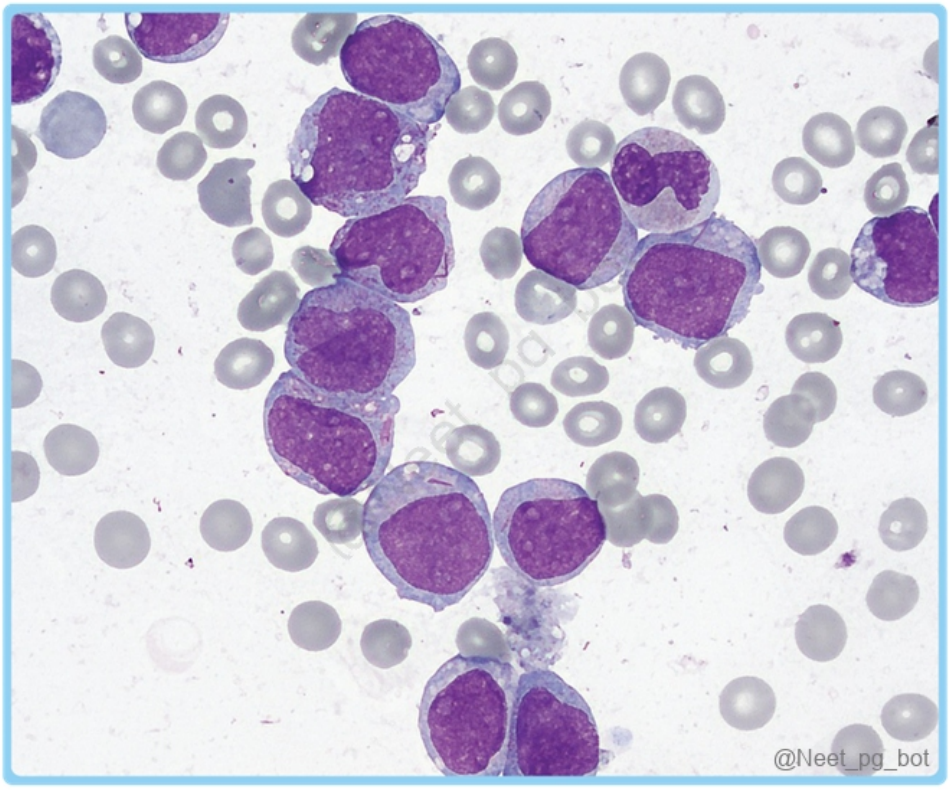
Q42: A 25-year-old male presented with low haemoglobin, a platelet count of 25,000/mL, gum bleeding, and raised PT and aPTT. The image of his peripheral smear is shown below. What is the likely diagnosis? (Q855440)

A. AML with t(8;21)

B. AML with inv(16)

C. AML with t(15;17)

D. AML with t(11;22)



See Answer in Part B → Q42

@Neet_pg_bot

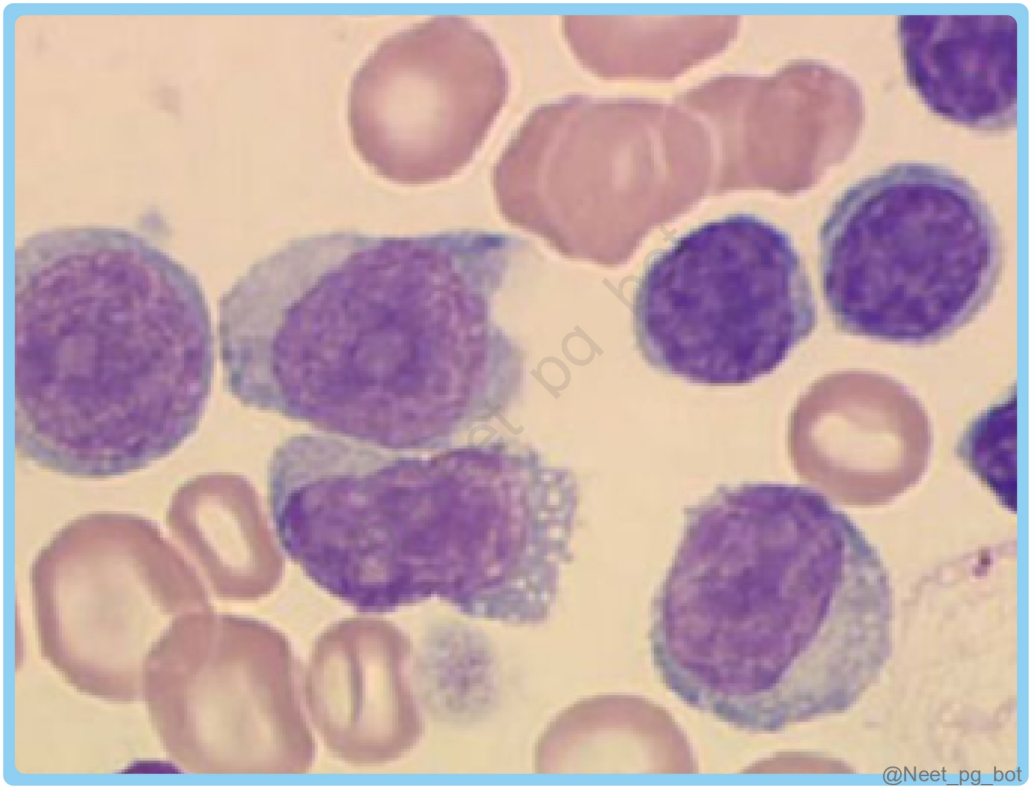
Q43: Which of the following leukaemias is associated with the given peripheral smear? (Q855099)

A. Acute lymphoblastic leukemia

B. Chronic lymphocytic leukemia

C. Acute myeloid leukemia

D. Chronic myelogenous leukemia



See Answer in Part B → Q43

@Neet_pg_bot

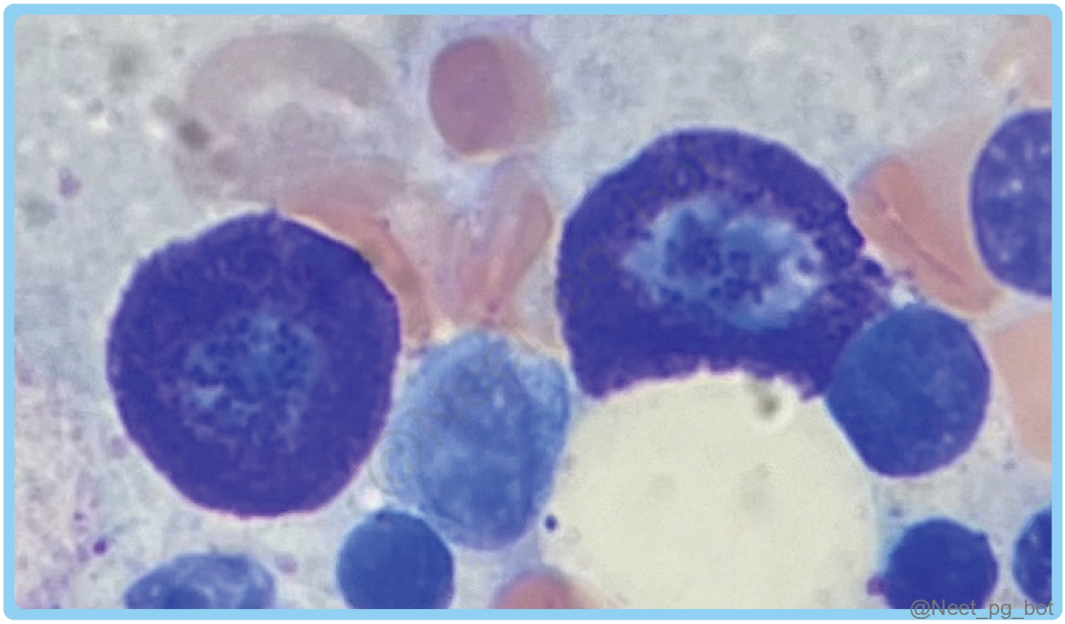
Q44: Identify the cell in the image below: (Q855101)

A. Mast cell

B. Macrophage

C. Plasma cell

D. Fibroblast



See Answer in Part B → Q44

@Neet_pg_bot

Q45: A patient with cervical lymphadenopathy has a positive t(11;14) translocation. Which of the following markers should be used to confirm the diagnosis? A. CD10 B. CD200 C. SOX11 D. Cyclin D1 (Q856913)

A. A, B

B. B, D

C. A, C

D. C, D

See Answer in Part B → Q45

@Neet_pg_bot

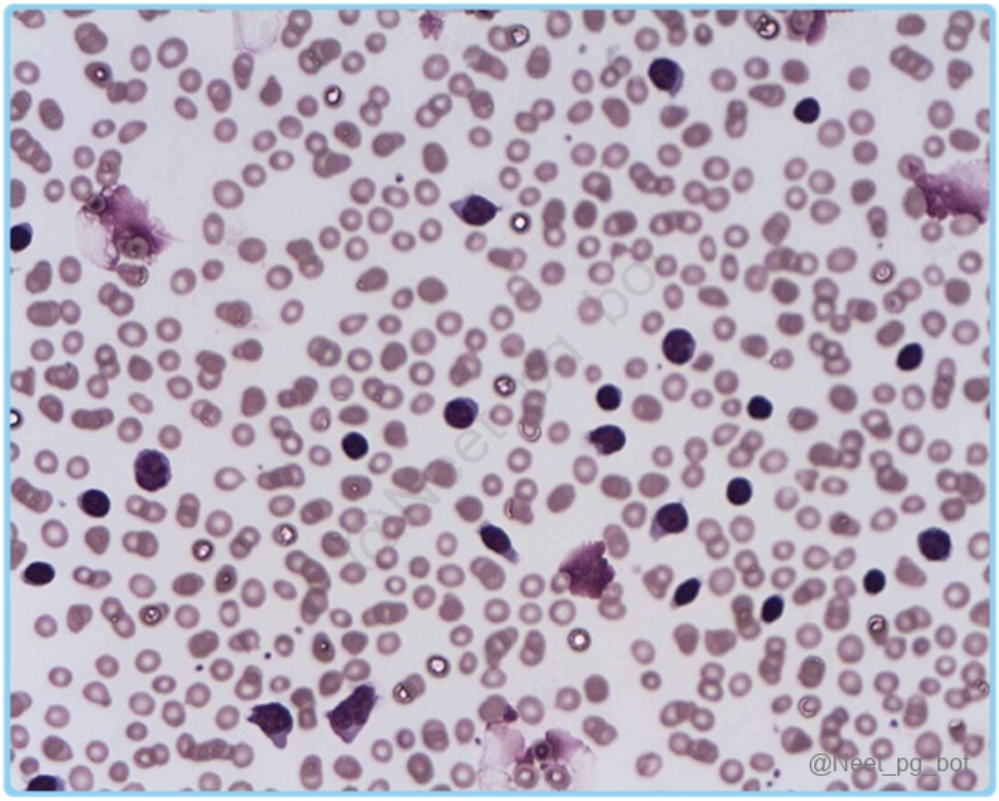
Q46: An elderly male presents for a routine medical examination. Laboratory investigations reveal a very high total leukocyte count (TLC). The peripheral smear shows findings as shown in the image. What is the appropriate next step for this patient? (Q855433)

A. Stem cell transplantation

B. Bone marrow biopsy

C. Flow cytometry

D. Start high-dose chemotherapy



See Answer in Part B → Q46

@Neet_pg_bot

Q47: A 38-year-old man presented with bleeding gums for 20 days. He has gingival hyperplasia and hepatosplenomegaly. On investigation, Hb-11 g/dL, platelet count-95,000 platelets/mm3, and WBC count-45000 cells/mm3. A bone marrow biopsy shows 100% cellularity, with many blast cells that are peroxidase-negative and non-specific esterase-positive . The most likely diagnosis is: (Q793658)

A. Acute myeloid leukemia M2 (AML M2)

B. Acute myeloid leukemia M0 (AML M0)

C. Acute myeloid leukemia M5 (AML M5)

D. Acute myeloid leukemia M7 (AML M7)

See Answer in Part B → Q47

@Neet_pg_bot

Q48: What is the most accurate test for evaluating the effectiveness of treatment in chronic myeloid leukemia (CML)? (Q857166)

A. ■■■

B. RT PCR

C. Cytogenetic test

D. FISH

See Answer in Part B → Q48

@Neet_pg_bot

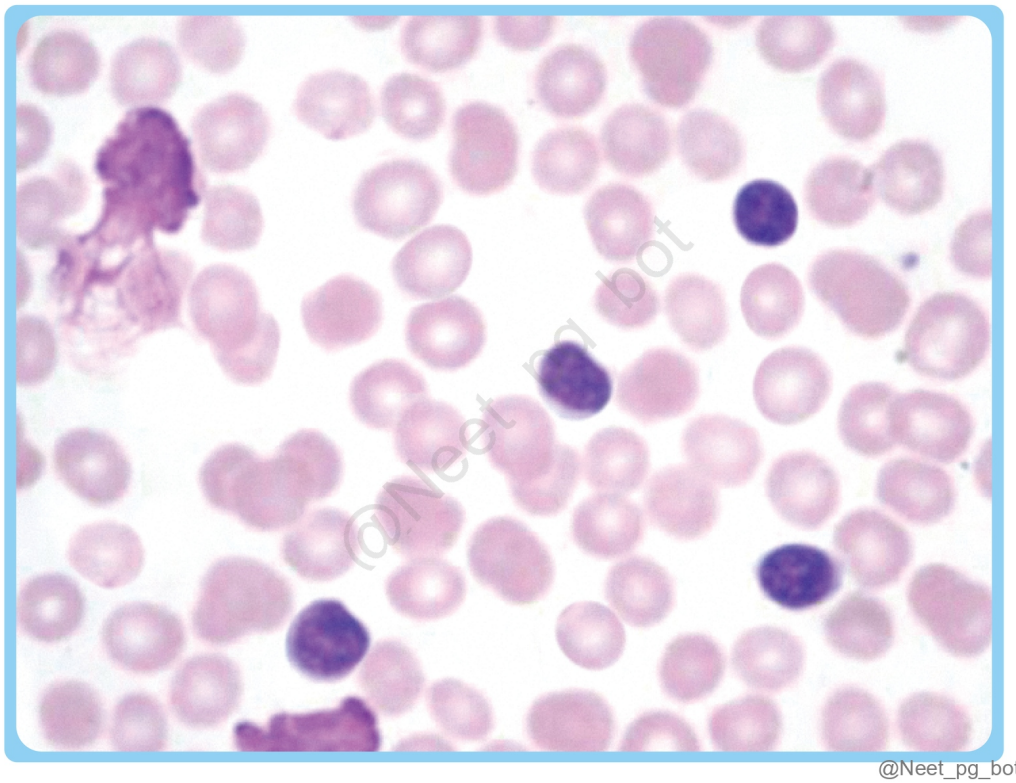
Q49: Which CD markers are typically positive in Chronic Lymphocytic Leukaemia (CLL)? . (Q866672)

A. CD3, CD5, CD8

B. CD10, CD19, CD22

C. CD19, CD20, CD23, CD5

D. CD13, CD33, CD117



See Answer in Part B → Q49

Q1: An 8-year-old girl has been brought to the pediatric clinic by her parents. She has been suffering from tiny cutaneous haemorrhages spread all over her body. She has been recovering for a week from a flu-like condition. Her Physical examination is unremarkable, and she is vitally stable. Her Laboratory investigations revealed a platelet count of 20,000/mL. The number of megakaryocytes in her bone marrow has increased. Which of the following is the most likely diagnosis for this girl? (Q882287)

A. Antiphospholipid antibody syndrome

B. Disseminated intravascular coagulation

C. Hemolytic-uremic syndrome

D. Idiopathic thrombocytopenic purpura

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 62-year-old hospitalized woman is evaluated for worsening skin lesions. She was admitted 6 days ago for total hip replacement surgery. The surgery was uncomplicated. She is receiving low-dose subcutaneous heparin for prophylaxis of DVT. O/E, there are several large purple/ black patches seen in the periumbilical region surrounded by erythema. Which of the following is true regarding heparin-induced thrombocytopenia (HIT)? (Q845960)

A. Type 1 is more common than type 2

B. Type 1 is due to antibodies against PF 4

C. HIT can lead to elevated fibrinogen levels

D. Type 2 occurs immediately after the initiation of heparin.

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old woman presents with easy bruising and recurrent nosebleeds. Laboratory investigations reveal a prolonged aPTT. A mixing study is performed, and the aPTT corrects after mixing with normal plasma. What is the most likely diagnosis? (Q845970)

A. Factor deficiency

B. Platelet dysfunction

C. Presence of lupus anticoagulant

D. Vitamin K deficiency

See Answer in Part B → Q3

@Neet_pg_bot

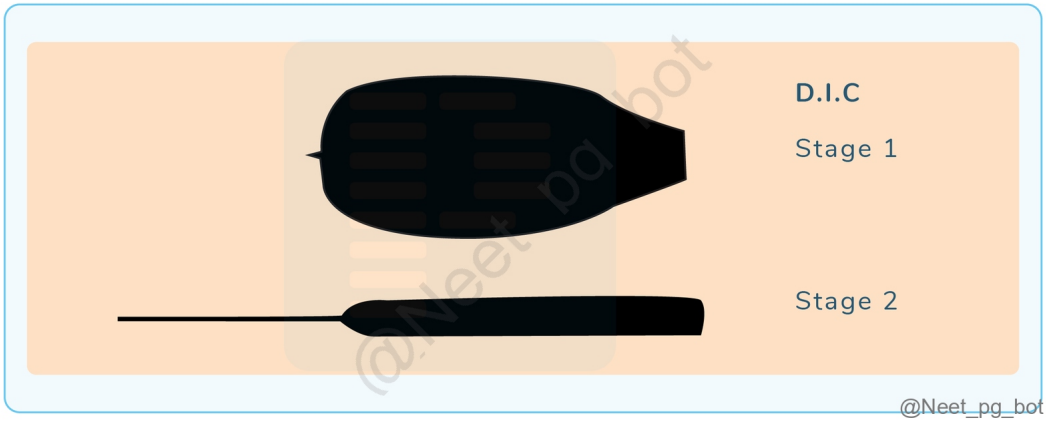
Q4: A 45-year-old male is admitted to the ICU following a road traffic accident. Upon arrival, he is hypotensive and tachycardic. Despite fluid resuscitation and transfusion of packed red blood cells, his condition deteriorates rapidly. Lab investigations show a sudden drop in platelet count and prolonged PT and aPTT. DIC is suspected. The thromboelastogram (TEG) graph is shown below: Which of the following is correct? (Q845969)

A. R time is more in Stage 1

B. K time is more in stage 2

C. Maximum amplitude is more in stage 2

D. Maximum amplitude is less in stage 1



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60 y/o man is brought to the hospital following a high-speed head-on collision. O/E, BP is 80/50mmhg and HR is 130bpm. Laboratory studies indicate a significant drop in platelet count, prolonged PT, and aPTT. DIC is suspected, and a thromboelastogram is performed. What term represents the time from the initiation of the test until the initial formation of the clot? (Q845968)

A. R time

B. K Time

C. Maximum Amplitude (MA)

D. LY30

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 10 y/o boy presents with a history of recurrent nosebleeds and easy bruising since early childhood. O/E, there are multiple petechiae and ecchymoses on his skin. Laboratory investigations reveal normal platelet count but markedly decreased platelet aggregation. Bernard-Soulier Syndrome is suspected. Which of the following features would commonly be observed in platelet aggregometry for this patient? (Q845967)

A. Normal aggregation with ristocetin

B. No aggregation with ristocetin

C. No aggregation with collagen

D. No aggregation with epinephrine

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 6-year-old girl presents with persistent bleeding from minor cuts and bruises since early childhood. On examination, there are multiple bruises and petechiae on her limbs. Lab investigations reveal normal platelet count but markedly decreased platelet aggregation. Glanzmann thrombasthenia is suspected. Which of the following agonists will be able to demonstrate decreased platelet aggregation? (Q845966)

A. Adenosine diphosphate (ADP)

B. Collagen

C. Epinephrine

D. All of the above

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old man presents with a history of easy bruising and recurrent nosebleeds. Laboratory investigations reveal normal platelet count but prolonged bleeding time. A Platelet aggregometry test is performed, showing a decrease in light transmission. What is the most likely interpretation of the platelet aggregometry results in this patient? (Q845965)

A. Platelet aggregation

B. No platelet aggregation

C. Increase in serum sodium

D. Increase in plasma fibrinogen

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 12-year-old male presents with a history of frequent nosebleeds and easy bruising. His parents report that he has had these symptoms for several years, but they seem to be worsening recently. On examination, petechiae are noted on his skin, particularly over his legs, and laboratory investigations reveal prolonged bleeding time, elevated aPTT, and PT within normal range. His platelet count is normal. Which of the following is the most likely diagnosis? (Q845964)

A. Hemolytic Uremic Syndrome (HUS)

B. Hemophilia

C. Bernard Soulier syndrome

D. Von Willebrand Disease (vWD)

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old mother underwent a C-section. On post-op day 1, she complains of shortness of breath and bleeding from catheter sites. Her vitals are unstable. Which of the following statements is false concerning her condition? (Q845963)

A. PT, and APTT are normal.

B. AMLM3 is associated with DIC

C. FDP & D-dimer levels are elevated

D. Meningococcemia is associated with DIC

See Answer in Part B → Q10

@Neet_pg_bot

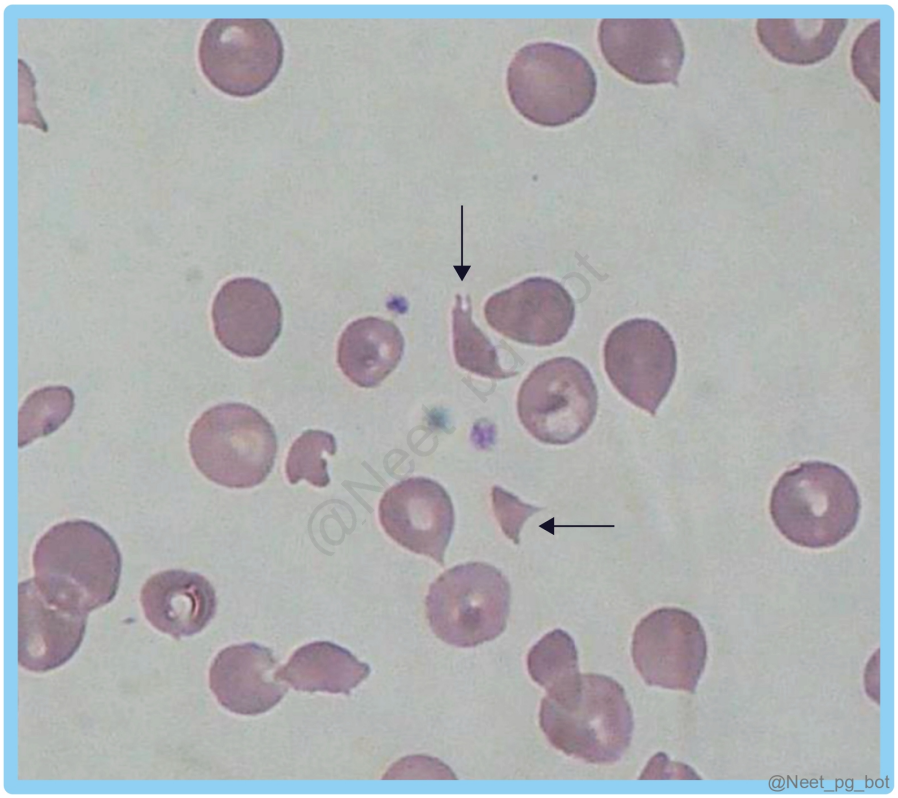
Q11: A 4-year-old child is brought to the emergency department with a history of bloody diarrhea followed by pallor, fatigue, and reduced urine output. Laboratory investigations reveal anemia, thrombocytopenia, and elevated serum creatinine. A peripheral blood smear is done and is given below. What is the most likely cause of this child's diarrhea? (Q845962)

A. O157:H7

B. Defect in ADAM-TS 13

C. Mutation in TGF-beta

D. Prosthetic valves



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 5-year-old boy is brought to the clinic with recurrent episodes of spontaneous bleeding into his joints. Laboratory tests reveal a prolonged activated partial thromboplastin time (aPTT) and reduced factor VIII levels. Based on these findings, what is the most likely diagnosis? (Q845961)

A. Hemophilia A

B. Hemophilia B

C. Hemophilia C

D. Pseudohemophilia

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 58-year-old woman presents with fatigue, early satiety, and left upper quadrant mass. Lab investigation reveals anemia and thrombocytopenia. Blood smear shows teardrop-shaped RBCs and nucleated RBCs. Bone marrow biopsy confirms myelofibrosis. Which megakaryocyte defect is characteristic in this condition? (Q845949)

A. Dwarf Megakaryocyte

B. Staghorn megakaryocyte

C. Pawn ball megakaryocyte

D. Cloud-like megakaryocyte

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Match the defect with the corresponding syndrome: Defect Syndrome 1. Gp1b/9 a. Hermanski pudlak syndrome 2. Alpha granules b. Bernard Soulier syndrome 3. Delta granules c. Glanzmann thrombasthenia 4. Gp2b/3a d. Gray platelet syndrome (Q845959)

A. 1-c, 2-a, 3-b, 4-b

B. 1-d, 2-c, 3-a, 4-b

C. 1-b, 2-a, 3-d, 4-c

D. 1-b, 2-d, 3-a, 4-c

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 34-year-old man comes to the physician complaining of occasional dizziness and palpitations in crowded spaces. He is an executive who travels frequently and reports high-stress levels at work. Labs: Hb= 14.0 Platelets = 80,000 Leukocytes = 7,200 RBCs= 5 million Peripheral smear shows a reduced platelet count without clumping or malignant cells. Which of the following is the most appropriate next test

for this patient? (Q845958)

A. EBV virus titers

B. Rapid plasma reagin test

C. Schilling test

D. HIV antibody test

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 14-year-old adolescent presents with recurrent episodes of unexplained swelling and pain following minor injuries or physical activity. Upon examination, there are signs of localized swelling and tenderness. Lab investigations reveal normal platelet counts and bleeding time, but clotting times are prolonged. Which symptom would strongly suggest a coagulation defect in this patient? (Q845957)

A. Petechiae

B. Purpura

C. Ecchymosis

D. Hemarthrosis

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 22-year-old woman presents to the clinic with a history of frequent nosebleeds and heavy menstrual periods. She reports prolonged bleeding after minor cuts and has noticed easy bruising. On physical examination, multiple small bruises are on her arms and legs. Which of the following tests is most likely to be abnormal? (Q845956)

A. Bleeding Time (BT)

B. Clotting Time (CT)

C. Prothrombin Time (PT)

D. Activated Partial Thromboplastin Time (aPTT)

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 2-week-old male infant is brought to the pediatrician by his parents because of prolonged bleeding from the umbilical stump. The parents report that the bleeding started soon after the umbilical cord fell off and has not stopped despite applying pressure. Laboratory tests show normal Prothrombin Time (PT), Activated Partial Thromboplastin Time (aPTT), and platelet count. Which of the following deficiencies is most likely causing the prolonged bleeding? (Q845955)

A. Factor VIII

B. Factor XIII

C. Factor IV

D. Factor IX

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 30-year-old woman presents with excessive bleeding following a tooth extraction. She reports a history of recurrent nosebleeds and easy bruising since childhood. Lab tests show prolonged activated partial thromboplastin time (aPTT) and normal prothrombin time (PT). Further testing reveals decreased levels of a clotting factor's activity. Which of the following is not an intrinsic factor? (Q845954)

A. Factor XII

B. Factor VII

C. Factor XI

D. Factor IX

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old male patient presents with a history of recurrent episodes of uncontrolled bleeding from minor injuries and easy bruising. Lab investigations reveal prolonged prothrombin time (PT) and activated partial thromboplastin time (aPTT). Considering a potential vitamin K deficiency, which specific clotting factors should be evaluated to confirm the diagnosis in this patient? (Q845953)

A. Tissue thromboplastinLabile factor

B. Labile factor

C. Hageman factor

D. Stable factor

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 32-year-old woman presents with easy bruising, heavy menstrual bleeding, and prolonged bleeding after cuts and dental extraction. Lab tests show normal platelet counts but impaired platelet function. Which of the following substances, primarily released from alpha granules, might be deficient in this patient's platelets? (Q845952)

A. Serotonin

B. Epinephrine

C. ADP

D. P-selectin

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 22 y/o woman arrives at the clinic complaining of heavy menstrual flow and recurrent nosebleeds. Upon physical inspection, her arms and legs have several minor bruises. Coagulation studies show high BT, APTT, and normal PT. She is diagnosed with von Willibrand disease. Which type of vWD shows a decrease in binding between VWF and Gp 1b/9? (Q845951)

A. Type 1

B. Type 2a

C. Type 2b

D. Type 3

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 30-year-old woman is diagnosed with von Willebrand Disease (vWD) after presenting with frequent nosebleeds and prolonged bleeding after minor cuts. Laboratory tests reveal a defect in the von Willebrand factor (vWF). Which of the following is also involved in the pathogenesis of this condition? (Q845950)

A. gp1b-IX

B. gpIIb-IIIa

C. Factor IX

D. Factor XIII

See Answer in Part B → Q23

@Neet_pg_bot

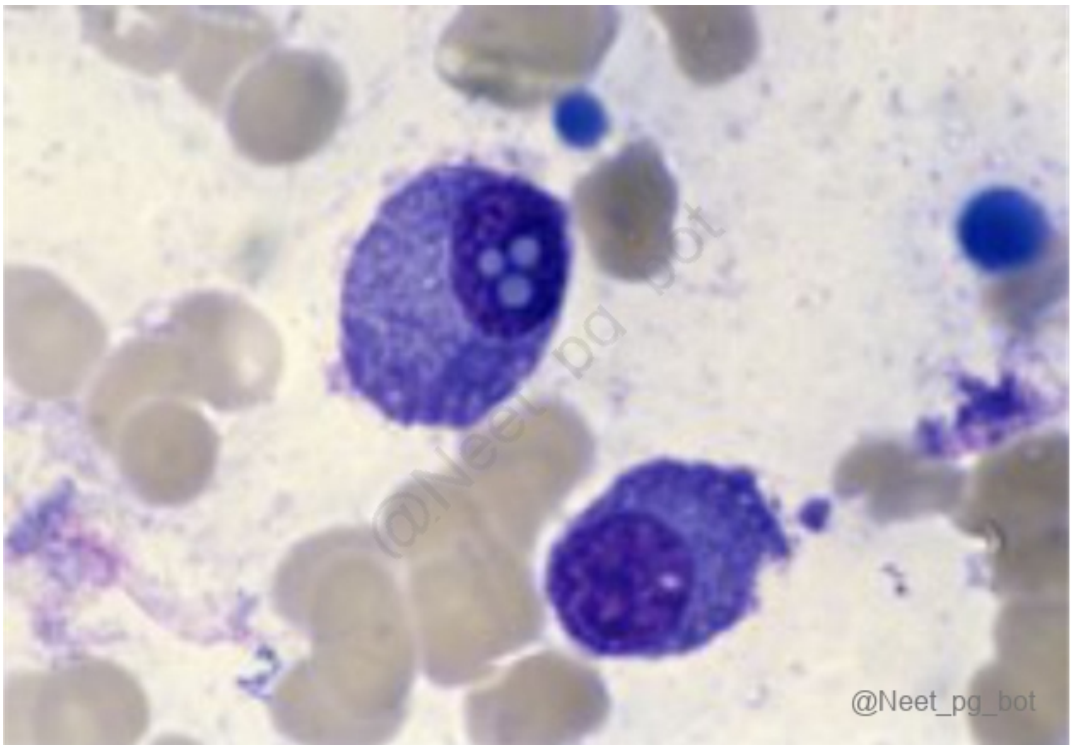
Q1: A patient presents with a tingling sensation in both legs, polyuria, and weight loss. Based on the given bone marrow aspirate findings, what is the most likely diagnosis? (Q844224)

A. Multiple myeloma with renal failure

B. SACD with vitamin B12 deficiency

C. SACD with diabetes

D. Waldenstrom's Macroglobulinemia



See Answer in Part B → Q1

@Neet_pg_bot

Q2: Most common cause of inherited coagulopathy is: (Q853370)

A. Factor V Leiden mutation

B. Antithrombin III deficiency

C. Protein C deficiency

D. Protein S deficiency

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following diseases are correctly associated with their respective inclusion bodies? (Q853377)

A. Rabies - Lewy bodies

B. Parkinson’s disease - Dutcher bodies

C. Multiple myeloma - Negri bodies

D. Malakoplakia - Michaelis Gutmann bodies

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Vacutainer used in serum electrolyte estimation: (Q853367)

A. Green

B. Lavender

C. Yellow

D. Grey

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Anticoagulant used in the test tube for estimating HbA1c? (Q853366)

A. Warfarin

B. Sodium Fluoride

C. EDTA

D. Heparin

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A child is brought to the emergency department with a large lesion on his forearm. As a surgery resident, you decide to excise the lesion in the emergency operation theatre. Which of the following investigations will test the entire coagulation

pathway? (Q856915)

A. Activated partial thromboplastin time

B. Prothrombin time

C. Thromboelastography

D. Bleeding time

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the commonest cause of a hypercoagulable state? (Q857441)

A. Antithrombin III deficiency

B. Protein C deficiency

C. Factor V Leiden mutation

D. G20210A prothrombin gene mutation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: How does Total plasma exchange help in the management of TTP (Q857426)

A. TPE removes the Von Willebrand factor

B. TPE removes the Antiplatelet antibodies

C. TPE removes Anti ADAMTS13 autoantibodies and thereby increases the ADAMTS protease activity

D. TPE replenishes the coagulation factor

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not seen in a delayed hemolytic transfusion reaction? (Q840056)

A. Raised LDH

B. Raised indirect bilirubin

C. No improvement in Hb despite transfusion

D. Cola-colored urine after 2 hrs

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In a trauma patient with an unknown blood group who is unstable and requires urgent blood transfusion, which type of blood should be transfused? (Q840032)

A. A positive

B. AB positive

C. O positive

D. O negative

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is used in the treatment of Hemophilia B? (Q840031)

A. Factor 9

B. Cryoprecipitate

C. Factor 8

D. Tranexamic acid

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Match the following blood products with their shelf lives. a. 1-Granulocytes A- 5 days b. 2- PRBC B- 24 hours c. 3- SDP C- 42 days d. 4- CRYO D- 1 year (Q840026)

A. 1-A, 2-C, 3D, 4-B

B. 1-B, 2-D, 3-A, 4-C

C. 1-C, 2-A, 3-B, 4-D

D. 1-B, 2-C, 3-A, 4-D

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A young boy presents with joint swelling after a fall. Lab investigations show normal PT and raised aPTT. What is the most likely diagnosis? (Q866666)

A. Von Willebrand Disease

B. Hemophilia

C. Iron Deficiency Anaemia (IDA)

D. Platelet function disorder

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is the most common inherited bleeding disorder? (Q865368)

A. Von Willebrand Disease

B. Disseminated Intravascular Coagulation

C. Factor V Deficiency

D. Hemophilia

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following clotting factor deficiencies will not affect clotting in vivo? (Q856490)

A. Factor VII

B. Factor V

C. Factor XII

D. Factor IX

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Leiden mutation is of factor: (Q856167)

A. V

B. VIII

C. I

D. X

See Answer in Part B → Q16

@Neet_pg_bot

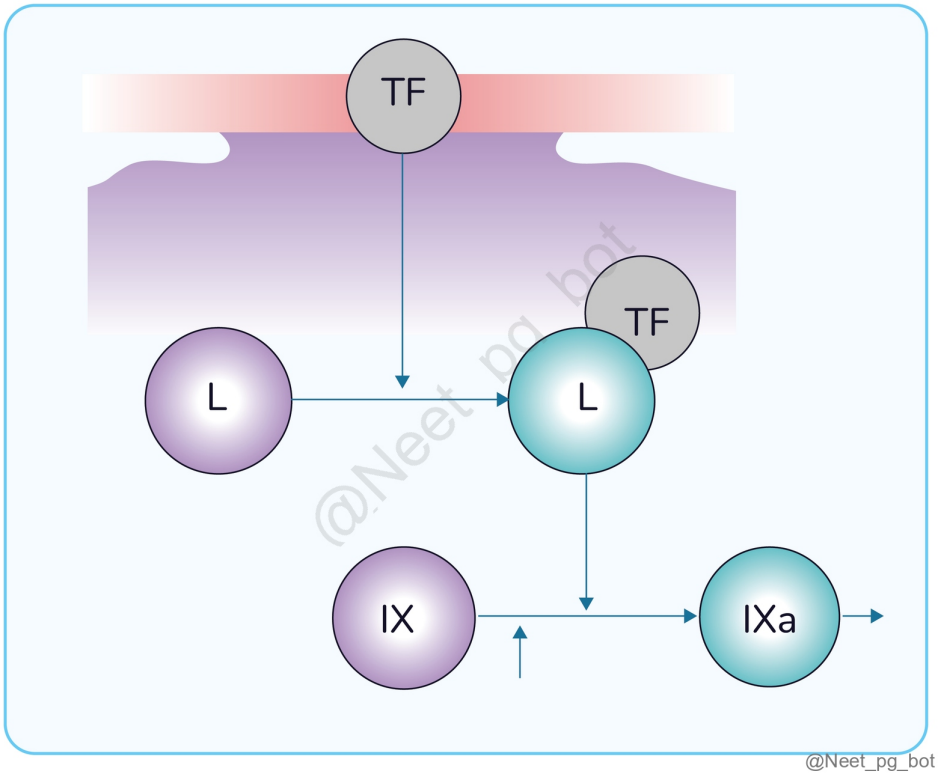
Q17: Below is an image of the coagulation cascade activation following closed endothelial injury. Identify the factor ‘L’, which combines with tissue factor to activate factor IX. (Q856684)

A. Factor XII

B. Factor VII

C. Factor VIII

D. vWF



See Answer in Part B → Q17

@Neet_pg_bot

Q18: Stellate granuloma is found in: (Q857169)

A. Cat scratch disease

B. Leprosy

C. Coccidomycosis

D. Histoplasmosis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following shows maximum amplitude on thromboelastography? (Q856011)

A. Platelets

B. Intrinsic

C. Extrinsic

D. von Willebrand Disease (vWD)

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A young patient presents with a large retroperitoneal hemorrhage and a history of intermittent knee swelling during strenuous exercise. There is no history of mucosal bleeding. Which of the following deficiencies is responsible for this condition ? (Q855429)

A. Factors VIII and IX

B. GP1b/IX

C. Von Willebrand factor

D. Lupus anticoagulant

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 26-year-old female with a bleeding disorder following autosomal dominant inheritance. She gave the history of her father and sister having the same bleeding disorders. What is the most likely disorder? (Q854692)

A. Von Willebrand disease

B. Hemophilia A

C. Christmas disease

D. Factor X deficiency

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following statements about Von Willebrand's disease is incorrect? (Q843976)

A. Type 2 von Willebrand disease is associated with a moderate bleeding tendency.

B. Type 3 von Willebrand disease is associated with a complete absence of von Willebrand factor.

C. Type 1 von Willebrand disease presents with severe bleeding since childhood.

D. Type 2 von Willebrand disease includes subtypes with varying defects in the von Willebrand factor.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A patient underwent ileal resection and subsequently developed anemia along with peripheral neuropathy and features of SACD. Laboratory findings show hemoglobin (Hb) of 9 g/dL and mean corpuscular volume (MCV) of 110 fL. What is the most likely cause of his anemia? (Q866386)

A. Iron deficiency anemia

B. Vitamin B12 deficiency

C. Folic acid deficiency

D. Sideroblastic anemia

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Bernard-Soulier syndrome is caused by a defect in which of the following platelet glycoproteins? (Q866676)

A. GpIIb/IIIa

B. GpIb/IX complex

C. GpIa/IIa

D. GpIV

@Neet_pg_bot

Q2: A 32-year-old male requires a blood transfusion after a severe bike accident. He is known to have the Bombay phenotype. Before the transfusion, his blood sample is sent to the laboratory for compatibility testing. Based on his blood group, which of the following statements is incorrect? (Q845926)

A. Lack of H, A and B antigens on RBCs

B. Lack of H, A and B substances in saliva

C. Lack of antigens of several blood group systems

D. H, A and B antibodies will always be present in the serum

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 23-year-old individual is scheduled to donate blood for a local blood drive. To ensure the safety of the blood supply, the donor's blood will be screened for various infectious diseases. Among the following options, which one is typically not included in the routine screening for donated blood? (Q845928)

A. Malaria

B. Hepatitis B

C. HIV

D. Dengue fever

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following can be used to store blood for up to 42 days? (Q845929)

A. ACD

B. CPD

C. CPDA

D. SAGM

See Answer in Part B → Q4

@Neet_pg_bot

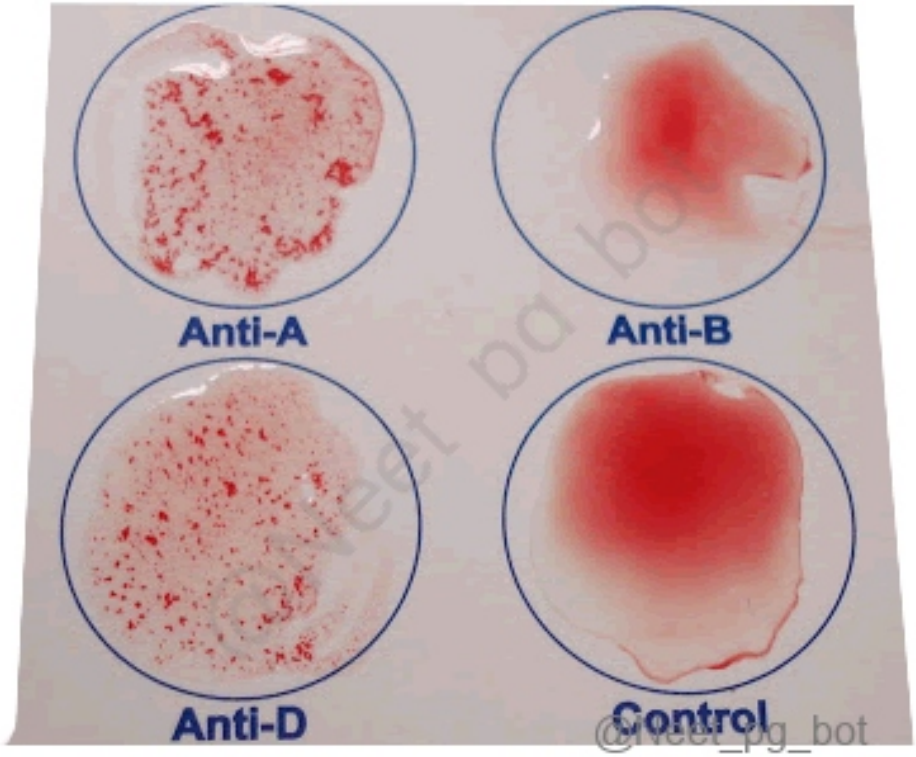
Q5: Based on the agglutination test shown below, what is the blood group? (Q845931)

A. B Positive

B. B negative

C. A positive

D. AB positive



See Answer in Part B → Q5

@Neet_pg_bot

Q6: Match the following: Blood Products Shelf Life A Packed Red Blood Cells (PRBCs) in CPD-A i 1 year B Fresh Frozen Plasma (FFP) ii 35 days C Platelets iii 42 days D PRBC in SAGM iv 5 days (Q845935)

A. A-iii, B-i, C-iv, D-ii

B. A-i, B-iii, C-iv, D-ii

C. A-ii, B-i, C-iv, D-iii

D. A-ii, B-iii, C-i, D-iv

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A unit of packed red blood cells is issued from the blood bank for transfusion to a patient in the emergency department. Due to delays in setting up the IV line, the staff asks how long the unit can safely remain out of refrigeration before the transfusion must be completed.What is the maximum allowable time for transfusing this RBC unit after removal from cold storage? (Q845936)

A. 1 hour

B. 4 hour

C. 8 hour

D. 24 hour

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the most common complication of blood transfusion? (Q845938)

A. TRALI

B. TACO

C. Delayed Hemolytic Reaction

D. Febrile Non-hemolytic reaction

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is defined as a massive blood transfusion? (Q845939)

A. Replacement of whole blood volume within 12 hours

B. Replacement of whole blood volume within 48 hours

C. Replacement of whole blood volume within 24 hours

D. Replacement of whole blood volume within 4 hours

See Answer in Part B → Q9

@Neet_pg_bot

Q10: All of the following are complications of massive blood transfusion except? (Q845941)

A. Metabolic Alkalosis

B. Metabolic Acidosis

C. Hyperkalemia

D. Hypocalcemia

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is a characteristic feature of Transfusion-Related Acute Lung Injury (TRALI)? (Q845942)

A. Non-cardiogenic pulmonary edema within 6 hours of transfusion

B. Cardiogenic pulmonary edema within 24 hours of transfusion

C. Acute onset of fever and chills without respiratory symptoms

D. Gradual onset of jaundice and anemia several days after transfusion

See Answer in Part B → Q11

Q1: A 28-year-old woman with a known history of beta-thalassemia undergoes a blood transfusion. During the transfusion, she develops symptoms of anxiety, hypotension, and fever. What is the next appropriate step in the management of this patient? (Q860282)

A. Stop the blood transfusion and restart after stabilization

B. Continue the blood transfusion and perform an ECG

C. Investigate for clerical errors in the blood transfusion process

D. Administer corticosteroids and monitor vital signs

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Blood transfusion requires screening of donor blood for all of the following infections except: (Q855917)

A. Hepatitis C virus

B. Dengue virus

C. HIV virus

D. Hepatitis B virus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient has been brought with severe bleeding to your ER. His blood group is unknown. Fresh frozen plasma from which of the following blood groups can be given? (Q855120)

A. O

B. AB

C. B

D. A

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following can be prevented by transfusing irradiated RBCs? (Q856715)

A. Graft versus host disease

B. HLA alloimmunization

C. Immunomodulation

D. Nonhemolytic Febrile Transfusion Reactions

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 24-year-old man, after being involved in a road traffic accident (RTA), was brought to the casualty 6 hours later. His B.P. was 90/60 mm Hg, heart rate was 110/min, and SpO2 was 92%. A blood transfusion was administered. A few hours later, the patient becomes febrile and tachypneic and starts bleeding from the IV and NG tube sites. His SpO2 levels begin to drop. What is the likely cause? (Q856483)

A. Transfusion reaction

B. Acute adrenal crisis

C. Fat embolism

D. Hemorrhagic shock

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following statement regarding blood donation is incorrect? (Q858506)

A. Voluntary blood donation day - 1st october

B. People aged 18-65yrs with comorbidities can not donate blood

C. For people with body weight >55 kg, 49 ml of anticoagulant is required

D. All are correct

Q1: A patient who presents with a painful, progressively enlarging growth from her left upper tibia is suspected to have chondrosarcoma and subjected to a biopsy and examination. The report states, “presence of osteoclast-type giant cells with intralesional bone formation”. Which of the following types of chondrosarcoma does this patient have? (Q845700)

A. Conventional

B. Mesenchymal

C. Clear cell

D. Dedifferentiated

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Match the tumours in column A to their genetic alterations in Column B Tumor Translocation A) Ewing's Sarcoma 1) t(x;18) B) Rhabdomyosarcoma 2) t(12;16) C) Liposarcoma 3) t(1;13) D) Synovial Sarcoma 4) t(11;22) (Q845734)

A. A-4, B-2, C-3, D-1

B. A-4, B-3,C-1, D-2

C. A-4, B-3, C-2, D-1

D. A-3, B-4, C-1, D-2

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old male, presents with a sudden onset of severe pain, redness, and swelling in his right big toe. The right big toe is red, swollen, and extremely tender to touch. There is no fever or other systemic symptoms. He enjoys red meat and seafood, and he drinks alcholol regularly. All of the following are true about his diagnosis except? (Q845728)

A. Deposition of monosodium urate crystals in joints.

B. Thiazide diuretics can precipitate attacks.

C. Rhomboid-shaped, weakly positively birefringent under polarised light confirms the diagnosis.

D. Elevated uric acid levels.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: All of the following are true about rhabdomyosarcoma except? (Q845726)

A. It is the most common soft tissue sarcoma in children.

B. Positive IHC staining for desmin and myogenin.

C. It commonly presents in the extremities of children and adolescents.

D. It has a benign clinical course and rarely metastasizes.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 38-year-old female presents with a 6-month history of heavy menstrual bleeding and a sensation of pelvic pressure. She reports that her periods have become increasingly heavy. There is no significant past medical history, and she is not

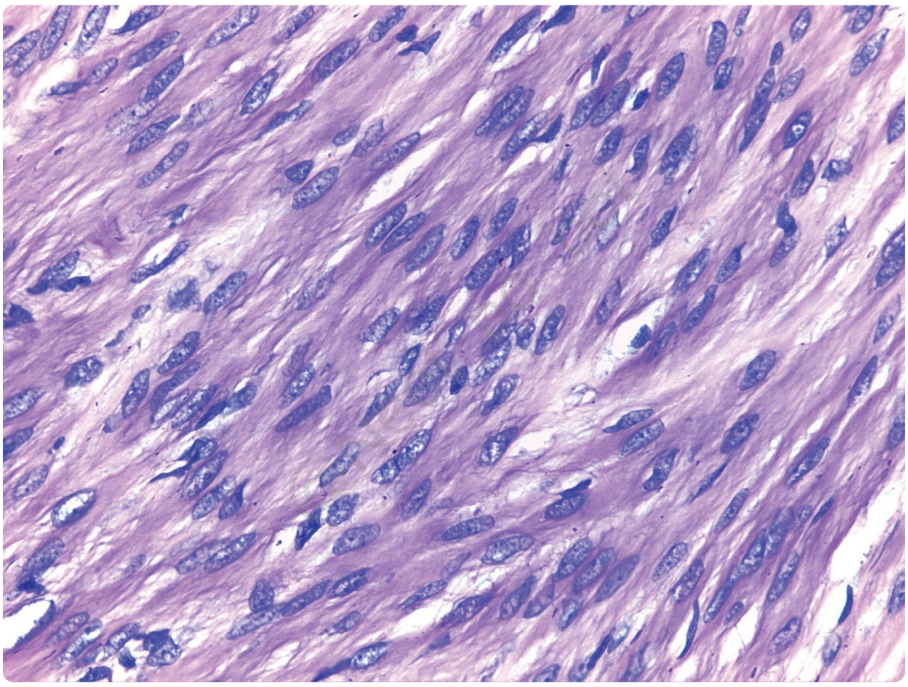
currently on any medication.Ultrasound reveals a heterogeneous, hypoechoic mass within the uterus. A histology image is given below. What is the most likely diagnosis? (Q845719)

A. Adenomyosis

B. Leiomyosarcoma

C. Endometrial carcinoma

D. Leiomyoma



@Neet_pg_bot

See Answer in Part B → Q5

@Neet_pg_bot

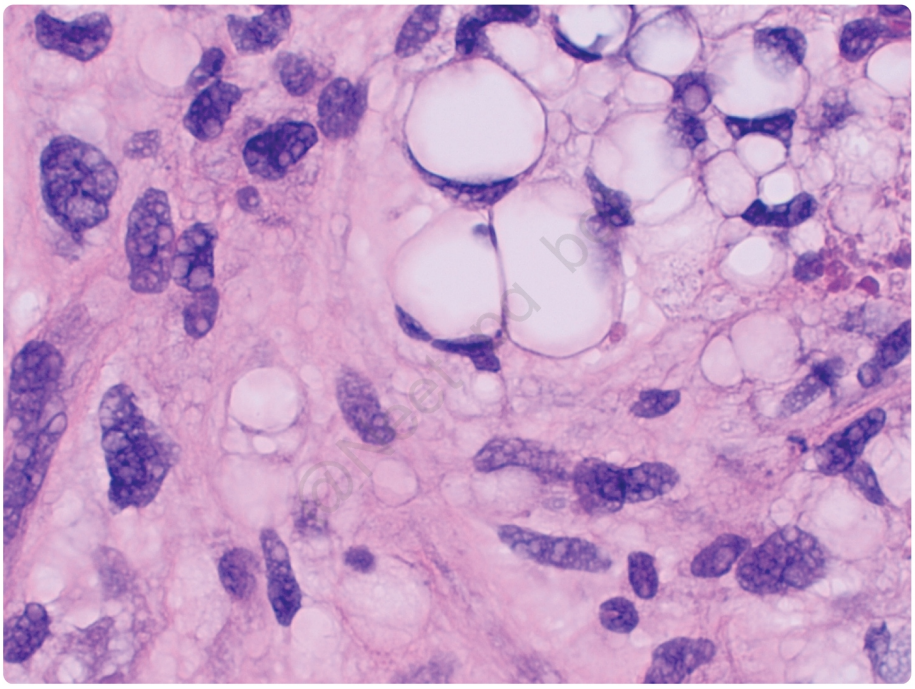
Q6: A 65-year-old male presented with an enlarging mass in his left thigh for the last three months. Physical examination revealed a non-tender, palpable mass with indistinct borders. He has a prior history of mass excision in the same location. A biopsy of the lesion is obtained. Based on the presentation, which of the following is the most likely diagnosis? (Q845711)

A. Lipoma

B. Liposarcoma

C. Leiomyosarcoma

D. Rhabdomyosarcoma



@Neet_pg_bot

See Answer in Part B → Q6

@Neet_pg_bot

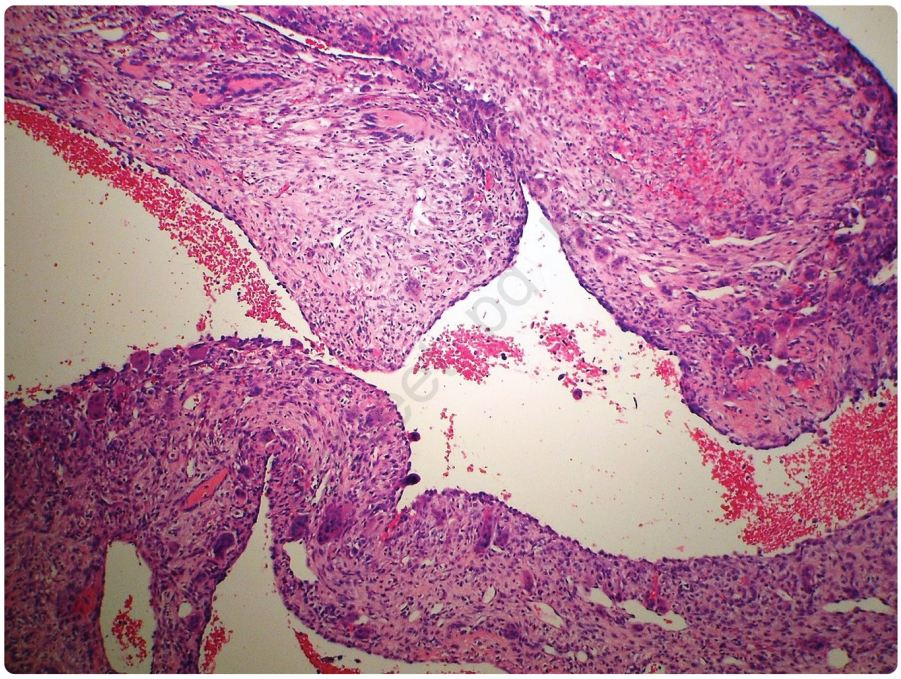
Q7: A 17-year-old female presents with worsening pain in her right tibia over the past few months. On examination, there is tenderness and swelling over the proximal right tibia. Biopsy results show blood-filled cystic spaces lined by fibrous septa containing giant cells. All the following statements are true regarding this condition except? (Q845708)

A. Characterised by uniloculated blood-filled spaces with eggshell appearance on x-ray.

B. Often aggressively growing and are frequently discovered in vertebral bodies.

C. Majority cases are found associated with USP6 gene involvement in chromosome 17

D. Nearly one third patients have a distinctive basophilic metaplastic matrix known as blue bone



@Neet_pg_bot

See Answer in Part B → Q7

@Neet_pg_bot

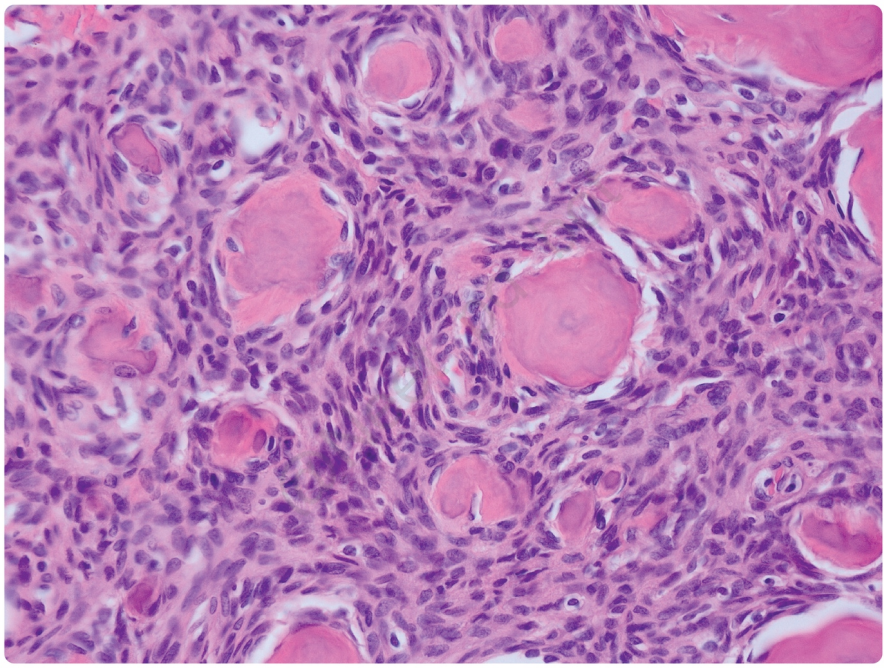
Q8: A 14-year-old male presents with left knee pain for several months. Physical examination reveals tenderness and X-ray demonstrates metaphyseal lesion of the distal femur. A biopsy image of the lesion is shown. What is the most likely diagnosis? (Q845706)

A. Chondrosarcoma

B. Ewing sarcoma

C. Non-ossifying fibroma

D. Giant cell tumor of bone



@Neet_pg_bot

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following statements are true regarding fibrous dysplasia? It is a malignant tumour with components of normal bone unable to differentiate into mature structures Associated with CSF 1 R gene mutation and soft tissue myxoma. Typically occurs in older individuals causing bones to become weak and easily fractured. Histopathological examination shows woven bone trabeculae with disorganised growth plates. Females commonly presents with precocious puberty and irregular dark skin lesions. (Q845705)

A. 1, 3 and 4

B. 2, 3 and 5

C. 3, 4 and 5

D. 4 and 5

See Answer in Part B → Q9

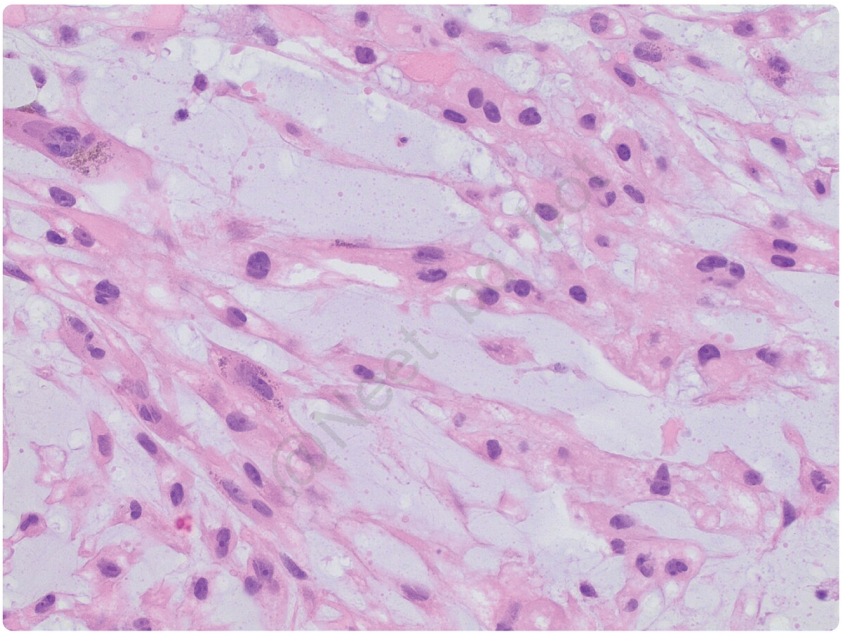
Q10: A 58-year-old male presents with worsening lower back pain and difficulty walking for the last few months. Molecular analysis revealed brachyury gene expression. A biopsy image of the lesion is shown. What is the most likely diagnosis? (Q845702)

A. Chordoma

B. Enchondroma

C. Ewing sarcoma

D. Chondrosarcoma



@Neet_pg_bot

See Answer in Part B → Q10

Q11: Which of the following statements regarding normal bone and bone marrow are true? 1. Bone marrow contains a rich network of blood vessels, nerves, and lymphatics, supporting its role as a hematopoietic organ. 2. Osteoblasts are responsible for bone formation, while osteoclasts are involved in bone resorption. 3. Hematopoietic stem cells in the bone marrow give rise to some blood cell lineages. 4. Bone marrow lacks hematopoietic elements and serves primarily as a site for fat storage. 5. Bone remodelling is solely regulated by hormonal factors. (Q845574)

A. Statements 1 and 2 are correct

B. Statements 3 and 4 are correct

C. Statements 4 and 5 are correct

D. Statements 1 and 5 are correct

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is incorrect about enchondromas? (Q845647)

A. Maffucci syndrome can also co-exist with brain glioma.

B. Mutations in isocitrate dehydrogenase enzyme genes are common.

C. Histology shows hyaline cartilage encased by reactive bone.

D. Ollier's disease presents as solitary juxta-cortical enchondromas.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 14-year-old boy presents with a swelling on his left tibia. An X-ray of the leg shows a destructive process with indistinct borders and an onion-skin pattern of the periosteal bone. A biopsy was performed, as shown in the image below. Identify the true statements regarding this condition. It is a malignant tumour characterised by primitive round cells with obvious differentiation. It affects boys more than girls. More than 90% of the cases are caused due to t(11;22)(q24;q12) mutation. The

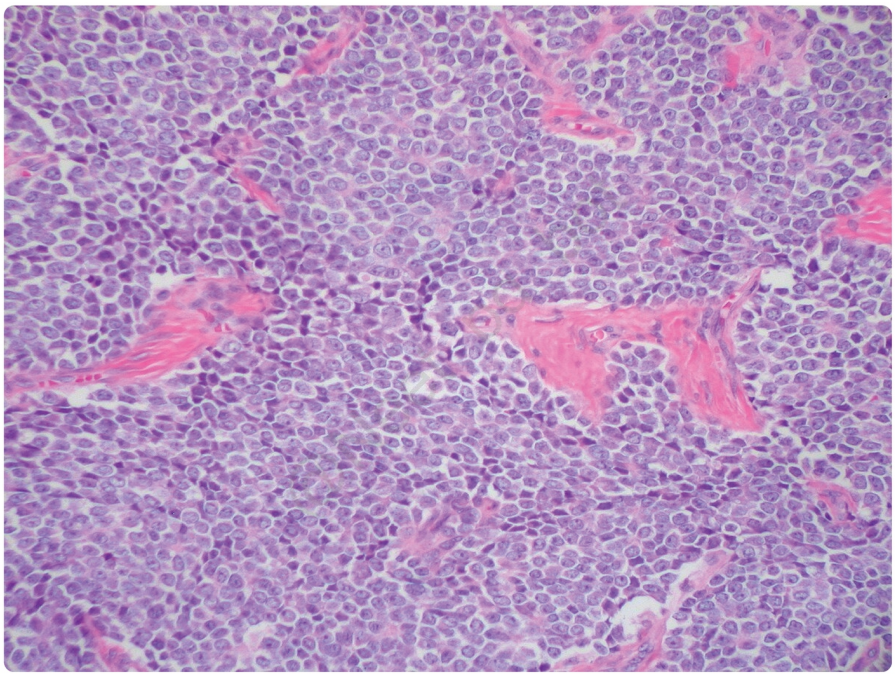
presence of rounded cell clusters with a central fibrillary core indicates neuroectodermal differentiation. Chemotherapy-induced necrosis is a negative prognostic indicator. (Q845646)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 3

D. 3, 4, 5



@Neet_pg_bot

See Answer in Part B → Q13

@Neet_pg_bot

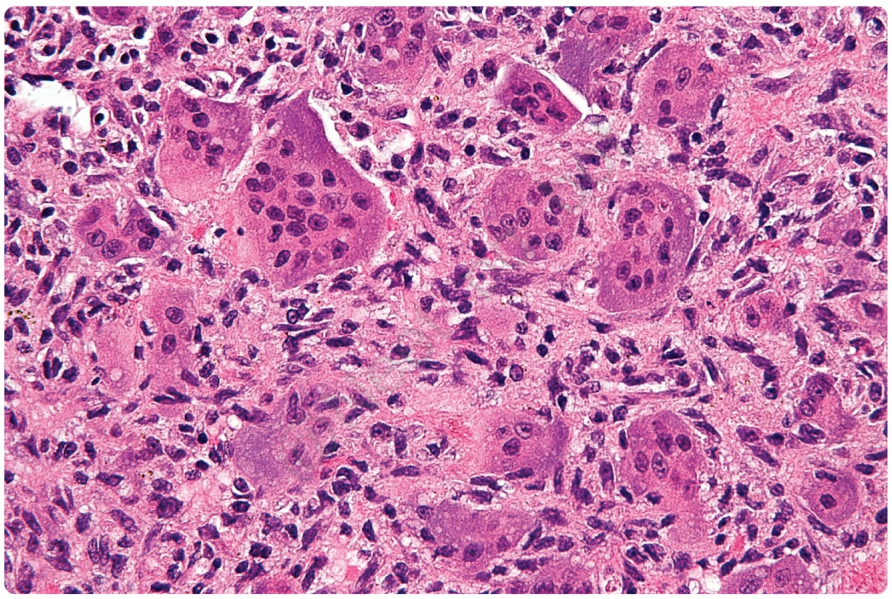
Q14: Histopathological examination of a lesion arising from the right distal femur is given as the image below with such characteristic cells. Which of the following is the most probable diagnosis? (Q845645)

A. Osteoclastoma

B. Chondrosarcoma

C. Osteochondroma

D. Ewing’s sarcoma



@Neet_pg_bot

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A patient presented with a hard mass over the right tibia, and subsequent imaging revealed the presence of sessile growth in the bone. Biopsy is done later, which shows the presence of “cartilage cap” over the lesion. What is the most likely diagnosis? (Q845604)

A. Osteochondroma

B. Chondroblastoma

C. Enchondroma

D. Chondrosarcoma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 15-year-old male presents with persistent knee pain and swelling of two months duration. The pain is persistent, severe at night and not relieved by NSAIDs. On examination there is a firm, tender mass around distal femur. X-ray shows destructive lesion with sunburst pattern and lifting of the perisoteum. A biopsy was performed, and it showed pleomorphism, large hyperchromatic nuclei, and bizarre giant cells producing unmineralised osteoid. What is the most likely diagnosis? (Q845601)

A. Osteoid osteoma

B. Osteoblastoma

C. Osteosarcoma

D. Osteoclastoma

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 25-year-old male presents with persistent pain in his right leg that worsens at night and is partially relieved by nonsteroidal anti-inflammatory drugs (NSAIDs). Imaging is given below. Based on the clinical presentation and imaging findings, which of the following is incorrect regarding this condition? (Q845596)

A. It has a predilection for the appendicular skeleton.

B. It is less than 2 cm in diameter.

C. It commonly affects the axial skeleton

D. Pain is relieved on taking aspirin

See Answer in Part B → Q17

@Neet_pg_bot

Q18: All of the following are associated with Gardner’s syndrome except? (Q845577)

A. Multiple osteoma

B. Colon polyps with risk of malignancy

C. Enchondroma

D. Supernumerary teeth

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following is not a metaphyseal tumour? (Q845576)

A. Osteosarcoma

B. Fibrous dysplasia

C. Giant cell tumour of the bone

D. Aneurysmal bone cyst

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 6-year-old boy presents with a history of frequent fractures, bone pain, and difficulty walking. On examination, he has short stature and cranial nerve palsies. The radiograph is revealed below. Which of the following is the most likely diagnosis? (Q845575)

A. Osteogenesis imperfecta

B. Osteopetrosis

C. Rickets

D. Paget disease of the bone

See Answer in Part B → Q20

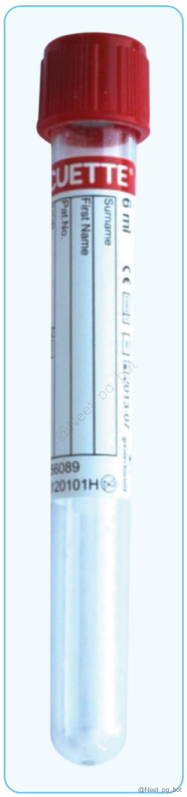
A. EDTA

B. Trisodium citrate

C. NAF - heparin

D. Clot activator



See Answer in Part B → Q7

@Neet_pg_bot

Q8: The following image shows an instrument used to estimate haemoglobin levels. What does it measure? (Q855893)

A. Alkaline hematin

B. Acid hematin

C. Oxyhemoglobin

D. Deoxyhemoglobin

@Neet_pg_bot

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following methods is iron in tissues stained? (Q855899)

A. Masson’s trichrome

B. Prussian blue

C. PAS

D. Fite-Faraco

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A woman presents with nodular lesions, 4-6 mm in size, on the inner thighs and peri-anal region. The lesions appear pale, and histopathological examination reveals

multiple intracytoplasmic inclusion bodies consistent with Henderson-Patterson bodies. What is the most likely diagnosis? (Q855907)

A. Trichodysplasia spinulosa

B. Condyloma acuminata

C. Molluscum contagiosum

D. Donovanosis

See Answer in Part B → Q10

@Neet_pg_bot

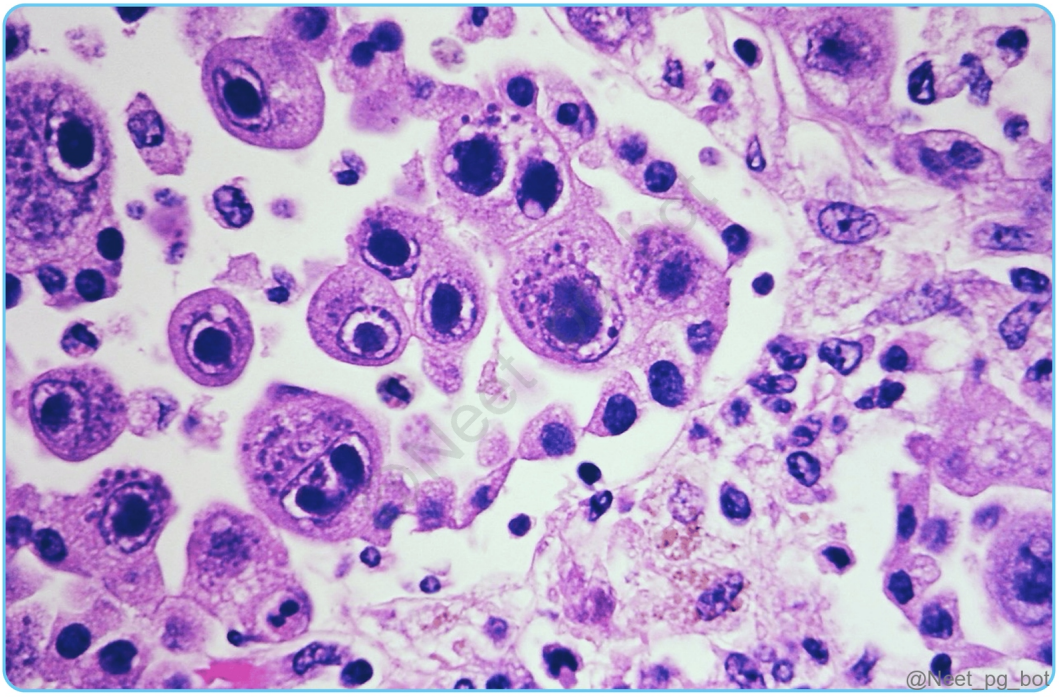
Q11: The given inclusion bodies are characteristic of which of the following organisms? (Q858119)

A. Human papillomavirus

B. Cytomegalovirus

C. Epstein-Barr virus

D. Herpes simplex virus



See Answer in Part B → Q11

@Neet_pg_bot

Q12: CD markers can be detected by which of the following tests? (Q866390)

A. Cytogenetics

B. Next-generation sequencing

C. Flow cytometry

D. Karyotype

See Answer in Part B → Q12

@Neet_pg_bot

Q13: In Pap smear cytology, which of the following is the most appropriate fixative used to preserve cellular details immediately after smearing? (Q866744)

A. 50% formaldehyde

B. 95% ethanol

C. 70% ethanol

D. 10% buffered formalin

See Answer in Part B → Q13

Q1: In which following layer of the epidermis would you most likely find the melanin-producing cells of the skin? (Q845865)

A. Stratum corneum

B. Stratum spinosum

C. Stratum granulosum

D. Stratum basale

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old male presents with a rash on his hands and feet characterised by clusters of small, fluid-filled blisters. Histopathological examination of a skin biopsy reveals intracellular oedema of keratinocytes. Which term best describes this histological finding? (Q845866)

A. Acanthosis

B. Ballooning

C. Spongiosis

D. Parakeratosis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 10-year-old child exhibits rough, scaly skin on the elbows, knees, and trunk, accompanied by hyperkeratotic plaques. Which skin condition is typically associated with this manifestation of excessive keratin buildup? (Q845867)

A. Freckles

B. Lentigo

C. Nevus

D. Ichthyosis

See Answer in Part B → Q3

@Neet_pg_bot

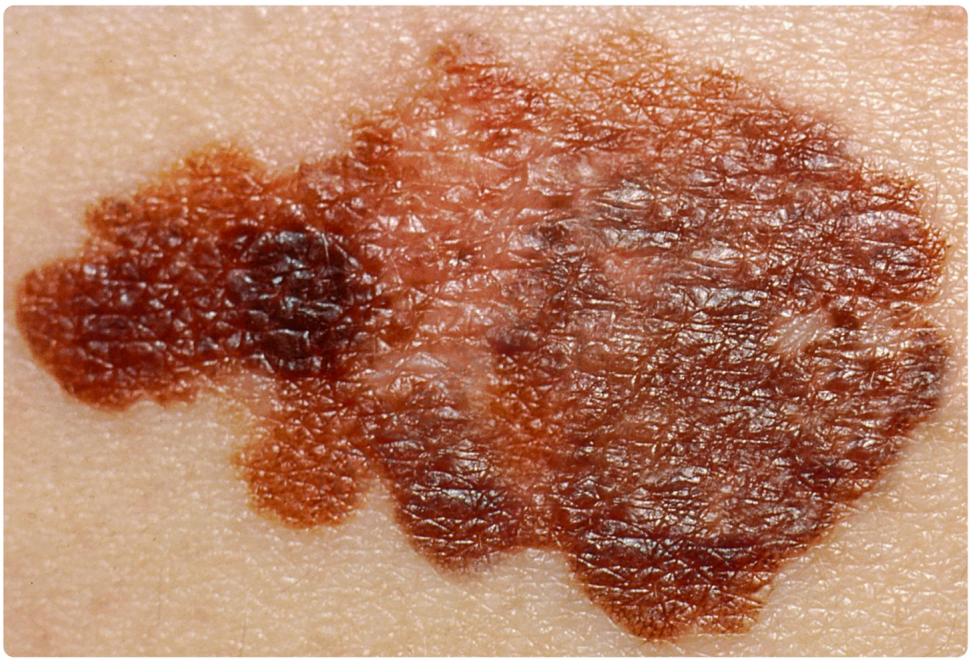
Q4: A 45-year-old woman presents with a dark, irregularly shaped mole on her back that has rapidly increased in size over the past few months. On examination, the lesion has uneven borders and varying shades of colour. Which of the following is true regarding its pathogenesis? (Q845868)

A. Associated with TERT mutations

B. Spreads radially with metastatic potential

C. Spreads vertically with no metastatic potential

D. Associated with mutations that decrease telomerase activity



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 70-year-old woman presents with a finding as shown in the image. A biopsy confirms basal cell carcinoma. Which molecular pathway is primarily involved? (Q845904)

A. Hippo pathway signaling

B. Hedgehog signaling pathway

C. WNT signaling

D. RAS/MAPK signaling

@Neet_pg_bot

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 25-year-old woman presents with multiple basal cell carcinomas (BCCs) on her face, neck, and back. She also has a history of medulloblastoma, diagnosed during childhood. On examination, she has palmar pits and macrocephaly. Which of the following is not true regarding this syndrome? (Q845906)

A. Associated with odontogenic keratocysts.

B. Associated with mutations in the PTCH gene

C. An Autosomal dominant disorder

D. Associated with loss of nucleotide excision repair mechanism

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 72-year-old man with a history of extensive sun exposure and recent organ transplant presents with a rapidly growing, painless, reddish nodule on his left cheek over two months. Biopsy shows small, round blue cells with salt and pepper chromatin and positivity for neuroendocrine markers. What marker is typically associated with this condition? (Q845908)

A. S-100

B. CK20

C. Melan-A

D. p40

See Answer in Part B → Q7

@Neet_pg_bot

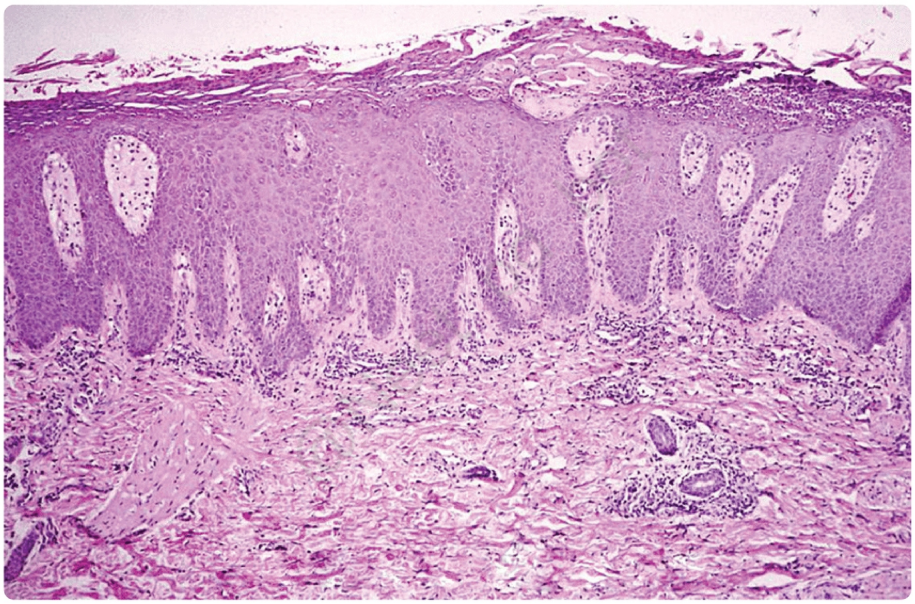
Q8: An 18-year-old female has multiple itchy silvery scales on her knees and elbows. A biopsy of the lesion revealed the presence of nuclei and neutrophilic infiltration in the stratum corneum. Match the following with their appropriate answers. a. Auspitz sign 1. Nucelated stratum corneum b. Munro's microabscess 2. Pinpoint bleed after scraping off old lesion c. Spongiform pustules of kogoj 3. Neutrophilic infiltrate in stratum corneum d. Parakeratosis 4. Neutrophilic infiltrate in stratum spinosum (Q845909)

A. a-2, b-4, c-3, d-1

B. a-2, b-3, c-4, d-1

C. a-1, b-3, c-4, d-2

D. a-2, b-4, c-3, d-1



@Neet_pg_bot

Q9: A 45-year-old female presents to the dermatology clinic with an itchy rash on her wrists and ankles. On examination, small, flat-topped, polygonal, purple papules with fine white lines on their surface are noted. Which of the following is a characteristic histological finding in this condition? (Q845911)

A. Munro microabscesses

B. Spongiform pustules

C. Sawtoothing of the dermo-epidermal junction

D. Follicular lipping

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old man presents with widespread blistering of the skin and oral mucosa. Skin biopsy reveals acantholysis and intraepidermal blister formation above the basal layer. Which of the following describes the location of the split in this bullous disorder? (Q845912)

A. Subcorneal split

B. Suprabasal split

C. Subepidermal split

D. Intraepidermal split

See Answer in Part B → Q10

@Neet_pg_bot

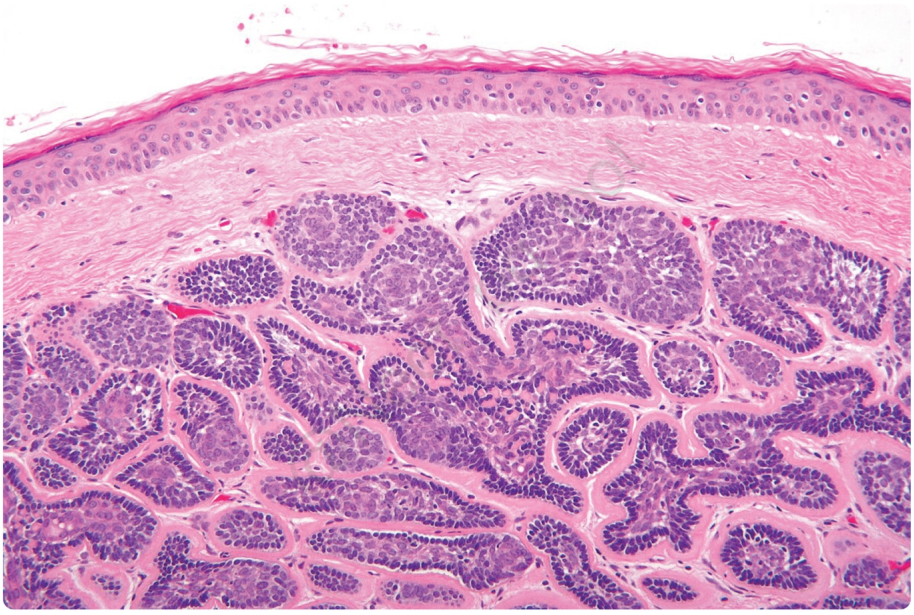
Q11: A 45-year-old woman presents with a slow-growing, painless nodule on her scalp that has recently enlarged. Examination reveals a firm, well-circumscribed nodule. Histopathology shows ductal differentiation with multiple cysts and papillary projections. Which of the following is the most likely diagnosis? (Q845913)

A. Cylindroma

B. Pilomatrixoma

C. Syringoma

D. Trichilemmoma



@Neet_pg_bot

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 38-year-old man complains of severe itching and recurrent skin lesions on his elbows, knees, and upper back. His medical history includes occasional gastrointestinal discomfort. Examination reveals bilateral, symmetric lesions with grouped vesicles. Skin biopsy reveals small microabscesses at the tips of dermal papillae. Which of the following is associated with a disease condition? (Q845916)

A. Associated with Crohn's disease

B. IgA deposits at dermal papilla tips

C. Subendothelial blisters

D. Linear deposits in immunofluorescence

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 3-year-old child has a chronic, non-healing scalp rash, showing red-brown papules and plaques with crusting on examination. Electron microscopy reveals tennis racket-like structures in histiocytes cytoplasm, and immunohistochemical staining confirms CD1a and S100 protein presence. Which mutation is likely associated with this condition? (Q845918)

A. TP53 mutation

B. RAS mutation

C. BRAF mutation

D. MET mutation

@Neet_pg_bot

See Answer in Part B → Q13

@Neet_pg_bot

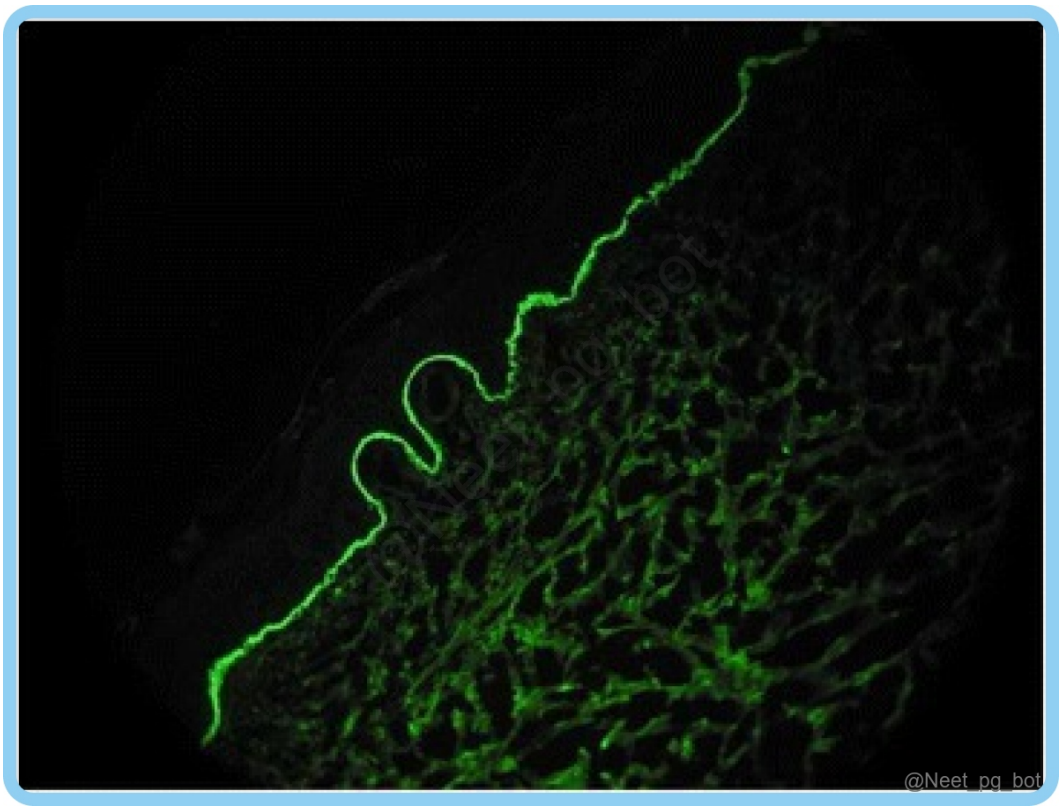
Q14: A 65-year-old male presents with tense blisters on his abdomen and extremities, filled with clear fluid. The skin appears normal between the blisters, which are painful but not itchy. A skin biopsy reveals a subepidermal blister with linear IgG and complement deposition along the basement membrane on direct immunofluorescence as shown in the image. What is the most likely diagnosis? (Q845920)

A. Epidermolysis Bullosa Acquisita

B. Bullous Pemphigoid

C. Pemphigus Vulgaris

D. Dermatitis Herpetiformis



See Answer in Part B → Q14

Q2: Which of the following is used in the treatment of Hemophilia B? (Q840031)

A. Factor 9

B. Cryoprecipitate

C. Factor 8

D. Tranexamic acid

See Answer in Part B → Q2

@Neet_pg_bot

Q3: In a trauma patient with an unknown blood group who is unstable and requires urgent blood transfusion, which type of blood should be transfused? (Q840032)

A. A positive

B. AB positive

C. O positive

D. O negative

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is not seen in a delayed hemolytic transfusion reaction? (Q840056)

A. Raised LDH

B. Raised indirect bilirubin

C. No improvement in Hb despite transfusion

D. Cola-colored urine after 2 hrs

See Answer in Part B → Q4

@Neet_pg_bot

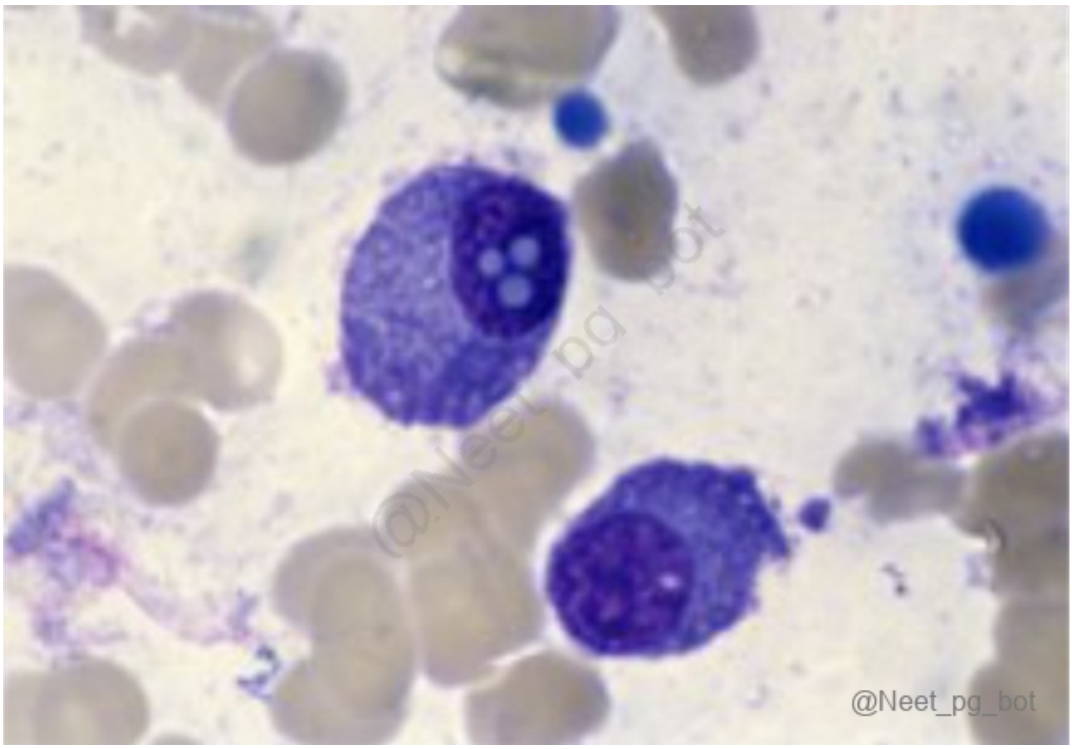
Q5: A patient presents with a tingling sensation in both legs, polyuria, and weight loss. Based on the given bone marrow aspirate findings, what is the most likely diagnosis? (Q844224)

A. Multiple myeloma with renal failure

B. SACD with vitamin B12 deficiency

C. SACD with diabetes

D. Waldenstrom's Macroglobulinemia



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A child is brought to the emergency department with a large lesion on his forearm. As a surgery resident, you decide to excise the lesion in the emergency operation theatre. Which of the following investigations will test the entire coagulation pathway? (Q856915)

A. Activated partial thromboplastin time

B. Prothrombin time

C. Thromboelastography

D. Bleeding time

See Answer in Part B → Q6

@Neet_pg_bot

Q7: How does Total plasma exchange help in the management of TTP (Q857426)

A. TPE removes the Von Willebrand factor

B. TPE removes the Antiplatelet antibodies

C. TPE removes Anti ADAMTS13 autoantibodies and thereby increases the ADAMTS protease activity

D. TPE replenishes the coagulation factor

See Answer in Part B → Q7

@Neet_pg_bot

Q8: What is the commonest cause of a hypercoagulable state? (Q857441)

A. Antithrombin III deficiency

B. Protein C deficiency

C. Factor V Leiden mutation

D. G20210A prothrombin gene mutation

See Answer in Part B → Q8

Q13 (p. 989)	*Q14 (p. 990)*	*Q15 (p. 991)*	*Q16 (p. 992)*		

Q1: Which of the following are pathological factors that contribute to the development of thrombosis? (Q879510)

A. Endothelial injury, abnormal blood flow, hypercoagulability

B. Increased vascular compliance, reduced platelet activity, and fibrinolysis

C. Decreased vascular tone, enhanced anticoagulant proteins, and vasodilation

D. Smooth muscle hypertrophy, hypocoagulability, and increased tissue perfusion

Correct Answer: A. Endothelial injury, abnormal blood flow, hypercoagulability

Explanation: The primary abnormalities that lead to intravascular thrombosis are the so-called “Virchow triad”. Components of Virchow triad: Endothelial injury- Leads to platelet activation, which almost inevitably underlies thrombus formation in the heart and the arterial circulation. Abnormal blood flow- Turbulence (chaotic blood flow) contributes to arterial and cardiac thrombosis by causing endothelial injury or dysfunction. Hypercoagulability- Refers to an abnormally high tendency of the blood to clot and is usually caused by alterations in coagulation factors.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: What is the most common cause of cell injury? (Q845267)

A. Hypoxia

B. Immunologic reactions

C. Drug-induced

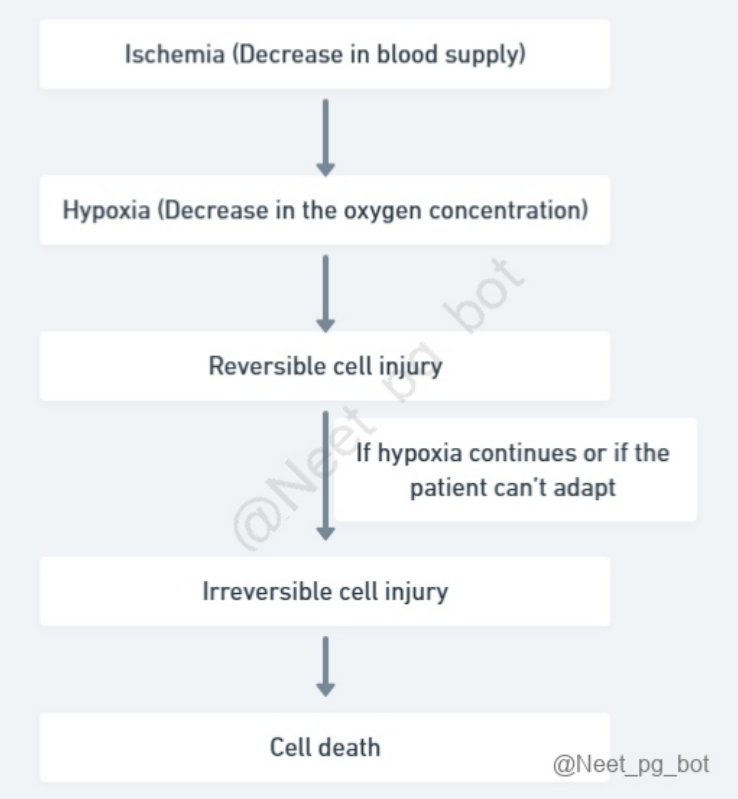
D. Nutritional imbalance

Correct Answer: A. Hypoxia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypoxia is the most common cause of cell injury. The mechanism of hypoxic cell injury is a decrease in oxygen concentration at the tissue level. The most common cause of hypoxia is ischemia. Ischemia is the hampered blood supply.



References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th edition, Page 31.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Identify the correct combination of most and least sensitive cells to hypoxia. (Q845270)

A. Most sensitive - hepatocytes and least sensitive - Lymphocytes

B. Most sensitive - bone marrow cells and least sensitive - nerve cells

C. Most sensitive - retina and least sensitive - adipose tissue

D. Most sensitive - neurons and least sensitive - fibroblasts

Correct Answer: D. Most sensitive - neurons and least sensitive - fibroblasts

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The cells most sensitive to hypoxia are neurons and the least sensitive are fibroblasts. Neurons or Brain cells : Features of cell injury can be seen after 3 to 5 minutes of hypoxia. Fibroblasts: Hypoxia can be tolerated for more than 60 minutes. Incorrect options: Most sensitive - hepatocytes and least sensitive - Lymphocytes (option A) Hepatocytes are moderately sensitive to hypoxia. Neurons are far more sensitive than hepatocytes (injury within 3–5 minutes). Lymphocytes tolerate hypoxia fairly well, but fibroblasts are the most resistant. Most sensitive - bone marrow cells and least sensitive - nerve cells (option B) Bone marrow cells are sensitive to radiation and toxins, but not the most sensitive to hypoxia . Most sensitive - retina and least sensitive - adipose tissue (option C) The retina is metabolically active but not more sensitive than neurons to hypoxia. Adipose tissue tolerates low oxygen but fibroblasts are even more hypoxia-resistant.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 37

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which among the following is not a feature of reversible cell injury? (Q845271)

A. Large amorphous densities in the mitochondria

B. Decrease in ATP generation

C. Swelling of the endoplasmic reticulum

D. Detachment of ribosomes from granular ER

Correct Answer: A. Large amorphous densities in the mitochondria

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Large amorphous densities are seen in the mitochondria in irreversible cell injury . Amorphous densities in the mitochondria mean calcium deposition in mitochondria, which occurs when the cell membrane has been ruptured. The following changes occur in reversible cell injury: Cellular swelling: Earliest change Na and water accumulate within the cell, causing cellular swelling (swelling of the endoplasmic reticulum) (Option C ruled out) ATP depletion leads to sodium-potassium pump failure (Option B ruled out) Due to ATP dysfunction, ribosomes detach from the endoplasmic reticulum, which stops protein synthesis (Option D ruled out)

References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 37

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following are features of irreversible cell injury? Increased eosinophilia Pyknosis Decrease in ATP production Small amorphous densities in mitochondria (Q845275)

A. 1, 2

B. 1, 2, 3, 4

C. 1, 2, 4

D. 2, 3

Correct Answer: A. 1, 2

Explanation: The correct statements regarding features of irreversible cell injury are statements 1 and 2. Irreversible cell injury: Defining features: Severe membrane damage. Severe mitochondrial damage leads to the formation of large, flocculant, amorphous densities due to increased calcium influx. (Not small as mentioned in statement 4) Two defining moments of irreversible cell injury are Severe Membrane Damage: The inflow of calcium occurs. It causes the activation of three enzymes: a. Phospholipase b. Protease c. Nuclease Severe Mitochondrial Damage: The calcium sits on the mitochondria causing Amorphous Flocculent Densities Nuclear Changes in Cell Injury: Three stages of nuclear changes in cell injury are: Pyknosis: The nucleus becomes small and dark due to the nuclear chromatin condensing. Karyorrhexis: There will be Nuclear Fragmentation Karyolysis : The nucleus gets dissolved. Increased eosinophilia is seen in H&E stains due to the loss of cytoplasmic RNA and accumulation of denatured cytoplasmic proteins (which bind the red dye eosin). Statements 3 and 4 : A decrease in ATP production and small amorphous densities in the mitochondria are features of reversible cell injury.

Reversible cell injury Irreversible cell injury Decreased ATP production - Failure of Na+ K+ ATPase pump - Cellular, ER, and mitochondrial swelling. Anaerobic glycolysis - Acidic pH- Clumping of nuclear chromatin Detachment of ribosomes from rough ER- Decreased protein synthesis and fatty change. Severe Membrane Damage: The inflow of calcium occurs. It causes the activation of three enzymes: a. Phospholipase b. Protease c. Nuclease Severe Mitochondrial Damage: The calcium sits on the mitochondria causing Amorphous Flocculent Densities Myelin figures/ concentric lamellations: seen in both reversible and irreversible cell injury.

@Neet_pg_bot

Q7: Which of the following is the most important electron microscopic finding in irreversible cell injury? (Q845288)

A. Small amorphous densities in the mitochondria

B. Swelling of the endoplasmic reticulum

C. Large amorphous densities in the mitochondria

D. Detachment of ribosomes from the granular endoplasmic reticulum

Correct Answer: C. Large amorphous densities in the mitochondria

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Large amorphous densities in the mitochondria are the most important electron microscopic finding in irreversible cell injury. It occurs due to an increased calcium influx in the mitochondria. Irreversible cell injury: Severe membrane damage leading to influx of calcium. Severe mitochondrial damage leads to the formation of large, flocculant, amorphous densities due to increased calcium influx. Reversible cell injury: Small amorphous densities in the mitochondria Swelling of the endoplasmic reticulum Detachment of ribosomes from the granular endoplasmic reticulum Feature Reversible Injury Irreversible Injury (Cell Death) Main Definition Pathological changes that can be reversed if the stimulus is removed. Permanent damage leading to cell death regardless of stimulus removal. Mitochondria Swelling (vacuolization) due to influx of water. Severe swelling and appearance of large, amorphous densities in the matrix. Plasma Membrane Blebbing, blunting, or loss of microvilli; structure remains intact. Loss of membrane integrity ; massive leakage of intracellular enzymes. Nucleus Clumping of chromatin. Nuclear shrinkage (pyknosis), fragmentation (karyorrhexis), or dissolution (karyolysis). Lysosomes Generally remain intact. Rupture and release of acid hydrolases into the cytoplasm (autolysis). Endoplasmic Reticulum Swelling and detachment of ribosomes (reduced protein synthesis). Lysis of the ER and total loss of ribosomes. Cytoplasm Increased eosinophilia (pinkness) and "cloudy swelling." Intense eosinophilia; presence of "myelin figures" (whorled phospholipid masses). Energy (ATP) ATP depletion occurs, but can be restored. Profound ATP depletion ; failure of all metabolic pathways.

@Neet_pg_bot

Q8: Which of the following statements regarding free radical injury is true? (Q845289)

A. Free radicals are highly stable molecules with unpaired electrons that contribute positively to cellular functions.

B. Free radical injury can lead to cell damage through lipid peroxidation, protein oxidation, and DNA strand breaks.

C. Antioxidants play a minor role in protecting cells from free radical damage.

D. Free radicals primarily cause cell death through apoptosis and do not contribute to necrosis.

Correct Answer: B. Free radical injury can lead to cell damage through lipid peroxidation, protein oxidation, and DNA strand breaks.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Free radical injury can indeed lead to cell damage through processes such as lipid peroxidation (which damages cell membranes), protein oxidation (which affects enzyme function and structural integrity), and DNA strand breaks (which can lead to mutations). Free radicals are highly unstable with unpaired electrons that contribute negatively to cellular functions. (Option A ruled out) Antioxidants play a major role in protecting cells from free radical damage; therefore, the diet should be rich in antioxidants, such as vitamins A, C, and E. (Option C ruled out) Free radicals cause cell death through apoptosis and also contribute to necrosis. (Option D ruled out) Free radical injury: Free Radical: Aka ROS (Reactive Oxygen Species) 3 types: Superoxide; Hydrogen peroxide; Hydroxyl (most potent) Protects every cell Reactive oxygen species → lipid peroxidation → produce Lipofuscin pigment (tell-tale sign) Formation: Protection: Antioxidants like vitamins A, C, and E Transport proteins Transferrin - Fe Ceruloplasmin - Cu Protective Enzymes: SOD, Catalase, Glutathione peroxidase Superoxide dismutase (Due to lamin mutation): 2 types: Cytoplasmic SOD (Cu-Zn SOD) Mitochondrial SOD (Mn SOD) SOD: Protects the brain SOD 1 gene mutation → ALS (Amyotrophic Lateral Sclerosis) M/E: Bunina bodies Affects both UMN and LMN disorders Enzymatic Antioxidants: Superoxide dismutase (SOD): Converts superoxide (O■■) to H■O■ + O■ (mitochondria/cytosol).■ Catalase: Breaks down H■O■ to H■O + ½O■ (peroxisomes).■ Glutathione peroxidase: Reduces H■O■/lipid peroxides using glutathione (cytosol/mitochondria). Non-Enzymatic Antioxidants: Glutathione (GSH): Major intracellular reductant; oxidized to GSSG.■ Vitamin E (α-tocopherol): Membrane-bound, chain-breaking antioxidant against lipid peroxidation.■ Vitamin C (ascorbic acid): Water-soluble, regenerates Vitamin E.■ β-carotene/Vitamin A: Membrane-associated, quenches singlet oxygen.

@Neet_pg_bot

Q9: Which of the following ultrastructural findings given below can be seen in irreversible cell injury? (Q845292)

A. Swelling of endoplasmic reticulum

B. Formation of myelin figures

C. Disaggregation of granular and fibrillar elements

D. Nuclear fragmentation

Correct Answer: B. Formation of myelin figures

Explanation: The given clinical presentation of a male with acute-on-chronic liver failure with severely elevated liver enzymes and hepatic encephalopathy can cause irreversible cell damage in the liver. In the context of irreversible cell injury, the formation of myelin figures is a characteristic ultrastructural finding. Myelin figures: They represent whorled arrangements of membranous material within the cytoplasm, indicating severe disruption and rearrangement of cellular membranes. It is commonly observed under electron microscopy. They are either phagocytosed by other cells or further degraded into fatty acids; calcification of such fatty acid residues results in the deposition of calcium-rich precipitates. Myelin figures can be seen in both reversible and irreversible cell injuries, but they are more common in irreversible injuries. OTHER OPTIONS: Options A and C: Swelling of endoplasmic reticulum and disaggregation of granular and fibrillar elements are electron microscopic features of reversible cellular injury. Option D: Nuclear fragmentation, also known as karyorrhexis , is a light microscopic finding seen in irreversible cellular injury.

@Neet_pg_bot

Q10: A sample of tissue preparation is subjected to oxidative stress under experimental conditions. Different types of free radicals are generated in the process. However, the researcher wants to work on the most potent and reactive free radicals among the ones generated. Which of the following will he be working on? (Q845294)

A. Hydroxyl radical (OH•)

B. Nitric oxide radical (NO•)

C. Superoxide anion radical (O2•-)

D. Peroxyl radical (ROO•)

Correct Answer: A. Hydroxyl radical (OH•)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: When a tissue sample is exposed to oxidative stress experimentally, various free radicals are produced, with the hydroxyl radical being the most potent and reactive among them. We have a total of 3 free radicals: Superoxide Hydrogen peroxide (H2O2) Hydroxyl (OH) The hydroxyl radical (OH•) is considered the most potent and reactive free radical due to its high reactivity and ability to quickly react with cellular components, leading to oxidative damage. Hydroxyl radicals are primarily formed through the Fenton reaction T he interaction of hydrogen peroxide (H2O2) with transition metal ions such as iron (Fe) or copper (Cu).

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 67,68

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following is a telltale sign of free radical injury in cells? (Q845295)

A. Increased antioxidant levels in the cell

B. Decreased lipid peroxidation products

C. Generation of Lipofuscin and stress markers such as malondialdehyde (MDA)

D. Enhanced cellular energy production.

Correct Answer: C. Generation of Lipofuscin and stress markers such as malondialdehyde (MDA)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The presence of lipofuscin and stress markers like malondialdehyde (MDA) is a telltale sign of free radical-induced cellular injury. Free radical injury results in oxidative stress (Lipid peroxidation), leading to the accumulation of oxidative stress markers such as malondialdehyde (MDA) and the generation of Lipofuscin. Lipofuscin is positive for Oil Red-O stain. These are the tell-tale signs of free radical injury.

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Pages 67,68

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: What is the primary function of superoxide dismutase (SOD) in cells? (Q845298)

A. Activation of inflammatory responses.

B. Generation of reactive oxygen species (ROS)

C. Neutralization of superoxide anion radicals (O2•-) into hydrogen peroxide (H2O2)

D. Promotion of lipid peroxidation.

Correct Answer: C. Neutralization of superoxide anion radicals (O2•-) into hydrogen peroxide (H2O2)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Neutralization of superoxide anion radicals (O2•-) into hydrogen peroxide (H2O2) is the primary function of Superoxide Dismutase (SOD) in cells. Dual functions of Superoxide dismutase (SOD): Generation of free radicals by converting superoxide into H2O2 Neutralization (Primary function) (Option C) Its primary function is to catalyze the conversion of superoxide radicals (O2•-) into oxygen (O2) and hydrogen peroxide (H2O2). The only antioxidant that can break free radicals in the brain is Superoxide dismutase. SOD1 gene mutation in humans is associated with Amyotrophic Lateral Sclerosis (ALS). Catalase: Catalase is located in peroxisomes It decomposes H■O■ (from SOD or fatty acid oxidation) into water and oxygen: 2H■O■ → 2H■O + O■. It prevents H■O■ accumulation, which could otherwise damage DNA, proteins, and lipids. It shows high activity in liver/kidney peroxisomes. Glutathione Peroxidase (GPx): GPx uses reduced glutathione (GSH) to reduce H■O■ and lipid hydroperoxides to water/alcohols: H■O■ + 2GSH → GSSG + 2H■O. It is selenium-dependent (at active site). It protects membranes from peroxidation. GSH is regenerated by glutathione reductase (NADPH-dependent).

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 50-year-old male presents with progressive weakness and muscle atrophy, primarily affecting his arms and legs. He reports difficulty with tasks such as buttoning shirts and lifting objects. On examination, you note fasciculations in his upper extremities and decreased muscle strength. His reflexes are brisk, and there is no sensory deficit. Nerve conduction studies show signs of denervation. Genetic testing reveals a mutation in the SOD1 gene. Based on this clinical scenario, what is the most likely diagnosis for this patient? (Q845300)

A. Multiple sclerosis

B. Myasthenia gravis

C. Amyotrophic lateral sclerosis

D. Guillain-Barré syndrome

Correct Answer: C. Amyotrophic lateral sclerosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This clinical scenario, marked by progressive limb weakness, muscle atrophy with fasciculations, brisk reflexes, denervation on nerve studies, and an SOD1 gene mutation, is diagnostic of Amyotrophic Lateral Sclerosis (ALS) . It is a disease of both upper and lower motor neurons. The SOD1 gene encodes for the enzyme superoxide dismutase 1 (SOD1), which plays a crucial role in protecting cells (Brain) from oxidative stress. Mutations in the SOD1 gene are associated with familial cases of amyotrophic lateral sclerosis (ALS). ALS is a progressive neurodegenerative disease that affects motor neurons in the brain and spinal cord, leading to muscle weakness, atrophy, and eventually paralysis. Bunina bodies are seen on brain biopsy of ALS patients. Clinical features: LMN: Flaccid weakness, atrophy, fasciculations, hyporeflexia early. UMN: Spasticity, hyperreflexia, Babinski. Bulbar: Dysarthria, dysphagia (25% onset). No sensory/cognitive/autonomic involvement (early); respiratory failure → death (3-5 years median). Diagnosis: El Escorial criteria (clinical + EMG denervation/reinnervation) Genetic testing Exclude mimics (anti-GM1, cervical spondylosis). Multiple sclerosis (Option A): Demyelinating CNS disease with sensory deficits, optic neuritis, and relapsing-remitting course; no SOD1 link or denervation on NCS. Myasthenia gravis (Option B): Neuromuscular junction disorder with fatigable weakness, ptosis, diplopia, and normal reflexes; fatigability absent here.■ ■■■■■■■Guillain-Barré syndrome (Option D): Acute inflammatory demyelinating polyneuropathy with ascending weakness, areflexia, sensory symptoms, and albuminocytologic dissociation in CSF; not progressive/chronic.

@Neet_pg_bot

Q14: Which of the following best describes the primary function of chaperones within the cellular environment? (Q845304)

A. Facilitating the degradation of misfolded proteins

B. Promoting protein folding and preventing misfolding

C. Catalyzing enzymatic reactions by providing a scaffold

D. Transporting proteins across cellular membranes

Correct Answer: B. Promoting protein folding and preventing misfolding

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The primary role of Chaperones (molecular chaperones like Hsp70, Hsp90, GroEL) in the cellular environment is to facilitate proper protein folding and prevent misfolding. Chaperones in the ER are responsible for properly folding newly synthesized proteins, and misfolded polypeptides are shuttled into the cytoplasm where they are ubiquitinated and targeted for proteolysis in proteasomes. Chaperons works by the Ubiquitin Proteasome Pathway (UPP): Corrects the misfolding. Bit if the misfolded protein cannot be corrected then it is sent proteolysis or breakdown. Disease Misfolded protein Creutzfeldt-Jacob disease Prions Cystic fibrosis Cystic fibrosis transmembrane conductance regulator (CFTR) (ΔF508 mutation most common; class II trafficking defect) Alzheimer's Disease Aβ (amyloid-β 40/42 from APP), Tau (hyperphosphorylated → NFTs) Parkinson's Disease α-Synuclein (Lewy bodies) Huntington's Disease Huntingtin (polyglutamine expansion >36 repeats) Amyotrophic Lateral Sclerosis (ALS) SOD1 (mutations), TDP-43, FUS Frontotemporal Dementia (FTD) Tau (some), TDP-43 Fatal Familial Insomnia Prion protein (PRNP mutation) Type 2 Diabetes Islet amyloid polypeptide (IAPP/amylin) Systemic AL Amyloidosis Immunoglobulin light chains (λ > κ) AA (Secondary) Amyloidosis Serum amyloid A (SAA, acute phase reactant) Transthyretin Amyloidosis (ATTR) Transthyretin (TTR, wild/mutant) Dialysis-Related Amyloidosis β■-Microglobulin

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 54

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 60-year-old man has been complaining of fatigue, unintentional weight loss, and swelling in his ankles and legs over the past few months. On physical examination, you notice hepatomegaly and proteinuria. Laboratory tests reveal elevated serum creatinine levels and microscopic hematuria. Which of the following types of amyloid is most likely responsible for this patient's presentation? (Q845308)

A. AA amyloidosis

B. AB amyloidosis

C. AL amyloidosis

D. ATTR amyloidosis

Correct Answer: C. AL amyloidosis

Explanation: AL amyloidosis, also known as primary systemic amyloidosis , is characterized by the deposition of amyloid fibrils derived from monoclonal immunoglobulin light chains (lambda or kappa) produced by clonal plasma cells. In this type of amyloidosis, the deposited amyloid fibrils can infiltrate various organs and tissues, including the kidneys, leading to organ dysfunction. Clinical manifestations commonly include Renal involvement causing proteinuria and renal impairment Hepatomegaly Peripheral oedema due to cardiac involvement. AA amyloidosis (Option A): AA amyloidosis, also known as secondary systemic amyloidosis, occurs secondary to chronic inflammatory conditions such as rheumatoid arthritis, inflammatory bowel disease, or chronic infections. In AA amyloidosis, the amyloid fibrils are derived from serum amyloid A protein, an acute-phase reactant synthesized predominantly by hepatocytes in response to inflammation. AB amyloidosis (Option B): AB amyloidosis is not a recognized subtype of amyloidosis. Amyloid fibrils derived from A Beta peptide are associated with Alzheimer's disease, but they are not a primary cause of systemic amyloidosis involving multiple organs. ATTR amyloidosis (Option D): ATTR amyloidosis, also known as transthyretin amyloidosis, occurs due to the deposition of amyloid fibrils derived from transthyretin protein, a transporter of thyroxine and retinol-binding protein. It can be hereditary (caused by mutations in the transthyretin gene) or acquired (due to wild-type transthyretin protein). It typically affects the heart and peripheral nerves, leading to cardiomyopathy and peripheral neuropathy, respectively.

@Neet_pg_bot

Q16: Which cellular pathway is primarily involved in the pathogenesis of Amyotrophic Lateral Sclerosis (ALS)?Which of the following pathways are responsible for the pathogenesis of ALS? (Q845311)

A. Autophagy-lysosome pathway

B. Ubiquitin-proteasome pathway

C. Endocytic pathway

D. Apoptotic pathway

Correct Answer: B. Ubiquitin-proteasome pathway

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ubiquitin-proteasome pathway plays a key role in the pathogenesis of ALS (Amyotrophic Lateral Sclerosis) . ALS is due to a mutation in the SOD-1 gene. Mutant proteins start accumulating in brain. The ubiquitin-proteasome pathway is primarily responsible for the degradation of misfolded proteins within the cell. In this pathway, misfolded or damaged proteins are tagged with ubiquitin molecules, which target them for

degradation by the proteasome, a large multi-subunit protein complex. Dysfunction of the ubiquitin-proteasome pathway can lead to the accumulation of misfolded proteins and contribute to the pathogenesis of neurodegenerative diseases such as amyotrophic lateral sclerosis (ALS) and Parkinson's disease. In the SOD-1 gene defect, UPP is not working because of cellular defect. Autophagy–lysosome pathway (Option A): Although involved in protein clearance, it is secondary and not the principal pathway in ALS pathology. Endocytic pathway (Option C): Endocytic defects may contribute to neuronal dysfunction but are not the primary mechanism in ALS. Apoptotic pathway (Option D): Apoptosis represents the final common pathway of neuron death, not the initiating pathogenic mechanism.

Q1: A construction worker involved in bridge building reports widespread bone pain. Imaging reveals ischemic necrosis affecting both femoral heads, the left tibia, and the right humerus. Which of the following factors is most likely responsible for this condition? (Q879491)

A. Alterations in ambient pressure

B. Changes in blood viscosity

C. Impaired blood flow

D. Increased coagulability

Correct Answer: A. Alterations in ambient pressure

Explanation: Exposure to rapid changes in ambient pressure, as encountered in compressed air work or tunnel construction, predisposes to dysbaric osteonecrosis. Nitrogen gas bubbles form within the marrow vasculature during decompression, causing vascular obstruction, ischemia, and aseptic bone necrosis, particularly affecting weight-bearing bones. Incorrect Options: Changes in blood viscosity (Option B): Although changes in blood viscosity can affect circulation, they are not the primary cause of ischemic bone necrosis in this scenario. Impaired blood flow (Option C): Impaired blood flow is a direct cause of ischemia, but here is secondary to ambient pressure-induced gas embolism. Increased coagulability (Option D): Increased coagulability is not the main factor involved in the pathogenesis of this type of osteonecrosis.

@Neet_pg_bot

Q2: Which of the following diseases is primarily attributed to protein misfolding, resulting in cellular dysfunction or apoptosis? (Q879402)

A. Cystic fibrosis

B. Familial hypercholesterolemia

C. Tay-Sachs disease

D. All of the above

Correct Answer: D. All of the above

Explanation: Protein misfolding disorders can affect multiple systems and often trigger ER stress and apoptosis if quality control mechanisms fail. Other examples include α1-antitrypsin deficiency, Alzheimer's disease, and Creutzfeldt-Jakob disease . Protein Misfolding and ER Stress: ER chaperones assist in the proper folding of newly synthesized proteins Misfolded proteins are sent to the cytoplasm → Ubiquitinated and degraded by proteasomes. Accumulation triggers the Unfolded Protein Response (UPR) : ↑ Chaperones ↑ Proteasomal degradation ↓ Protein translation (to reduce ER stress) Misfolded proteins are implicated in neurodegenerative diseases and other disorders. Disease Protein Misfolded Effect Cystic fibrosis CFTR Defective chloride transpor Familial hypercholesterolemia LDL receptor Impaired cholesterol clearance Tay-Sachs disease Hexosaminidase β subunit Lysosomal GM2 ganglioside accumulation α1-Antitrypsin deficiency α1-Antitrypsin Hepatocyte apoptosis and lung emphysema Creutzfeldt-Jacob disease Prions (PrP^Sc) Neuronal cell death Alzheimer's disease Aβ peptide Neuronal aggregation and apoptosis

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 54,55

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 65-year-old patient with a neurodegenerative disorder is found to have neuronal death associated with iron accumulation and lipid peroxidation. Which form of cell death is most likely involved? (Q879401)

A. Apoptosis

B. Necrosis

C. Ferroptosis

D. Pyroptosis

Correct Answer: C. Ferroptosis

Explanation: Ferroptosis is a regulated, iron-dependent form of cell death triggered by excessive reactive oxygen species (ROS) and lipid peroxidation, leading to loss of plasma membrane integrity. A regulated, iron-dependent form of cell death triggered by excess intracellular iron or reactive oxygen species (ROS) overwhelming glutathione-dependent antioxidant defenses. Mechanism: Unchecked lipid peroxidation → Disrupting membrane fluidity, lipid-protein interactions, ion/nutrient transport, and signaling → Ultimately leading to loss of plasma membrane integrity . Morphology: Resembles necrosis but is signal-regulated . Ultrastructurally → Loss of mitochondrial cristae and ruptured outer mitochondrial membrane . Prevention: Inhibited by reducing iron levels or limiting lipid peroxidation. Clinical relevance: Implicated in cancer, neurodegenerative diseases, and stroke (role in normal physiology is still uncertain).

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 47,48

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 30-year-old individual has cells that resist Fas-mediated apoptosis despite Fas ligand binding. Which of the following proteins is most likely responsible for blocking caspase-8 activation in this scenario? (Q879400)

A. Bcl-2

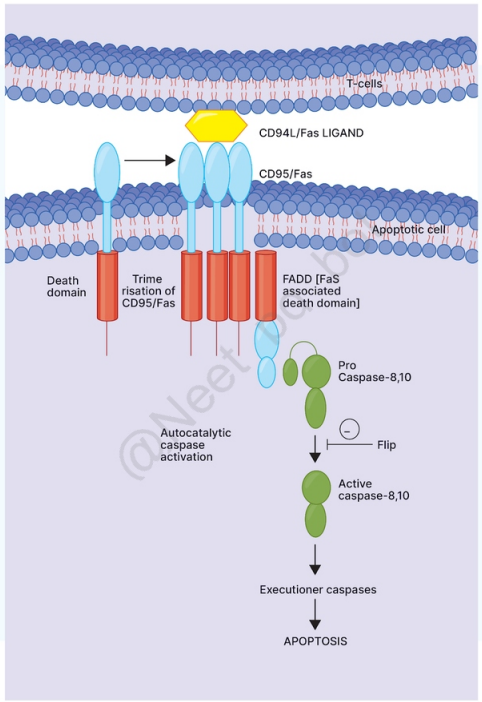
B. FLIP

C. BID

D. FADD

Correct Answer: B. FLIP

Explanation: FLIP protein inhibits the extrinsic apoptosis pathway by binding to pro-caspase-8 , preventing its recruitment to FADD and blocking activation. It does not activate caspase-8. The extrinsic pathway of apoptosis occurs in the following order: Presence of Fas on the outer part of the cell membrane The binding of the Fas ligand of T cells to Fas Trimerization of Fas Formation of FADD Activation of caspase 8, 10. This, along with the activation of the intrinsic pathway, leads to the execution phase and apoptosis. FLIP protein → Inhibits the conversion of Procaspases to caspases.



@Neet_pg_bot

Q5: Which of the following statements about caspases is true? (Q879392)

A. Caspases function independently of apoptotic signaling pathways

B. Caspases cleave at cysteine residues

C. Caspases act on asparagine residues

D. Caspases are cysteine proteases

Correct Answer: D. Caspases are cysteine proteases

Explanation: Caspases are cysteine proteases that cleave target proteins after aspartic residues . They exist as inactive zymogens (pro-caspases) and are activated via proteolytic cleavage. This activation triggers the initiation and execution phases of apoptosis .

@Neet_pg_bot

Q6: Which of the following represents pathological apoptosis rather than physiological apoptosis? (Q879391)

A. Regression of the lactating breast after weaning

B. Elimination of autoreactive T-lymphocytes in the thymus

C. Death of hepatocytes during viral hepatitis

D. Removal of neutrophils after resolution of acute appendicitis

Correct Answer: C. Death of hepatocytes during viral hepatitis

Explanation: Hepatocyte apoptosis in viral hepatitis is a pathological process triggered by viral infection and immune-mediated injury. This is not part of normal tissue homeostasis. Apoptosis in physiological conditions Apoptosis in pathological conditions The removal of supernumerary cells (in excess of the required number) during development. DNA damage. Involution of hormone-dependent tissues on hormone withdrawal, such as endometrial cell breakdown during the menstrual cycle. Accumulation of misfolded proteins Elimination of potentially harmful self-reactive lymphocytes to prevent immune reactions against one’s own tissues Apoptosis can be induced during certain infections, as adenovirus and HIV infections, and viral hepatitis. Death of host cells that have served their useful purpose, such as neutrophils in an acute inflammatory response and lymphocytes at the end of an immune response. It may also contribute to pathologic atrophy in parenchymal organs after duct obstruction, such as occurs in the pancreas, parotid gland, and kidney

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 42,43

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A pathology slide shows necrotic cells with intense eosinophilic cytoplasm on H&E staining. Which of the following best explains this increased eosinophilia? (Q879390)

A. Loss of glycogen and lipid droplets

B. Accumulation of denatured cytoplasmic proteins that bind eosin

C. Swelling of mitochondria with amorphous densities

D. Presence of intracytoplasmic myelin figures

Correct Answer: B. Accumulation of denatured cytoplasmic proteins that bind eosin

Explanation: In necrotic cells, increased eosinophilia is mainly due to loss of cytoplasmic RNA (less basophilia) and denatured cytoplasmic proteins binding more eosin dye . This makes the cytoplasm appear bright pink/red. Morphologic Features of Necrotic Cells Increased eosinophilia Due to loss of cytoplasmic RNA (reduced basophilia) and accumulation of denatured cytoplasmic proteins that strongly bind eosin. Glassy homogeneous appearance Primarily caused by the loss of glycogen particles . Vacuolated (“moth-eaten”) cytoplasm Occurs when enzymes digest cell organelles. Myelin figures Large whorled phospholipid precipitates. It may be phagocytosed by other cells or degraded into fatty acids (undergo calcification → calcium-rich deposits). Ultrastructural changes (electron microscopy) Discontinuities in plasma and organelle membranes. Marked mitochondrial dilation with amorphous densities. Intracytoplasmic myelin figures. Amorphous debris and aggregates of fluffy material (denatured proteins).

@Neet_pg_bot

Q8: Which of the following is true about apoptosis? (Q879389)

A. It is an irreversible type of cell injury

B. It is associated with inflammation

C. It results in nuclear changes such as pyknosis, karyorrhexis, and karyolysis

D. It is an active process

Correct Answer: D. It is an active process

Explanation: Apoptosis is an active process, requiring ATP Apoptosis Necrosis Definition Programmed cell death, an orderly, regulated process Both Physiologic and pathologic Unregulated cell death due to injury or stress Always pathological Triggering Controlled signals (e.g., intrinsic or extrinsic pathways) Acute cell injury (e.g., trauma, infection, ischemia) Cellular Morphology Cell shrinkage, chromatin condensation, and membrane blebbing. Cell swelling, membrane rupture, organelle damage, Nucleus (Pyknosis, Karyorrhexis, Karyolysis). Inflammation No inflammation; phagocytes quickly remove apoptotic bodies Induces inflammation due to the

release of cell contents Energy Dependency Requires ATP and energy; active process Does not require energy; passive process Marker DNA electrophoresis: Step ladder pattern Annexin V, CD95/Fas Tunel stain positive DNA electrophoresis: Smear pattern Tunel stain negative

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 42

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A pathology student is reviewing the sequence of nuclear and cellular changes that occur during necrosis. Which of the following correctly represents the order of events? 1. Cell swelling 2. Karyolysis 3. Karyorrhexis 4. Pyknosis (Q879387)

A. 1 → 2 → 3 → 4

B. 1 → 4 → 3 → 2

C. 2 → 3 → 4 → 1

D. 4 → 3 → 2 → 1

Correct Answer: B. 1 → 4 → 3 → 2

Explanation: The earliest change in necrosis is cell swelling due to ATP depletion and loss of ionic homeostasis. Nuclear changes then follow in a characteristic sequence: pyknosis (chromatin condensation), karyorrhexis (fragmentation of the pyknotic nucleus), and finally karyolysis (enzymatic degradation of DNA leading to nuclear fading). The order of nuclear changes in necrosis is: Pyknosis → Karyorrhexis → Karyolysis. Pyknosis Shrinking of the nucleus and clumping of nuclear chromatin Karyorrhexis Nuclear fragmentation Karyolysis Dissolution of the nucleus

@Neet_pg_bot

Q10: Which of the following are involved in the pathogenesis of pyroptosis? (Q845353)

A. Caspase 8 and FADD

B. RIPK3 and MLKL

C. Caspase 1 and inflammasome

D. Iron and glutathione antioxidants

Correct Answer: C. Caspase 1 and inflammasome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Caspase 1 and the inflammasome are the entities responsible for a form of cell death known as Pyroptosis . A form of apoptosis in which there is release of the fever-inducing cytokine IL-1. Seen in response to bacterial infections like Salmonella and Shigella. Microbial products entering infected cells are recognized by cytoplasmic receptors, activating the multiprotein complex inflammasome . Inflammasomes are involved in recognition & clearance of necrotic cells. Inflammasome activates caspases 1, 4, 5, and 11. They will together result in the killing of the cell (apoptosis). Caspase 1, which converts the inactive IL-1 to active IL-1, causing fever, inflammation and leucocyte recruitment Caspase 8 and FADD (Option A) are involved in the extrinsic pathway of apoptosis. RIPK3 and MLKL (Option B) are involved in necroptosis. Iron and glutathione antioxidants (Option D) are involved in ferroptosis.

@Neet_pg_bot

Q11: Which type of cell death prevents metastasis? (Q845357)

A. Necroptosis

B. Pyroptosis

C. Anoikis

D. Necrosis

Correct Answer: C. Anoikis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Anoikis is a type of cell death which prevents metastasis. A type of apoptosis in which the cell undergoes programmed cell death when cells detach from the surrounding extracellular matrix (ECM) or neighbouring cells. When cancer cells detach from the primary tumor, they are susceptible to anoikis. Acts as a barrier against the survival and dissemination of these detached cancer cells Anoikis is a type of cell death which, if occurs, prevents spread of cancer or metastasis. Incorrect options: Necroptosis (option A) Programmed necrosis triggered by TNF or other signals. Inflammatory, but does not specifically prevent metastasis. Pyroptosis (option B) Caspase-1-dependent inflammatory cell death. Mainly involved in pathogen defense, not anti-metastatic. Necrosis (option D) ■■■■■■■■■■■■■■■■ Uncontrolled cell death from injury. Can promote inflammation and tumor progression, not prevent metastasis.

@Neet_pg_bot

Q12: Which of the following is true about programmed necroptosis? (Q845354)

A. Caspase-independent programmed cell death.

B. It is non-inflammatory.

C. It is only pathological.

D. It helps kill the Herpes simplex virus.

Correct Answer: A. Caspase-independent programmed cell death.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Necroptosis is a caspase-independent programmed cell death. Programmed necrosis is also known as Necroptosis. It is a type of caspase-independent programmed cell death that presents with Inflammation. (Option B ruled out) It has features of both necrosis and apoptosis. It is both physiological and pathological (Option C ruled out) It helps in killing Cytomegalovirus (CMV) and not HSV. (Option D ruled out)

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 47

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following is true about coagulative necrosis? (Q845314)

A. It is the least common type of necrosis

B. Brain is most likely to undergo coagulative necrosis

C. It causes a wedge-shaped necrosis in the affected organs

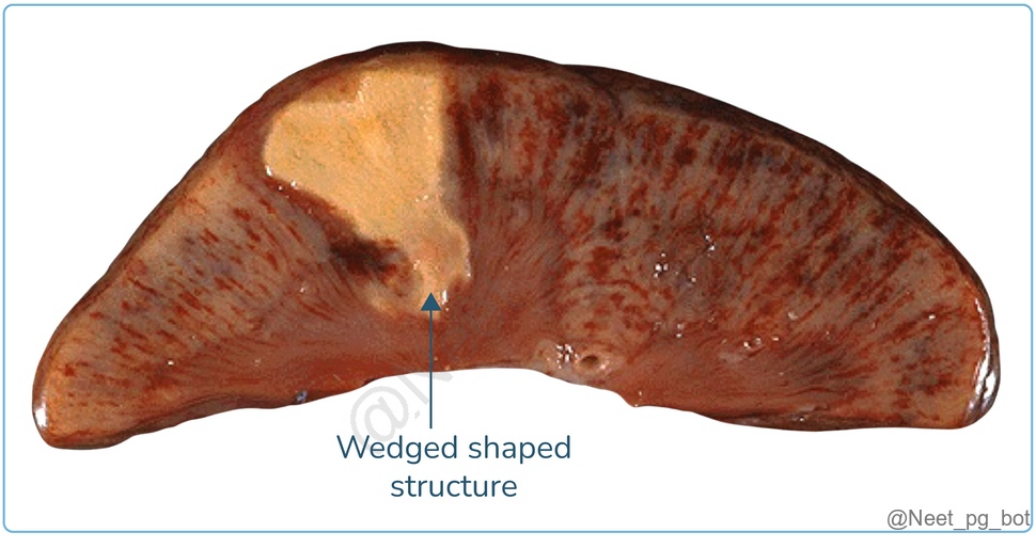
D. The tissue architecture is lost

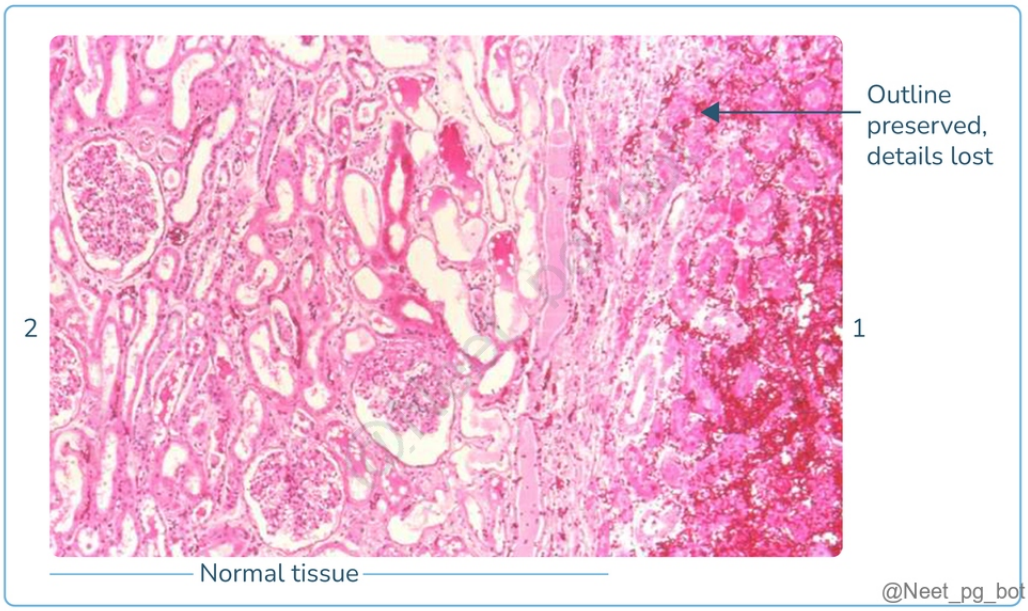
Correct Answer: C. It causes a wedge-shaped necrosis in the affected organs

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Coagulative Necrosis causes a wedge-shaped necrosis in the affected organs. Most common type of necrosis. (Option A ruled out) Seen in solid organs like the kidney, liver, and heart (Option B ruled out) . Brain and Pancreas show liquefactive necrosis Most common cause - Thromboembolism Grossly, wedge-shaped necrosis is seen. Usually seen following an infarct (when blood supply is hampered) Tissue architecture is preserved. (Option D ruled out) Microscopically, ghost cells are seen. These show preserved outlines but details are lost. {{caption_text}} {{caption_text}}





References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 39

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Which of the following cell deaths is most likely to show pattern B? (Q845352)

A. Apoptosis

B. Necrosis

C. Both

D. None of the above

Correct Answer: A. Apoptosis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Pattern B shows regular DNA bands (~180–200 bp), forming a “ DNA ladder ,” which is a hallmark of apoptosis. Apoptosis vs Necrosis on Agarose Gel: Feature Apoptosis Necrosis DNA Cleavage Internucleosomal, specific Random and nonspecific Enzyme Involved Activated endonucleases Non-specific degradation by cellular enzymes Electrophoresis Result Ladder pattern (discrete bands) Smear pattern (continuous degradation) Fragment Size Multiples of ~180–200 base pairs Heterogeneous, unorganized fragments Interpretation Indicates controlled cell death Indicates uncontrolled cell death

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Which of the following substances is not a component of ‘eat-me signals’ of efferocytosis? (Q845351)

A. C1q

B. Thrombospondin

C. Phosphatidyl serine

D. Fas Ligand

Correct Answer: D. Fas Ligand

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Fas ligand is a death receptor ligand that induces apoptosis and not a component of efferocytosis. Its involved in apoptosis initiation. Efferocytosis: The apoptotic bodies give the eat-me signals , which are expressed as C1q, Thrombospondin, and PS (Phosphatidyl Serine) . In the normal cell, the Phosphatidyl Serine is present in the inner leaflet, but in the apoptotic cell, it comes out. This is known as Phosphatidyl Serine Flipping (Defective in Scott syndrome). Based on this flipping, the Macrophage engulfs the apoptotic bodies, which is called Efferocytosis. Apoptotic bodies contain portions of the cytoplasm and nucleus. Eat-me signals list: Phosphatidylserine (PtdSer) Oxidized phospholipids Sugar residues (such as galactose) Deoxyribonucleic acid (DNA) Calreticulin (CALR) Annexin A1 Histones Pentraxin-3 (PTX3) Modified ICAM-3 Cardiolipin

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 46

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following forms the apoptosome complex? (Q845350)

A. SMAC, DIABLO

B. Cyt C and Apaf

C. Procaspase 9 and Caspase 9

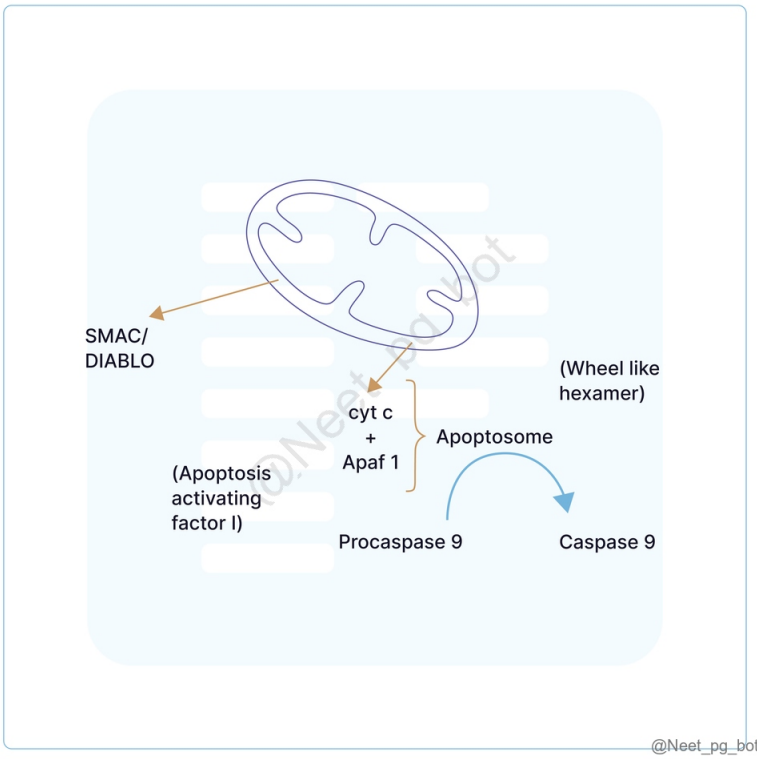
D. Caspase 3, 6, 7

Correct Answer: B. Cyt C and Apaf

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The A poptosome is a multi-protein complex that plays a critical role in the intrinsic (mitochondrial) pathway of apoptosis, formed when cytochrome C (Cyt C) is released from mitochondria into the cytosol in response to cellular stress or damage. Once in the cytosol: Cytochrome c binds to Apaf-1 (apoptotic protease-activating factor-1) in the presence of dATP/ATP This triggers the formation of the apoptosome complex SMAC/DIABLO (co-released with Cyt C) bind IAPs (XIAP/cIAPs), inhibiting their inhibition of Caspase-9 to amplify apoptosis. (Option A) The apoptosome then recruits and activates procaspase-9, which leads to activation of downstream executioner caspases (3, 6, 7) (Options C & D) Structurally, apoptosomes are composed of a wheel-like hexamer configuration. {{caption_text}} Apoptosis involves both intrinsic and extrinsic pathways of programmed cell death.



References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 44,45.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Arrange the steps of the extrinsic pathway of apoptosis in the correct order. i. Binding of Fas ligand of T cells to Fas ii. Trimerization of Fas iii. Activation of caspase 8, 10. iv. Formation of FADD (Q845349)

A. i>ii>iii>iv

B. iii>i>ii>iv

C. i>ii>iv>iii

D. iv>i>ii>iii

Correct Answer: C. i>ii>iv>iii

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Apoptosis occurs in two steps: Initiation and execution. The initiation phase contains extrinsic and intrinsic pathways. Extrinsic pathway: The extrinsic pathway of apoptosis starts outside the cells in the following order: Presence of Fas/CD95 on the outer part of the cell membrane Binding of Fas/CD95 ligand of T cells to Fas Trimerization of Fas Formation of FADD (Fas-associated death domain) Activation of caspase 8, 10 (by conversion of procaspase 8 and 10 to caspase 8 and 10) Intrinsic pathway: Sequence: This pathway responds to internal stresses like DNA damage or hypoxia, involving mitochondria. Activation of Pro-apoptotic Proteins: Internal stress signals activate proteins like Bax and Bak . Mitochondrial Permeabilization (MOMP): Bax and Bak form pores in the outer mitochondrial membrane, often called the "point of no return" . Release of Cytochrome c: Pores allow cytochrome c to leak from the mitochondria into the cytoplasm. Apoptosome Formation: In the cytoplasm, cytochrome c binds with Apaf-1 and procaspase-9 to form a complex known as the apoptosome . Caspase Activation: The apoptosome activates the initiator caspase-9 , which then triggers executioner caspases like caspase-3 . Cell Dismantling: Executioner caspases break down cellular components, leading to DNA fragmentation, cell shrinkage, and the final formation of apoptotic bodies . Step Extrinsic Pathway ■■ Intrinsic Pathway Trigger External ligand (FasL/TNF) binds death receptor Internal stress (DNA damage, hypoxia) via p53/Bcl-2 family Key Complex DISC (FADD + caspase-8) Apoptosome (cytochrome c + Apaf-1 + caspase-9) Initiator Caspase Caspase-8 (-10) Caspase-9 Mitochondrial Link Optional (caspase-8 cleaves Bid → tBid → MOMP) Required (Bax/Bak → MOMP → cyt c release) Convergence Executioner caspases-3/6/7 activated Executioner caspases-3/6/7 activated

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 45, 46

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Match the following apoptotic genes with their functions: 1. BCL2 , MCL1 a. Allows cytochrome c leakage 2. BAX, BAK b. Initiates apoptosis when upregulated 3. BAD, BID, NOXA c. Prevents leakage of cytochrome C from the cytosol (Q845346)

A. 1-b , 2-c , 3-a

B. 1-c , 2-a , 3-b

C. 1-a , 2-b , 3-c

D. 1-b , 2-a , 3-c

Correct Answer: B. 1-c , 2-a , 3-b

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Anti Apoptotic genes :- BCL-2 , BCL-XL , MCL-1 Pro Apoptotic genes:- BAX and BAK Apoptosis initiators (Stress sensors):- BAD, BIM, BID, Noxa and Pum

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 45, 46

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Which of the following statements about apoptosis is false? (Q845342)

A. Characterized by the activation of caspases leading to DNA fragmentation by endonuclease

B. Inflammatory response and release of damage-associated molecular patterns (DAMPs).

C. Chromatin condensation and formation of cytoplasmic blebs.

D. Eliminates cells that are injured beyond repair without eliciting a host reaction.

Correct Answer: B. Inflammatory response and release of damage-associated molecular patterns (DAMPs).

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Apoptosis is a non-inflammatory , programmed cell death process. It does not release DAMPs in a way that triggers a strong inflammatory response, unlike necrosis , which does cause inflammation and DAMP release. Apoptosis (Caspase dependent programmed cell death): It is an active process. It eliminates cells that are injured beyond repair without eliciting a host reaction, thus limiting collateral tissue damage. (Option D ruled out) Apoptosis results from the activation of enzymes called caspases leading to DNA fragmentation by endonuclease. (Option A ruled out) Hallmark of apoptosis: Nuclear chromatin condensation and formation of cytoplasmic blebs. (Option C ruled out) Apoptotic bodies

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 42,43

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: Identify the correctly matched pair among the following (Q845340)

A. Coagulative necrosis- Leucocytic enzymes- Brain

B. Liquefactive necrosis- Lysosomal enzymes - Heart

C. Fat necrosis- Pancreatic lipase- Omentum

D. Fibrinoid necrosis- Bacterial enzymes- Leg

Correct Answer: C. Fat necrosis- Pancreatic lipase- Omentum

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, the correctly represented pathology is fat necrosis caused by pancreatic lipases in the breast. In cases of acute pancreatitis, lipase is released from the pancreas which goes to omentum and breaks fat there causing fat necrosis. Type of necrosis Pathology Conditions Coagulative Lysosomal enzymes derived from infiltrating leukocytes Ischemia in all organs except the brain Liquefactive Microbes stimulating leukocyte enzymes Bacterial and fungal infections Ischemia in brain Caseous Formation of granuloma by lymphocytes and activated macrophages (giant cells, epithelioid cells). Tuberculosis,Fungal infections(Histoplasmosis, Coccidioidomycosis) ,Syphilis Gangrenous Ischemia and necrosis Lower and upper limb Fat necrosis Pancreatic enzymes leak out of damaged acinar cells Pancreatitis, traumatic fat necrosis of the breast. Fibrinoid Immune reactions involving blood vessels Polyarteritis nodosa, SLE, Arthus reaction, rheumatic heart disease, malignant hypertension, etc.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 40-41

Cell Liquefactive Necrosis - StatPearls - NCBI Bookshelf (nih.gov)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: Based on the provided image, which features are indicative of the type of gangrene depicted? {{caption_text}} (Q845334)

A. Presence of gas bubbles in the affected tissue

B. Formation of bullae filled with fluid

C. Dry, shrunken, and mummified appearance with a clear demarcation

D. Presence of foul-smelling discharge and crepitus on palpation

Correct Answer: C. Dry, shrunken, and mummified appearance with a clear demarcation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The image shows dry gangrene, characterized by a dry, shrunken, mummified appearance with a well-defined line of demarcation. Difference between dry gangrene and wet gangrene: Dry gangrene Wet gangrene Site Commonly limbs More common in the bowel Mechanism Arterial occlusion More commonly, venous obstruction Pathology Coagulative necrosis Liquefactive necrosis Macroscopy Organ dry, shrunken, and black Part is moist, soft, swollen, rotten, and dark Line of demarcation Present - at the junction between healthy and gangrenous part No clear-cut line of demarcation Infection No infection, therefore no pus or any fluid Infection present, with pus formation Prognosis Generally better due to little septicemia. Generally poor due to profound toxaemia. Presence of gas bubbles in the affected tissue (Option A) and Presence of foul-smelling discharge and crepitus on palpation (Option D) describe features more characteristic of gas gangrene because of development of gas or bacterial formation leading to formation of gas bubbles. Formation of bullae filled with fluid (Option B) is a feature of Wet gangrene : Wet, swollen, blistered skin that leaks pus/watery fluid with bad smell (infection makes tissue soggy). This image is dry, no blisters/swelling .

@Neet_pg_bot

Q22: Which of the following conditions does not involve fibrinoid necrosis? (Q845330)

A. Systemic Lupus Erythematosus.

B. Malignant hypertension

C. Atherosclerosis

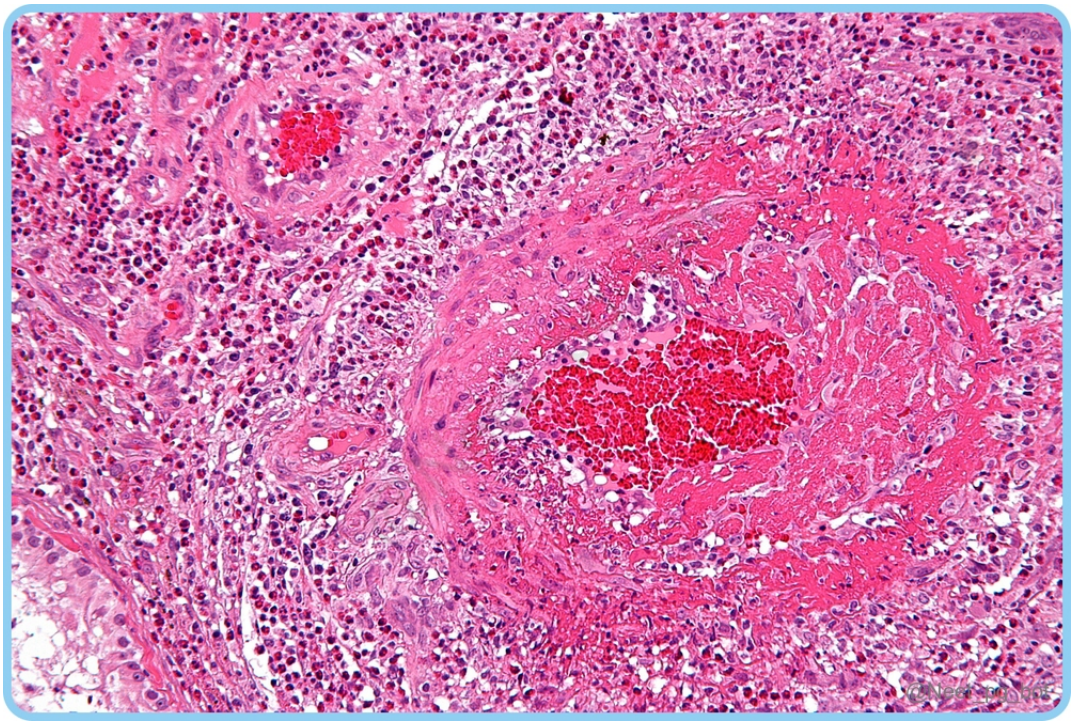
D. Polyarteritis Nodosa (PAN)

Correct Answer: C. Atherosclerosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Atherosclerosis (cholesterol or fat deposition in blood vessels) is not involved in Fibrinoid Necrosis. Fibrinoid necrosis: It is associated with antibody-antigen complex → immune complex deposition in vessel walls → a fibrin-like appearance in vessel walls. It's seen in type I or III hypersensitivity reactions. Observed in conditions like, Polyarteritis nodosa (PAN) (Option D) Rheumatic heart disease (with Aschoff bodies), Systemic lupus erythematosus (SLE) (Option A) Malignant hypertension (Option B) {{caption_text}} Note: Fibrinoid necrosis = plasma proteins (fibrinogen) leak through damaged endothelium → polymerize in vessel wall (eosinophilic, Congo-red negative). Atherosclerosis involves chronic lipid-driven inflammation without this acute vascular wall fibrin deposition.



References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 41

↑ *Back to this question in Part A*

@Neet_pg_bot

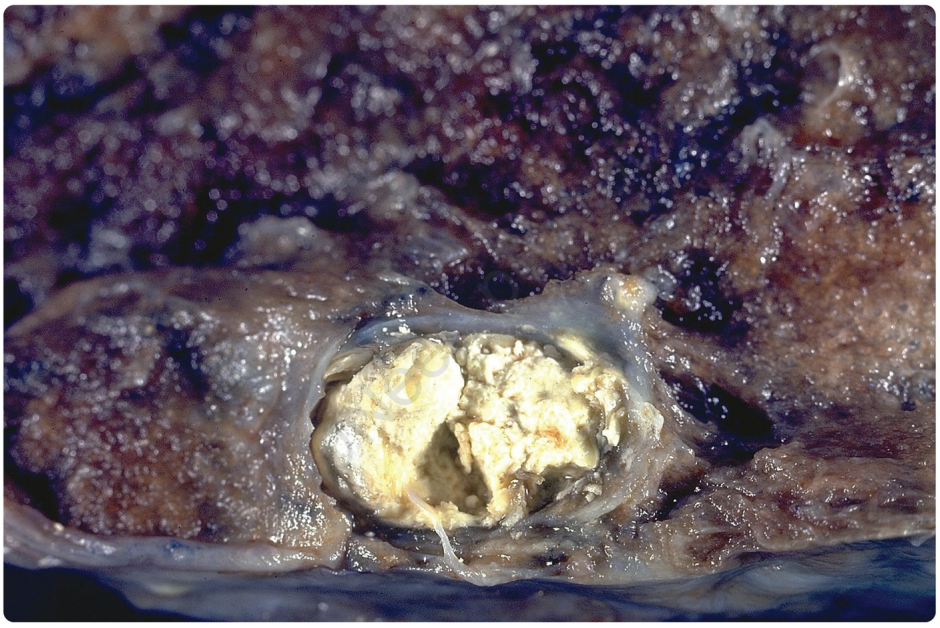
Q23: A 45-year-old man presents to the clinic with a persistent cough, weight loss, and night sweats. A chest X-ray shows cavitary lesions in the upper lobes of the lungs. Sputum analysis is positive for acid-fast bacilli. A biopsy is taken, and a cut section of the lung is shown below.What type of necrosis is most likely present in this patient's lung tissue? (Q845324)

A. Coagulative necrosis

B. Caseous necrosis

C. Fatty necrosis

D. Liquefactive necrosis



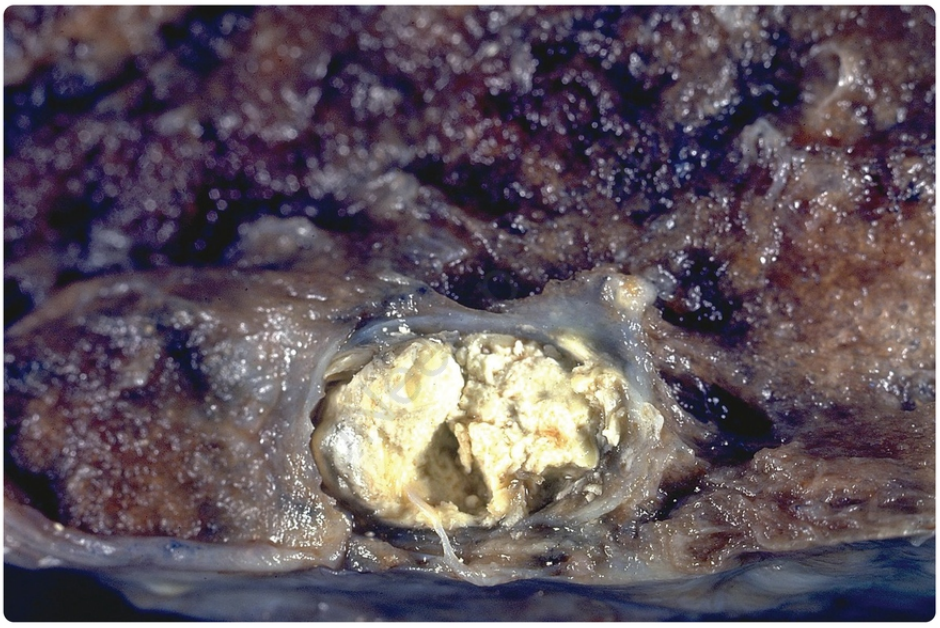
@Neet_pg_bot

Correct Answer: B. Caseous necrosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This is a case of Pulmonary tuberculosis which presents with Caseous Necrosis in the lungs. Caseous necrosis is characterized by a cheese-like appearance of affected tissues (Option B) Results from the combination of coagulative necrosis (most common form of necrosis) and liquefactive necrosis. It is associated with high lipid content in the cell walls Commonly seen in conditions (high lipid content) such as Tuberculosis (caseating granuloma with mycolic acid deposition), Fungal infections (histoplasmosis, coccidioidomycosis), Syphilis. {{caption_text}}



References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 40

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 65 year male presents with weakness on the right half of his body. He is a known case of atrial fibrillation, not on any treatment. CT angiography shows a complete occlusion of a small branch of the middle cerebral artery. What is the most likely change seen in this pathology? (Q845318)

A. Coagulative necrosis

B. Liquefactive necrosis

C. Apoptosis

D. Fibrinoid necrosis

Correct Answer: B. Liquefactive necrosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario is suggestive of ischemic stroke due to thromboembolism - affected area of the brain shows liquefaction necrosis/colliquative necrosis. Coagulative Necrosis (Option A) is seen in solid organs like the kidney, liver, and heart (Most common) Fibrinoid Necrosis (Option D) is seen in cases where antigen-antibody complexes are formed (E.g., PAN, RHD, Malignant HTN and SLE) Apoptosis (Option C) is a programmed cell death. Physiological: Organogenesis or Embryogenesis. Pathological: 2 bodies: Councilman bodies seen with Hepatitis-C Virus Colloid bodies or Civatte bodies seen in Lichen planus. {{caption_text}}

Q1: Which option best characterizes the cellular phenomenon known as anaplasia? (Q879557)

A. Abnormal increase in cell size

B. Loss of cellular differentiation

C. Replacement of one mature cell type with another

D. Physiological increase in cell number

Correct Answer: B. Loss of cellular differentiation

Explanation: The term anaplasia literally means “backward formation”, implying dedifferentiation, or loss of the structural and functional differentiation of normal cells. Tumors composed of undifferentiated cells are said to be anaplastic, a feature that is a reliable indicator of malignancy.

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 188

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Bronchial biopsy in a middle-aged chronic smoker shows replacement of columnar epithelium by squamous epithelium. Deficiency of which vitamin can contribute to this metaplastic change? (Q879553)

A. Vitamin K

B. Vitamin E

C. Vitamin D

D. Vitamin A

Correct Answer: D. Vitamin A

Explanation: Vitamin A (retinoic acid) deficiency can also induce squamous metaplasia in the respiratory epithelium and in the cornea, the latter with highly deleterious effects on vision.

References:

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 18

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following conditions is associated with metaplastic transformation into connective tissue? (Q879547)

A. Myositis ossificans

B. Squamous metaplasia of bronchi

C. Barrett's esophagus

D. Chronic gastric reflux

Correct Answer: A. Myositis ossificans

Explanation: Connective tissue metaplasia is the formation of cartilage, bone, or adipose cells (mesenchymal tissues) in tissues that normally do not contain these elements. Myositis ossificans- Bone formation in muscle occasionally occurs after intramuscular hemorrhage. This type of metaplasia is less clearly seen as an adaptive response and may be a result of cell or tissue injury. Unlike epithelial metaplasia, this type of metaplasia is not associated with increased cancer risk.

References:

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page no. 61

↑ *Back to this question in Part A*

@Neet_pg_bot

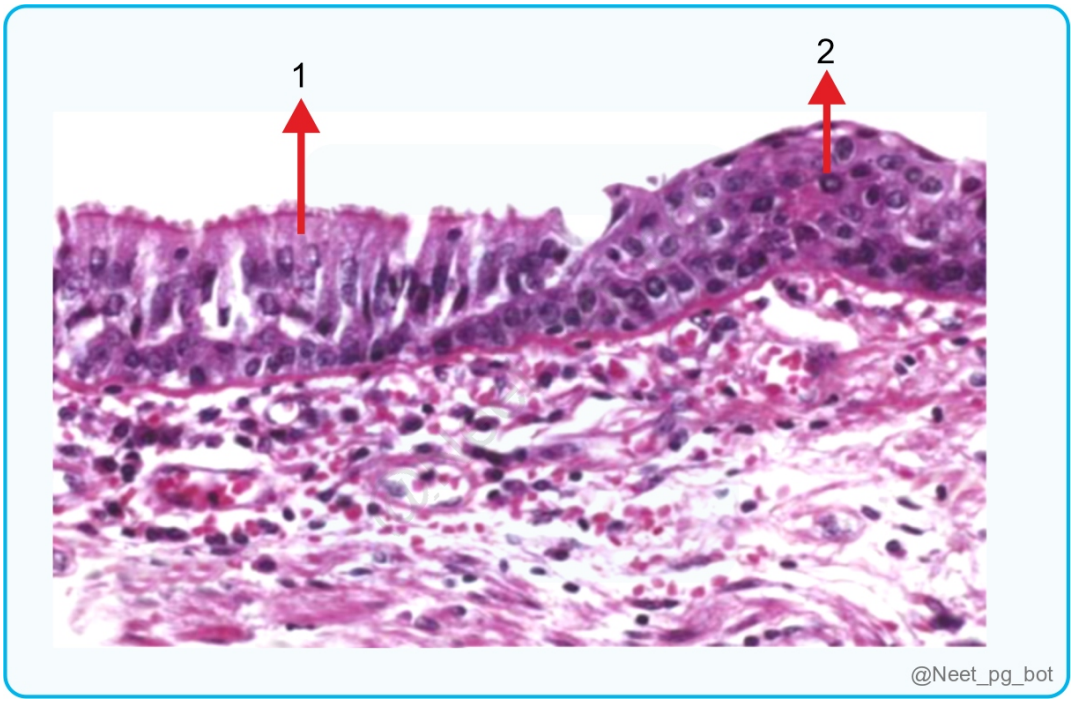
Q4: The image below is the lining epithelium of a middle-aged man who is a chronic smoker. Which of the following is the correct marking? (Q879540)

A. 1. Normal columnar epithelium 2. Squamous metaplasia

B. 1. Columnar metaplasia 2. Normal squamous epithelium

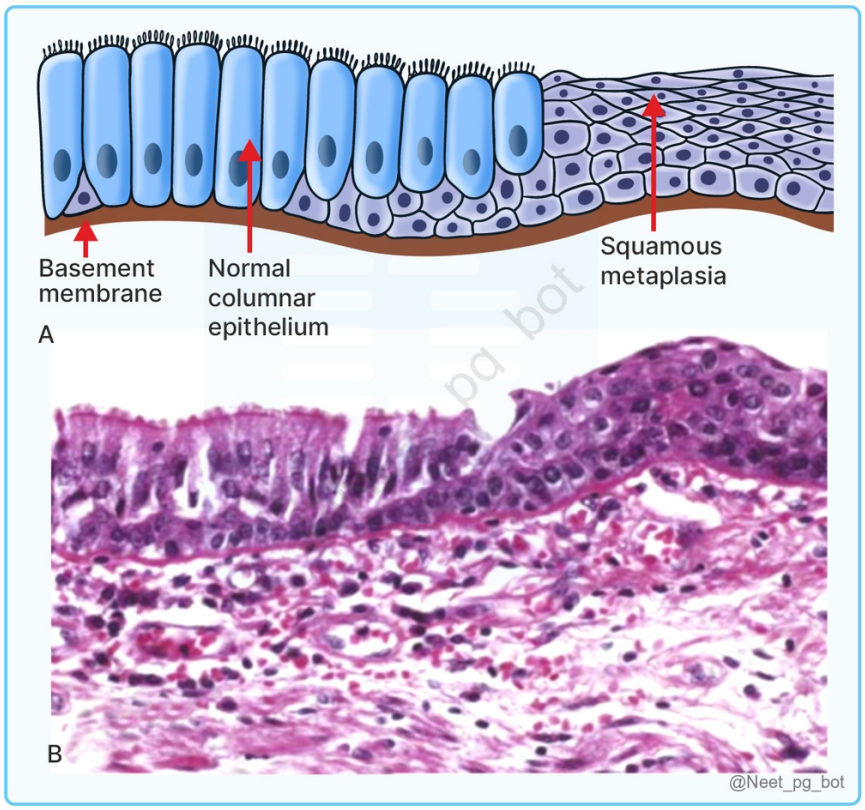
C. 1. Normal squamous epithelium 2. Columnar metaplasia

D. 1. Normal columnar epithelium 2. Normal squamous epithelium



Correct Answer: A. 1. Normal columnar epithelium 2. Squamous metaplasia

Explanation: Epithelial metaplasia is exemplified by the change in the respiratory epithelium that occurs with prolonged cigarette smoking. In this process, the normal, relatively delicate ciliated columnar epithelial cells of the trachea and bronchi are replaced by tough stratified squamous epithelial cells, which are better suited to withstand the noxious chemicals in cigarette smoke.



References:

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 18

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which epithelial transformation is encountered most frequently as an example of metaplasia? (Q879538)

A. Replacement of squamous epithelium by columnar epithelium

B. Replacement of squamous epithelium by transitional epithelium

C. Replacement of columnar epithelium by transitional epithelium

D. Replacement of columnar epithelium by squamous epithelium

Correct Answer: D. Replacement of columnar epithelium by squamous epithelium

Explanation: The most common epithelial metaplasia is columnar to squamous, as occurs in the respiratory tract in response to chronic irritation. In the habitual cigarette smoker, the normal ciliated columnar epithelial cells of the

trachea and bronchi are often replaced by stratified squamous epithelial cells.

References:

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page no. 61

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Below is the image of a 79-year-old male with a history of long-standing atherosclerosis who presented with progressive cognitive decline and neurological deficits. What type of atrophy is noticed in the image? (Q879536)

A. Nutritional atrophy

B. Neurogenic atrophy

C. Pressure atrophy

D. Ischemic atrophy

Correct Answer: D. Ischemic atrophy

Explanation: Based on the clinical scenario, the patient had atherosclerotic cerebrovascular disease, and the gross image shows ischemic atrophy. Findings noted: Atrophy of the brain is due to aging and reduced blood supply. Note that loss of brain substance narrows the gyri and widens the sulci. The meninges have been stripped from the bottom half of each specimen to reveal the surface of the brain.

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 18

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: In which of the following scenarios do both physiological hypertrophy and hyperplasia occur? (Q879535)

A. Enlargement of skeletal muscle with exercise

B. Left ventricular thickening in hypertension

C. Uterine growth during pregnancy

D. Enlargement of breast tissue at puberty

Correct Answer: C. Uterine growth during pregnancy

Explanation: Physiologic enlargement of the uterus during pregnancy occurs as a consequence of estrogen-stimulated smooth muscle hypertrophy and hyperplasia. Enlargement of skeletal muscle with exercise (Option A): Skeletal muscles undergo only hypertrophy, as these cell types have a limited capacity to divide. Left ventricular thickening in hypertension (Option B): Left ventricular hypertrophy is a pathological type of hypertrophy occurring due to hypertension. Enlargement of breast tissue at puberty (Option D): Enlargement of breast tissue at puberty due to proliferation of the glandular epithelium is a physiological type of hyperplasia

References:

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Pages 16 & 17

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following organs undergoes only hypertrophy? (Q879516)

A. Breast

B. Heart

C. Liver

D. Uterus

Correct Answer: B. Heart

Explanation: In response to increased workload, the striated muscle cells in both the skeletal muscle and the heart undergo only hypertrophy, as these cell types have a limited capacity to divide.

References:

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 16

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: By which of the following mechanisms does muscle hypertrophy occur? (Q879514)

A. ■-myosin heavy chain is replaced by the ■ form of the myosin heavy chain

B. ■-myosin heavy chain is replaced by the ■ form of the myosin light chain

C. ■-myosin light chain is replaced by the ■ form of the myosin heavy chain

D. ■ form of the myosin light chain is replaced by the ■-myosin heavy chain

Correct Answer: A. ■-myosin heavy chain is replaced by the ■ form of the myosin heavy chain

Explanation: Activation of signal transduction pathways induces the expression of genes that encode several cellular proteins, resulting in: Synthesis of more myofilaments per cell, which increases the force generated with each contraction, enabling the cell to meet increased work demands. Also, there may be a switch of contractile proteins from adult to fetal or neonatal forms. For example, during hypertrophy, the ■ -myosin heavy chain is replaced by the ■ form of the myosin heavy chain, which produces slower, more energetically efficient contractions.

References:

Robbins & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 16

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following statements accurately describes cellular adaptations in response to environmental changes? (Q879512)

A. Hypertrophy refers to an increase in cell number without a change in cell size

B. Hyperplasia is an increase in cell size without an increase in cell number

C. Metaplasia is a reversible change of one differentiated cell type to another

D. Atrophy results from a combination of increased protein synthesis and decreased protein degradation

Correct Answer: C. Metaplasia is a reversible change of one differentiated cell type to another

Explanation: Metaplasia is a reversible change in which one adult cell type is replaced by another adult cell type. Metaplasia is thought to usually arise by reprogramming of stem cells to differentiate along a new pathway rather than a phenotypic change of differentiated cells (transdifferentiation). Incorrect Options: Hypertrophy refers to an increase in cell number without a change in cell size (Option A): Hypertrophy refers to an enlargement of cells that results in increase in the size of the organ. Hyperplasia is an increase in cell size without an increase in cell number (Option B): Hyperplasia is an increase in the number of cells in an organ that stems from increased proliferation, either of differentiated cells or, in some instances, progenitor cells. Atrophy results from a combination of increased protein synthesis and decreased protein degradation (Option D): Atrophy results from a combination of decreased protein syn- thesis and increased protein degradation.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 55.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A pathology resident is reviewing special stains for detecting tissue deposits. Which of the following stains is not used for demonstrating calcium in histological sections? (Q879411)

A. Congo red

B. Von Kossa stain

C. Alizarin Red S

D. Azan stain

Correct Answer: A. Congo red

Explanation: Congo red is used for amyloid detection, not calcium. Von Kossa stain identifies (Option B) calcium salts as black deposits via silver reduction. Alizarin Red S (Option C) binds calcium directly, producing orange-red coloration. Azan stain (Option D) is mainly for connective tissue, but can highlight calcium secondarily.

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 230,

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 55-year-old man with long-standing hyperlipidemia presents with multiple yellowish nodules over his Achilles tendon and extensor tendons of the hands. Biopsy of one lesion shows foam cells packed with cholesterol and cholesterol esters. Which of the following conditions does this represent? (Q879407)

A. Fabry's disease

B. Xanthoma

C. Niemann-Pick disease type C

D. Strawberry gallbladder

Correct Answer: B. Xanthoma

Explanation: Xanthomas are nodular lesions composed of lipid-laden macrophages filled with cholesterol and cholesterol esters , often seen in hyperlipidemic states. Incorrect Options: Fabry disease (Option A) involves the buildup of sphingolipids (ceramide trihexoside), not cholesterol. Niemann-Pick disease type C (Option C) is a disorder of cholesterol transport, leading to systemic lysosomal storage of cholesterol, not just localized deposits. Strawberry gallbladder(Option D) shows cholesterolosis, where macrophages in the gallbladder wall accumulate cholesterol esters, giving the mucosa a speckled “strawberry” appearance.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 57,136.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following statements regarding metaplasia is true? (Q845260)

A. Metaplasia refers to the abnormal growth of cells, often leading to cancer.

B. It is a reversible change in which one adult cell type is replaced by another adult cell type.

C. Metaplasia is always a pathological process and never occurs in response to normal physiological stimuli.

D. Metaplasia is characterized by the replacement of differentiated cells with undifferentiated stem cells.

Correct Answer: B. It is a reversible change in which one adult cell type is replaced by another adult cell type.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Metaplasia is a reversible process in which one adult cell type is replaced by another, typically in response to chronic irritation or inflammation. Either 1 epithelium can change into another or 1 mesenchymal cell can change into another mesenchymal cell In metaplasia, normal cells are involved. If cells are abnormal, then it is Dysplasia (Option A ruled out) Metaplasia can sometimes occur in response to normal physiological stimuli (Option C ruled out) In metaplasis, the programming of stem cells is changing, because of which previous epithelium is replaced by new epithelium (Option D ruled out) Key features of metaplasia: Nature: Reversible if the stimulus (stressor) is removed. Mechanism: Reprogramming of stem cells (not existing cells changing their "shape"). Survival Advantage: The new cells are tougher and can survive the stress better. Functional Loss: The new cells lack the original function (e.g., loss of mucus secretion or cilia in the lungs). Malignant Potential: If the stress persists, metaplasia can progress to Dysplasia and eventually Cancer . Examples of Metaplasia: Epithelial Metaplasia (The most common type): Squamous metaplasia in the respiratory tract: Replacement of ciliated columnar epithelium by stratified squamous epithelium in the lungs of chronic smokers. Barrett’s Esophagus (Gastric/Intestinal metaplasia): Replacement of squamous epithelium of the esophagus by columnar (goblet) cells due to chronic acid reflux (GERD). Squamous metaplasia of the uterine cervix: Replacement of simple columnar epithelium by stratified squamous epithelium due to chronic inflammation or changes in vaginal pH. Squamous metaplasia in the bladder: Replacement of transitional epithelium (urothelium) by squamous epithelium due to irritation from bladder stones or Schistosoma haematobium infection. Squamous metaplasia of the gallbladder: Replacement of columnar epithelium by squamous epithelium due to chronic irritation from gallstones (cholelithiasis). Ductal squamous metaplasia: Replacement of the columnar lining of ducts (salivary glands, pancreas, or bile ducts) by squamous epithelium, usually due to stones (calculi). Connective Tissue (Mesenchymal) Metaplasia: Myositis ossificans: The formation of bone (osseous tissue) within skeletal muscle following a severe intramuscular hematoma or repetitive trauma. Cartilaginous metaplasia: The formation of cartilage in soft tissues where it does not normally belong, often following chronic injury.

@Neet_pg_bot

Q14: Which of the following statements best describes the role of telomerase in cellular ageing? (Q845194)

A. Telomerase accelerates ageing by reducing the length of telomeres with each cell division

B. Telomerase maintains the constant telomere length in somatic cells throughout their lifespan.

C. Telomerase prevents the shortening of telomeres by adding DNA sequences to the ends of chromosomes, thus potentially extending cell's lifespan.

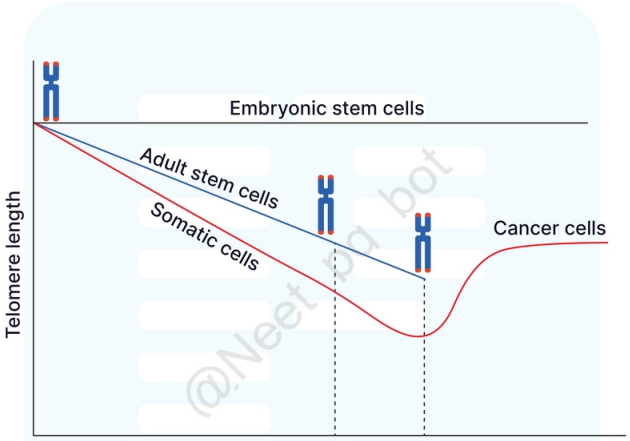
D. Telomerase is a Ribozyme delaying cell aging.

Correct Answer: C. Telomerase prevents the shortening of telomeres by adding DNA sequences to the ends of chromosomes, thus potentially extending cell's lifespan.

Listen (English)

Listen (Hindi)

Explanation: Telomerase prevents the shortening of telomeres by adding DNA sequences to the ends of chromosomes, thus potentially extending cells' lifespan. Telomere: It is the sequence present on the terminal of chromosomes. Ageing is due to the shortening of telomeres as the person grows. Telomerase , also known as the immortality gene, is an RNA-dependent DNA polymerase enzyme that adds DNA sequences to the ends of chromosomes, preventing telomere shortening during cell division.



@Neet_pg_bot

Q15: Which type of metaplasia characterizes the histological changes observed in Barrett's oesophagus? (Q845257)

A. Transformation of columnar epithelium to squamous epithelium

B. Replacement of squamous epithelium with columnar epithelium containing goblet cells

C. Conversion of glandular epithelium to squamous epithelium

D. Substitution of mesenchymal cells with epithelial cells

Correct Answer: B. Replacement of squamous epithelium with columnar epithelium containing goblet cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Barrett's oesophagus is characterized by the replacement of the normal squamous epithelium of the lower oesophagus with columnar epithelium containing goblet cells. (Goblet cells contain acidic mucin staining positive with alcian blue, which helps to differentiate from intestinal epithelium) This metaplastic change is considered an adaptive response to chronic exposure to gastric acid and bile reflux in the setting of gastroesophageal reflux disease (GERD). {{caption_text}} Metaplasia: Metaplasia is a reversible change in which one differentiated cell type (epithelial or mesenchymal) is replaced by another adult cell type. Key features of metaplasia: Nature: Reversible if the stimulus (stressor) is removed. Mechanism: Reprogramming of stem cells (not existing cells changing their "shape"). Survival Advantage: The new cells are tougher and can survive the stress better. Functional Loss: The new cells lack the original function (e.g., loss of mucus secretion or cilia in the lungs). Malignant Potential: If the stress persists, metaplasia can progress to Dysplasia and eventually Cancer . Some important metaplasias: Epithelial Metaplasia: Squamous metaplasia (columnar → squamous) : Bronchi in smokers: Ciliated columnar → stratified squamous for durability.■ Salivary ducts/pancreas/bile ducts: Due to stones.■ Endocervix: In prolapse/old age.■ Renal pelvis: Chronic stones.■ Intestinal metaplasia (squamous/columnar → intestinal columnar with goblet cells) : Stomach (H. pylori/chronic gastritis).■ Barrett's esophagus (already discussed).■ Other : Breast: Acinar → apocrine cells (fibrocystic changes).■ Mesenchymal Metaplasia: Osseous metaplasia (soft tissue → bone): Arterial wall (Mönckeberg's sclerosis: aging/diabetes).■ Myositis ossificans (muscle → bone post-trauma).■■ Larynx/bronchi cartilage (elderly).■ Tumor stroma/scars.

@Neet_pg_bot

Q16: Which type of atrophy is observed in a patient with smaller and weaker muscles who is bedridden for several weeks? (Q845255)

A. Disuse atrophy

B. Neurogenic atrophy

C. Endocrine atrophy

D. Senile atrophy

Correct Answer: A. Disuse atrophy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Disuse atrophy is seen in a patient with smaller, weaker muscles after being bedridden for several weeks. During prolonged periods of immobility, such as extended bed rest, the muscles experience decreased mechanical loading and activity. This lack of stimulation decreases muscle protein synthesis and increases protein breakdown, resulting in muscle wasting and weakness. Neurogenic atrophy (Option B): Atrophy due to hampered nerve supply. E.g.- In polio patients, the muscle will become immobile, leading to neurogenic atrophy. Endocrine

atrophy (Option C): Atrophy due to a decrease in hormones. E.g. - A decrease in the level of estrogens leading to endometrial atrophy, which is seen in postmenopausal women. Senile atrophy (Option D): Seen in old age and in patients with Alzheimer's disease.

@Neet_pg_bot

Q17: Which of the following is an example of physiological atrophy? (Q845254)

A. Testicular atrophy due to hypogonadism

B. Intestinal villi atrophy in malabsorption syndromes

C. Reduction in thymus gland size during ageing

D. Brain atrophy in neurodegenerative diseases

Correct Answer: C. Reduction in thymus gland size during ageing

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Reduction in thymus gland size during ageing is an example of physiological atrophy. Physiological atrophy refers to the normal, programmed decrease in the size or mass of tissues, organs, or structures in the body. The thymus gland, which is involved in the development of the immune system, tends to decrease in size and activity with age, which is an example of physiological atrophy. Some other examples of Physiological atrophy: Reduction in the notochord size during the formation of the vertebral column. Disappearance of the thyroglossal duct during fetal development. Atrophy of the ductus arteriosus after birth to become the ligamentum arteriosum. Atrophy of the umbilical arteries and vein after birth. Atrophy of the branchial clefts during embryonic facial development. Regression of the Wolffian ducts in females and Müllerian ducts in males during fetal sex differentiation. Reduction in size of tonsils and adenoids during late adolescence and adulthood. Reduction in uterine size following childbirth (post-partum involution). Atrophy of mammary glands after the cessation of lactation. Reduction in endometrial thickness following menopause. Atrophy of the ovaries after menopause. Pathological atrophy , on the other hand, refers to the abnormal decrease in the size or mass of tissues, organs, or structures due to disease, injury, or other abnormal conditions. Testicular atrophy, intestinal atrophy and brain atrophy are examples of pathological atrophy. (Options A, B, D ruled out) Some other examples: Disuse Atrophy (Lack of Activity): Reduction in skeletal muscle mass in a limb immobilized by a plaster cast. Atrophy of muscles in patients restricted to prolonged bed rest. Denervation Atrophy (Loss of Nerve Supply): Wasting of skeletal muscles following a spinal cord injury. Reduction in muscle bulk due to damage from poliomyelitis. Atrophy of facial muscles following permanent damage to the facial nerve (Bell's Palsy). Ischemic Atrophy (Reduced Blood Supply): Reduction in brain size (thinning of gyri) due to chronic atherosclerosis of the carotid arteries. Atrophy of the kidneys due to narrowing of the renal arteries (Renal Artery Stenosis). Endocrine Atrophy (Pathological Loss

of Stimulation): Atrophy of the adrenal cortex due to the long-term use of exogenous corticosteroids. Reduction in the size of the thyroid gland due to a lack of TSH from a diseased pituitary gland. Atrophy of the testes following the use of exogenous anabolic steroids or due to hypogonadism

@Neet_pg_bot

Q18: Which of the following statements about the mechanism of hypertrophy is inaccurate? (Q845250)

A. Activation of G-protein-coupled receptor-initiated pathways

B. Stimulation of growth factor production such as TGF-β and IGF1

C. Inhibition of transcription factors like GATA4, MEF2, NFAT

D. Activation of downstream pathways including the PI3K/AKT pathway

Correct Answer: C. Inhibition of transcription factors like GATA4, MEF2, NFAT

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypertrophy actually involves the activation (not inhibition) of transcription factors such as GATA4, NFAT, and MEF2. They enhance the expression of genes encoding muscle proteins, promoting cellular growth and hypertrophy. When transcription factors will increase: More DNA will be converted to RNA, which will create more proteins, leading to an increase in cell size (hypertrophy). Activation of G-protein-coupled receptor-initiated pathways (Option A): Many hypertrophic stimuli (e.g., catecholamines, angiotensin II, endothelin) act via G■protein–coupled receptors (GPCRs) on the cell membrane. These receptors signal through G proteins (especially Gq, Gi) to activate phospholipase C, PKC and MAPK pathways, which promote gene transcription and protein synthesis leading to hypertrophy. Stimulation of growth factor production such as TGF-β and IGF1 (Option B): Growth factors such as TGF■β and IGF■1 are upregulated in response to increased workload or injury and act as potent pro■hypertrophic mediators. IGF■1 in particular drives physiological cardiac and skeletal muscle hypertrophy via its receptor tyrosine kinase, triggering downstream PI3K/AKT signaling and increased protein synthesis. Activation of downstream pathways including the PI3K/AKT pathway (Option D): The PI3K/AKT pathway is a central pro■growth signaling cascade in physiological hypertrophy, especially downstream of IGF■1. Activation of AKT promotes protein synthesis and cell survival and suppresses atrophy pathways (e.g., via inhibition of FOXO), leading to increased cell size consistent with hypertrophy.

Robbins and Cotran Pathologic basis of disease, 10th Edition, Page 57, 58

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 45-year-old female presents with irregular and heavy menstrual bleeding for the past six months. She reports experiencing prolonged periods lasting more than ten days with excessive bleeding, abdominal discomfort, and pelvic pain during her menstrual cycle. On further evaluation, transvaginal ultrasound reveals thickening of the endometrial lining. Endometrial biopsy confirms the presence of abnormal glandular proliferation without cytologic atypia. Which of the following best describes the cellular adaptation observed in this clinical scenario? (Q845248)

A. Physiological hypertrophy

B. Pathological hypertrophy

C. Physiological hyperplasia

D. Pathological hyperplasia

Correct Answer: D. Pathological hyperplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This is a case of endometrial hyperplasia, a pathological hyperplasia. Definition Examples Physiological hypertrophy (Option A) Increase in the size of cells or organs. Uterine hypertrophy during pregnancy due to estrogenic hormone signalling. Pathological hypertrophy (Option B) Cell enlargement occurs in response to increased workload or stress Heart enlargement from hypertension or valvular disease. Physiological hyperplasia (Option C) An increase in the number of cells in response to hormonal or growth factor stimulation. Breast glandular epithelium proliferation during puberty or pregnancy. Pathological hyperplasia (Option D) Occurs when there is an abnormal increase in the number of cells in an organ or tissue due to excessive or inappropriate hormonal or growth factor stimulation Endometrial hyperplasia due to disturbance in estrogen-progesterone balance.

Robbins and Cotran Pathologic basis of disease, 10th Edition, Pages 57-59

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: Which statement accurately distinguishes between hypertrophy and hyperplasia? (Q845245)

A. Hypertrophy involves an increase in cell number, while hyperplasia involves an increase in cell size.

B. Hypertrophy increases tissue mass, while hyperplasia maintains tissue mass.

C. Hypertrophy is irreversible, while hyperplasia is reversible.

D. Hypertrophy results from increased cellular protein production, while hyperplasia involves growth factor-driven proliferation of mature cells.

Correct Answer: D. Hypertrophy results from increased cellular protein production, while hyperplasia involves growth factor-driven proliferation of mature cells.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypertrophy results from increased cellular protein production, while hyperplasia involves growth factor-driven proliferation of mature cells. Hypertrophy Hyperplasia Hypertrophy is characterized by increased cellular protein (GATA4, NFAT, MEF2) production, which leads to the enlargement of cells and tissues due to an increase in cell size. An increase in cellular proteins occurs either through enhanced central dogma processes (transcription and translation) or through an increase of transcription factors. Hyperplasia is described as the result of growth factor-driven proliferation of mature cells. In hyperplasia, the number of cells within an organ or tissue increases. Hypertrophy involves an increase in cell size, while hyperplasia involves an increase in cell number. (Option A ruled out) Both hypertrophy and hyperplasia increase tissue mass. (Option B ruled out) Hypertrophy can be reversible. (Option C ruled out)

@Neet_pg_bot

Q21: Which of the following biomarkers is associated with autophagy? (Q845243)

A. Annexin A1

B. Annexin V

C. Beclin 1

D. LC3

Correct Answer: D. LC3

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: LC3, or Microtubule-associated protein 1 light chain 3, is a reliable marker of autophagy. Most important gene for autophagy: ATG1 gene Annexin A1 (Option A): Annexin A1 is a marker of hairy cell leukaemia. Annexin 5 (Option B): Marker of apoptosis Beclin 1 (Option C): Beclin-1 is not a direct marker of autophagy but plays a crucial role in initiating autophagy

References:

Robbins and Cotran Pathologic basis of disease, 10th Edition, Page48

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: What is the mechanism by which chaperone-mediated autophagy (CMA) targets misfolded proteins for degradation? (Q845240)

A. Direct uptake by lysosomes via endocytosis

B. Activation of mTOR leading to inhibition of ULK1 complex

C. Selective degradation of damaged or dysfunctional mitochondria

D. Binding of chaperones to misfolded proteins, followed by lysosomal entry via LAMP2A for autophagy

Correct Answer: D. Binding of chaperones to misfolded proteins, followed by lysosomal entry via LAMP2A for autophagy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In chaperone-mediated autophagy, chaperone proteins (Eg, Heat shock proteins) recognize and bind to specific protein substrates that are misfolded or damaged. The chaperone-substrate complex then interacts with the lysosomal-associated membrane protein LAMP2A, facilitating the substrate protein's translocation into the lysosome for degradation. Direct uptake by lysosomes via endocytosis (Option A) is mechanism is observed in Microautophagy. Inhibition of mTOR leading to activation of ULK1 complex (Option B) is seen in Macroautophagy. Selective degradation of damaged or dysfunctional mitochondria (Option C) is seen in Mitophagy.

References:

Robbins and Cotran Pathologic basis of disease, 10th Edition, Page 60.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: Which cellular process is primarily responsible for the degradation and recycling of unnecessary or dysfunctional cellular components? (Q845237)

A. Autophagy

B. Necrosis

C. Apoptosis

D. Pyroptosis

Correct Answer: A. Autophagy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Autophagy (aka cell cannibalism) is a cellular process by which a cell eats its own contents and plays a critical role in maintaining cellular homeostasis, responding to stressors such as nutrient deprivation, and eliminating potentially harmful cellular materials. Autophagy has 4 types: Macro-autophagy: Eats substrate by forming a membrane around it (Autophagosome) Micro-autophagy: Eats substrate by endocytosis Chaperone-mediated autophagy Mitophagy: Mitochondria are eaten Marker of autophagy: LC3 Most important gene for autophagy: ATG1 gene

@Neet_pg_bot

Q24: A 36-year-old male presents to the clinic with complaints of bilateral cataracts, short stature, premature greying and loss of hair, and skin changes. He also reports joint stiffness and pain, as well as type 2 diabetes mellitus. On examination, the patient appears older than his stated age, with characteristic "bird-like" facies and a high-pitched voice. Which of the following conditions is most likely to be associated with his presentation? (Q845202)

A. Hutchinson-Gilford Syndrome

B. Werner syndrome

C. Wermer syndrome

D. Cockayne Syndrome

Correct Answer: B. Werner syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation points towards Werner syndrome, also known as Adult Progeria Syndrome , an autosomal recessive disorder characterized by premature ageing features that typically manifest in adulthood . It is associated with a DNA helicase defect. Patients with Werner Syndrome are typically present in their third decade of life with symptoms of accelerated ageing. Clinically present with premature ageing features, including bilateral cataracts, short stature, premature greying and loss of hair, skin changes, joint stiffness and pain, and metabolic abnormalities such as type 2 diabetes mellitus. The characteristic "bird-like" facies and high-pitched voice are distinctive features of Werner Syndrome. Genetic mutation: WRN gene . [WRN = Werner syndrome gene (on chromosome 8)]. {{caption_text}} Hutchinson-Gilford Syndrome (Option A): It is a rare genetic

progeroid syndrome characterized by severe premature ageing features that begin in childhood . It is a Laminopathy due to a Lamin-A (LMNA) gene mutation. Wermer Syndrome (Option C): Wermer Syndrome is for as multiple endocrine neoplasia type 1 (MEN 1). Cockayne Syndrome (Option D): It is also a rare autosomal recessive progeroid syndrome. However, it typically presents in childhood. ERCC gene defect.

@Neet_pg_bot

Q25: How do “Sirtuins” contribute to cellular ageing? (Q845198)

A. By accelerating telomere shortening.

B. By enhancing cell repair mechanisms and exerting anti-ageing effects.

C. By functioning as histone acetyltransferases, promoting chromatin condensation.

D. By decreasing insulin sensitivity

Correct Answer: B. By enhancing cell repair mechanisms and exerting anti-ageing effects.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Sirtuins are a family of NAD-dependent protein deacetylases produced by SIRT genes (SIRT1-7) that play a key role in DNA repair mechanisms and are involved in maintaining genomic stability Functions/benefits of sirtuins: Anti-ageing Prevents telomeres from shortening (Option A ruled out) Cell repair Increases the insulin sensitivity of tissues: Beneficial for DM patients and slows down ageing. (Option D ruled out) Sirtuins are histone deacetylases (Option C ruled out) Sirtuins increase insulin sensitivity

References:

Robbins and Cotran Pathologic basis of disease, 10th Edition, Page 80.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: Which of the following statements is correct about the concept of the Hayflick Limit? (Q845196)

A. The ageing of cells is not determined by telomere length.

B. It refers to the age at which cells cease all metabolic activities and undergo apoptosis.

C. A cell typically undergoes 20-40 cell divisions before reaching senescence.

D. It represents the average number of times a cell can divide before experiencing replicative senescence.

Correct Answer: D. It represents the average number of times a cell can divide before experiencing replicative senescence.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Hayflick limit or Hayflick’s phenomenon represents the number of cell divisions a cell undergoes before reaching its replicative senescence or ageing. Somatic cells typically undergo around 60 -100 divisions before entering a state of replicative senescence. Cells start to show signs of ageing after a finite number of divisions due to factors like telomere shortening and changes in gene expression. The limit acts as a safeguard against cancer by preventing cells from dividing uncontrollably. Mechanism: The primary driver of the Hayflick Limit is the telomere . Telomeres are protective "caps" of repetitive DNA sequences at the ends of chromosomes. The End Replication Problem: Each time a cell divides, DNA polymerase cannot fully replicate the very tips of the chromosomes. Gradual Erosion: With every division, the telomeres get slightly shorter. Critical Length: Eventually, the telomeres become so short that they can no longer protect the DNA. This sends a signal to the cell to stop dividing to prevent genomic instability. Exceptions to the Rule: Not all cells are bound by the Hayflick Limit. Some have found ways to bypass the "biological countdown": Stem Cells: These cells express an enzyme called telomerase , which rebuilds the telomeres, allowing them to divide much longer (or indefinitely). Germ

Cells: (Sperm and eggs) also maintain telomerase to ensure the next generation starts with full-length telomeres.
Cancer Cells: Most cancer cells "hijack" the telomerase enzyme. This allows them to become immortal , dividing far past the Hayflick Limit and forming tumors.

Q7 (p. 1049) *Q8 (p. 1051)* *Q9 (p. 1053)* *Q10 (p. 1055)* *Q11 (p. 1055)* *Q12 (p. 1056)*

Q1: Which of the following pathological conditions involves the accumulation of pigments through exogenous sources? (Q845361)

A. Chronic venous insufficiency

B. Vitiligo

C. Obstructive jaundice

D. Coal worker’s pneumoconiosis

Correct Answer: D. Coal worker’s pneumoconiosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, coal workers' pneumoconiosis involves the accumulation of pigments through exogenous sources. Pigments in pathology Endogenous pigments → produced inside the body (melanin, hemosiderin, bilirubin, lipofuscin). Exogenous pigments → come from outside (carbon, dust, tattoo ink). Pneumoconiosis Lung disease due to inhalation & deposition of exogenous dust particles . Most common form → Coal workers’ pneumoconiosis (Anthracosis) . Anthracosis (Black Lung Disease) Caused by the accumulation of carbon particles in alveolar macrophages (“dust cells”). Called Black Lung because the lungs appear black from heavy carbon deposition. The term Anthracosis comes from “Anthrakos” (Greek = coal/charcoal). Caplan Syndrome: Caplan syndrome (rheumatoid pneumoconiosis) is coal dust exposure + rheumatoid arthritis causing multiple peripheral lung nodules (0.5-5 cm) with necrotic centers, resembling rheumatoid nodules but dust-laden. Often asymptomatic; cough/dyspnea if advanced. Seen in miners; nodules appear rapidly, may cavitate/resolve. Differs from simple coal workers' pneumoconiosis by RA association .

@Neet_pg_bot

Q2: A 83-year-old man presents to his gastroenterologist with complaints of fatigue and discomfort in the upper abdomen. He has a history of hypertension and type 2 diabetes mellitus, for which he takes medications regularly. On physical examination, the liver edge is palpable below the right costal margin, indicating hepatomegaly. Laboratory investigations reveal mildly elevated liver enzymes. Which of the following pigments is most likely responsible for the brown discolouration of the liver observed in this patient? (Q845363)

A. Melanin

B. Glycogen

C. Lipofuscin

D. Bilirubin

Correct Answer: C. Lipofuscin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: An 83-year-old man presents with fatigue and upper abdominal discomfort, and physical examination reveals hepatomegaly; mildly elevated liver enzymes are noted on lab tests, and the brown discoloration of the liver is most likely due to the pigment Lipofuscin . Lipofuscin, also known as lipochrome or wear-and-tear pigment, is an insoluble pigment derived from the peroxidation of polyunsaturated lipids in intracellular membranes. It is a telltale sign of free radical injury and lipid peroxidation. It is responsible for the brown atrophy of the liver and heart, where lipofuscin accumulates in the hepatocytes and cardiac myocytes, respectively, due to oxidative damage and impaired cellular turnover, particularly with increasing age. It is also seen in senile atrophy (pigment of the old age). In histopathological examination, it appears as a yellow-brown, finely granular cytoplasmic pigment, often deposited in the perinuclear region. The special stain used for lipofuscin is Oil red O and Acid-fast / Ziehl–Neelsen stain. {{caption_text}} Hemosiderin: Golden-brown iron pigment (Prussian blue+); seen in hemochromatosis (diabetes link), distinguished by iron stain (lipofuscin negative).

Robbins and Cotran pathologic basis of disease, 10th edition, Page 76, 77

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 45-year-old woman presents with a painless, slow-growing, pigmented lesion on her back with irregular borders and varying shades of brown and black. Excisional biopsy of the lesion is performed, and histopathological examination reveals nests of melanocytes within the dermis, with prominent melanin pigment deposition. Which of the following staining techniques would be most suitable for visualization of the melanin pigment within the melanocytes in this patient's biopsy specimen? (Q845365)

A. Massaon Fontana stain

B. Masson Trichome stain

C. Periodic-Acid-Schiff (PAS) stain

D. Immunohistochemical staining for Melan- A

Correct Answer: A. Massaon Fontana stain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 45-year-old woman presents with a painless, slow-growing pigmented lesion on her back characterized by irregular borders and varying shades of brown and black; histopathological examination of an excisional biopsy reveals nests of melanocytes in the dermis with prominent melanin deposition, best visualized using the Masson-Fontana stain . Best for seeing the amount & distribution of melanin pigment (inside/outside melanocytes)-Masson–Fontana stain Other methods: Schmorl’s stain → also for melanin pigment. Enzymatic method (DOPA oxidase test) → best test for melanin production capacity. Immunohistochemistry (for melanocytes / pigment-producing cells): HMB-45 Melan-A It is a marker for melanocytes and melanoma cells and is particularly useful in distinguishing melanocytic lesions from other types of skin tumours or metastatic cancers. On the other side, Masson Fontana staining helps to assess the extent of melanin production within tumors. (Option D ruled out) Key distinction: Pigment visualization → Masson–Fontana Cell identification (melanocytes) → HMB-45, Melan-A {{caption_text}} {{caption_text}} Masson Trichome stain (Option B): Masson Trichrome stain primarily differentiates between collagen and smooth muscle fibres. Periodic-Acid-Schiff (PAS) stain (Option C): Periodic Acid-Schiff (PAS) stain detects carbohydrates such as glycogen and mucin.

@Neet_pg_bot

Q4: A 45-year-old man presents with complaints of fatigue, joint pain, and abdominal discomfort. On examination, he exhibits bronze-coloured skin pigmentation mainly on the face and hands. Laboratory tests reveal elevated serum ferritin levels and transferrin saturation. Which of the following staining techniques would be most appropriate to visualize hemosiderin deposition in tissues in this patient? (Q845368)

A. Perl’s stain

B. Lillie's stain

C. Rhodanine stain

D. Supravital stains

Correct Answer: A. Perl’s stain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 45-year-old man presents with fatigue, joint pain, and abdominal discomfort, along with bronze-colored skin pigmentation on the face and hands; laboratory tests show elevated serum ferritin and transferrin saturation, and the most appropriate staining technique to visualize tissue hemosiderin deposition in this patient is Perls' stain . Perl's stain, also known as Prussian Blue stain is the stain used to detect hemosiderin. Gold standard for Fe^{3}■ iron (gives blue color). The given clinical scenario suggests the patient is suffering from Hemochromatosis, an iron overload disorder in which excessive iron is deposited in various tissues as hemosiderin, a golden yellow to brown, granular, or crystalline pigment. Lillie's stain (Option B): Lillie's stain also known as Lillie-Mayer's hematoxylin-eosin stain might help in detecting Ferrous ions (Fe2+) but is not useful for hemosiderin, which is ferric iron (Fe3+) Rhodanine stain (Option C): Rhodanine is utilized as a selective stain for the detection and localization of copper ions that accumulate in tissues such as the liver and brain in copper metabolism disorders, such as Wilson's disease (not to be confused with Rhodamine in microbiology for Mycobacterium TB). Supravital stains (Option D) : Supravital stains are a group of dyes used to stain living cells or tissues without causing cell death. New methylene blue and Brilliant cresyl blue target ribonucleic acid residues in reticulocytes and provide the characteristic blue reticular staining pattern.

Q5: Which of the following pathological conditions is associated with the 'Tabby cat' effect? (Q845369)

A. Diphtheria myocarditis

B. Xanthomas

C. Cholesterolosis

D. Fatty liver

Correct Answer: A. Diphtheria myocarditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Diphtheria myocarditis is associated with the 'Tabby Cat' Effect. Fat accumulation in the heart gives a characteristic Tigroid or Tabby cat appearance, which appears as yellowish streaks (fatty change) alternating with

reddish streaks (unaffected myocardium). This appearance is seen in conditions such as Diphtheria myocarditis Arrhythmogenic Right Ventricular Cardiomyopathy (ARVCM) Cell injury. Xanthomas (Option B): Xanthomas are found in skin and in tendons. Cholesterolosis (Option C): Cholesterolosis refers to the cholesterol-laden macrophages in the lamina propria of the gallbladder aka strawberry gallbladder. Fatty liver (Option D): Fatty liver, also known as hepatic steatosis, is characterized by the abnormal accumulation of triglycerides within hepatocytes (liver cells).

@Neet_pg_bot

Q6: Which of the following stains is not typically employed for the detection of lipid accumulation in histological samples? (Q845371)

A. Sudan Black

B. Sudan IV

C. Oil red O

D. Toluidine blue

Correct Answer: D. Toluidine blue

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Toluidine Blue is not typically employed for the detection of lipid accumulation in histological samples. A special stain for Mast cells and Basophils. It is a metachromatic stain Solution - Blue coloured Colour stained to mast cells and basophils - Purple Stains for fat To preserve fat, tissue is cut as a frozen section (no organic solvents → fat remains in place). Then stains given below can be used to demonstrate lipids. Oil Red O (Option C) Sudan Black B (Option A) Sudan IV (Option B) Osmium Tetroxide {{caption_text}} Note: Toluidine Blue is a special stain for Mast cells and Basophils.

@Neet_pg_bot

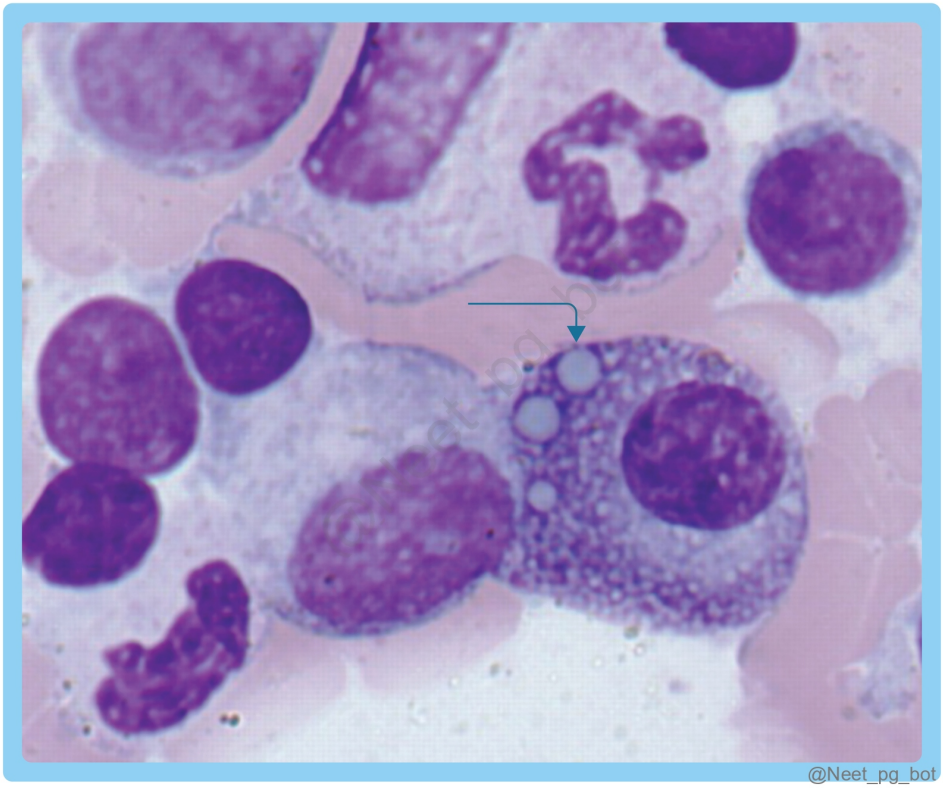
Q7: A 60-year-old woman presents with bone pain and tenderness over her lower back. Imaging reveals multiple lytic lesions in the vertebral column. Laboratory tests indicate anaemia, elevated serum calcium levels, and monoclonal gammopathy. A bone marrow biopsy confirms plasma cell proliferation. Microscopic examination of the biopsy reveals intracellular inclusions, as shown in the image. What is the composition of the intracellular inclusions marked in the image? {{caption_text}} (Q845373)

A. Aggregates of misfolded proteins

B. Clusters of ribosomes

C. Accumulations of immunoglobulins

D. Vacuoles containing lipids



Correct Answer: C. Accumulations of immunoglobulins

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The clinical presentation is highly suggestive of multiple myeloma, a plasma cell dyscrasia characterized by bone pain, lytic lesions, anaemia, hypercalcemia, and monoclonal gammopathy. Microscopic examination of the bone marrow biopsy may reveal the presence of intracellular inclusions, such as Russell bodies (Immunoglobulins in the cytoplasm) and Dutcher bodies (containing Ig in the nucleus), within some plasma cells. {{caption_text}}

@Neet_pg_bot

Q8: Following the resection of the pituitary adenoma in a patient with Cushing's disease, which intracellular change is most likely in residual adenoma cells? (Q845374)

A. Mallory-Denk bodies

B. Lewy bodies

C. Crooke hyaline change

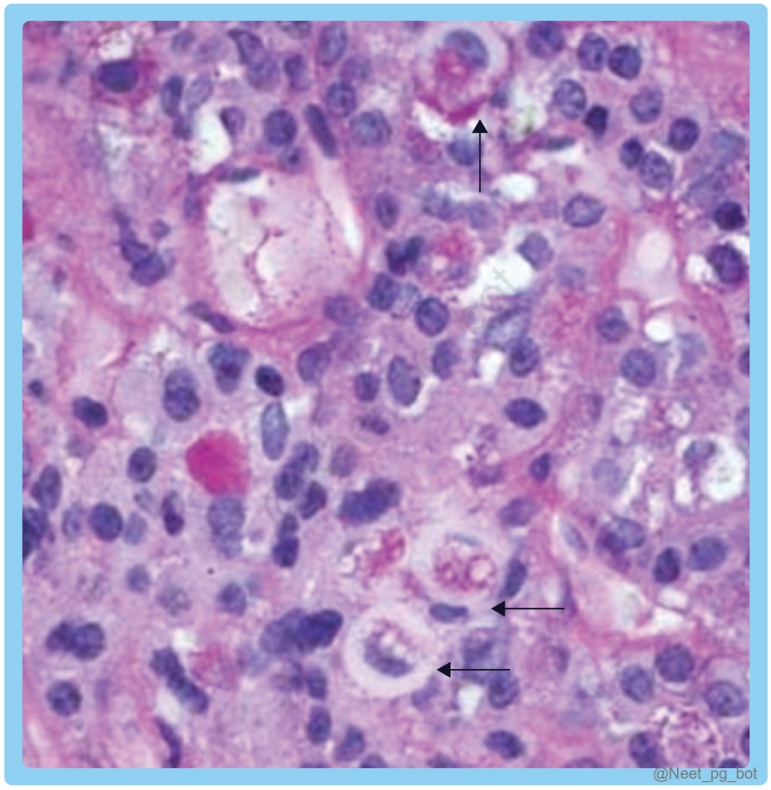
D. Civatte bodies

Correct Answer: C. Crooke hyaline change

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Following resection of a pituitary adenoma in a patient with Cushing's disease, the most likely intracellular change observed in the residual adenoma cells is Crooke's Hyaline Change . It is a histopathological finding seen in the pituitary gland, particularly in corticotroph adenomas associated with Cushing's disease. In crooke hyaline change, the normal granular, basophilic cytoplasm of ACTH-producing cells becomes homogenous and paler due to the accumulation of intermediate cytokeratin (CK) filaments. These changes occur as a response to chronic hypercortisolism. {{caption_text}} Mallory-Denk bodies (Option A): Mallory-Denk bodies or Mallory hyaline bodies are eosinophilic, intracytoplasmic inclusions composed of intermediate filaments, particularly cytokeratin 8 and 18, commonly seen in hepatocytes in conditions such as alcoholic liver disease. {{caption_text}} Lewy bodies (Option B): Lewy bodies are eosinophilic intracytoplasmic inclusions composed of aggregated alpha-synuclein protein and are characteristic of neurodegenerative disorders such as Parkinson's disease and Lewy body dementia. {{caption_text}} Civatte bodies (Option D): They are also known as Colloid Bodies/ Cytoid Bodies and are seen in Lichen Planus.



@Neet_pg_bot

Q9: Which of the following stains would be most appropriate for visualizing glycogen deposits? (Q845375)

A. Hematoxylin and eosin (H&E) stain

B. Periodic acid-Schiff (PAS) stain

C. Masson's trichrome stain

D. Oil Red O stain

Correct Answer: B. Periodic acid-Schiff (PAS) stain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Periodic acid-Schiff (PAS) stain would be most appropriate for visualizing glycogen deposits, among the given options. Glycogen is PAS +ve ; Diastase sensitive Hematoxylin and eosin (H&E) stain (Option A) is a basic stain that stains nuclei blue-purple (hematoxylin) and cytoplasm and extracellular matrix pink (eosin). While it can highlight muscle fibre morphology, it does not specifically stain glycogen. Masson's trichrome stain (Option C) : is used to distinguish collagen fibers, which stain blue, from other tissue components; it stains muscle fibers red, collagen blue, and nuclei blue-black, but it is not specific for detecting glycogen Oil Red O stain (Option D) is used to detect lipids and fat droplets.

@Neet_pg_bot

Q10: Which of the following statements is incorrect about dystrophic calcification? (Q845376)

A. It occurs in damaged or necrotic tissues.

B. It is characterized by the deposition of calcium salts in normal tissues.

C. It is often seen in areas of chronic inflammation.

D. Serum calcium levels are normal

Correct Answer: B. It is characterized by the deposition of calcium salts in normal tissues.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Calcium deposition is in dead or degenerating tissues. Dystrophic Calcification Metastatic Calcification Dead or degenerating tissues are seen. (Option A ruled out) There will be a normal blood calcium count. (Option D ruled out) Some examples: Dead Parasite TB (chronic inflammation) (Option C ruled out) Atheroma Monckeberg Sclerosis It is also called calcific medial degeneration. It happens in the tunica media. Calcium occurs blue in color It occurs only as an old age phenomenon without any clinical significance. Psammoma Bodies: It is present as a concentric lamellation. It shows an onion-peel appearance Seen in: Papillary carcinoma of thyroid. Papillary renal cell cancer. meningioma. Prolactinoma Serous Cystadenocarcinoma of ovary. Normal tissues are seen. The blood calcium level is elevated The most common organ affected due to Metastatic calcification - The Lungs Some Examples: Hyperparathyroidism Cancer: RCC and Breast cancer show an increase of calcium. Vitamin D intoxication Milk alkali syndrome Multiple myeloma Sarcoidosis

References:

Robbins and Cotran pathologic basis of disease, 10th edition, Page 77

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following case scenarios is not indicative of metastatic calcification? (Q845378)

A. A 60-year-old male with a history of chronic renal failure presented with shortness of breath and bilateral lung opacities on chest X-ray.

B. A 45-year-old female with spinal tuberculosis complained of back pain.

C. A 30-year-old male with a long-standing history of heavy milk and calcium carbonate intake now experiencing recurrent kidney stones.

D. A 55-year-old female with sarcoidosis demonstrated elevated levels of serum vitamin D and calcium.

Correct Answer: B. A 45-year-old female with spinal tuberculosis complained of back pain.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In tuberculosis, tissue death and degeneration lead to dystrophic calcification, which occurs despite normal serum calcium levels. Tuberculosis can lead to dystrophic calcification in bone tissue, resulting in symptoms such as bone pain and fractures. Metastatic calcification → elevated serum calcium Dystrophic calcification → normal serum calcium, dead/degenerating tissue There are four principal causes of hypercalcemia: Increased secretion of parathyroid hormone (PTH) with subsequent bone resorption, as in hyperparathyroidism due to parathyroid tumours, and ectopic secretion of PTH-related protein by malignant tumours Resorption of bone tissue, secondary to primary tumours of bone marrow (e.g., multiple myeloma, leukaemia) or diffuse skeletal metastasis (e.g., breast cancer), accelerated bone turnover (e.g., Paget disease), or immobilization. Vitamin D–related disorders, including vitamin D intoxication, sarcoidosis (in which macrophages activate a vitamin D precursor), and idiopathic hypercalcemia of infancy (Williams syndrome), characterized by abnormal sensitivity to vitamin D (Option D ruled out) Renal failure, which causes phosphate retention, leads to secondary hyperparathyroidism. (Option A ruled out) A 30-year-old male with a long-standing history of heavy milk and calcium carbonate intake now experiencing recurrent kidney stones (Option C): This will lead to increased serum calcium levels whereas dystrophic calcification occurs despite normal calcium levels.

@Neet_pg_bot

Q12: Which staining technique is commonly used to visualize calcium deposits in tissues and is particularly useful for detecting minute amounts of calcium? (Q845380)

A. Masson's trichrome stain

B. Prussian blue stain

C. Alizarin Red S stain

D. Wright-Giemsa stain

Correct Answer: C. Alizarin Red S stain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Alizarin Red S Stain is commonly used to visualize calcium deposits in tissues and is particularly useful for detecting minute amounts of calcium, giving red color to calcium deposits. Stains of Calcium: Von Kossa Stain Imparts black color to calcium. {{caption_text}} Alizarin Red S Imparts red color to calcium. Used for staining minor amounts of calcium. Calcein Fluorescent stain for calcium {{caption_text}} Azan Stain To differentiate mineralized bone from osteoid. {{caption_text}} Masson’s trichrome (Option A): To differentiate collagen (blue) and muscle fibers (red). Prussian blue (Option B): Used for staining Iron. Wright-Giemsa stain (Option D): Used for hematology slides. Important stains: Stain Demonstrates Key Pathology/Example Pigments/Minerals: Perl's Prussian Blue Hemosiderin (iron) Hemochromatosis, hemosiderosis Rhodanine/Rubeanic acid Copper Wilson's disease Von Kossa/Alizarin Red Calcium Dystrophic calcification Carbohydrates/Mucin PAS (Periodic Acid-Schiff) Glycogen, neutral mucin, fungi, basement membrane Glycogen storage disease, Whipple's, alpha-1 AT deficiency (globules), fungi Alcian Blue Acid mucin Intestinal metaplasia, adenocarcinoma Amyloid/Proteins: Congo Red Amyloid (apple-green birefringence) AA/AL amyloidosis Sulfated Alcian Blue Amyloid (pre-Congo Red screen) - Connective Tissue/Fibrosis: Masson's Trichrome Collagen (blue), muscle (red) Cirrhosis, fibrosis Reticulin (Silver) Reticulin fibers Cirrhosis, hepatocellular CA Van Gieson Collagen (red), muscle (yellow) Fibrosis Microorganisms: Ziehl-Neelsen (ZN) Acid-fast bacilli TB, leprosy Wade-Fite Mycobacteria (weaker AF) Leprosy GMS (Gomori Methenamine Silver) Fungi, Pneumocystis Aspergillosis, PCP Giemsa H. pylori, parasites, trypanosomes Gastritis, malaria Gram Bacteria (Gram +/-) General infections Levaditi/Warthin-Starry Spirochetes Syphilis, H. pylori Lipids: Oil Red O/Sudan Black Lipids (frozen sections) Xanthomas, fatty liver Others: Mucin (Mayer's) Mucin Adenocarcinoma Fontana-Masson Melanin Melanoma Immunohistochemistry Specific antigens (e.g., CK7/20, S100) Tumor typing

Q1: Identify the correct statements regarding amyloidosis. Amyloidosis is called so because it looks like the deposition of starch. Beta-pleated sheets are seen. AL is a type of secondary amyloidosis. It is an extracellular protein. (Q857424)

A. 1, 2 and 3

B. 1, 4

C. 2, 3 and 4

D. 1, 2 and 4

Correct Answer: D. 1, 2 and 4

Explanation: Amyloidosis is a group of disorders characterized by the extracellular deposition of amyloid fibrils that are produced by the aggregation of misfolded proteins. (Statement 4) The presence of abundant charged sugar groups in these adsorbed proteins gives the deposits staining characteristics that were thought to resemble starch (amylose). Therefore, the deposits were called amyloid (Statement 1). 95% of amyloid consists of fibril proteins, with the remaining 5% being glycosaminoglycans (dermatan sulfate and heparan sulfate) and plasma proteins, notably serum amyloid P . AL amyloidosis is a primary form of amyloidosis, whereas secondary form can be caused by various etiologies and is associated with characteristic amyloid deposition (Statement 3). Physical nature of amyloid: Light microscopy with H & E stains: Amyloid is an amorphous , eosinophilic , hyaline , and extracellular substance. Electron microscopy: All types of amyloid, regardless of clinical setting or chemical composition, consist of continuous, nonbranching fibrils with a diameter of approximately 7.5 to 10 nm. X-ray crystallography and infrared spectroscopy: Characteristic cross-β-pleated sheet conformation, which is responsible for the distinctive Congo-red staining and apple-green birefringence of the amyloid. (Statement 2)

@Neet_pg_bot

Q2: A diabetic male presented with seizures. Radiological examination shows a lesion. Histopathological examination shows liquefactive necrosis. What is the most important mechanism responsible for this? (Q866754)

A. Enzymatic degradation

B. Mechanical

C. Ischemic

D. Pressure

Correct Answer: A. Enzymatic degradation

Explanation: Diabetic patient with seizures → raises suspicion for a brain lesion (possibly abscess, infarct, or infection-related pathology). Histopathology: liquefactive necrosis → classic type of necrosis seen in brain tissue. Liquefactive necrosis in brain is mainly due to hydrolytic enzyme action breaking down tissue. In the CNS, ischemia or infection activates microglia and infiltrating neutrophils. These cells release lysosomal hydrolytic enzymes. Brain tissue is rich in lipids and has little structural stroma, so enzymatic digestion quickly converts tissue into a liquid mass. Mechanism: enzymatic degradation > structural breakdown → liquefactive necrosis. Mechanical (Option B): Trauma can cause hemorrhage or contusion, but necrosis type is not primarily from

mechanical injury alone, here histology points to enzymatic breakdown. Ischemic (Option C): Ischemia in most organs causes coagulative necrosis, except in the brain, where it still leads to liquefactive necrosis, but the mechanism is enzymatic digestion, not ischemia per se. Pressure (Option D): Increased intracranial pressure can cause herniation or atrophy, not liquefactive necrosis by itself.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following is pro-apoptotic? (Q866665)

A. Bcl-2

B. Bcl-xL

C. Mcl-1

D. Bax

Correct Answer: D. Bax

Explanation: The correct answer is Bax , because it is a pro-apoptotic member of the Bcl-2 protein family. The Bcl-2 family regulates the intrinsic (mitochondrial) apoptosis pathway. Members are divided into: Anti-apoptotic : Bcl-2, Bcl-xL, Mcl-1 → preserve mitochondrial membrane integrity, prevent cytochrome c release. Pro-apoptotic : Bax, Bak, Bok → promote mitochondrial outer membrane permeabilisation (MOMP), allowing cytochrome c release and caspase activation. Mnemonic: "Bax and Bak Break" (break the mitochondrial membrane) → pro-apoptotic. "Bcl and Bcl-xL Build" (preserve the membrane) → anti-apoptotic.

@Neet_pg_bot

Q4: Which of the following types of cell death involves activation of caspase enzymes? (Q866340)

A. Necrosis and Apoptosis

B. Apoptosis and Pyroptosis

C. Apoptosis and necroptosis

D. Apoptosis only

Correct Answer: B. Apoptosis and Pyroptosis

Explanation: Apoptosis and Pyroptosis involves activation of caspase enzymes. Apoptosis A tightly regulated suicide program where cells activate enzymes to degrade their DNA and proteins. It’s an active process

eliminating irreparably damaged cells without causing inflammation or tissue damage. Driven by activation of caspases that cause DNA fragmentation Phases: (Option B) Initiation phase: Activation of caspases 8, 9, 10 triggers a cascade. Execution phase: Terminal caspases 3, 6, 7 lead to cellular breakdown. Morphological features: Cell shrinkage Chromatin condensation Cytoplasmic blebs and formation of apoptotic bodies Phagocytosis of apoptotic bodies by macrophages Histopathology: Apoptotic cells appear as round/oval with intensely eosinophilic cytoplasm and dense nuclear chromatin fragments. Pyroptosis It is a form of programmed cell death involving release of IL-1, a fever-inducing cytokine. Microbial products in cells activate the inflammasome complex. Inflammasome activates caspase-1, which converts inactive IL-1 to active IL-1. (Option B) Active IL-1 causes fever, inflammation, and leukocyte recruitment. Pyroptosis helps eliminate infected cells and triggers local inflammation. Necrosis (Option A) is a form of accidental cell death that does not involve caspases. Necroptosis (Option C) is a programmed form of necrosis that occurs independently of caspases.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Caspase-1 is primarily involved in which type of programmed cell death? (Q865391)

A. Apoptosis

B. Pyroptosis

C. Necroptosis

D. Necrosis

Correct Answer: B. Pyroptosis

Explanation: Caspase-1 plays a central role in Pyroptosis , a form of programmed cell death associated with inflammation. It is a form of apoptosis in which there is release of the fever-inducing cytokine IL-1. Microbial products entering infected cells are recognized by cytoplasmic receptors, activating the multiprotein complex inflammasome. This complex activates caspase 1 which converts the inactive IL-1 to active IL-1, causing fever, inflammation and leucocyte recruitment. (Option B) Pyroptosis is the mechanism by which some microbes cause the death of infected cells and trigger local inflammation. Apoptosis (Option A) is a controlled, non-inflammatory cell death involving caspases-8, -9, -3, and -7, but not caspase-1, and serves to remove damaged cells without triggering an immune response. Necroptosis (Option C) is a programmed inflammatory cell death triggered when apoptosis is blocked, involving RIPK1, RIPK3, and MLKL—but not caspase-1, distinguishing it from pyroptosis. Necrosis (Option D) is an uncontrolled, non-programmed cell death due to injury (e.g., trauma or ischemia), causing inflammation without involving caspases, including caspase-1.

References:

Textbook of Robbin and Cotran’s Pathological Basis of Diseases, 10th Edition, Page 46-48.

↑ *Back to this question in Part A*

Q6: Apoptotic bodies comprise of? (Q860513)

A. Include cytoplasm + intranuclear material + organelle

B. Cytoplasm + organelle

C. Organelle + intranuclear material

D. Only organelle

Correct Answer: A. Include cytoplasm + intranuclear material + organelle

Explanation: Apoptotic bodies are comprised of cytoplasm, intranuclear material and cellular organelles. Apoptosis (caspase-dependent programmed cell death): It is a type of cell death that is induced by a tightly regulated suicide program in which cells destined to die activate intrinsic enzymes that degrade the cells' genomic DNA and nuclear and cytoplasmic proteins. It is an active process. It eliminates cells that are injured beyond repair without eliciting a host reaction, thus limiting collateral tissue damage. Apoptosis results from the activation of enzymes called caspases, which leads to DNA fragmentation. The process of apoptosis may be divided into: Initiation phase: Caspases 8,9,10 become catalytically active and unleash a cascade of other caspase Execution phase: During which the terminal caspases 3,6,7 trigger cellular fragmentation. Morphological features:- Cell shrinkage Chromatin condensation Formation of cytoplasmic blebs and apoptotic bodies (cytoplasm and tightly packed organelles, with or without nuclear fragments) (Option A) Phagocytosis of apoptotic bodies, usually by macrophages. Histopathology: The apoptotic cell appears as a round or oval mass of intensely eosinophilic cytoplasm with fragments of dense nuclear chromatin. {{caption_text}} The cell is reduced in size and contains brightly eosinophilic cytoplasm and a condensed nucleus. Types: Apoptosis occurs in two broad contexts: Physiological apoptosis. Pathological apoptosis. Physiological Apoptosis Pathological Apoptosis The removal of supernumerary cells (in excess of the required number) during development. Involution of hormone-dependent tissues on hormone withdrawal, such as endometrial cell breakdown during the menstrual cycle. Elimination of potentially harmful self-reactive lymphocytes to prevent immune reactions against one's own tissues. Death of host cells that have served their useful purpose, such as neutrophils in an acute inflammatory response and lymphocytes at the end of an immune response. DNA damage. Accumulation of misfolded proteins Apoptosis can be induced during certain infections- as in adenovirus and HIV infections and viral hepatitis. It may also contribute to pathologic atrophy in parenchymal organs after duct obstruction, such as occurs in the pancreas, parotid gland, and kidney.

@Neet_pg_bot

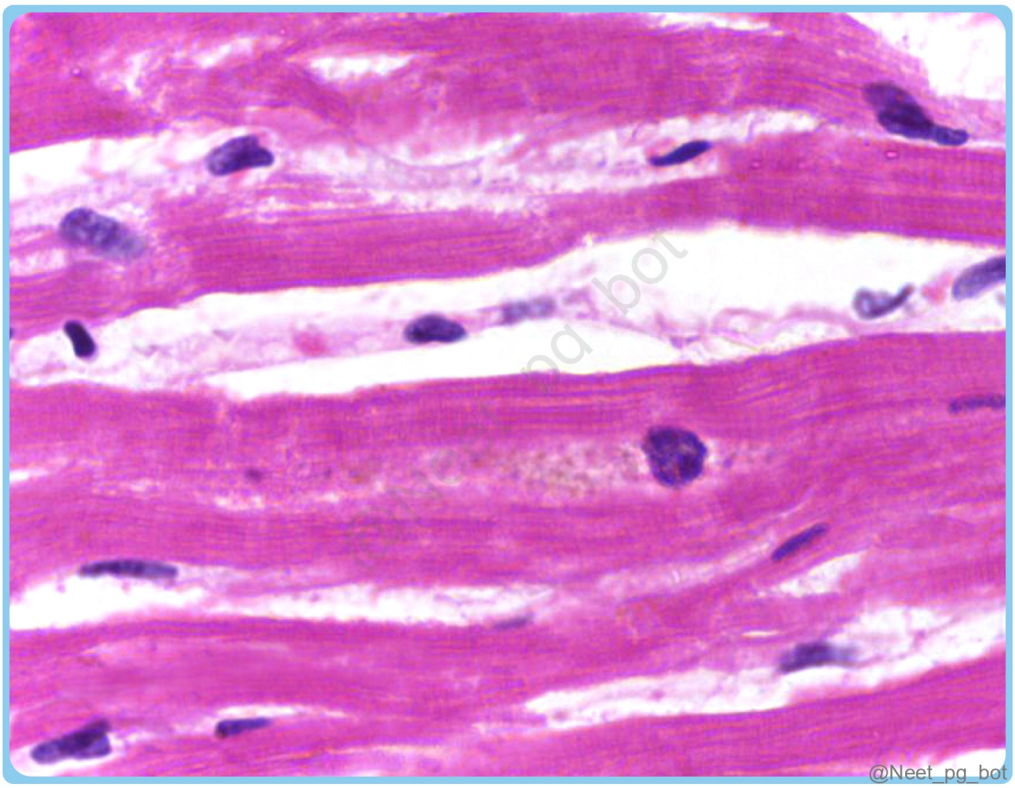
Q7: The body of an 82-year-old man has been seen for a post-mortem to determine the cause of death. You are examining a histopathological slide containing a section of his cardiac tissue where you notice some pigmentation. Which is the substance that is seen in the image given below? (Q859859)

A. Melanin

B. Lipofuscin

C. Hemosiderin

D. Iron



Correct Answer: B. Lipofuscin

Explanation: The histopathological image shows lipofuscin in the section of cardiac tissue. Lipofuscin is a yellow to red-brown pigment found in cardiac muscle cells, particularly around the nucleus in the hearts of elderly, debilitated people. {{caption_text}} Melanin (Option A) is a black or brown pigment found in skin, hair, and certain brain areas, not typically seen in cardiac tissue. Hemosiderin (Option C) is an iron-storage complex resulting from the breakdown of haemoglobin, typically associated with conditions like haemorrhage or hemochromatosis. Iron (Option D) : Elemental iron deposition in tissues is pathological and associated with diseases like hemochromatosis or chronic blood transfusions. Staining with Prussian blue would help confirm iron presence.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Among the following, which molecule is required for the presentation of the antigens by the APCs to TH2 cells? (Q859298)

A. NK cells

B. G-protein coupled receptor

C. MHC

D. Lectin receptor

Correct Answer: C. MHC

Explanation: Antigen-presenting cells (APCs) such as dendritic cells, macrophages, and B cells play a crucial role in the adaptive immune response by presenting antigens to T-helper (TH2) cells . This process requires Major Histocompatibility Complex (MHC) Class II molecules , which are essential for the activation of CD4+ T cells, including TH2 cells. MHC Molecule Role : APCs process antigens and present them on their surface bound to MHC Class II molecules. MHC Class II molecules interact with the T-cell receptor (TCR) on CD4+ T cells. This interaction is critical for the differentiation and activation of TH2 cells, which secrete cytokines to mediate humoral immunity. Incorrect Options: NK cells (Option A) are part of the innate immune system and do not present antigens or directly interact with TH2 cells. G-protein coupled receptors (Option B) are involved in cell signalling but are not involved in antigen presentation to T cells. Lectin receptors (Option D) are involved in innate immune recognition, particularly of carbohydrate molecules, but they do not mediate antigen presentation to TH2 cells.

@Neet_pg_bot

Q9: Supravital stains are used in the identification of all except? (Q857588)

A. Reticulocytes

B. Copper in tissue

C. Heinz bodies

D. Ribosomal RNA

Correct Answer: B. Copper in tissue

Explanation: Supravital stains are typically used to identify cellular components such as reticulocytes (immature red blood cells), Heinz bodies (denatured haemoglobin), and ribosomal RNA (which is seen in reticulocytes as a network). However, copper in tissue is not identified using supravital stains; it requires special staining techniques like rhodanine stains. {{caption_text}}

@Neet_pg_bot

Q10: Which of the following is an anti-apoptotic gene? (Q857450)

A. BAK

B. MCL1

C. PUMA

D. BAD

Correct Answer: B. MCL1

Explanation: MCL1 is an anti-apoptotic gene and part of the BCL-2 family. Apoptosis is a key process for maintaining cell balance and eliminating damaged cells, regulated by the interplay between pro-apoptotic and anti-apoptotic genes. MCL1 inhibits apoptosis by preventing the activation of pro-apoptotic proteins, thereby promoting cell survival. Apoptotic genes: Anti Apoptotic genes :- BCL-2 , BCL-XL , MCL-1 Pro Apoptotic

genes:- BAX and BAK (Option A ruled out) Apoptosis initiators:- BAD, BIM, BID, Noxa and Puma (Option C & D ruled out)

@Neet_pg_bot

Q11: Which of the following diseases is caused by abnormal folding of proteins? (Q857433)

A. Creutzfelt Jakob disease

B. Cirrhosis

C. Nephritic syndrome

D. Sickle cell anemia

Correct Answer: A. Creutzfelt Jakob disease

Explanation: Creutzfeldt-Jakob disease (CJD) is a type of prion disease caused by the abnormal folding of proteins, specifically prion proteins (PrP), which leads to neurodegeneration. It is irreversible and fatal . The disease progresses quickly, and death usually occurs within a year. It is characterised by Rapidly progressive dementia Myoclonus Ataxia Visual disturbances Diagnosis: It is confirmed via MRI (increased signal in basal ganglia) and EEG findings Cirrhosis (Option B) is liver scarring typically caused by chronic liver diseases (e.g., hepatitis, alcoholism), not protein misfolding. Nephritic syndrome (Option C) is a kidney disorder involving inflammation, typically due to immune complex deposition, not protein misfolding. Sickle cell anaemia (Option D) is caused by a genetic mutation in the haemoglobin gene (HbS) that leads to abnormal haemoglobin, but not a misfolding of proteins in the same sense as prion diseases.

@Neet_pg_bot

Q13: A 24-year-old male was brought to the emergency department after suffering severe injuries in a motorcycle accident. His blood pressure was 80/60 mm Hg, and he was tachycardic with cold, clammy skin. An ultrasound examination revealed a ruptured spleen. Arterial blood gas analysis was suggestive of metabolic acidosis. Which of the following conditions most likely caused the patient to suffer? (Q857122)

A. Cardiogenic shock

B. Septic shock

C. Hypovolemic shock

D. Neurogenic shock

Correct Answer: C. Hypovolemic shock

Explanation: Hypovolemic shock occurs due to significant blood or fluid loss, leading to reduced blood volume and inadequate tissue perfusion. This patient's low blood pressure, tachycardia, cold, clammy skin, and metabolic acidosis suggest shock caused by blood loss from the ruptured spleen. Shock is a state of circulatory failure that impairs tissue perfusion and leads to cellular hypoxia. Initially, cellular injury is reversible, but prolonged shock can cause irreversible tissue damage and may be fatal. It can result from various conditions, such as severe

haemorrhage, extensive trauma, burns, myocardial infarction, pulmonary embolism, and microbial sepsis. The causes of shock can be categorised into three main types: Cardiogenic shock: (Option A) Caused by low cardiac output due to myocardial pump failure. This may result from intrinsic myocardial damage (e.g., infarction), ventricular arrhythmias, extrinsic compression (e.g., cardiac tamponade), or outflow obstruction (e.g., pulmonary embolism). Hypovolemic shock: Occurs due to low blood volume, often from massive haemorrhage or fluid loss (e.g., severe burns). This leads to reduced cardiac output and impaired tissue perfusion. Septic shock: (Option B) Sepsis : Life-threatening organ dysfunction due to a dysregulated host response to infection. Septic Shock : A subset of sepsis with profound circulatory, cellular, and metabolic abnormalities that increase mortality risk. Systemic Inflammatory Response Syndrome (SIRS) : A sepsis-like condition triggered by non-microbial insults, such as burns, trauma, or pancreatitis. Both SIRS and septic shock are marked by a massive release of inflammatory mediators, causing arterial vasodilation, vascular leakage, and venous blood pooling, leading to tissue hypoperfusion, cellular hypoxia, and organ dysfunction. Neurogenic Shock (Option D) : Occurs following spinal cord injury, leading to acute vasodilation and hypotension. Anaphylactic Shock : Caused by an IgE-mediated hypersensitivity reaction, resulting in acute vasodilation, hypotension, and tissue hypoperfusion.

@Neet_pg_bot

Q14: All of the following are crosslinking fixatives except? (Q856893)

A. Glutaraldehyde

B. Formaldehyde

C. Methanol

D. Osmium tetroxide

Correct Answer: C. Methanol

Explanation: Methanol is not a crosslinking fixative. It is a dehydrant coagulant fixative. Fixatives are chemicals that preserve biological tissues by stabilizing cellular structures and preventing decay or degradation. The goal is to maintain the tissue in a life-like state as much as possible for microscopic examination. Fixation helps maintain the tissue's integrity by preventing autolysis (self-digestion) and putrefaction (bacterial decay). Crosslinking Fixatives: These fixatives work by forming covalent bonds between the proteins and other cellular structures, effectively "locking" them in place. This preserves the tissue’s structural integrity. Formaldehyde (Option B) : Most commonly used in the form of 10% neutral-buffered formalin. Glutaraldehyde (Option A) : Often used for electron microscopy due to its ability to preserve fine cellular structures. Osmium tetroxide (Option D) : Used primarily for electron microscopy, particularly for preserving lipids and membranes. Precipitating Fixatives: These work by precipitating proteins and other cellular components, which makes them less soluble and helps preserve their structure. Methanol Ethanol Additive Fixatives: They chemically bind to tissue components, such as proteins

or nucleic acids, and stabilize them. They are typically more gentle and produce better preservation of ultrastructure. Formaldehyde Glutaraldehyde Non-Additive Fixatives: Alcohol Acetone

@Neet_pg_bot

Q15: Which of the following caspases binds to Cyt c and the APAF-1 complex? (Q856488)

A. Caspase 1

B. Caspase 8

C. Caspase 9

D. Caspase 4

Correct Answer: C. Caspase 9

Explanation: In the intrinsic apoptotic pathway , the release of cytochrome c (Cyt c) from the mitochondria triggers the formation of the apoptosome, a complex consisting of Cyt c, apoptotic protease-activating factor 1 (APAF-1), and procaspase 9. This complex is essential for initiating the caspase cascade that leads to cell death. Apoptosis (Caspase-dependent programmed cell death): Apoptosis is a type of cell death that is induced by a tightly regulated suicide program in which cells destined to die activate intrinsic enzymes that degrade the cells' genomic DNA and nuclear and cytoplasmic proteins. It is an active process. It eliminates cells that are injured beyond repair without eliciting a host reaction, thus limiting collateral tissue damage. Apoptosis results from activating enzymes called caspases, leading to DNA fragmentation. The process of apoptosis may be divided into an initiation phase , during which caspases 8,9,10 become catalytically active and unleash a cascade of other caspases, and an execution phase , during which the terminal caspases 3,6,7 trigger cellular fragmentation. Morphological features:- Cell shrinkage Chromatin condensation Formation of cytoplasmic blebs and apoptotic bodies Phagocytosis of apoptotic bodies, usually by macrophages. Histopathology: In H&E-stained tissue, the apoptotic cell appears as a round or oval mass of intensely eosinophilic cytoplasm with fragments of dense nuclear chromatin. {{caption_text}} The above image shows apoptosis of an epidermal cell in an immune reaction. The cell is reduced in size and contains brightly eosinophilic cytoplasm and a condensed nucleus Types: Apoptosis occurs in two broad contexts: Physiological apoptosis. Pathological apoptosis. Apoptosis in physiological conditions Apoptosis in pathological conditions 1. The removal of supernumerary cells (in excess of the required number) during development. 2. Involution of hormone-dependent tissues on hormone withdrawal, such as endometrial cell breakdown during the menstrual cycle. 3. Elimination of potentially harmful self-reactive lymphocytes to prevent immune reactions against one's own tissues. 4. Death of host cells that have served their useful purpose, such as neutrophils in an acute inflammatory response and lymphocytes at the end of an immune response. 1. DNA damage. 2. Accumulation of misfolded proteins 3. Apoptosis can be induced during infections

such as adenovirus , HIV , and viral hepatitis . 4. It may also contribute to pathologic atrophy in parenchymal organs after duct obstruction, such as occurs in the pancreas, parotid gland, and kidney

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A chronic alcoholic patient presented with increasing abdominal girth. On examination, shifting dullness was present, and the liver span was less than 7cm. Histopathological examination revealed the presence of intracytoplasmic eosinophilic inclusions in hepatocytes. What is the content of these inclusions? (Q856152)

A. Intermediate filaments

B. Actin

C. Microtubules

D. Fibronectin

Correct Answer: A. Intermediate filaments

Explanation: The presence of intracytoplasmic eosinophilic inclusions in hepatocytes is a key finding in alcoholic liver disease. Mallory-Denk bodies or Mallory hyaline bodies are eosinophilic , intracytoplasmic inclusions composed of intermediate filaments, particularly cytokeratin 8 and 18, commonly seen in hepatocytes in conditions such as alcoholic liver disease. Conditions where Mallory Hyaline bodies are seen are (Mnemonic: N ew Indian WATCH) N on-alcoholic fatty liver disease (NAFLD) Indian childhood cirrhosis W ilson's disease A lpha-1 antitrypsin deficiency ; A lcoholic Liver Disease T umor of the liver (Hepatocellular carcinoma) Chronic C holestatic conditions H epatic or Primary Biliary cirrhosis (not seen in Secondary biliary cirrhosis) {{caption_text}} Actin (Option B) is a structural protein found in microfilaments but does not typically form eosinophilic inclusions in alcoholic liver disease. Microtubules (Option C) are involved in intracellular transport and cell division but do not form eosinophilic inclusions in hepatocytes. Fibronectin (Option D) is an extracellular matrix protein , and although it plays a role in tissue repair and scarring , it is not associated with the formation of intracytoplasmic inclusions in liver cells, especially in alcoholic liver disease.

@Neet_pg_bot

Q17: A 70-year-old patient presented with cough, fatigue, and weight loss. He was diagnosed with squamous cell carcinoma on bronchoscopy. The resected specimen had a hilar lymph node that was 1 cm in size and showed a black pigment. What is the black pigment likely to be? (Q856097)

A. Anthracotic pigment

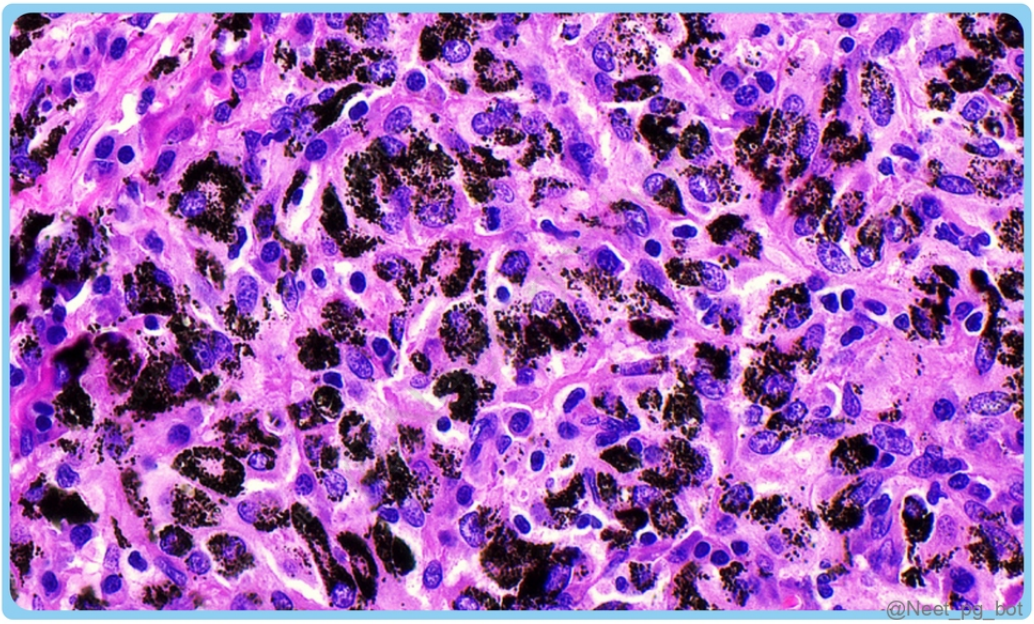
B. Melanin

C. Lipochrome

D. Hemosiderin

Correct Answer: A. Anthracotic pigment

Explanation: Anthracotic pigment is a black, carbon-based pigment commonly seen in lymph nodes and lungs, as well as in individuals with chronic smoking or environmental pollution exposure. These particles are engulfed by macrophages in the lungs and then transported to nearby lymph nodes, often leading to anthracosis . HPE shows carbon-laden macrophages. In patients with lung cancer , particularly squamous cell carcinoma , the presence of hilar lymphadenopathy and black pigment is a common finding due to the direct proximity of the lungs and lymphatic drainage of carbon particles. {{caption_text}} Melanin (Option B) is responsible for skin and hair pigmentation and protects against UV radiation. While it can sometimes be found in melanomas (a type of skin cancer), it is not typically found in the lungs or lymph nodes. {{caption_text}} Lipochrome (Option C) is a group of yellow to brown pigments that arise from the breakdown of lipids (fats). On microscopy, it appears as a yellow-brown, finely granular cytoplasmic pigment, often deposited in the perinuclear location. These pigments can be found in various tissues but are not typically associated with lung diseases or lymph node involvement . {{caption_text}} Hemosiderin (Option D) is an iron-containing pigment derived from the breakdown of hemoglobin . While hemosiderin can appear brown, it does not appear as a black pigment in the context of smoking-related lung disease or cancer . {{caption_text}}



@Neet_pg_bot

Q18: Senile atrophy occurs due to which of the following? (Q856024)

A. Denervation

B. Decreased nutrition

C. Decreased workload

D. Reduced blood supply

Correct Answer: D. Reduced blood supply

Explanation: Chronic ischemia from progressive arterial occlusion leads to tissue atrophy. In older adults, reduced cerebral blood flow due to atherosclerosis causes senile atrophy of the brain. Loss of innervation (denervation atrophy) (Option A) : Skeletal muscle metabolism and function rely on nerve supply. Damage to the nerves results

in atrophy of the muscle fibres they innervate. Inadequate nutrition (Option B) : Severe protein-calorie malnutrition, such as marasmus , causes the breakdown of skeletal muscle proteins for energy after fat stores are depleted, leading to muscle wasting (cachexia) . This is common in chronic inflammatory diseases and cancer. In cachectic states, excessive TNF production contributes to appetite suppression and lipid depletion, further exacerbating muscle atrophy. Decreased workload (disuse atrophy) (Option C) : Immobilization of bones, such as through a plaster cast or prolonged bed rest, leads to rapid muscle atrophy. Initially, the decrease in cell size is reversible upon resumption of activity. However, with prolonged disuse, muscle fibres shrink in size and number (due to apoptosis), and muscle atrophy may be accompanied by increased bone resorption, resulting in disuse osteoporosis.

@Neet_pg_bot

Q19: Which of the following measures is associated with an increased life span? (Q855961)

A. Regular moderate exercise for 30 min

B. Decrease stress

C. Decreasing calorie intake by 30%

D. Pharmacological intervention with proton pump inhibitors

Correct Answer: C. Decreasing calorie intake by 30%

Explanation: aloric restriction has increased lifespan across various species, including nonhuman primates and humans. This is linked to two key neurohormonal circuits regulating metabolism: Insulin and IGF-1 Signaling IGF-1, produced in response to growth hormone, mimics insulin signalling, promoting an anabolic state, cell growth, and replication. Sirtuins These are NAD-dependent deacetylases that help adapt to stressors like food deprivation and DNA damage. They promote longevity by regulating genes that reduce metabolic activity, apoptosis, and oxidative damage. Sirtuins also improve insulin sensitivity and glucose metabolism. Caloric restriction reduces IGF-1 signalling, which may reduce cellular damage while simultaneously increasing sirtuins, particularly sirtuin-6 , to promote DNA repair and metabolic adaptation. Hence, caloric restriction, particularly a reduction in calories by about 20-30%, can reduce IGF-1 signalling and increase sirtuin activity, which together is thought to extend lifespan. Regular moderate exercise for 30 min (Option A) is associated with numerous health benefits, like improved cardiovascular health, better metabolic function, and reduced risk of chronic diseases. While it may increase health span , it is not as directly proven to increase lifespan compared to caloric restriction. Decrease stress (Option B): Chronic stress is associated with a range of negative health effects, all of which can reduce lifespan. Stress management techniques can help improve health and increase longevity, but this relationship is more indirect and variable. Pharmacological intervention with proton pump inhibitors (Option D) :

PPIs are used to reduce stomach acid and treat conditions like GERD and peptic ulcers. While they are effective for symptom relief, they are not associated with increased lifespan.

@Neet_pg_bot

Q20: Choose the correct statement regarding the telomerase theory of ageing: (Q855914)

A. Telomere stability is associated with ageing

B. Abnormal telomerase activation is associated with ageing

C. Decreased telomere length is associated with ageing

D. Increased telomere length is associated with ageing

Correct Answer: C. Decreased telomere length is associated with ageing

Explanation: : Telomere stability refers to maintaining the length of telomeres, which are protective caps at the ends of chromosomes. As we age, telomeres shorten rather than remain stable, which is a key factor in cellular ageing, not stability. Abnormal telomerase activation is associated with ageing (Option B): Abnormal telomerase activation is more commonly associated with cancer (where cells avoid normal ageing and continue to divide) rather than the ageing process itself. In ageing, telomerase activity tends to decline, not increase.

Robbins and Cotran, Pathologic Basis of Disease, 10th Edition, Pages 67, 68

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: Which of the following is true regarding sirtuins? Increases insulin sensitivity and glucose metabolism Promotes genes that increase longevity They are of 7 types They are one of the types of histone deacetylases (Q855087)

A. 1, 2, 3

B. 1, 2, 3, 4

C. 2, 3

D. 2, 4

Correct Answer: B. 1, 2, 3, 4

Explanation: Sirtuins are NAD-dependent protein deacetylases. (Statement 4) Seven types (Statement 3) of sirtuins exist in mammals, each with unique functions. They help the body adapt to environmental stresses like food deprivation and DNA damage . Longevity : Sirtuins promote genes that increase longevity (Statement 2) , reduce metabolism, inhibit apoptosis, and protect against oxidative damage. Sirtuins enhance insulin sensitivity and glucose metabolism (Statement 1) Caloric restriction : Increases sirtuin activity, reducing IGF-1 signalling, leading to slower cell growth, reduced metabolism, and cellular damage. Sirtuin-6 : Plays a key role in metabolic adaptations and DNA repair by activating repair enzymes. Anti-ageing : Sirtuins are linked to anti-ageing effects. Red wine : A compound in red wine is believed to activate sirtuins, potentially contributing to increased lifespan.

@Neet_pg_bot

Q22: Cell-in-cell appearance is seen in which of the following? (Q855076)

A. Necrosis

B. Apoptosis

C. Necroptosis

D. Entosis

Correct Answer: D. Entosis

Explanation: Entosis refers to the process where one cell is engulfed by another, leading to a "cell-in-cell" appearance. Entosis : It refers to a homotypic process where one epithelial cell invades the cytoplasm of another epithelial cell. The host cell forms a vacuole around the internalized cell, which deforms its organelles, including the nucleus. The inner cell may survive within the host cell for up to 12 hours or longer, eventually being digested by the outer cell through an autophagosomal mechanism, or it may escape. {{caption_text}} Necrosis (Option A) is an uncontrolled form of cell death characterized by cell swelling, rupture, and inflammation. Apoptosis (Option B) is a controlled, programmed cell death where cells shrink and fragment into apoptotic bodies. Necroptosis (Option C) is a form of regulated cell death that mimics necrosis but is genetically controlled. Unlike apoptosis, it is associated with inflammation and occurs via receptor-interacting protein kinases (RIPK1 and RIPK3), leading to membrane rupture and the release of intracellular contents.

@Neet_pg_bot

Q23: Which among the following is less related to irreversible cell injury? (Q820573)

A. Blebs formation

B. Karyolysis

C. Amorphous densities

D. Pyknotic nucleus

Correct Answer: A. Blebs formation

Explanation: Correct Option A - Blebs formation: Blebs formation is actually a characteristic feature of reversible cell injury, not irreversible injury. Blebs formation is less related to irreversibility when compared to other features given in the options. Blebs are small, bubble-like protrusions on the cell membrane that result from cytoskeletal and membrane alterations. They can be observed in conditions like ischemia and toxic injury. Reversibility implies that the cell can recover its normal structure and function when the damaging stimulus is removed. Incorrect Options: Option B - Karyolysis: Karyolysis refers to the dissolution of the cell nucleus due to DNA degradation. This is indeed a feature of irreversible cell injury. In irreversible injury, the cell's nuclear structure and DNA integrity are compromised beyond repair, leading to processes like karyolysis. Option C - Amorphous Densities: The presence of amorphous densities is often associated with irreversible cell injury. These densities can be observed under electron microscopy and represent aggregates of denatured or altered proteins, lipids, and other cellular components. They are a sign of severe damage and cell death. Option D - Pyknotic Nucleus: Pyknosis is the irreversible condensation of chromatin within the nucleus, resulting in a small, darkly stained and shrunken nucleus. This is indeed a feature of irreversible cell injury. Pyknotic nuclei indicate severe cellular damage that cannot be reversed, leading to cell death.

@Neet_pg_bot

Q24: Metastatic calcification occurs in all except ? (Q793597)

A. Kidney

B. Fundus of the stomach

C. Pulmonary veins

D. Atheroma

Correct Answer: D. Atheroma

Explanation: Correct Option D - Atheroma: The type of calcification seen in atheroma is dystrophic calcification. Metastatic calcification: Metastatic calcification is caused by increased calcium phosphate in the blood and may result from hypercalcemia, hyperphosphatemia, or both. It is commonly associated with hyperparathyroidism, sarcoidosis, metastatic disease, and myeloma. Dystrophic calcification: The deposition of calcium salt in degenerated tissues in the absence of a systemic imbalance is called dystrophic calcification. It is mostly associated with trauma, inflammation, or infection. ■■■■■■■ Incorrect Options: Metastatic calcification occurs in options A, B, and C .

References:

.

@Neet_pg_bot

Q25: Which of the following are features describing necrosis? Cell swelling Disrupted cell membrane Induces inflammation Physiological (Q857443)

A. 1 and 2

B. 1, 2 and 4

C. 1, 2 and 3

D. 1 and 3

Correct Answer: C. 1, 2 and 3

Explanation: Necrosis is a form of pathological cell death (Statement 4 ruled out) , often occurring due to various injuries, such as physical trauma, ischemia, infection, or exposure to toxic substances. It is characterized by cell swelling, membrane rupture, organelle damage, and nuclear changes (Pyknosis, Karyorrhexis, Karyolysis). Cell swelling occurs because of the loss of cellular integrity and failure of ion pumps (such as the Na+/K+ ATPase pump), leading to an influx of water into the cell. In necrosis, the plasma membrane of the cell is disrupted , allowing the release of intracellular contents. The released substances trigger an immune response, leading to an inflammatory reaction, which is a characteristic of necrosis.

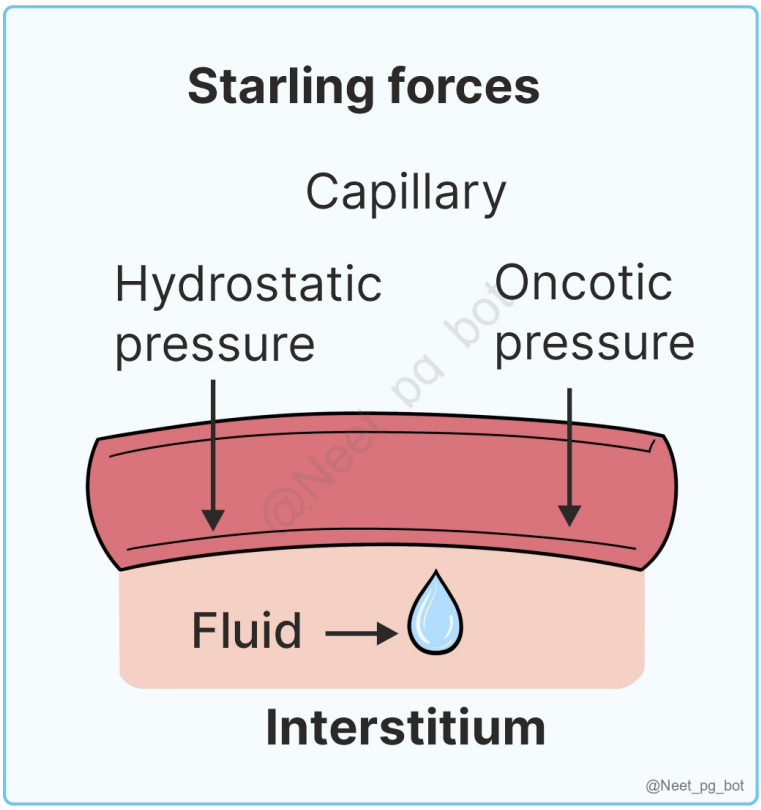
Q1: A 42-year-old man comes with swelling of both ankles. On examination, pitting oedema is noted. Which of the following alterations in Starling forces could contribute to the development of this condition? Increased capillary hydrostatic pressure Decreased capillary hydrostatic pressure Increased plasma oncotic pressure Decreased plasma oncotic pressure (Q879471)

A. 1 and 3

B. 2 and 3

C. 1 and 4

D. 2 and 4



Correct Answer: C. 1 and 4

Explanation: Edema results when the normal balance of Starling forces is disturbed. Increased capillary hydrostatic pressure (e.g., congestive heart failure, venous obstruction) promotes fluid movement out of the vasculature. Decreased plasma oncotic pressure (e.g., hypoalbuminemia from nephrotic syndrome or liver disease) reduces the inward pull of fluid back into capillaries. Both mechanisms lead to the accumulation of interstitial fluid and manifest as pitting oedema. Incorrect Options: 1 and 3 (Option A): Increased capillary hydrostatic pressure increases filtration, but raised plasma oncotic pressure does not favour oedema formation. 2 and 3 (Option B): Decreased capillary hydrostatic pressure and increased plasma oncotic pressure both work to oppose fluid leakage and oedema. 2 and 4 (Option D): Decreased capillary hydrostatic pressure opposes, rather than promotes, oedema.

@Neet_pg_bot

Q2: Which of the following inflammatory cells contains granules rich in major basic protein, toxic to helminths? (Q879443)

A. Neutrophils

B. Eosinophils

C. Basophils

D. Macrophages

Correct Answer: B. Eosinophils

Explanation: Eosinophils contain major basic protein (MBP) in their granules, which is toxic to helminths and contributes to tissue damage in allergies/asthma. Incorrect Options: Neutrophils (Option A) contain myeloperoxidase and elastase, not MBP. Basophils (Option C) contain histamine and heparin . Macrophages (Option D) contain lysosomal enzymes but no MBP.

@Neet_pg_bot

Q3: A child presents with recurrent pyogenic infections, partial oculocutaneous albinism, and peripheral neuropathy. Which immunodeficiency is most likely due to defective phagolysosome fusion? (Q879442)

A. Chronic granulomatous disease

B. Chediak-Higashi syndrome

C. Mannose-binding lectin deficiency

D. Glanzmann-Rinicker syndrome

Correct Answer: B. Chediak-Higashi syndrome

Explanation: Correct Option B - Chediak-Higashi syndrome Chediak-Higashi syndrome is caused by a defect in the LYST gene, leading to impaired phagolysosome fusion. Clinically presents with recurrent pyogenic infections, partial albinism, and neuropathy. The defect leads to giant, dysfunctional lysosomal granules in various cells, especially neutrophils, melanocytes and nerve cells. Incorrect Options: Chronic granulomatous disease (Option A) Due to an NADPH oxidase defect, resulting in defective respiratory burst rather than defective fusion. Mannose-binding lectin deficiency (Option C) Involves a defect in the complement pathway and is not related to phagolysosome function. Glanzmann thrombasthenia (Option D) A platelet aggregation disorder, not an immune cell fusion defect.

Q4: Which of the following enzymes/proteins is not involved in neutralizing reactive oxygen species? (Q879440)

A. Myeloperoxidase

B. Ceruloplasmin

C. Catalase

D. Glutathione peroxidase

Correct Answer: A. Myeloperoxidase

Explanation: Myeloperoxidase generates hypochlorous acid from H■O■ in neutrophils (microbicidal, not antioxidant). Incorrect Options: Ceruloplasmin (Option B) acts as a ferroxidase, limiting iron-catalyzed free radical formation. Catalase (Option C) decomposes hydrogen peroxide to water and oxygen. Glutathione peroxidase (Option D) reduces hydrogen peroxide and lipid peroxides using glutathione.

Q5: Which infection is characteristically associated with prolonged neutrophilic infiltration at the site of inflammation, even after 2–3 days? (Q879436)

A. Pseudomonas

B. Staphylococcus

C. Fungal infection

D. Viral infection

Correct Answer: A. Pseudomonas

Explanation: In most infections, neutrophils dominate only in the first 24–48 hours, after which macrophages take over. Pseudomonas is the exception, where neutrophils remain the predominant cell type due to continuous recruitment, even beyond the typical 2–3 day window. Helps differentiate Pseudomonas from other bacterial infections histologically.

Robbins and Cotran, Pathologic Basis of Disease, 11th edition, Page no.71

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 40-year-old woman develops acute pyelonephritis. Within the first 2 days of infection, she experiences high fever, flank pain, and dysuria. Urine microscopy reveals abundant pus cells. Which cell type is the main mediator of tissue damage in this stage of inflammation? (Q879435)

A. Neutrophils

B. Eosinophils

C. Macrophages

D. Plasma cells

Correct Answer: A. Neutrophils

Explanation: Acute inflammation is dominated by neutrophils, which arrive within the first 24–48 hours. They release reactive oxygen species, proteases, and lysosomal enzymes that kill pathogens but also cause collateral tissue injury. Incorrect Options: Eosinophils (Option B) mediate parasitic and allergic responses. Macrophages (Option C) dominate after 48–72 hours and are more important in chronic inflammation. Plasma cells (Option D) are seen in prolonged/chronic inflammation, producing antibodies.

@Neet_pg_bot

Q7: Which of the following adhesion molecules does not serve as a ligand for integrins during leukocyte adhesion? (Q879419)

A. CD54 (ICAM-1)

B. CD102 (ICAM-2)

C. CD106 (VCAM-1)

D. CD34

Correct Answer: D. CD34

Explanation: Integrins on leukocytes bind to members of the immunoglobulin superfamily such as ICAM-1 (CD54), ICAM-2 (CD102), and VCAM-1 (CD106) expressed on endothelial cells. CD34, on the other hand, is a ligand for L-selectin, not integrins.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th edition, Page no. 71.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following statements regarding selectins are correct? They mediate the initial rolling of leukocytes on the endothelium There are three main types: L-selectin, E-selectin, and P-selectin P-selectin is expressed on endothelial cells and platelets Selectins mediate firm, high-affinity adhesion of leukocytes (Q879417)

A. 1 and 2 only

B. 1, 2 and 3

C. 2, 3 and 4

D. 1 and 4 only

Correct Answer: B. 1, 2 and 3

Explanation: Selectins are adhesion molecules that mediate low-affinity rolling of leukocytes along the vascular endothelium. The three types are L-selectin (on leukocytes), E-selectin (on endothelial cells), and P-selectin (on platelets and endothelial cells). Firm, high-affinity adhesion is mediated by integrins, not selectins. (Statement 4)

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th edition, Page no. 69.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: During normal laminar blood flow in venules, the phenomenon of axial streaming determines the distribution of blood cells. Which cells predominantly occupy the central axial column? (Q879414)

A. Red blood cells

B. Neutrophils

C. Platelets

D. Lymphocytes

Correct Answer: A. Red blood cells

Explanation: In laminar flow, RBCs concentrate in the central axial stream of blood. Leukocytes and platelets are displaced toward the periphery (close to the endothelium), allowing them to migrate out during inflammation or vascular injury. This arrangement facilitates efficient oxygen transport and also enables rapid recruitment of WBCs during acute inflammation.

@Neet_pg_bot

Q10: A 30-year-old female presents to the clinic with complaints of abdominal discomfort and bloating. Upon further evaluation, an abdominal ultrasound reveals a heterogeneous mass within the right ovary. Subsequent histopathological examination of the ovarian mass demonstrates the presence of entotic cells. Which of the following best describes the process observed in the histopathological findings? (Q845364)

A. Phagocytosis of apoptotic cells by neighboring cells

B. Engulfment of live cells by neighboring cells

C. Fusion of lysosomes within a cell leading to autophagy

D. Exocytosis of cellular debris from a damaged cell

Correct Answer: B. Engulfment of live cells by neighboring cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 30-year-old female presents with abdominal discomfort and bloating, and abdominal ultrasound reveals a heterogeneous mass in the right ovary; histopathological examination shows entotic cells, indicating the engulfment of live cells by neighboring cells. Entosis is a phenomenon where live cells are engulfed and internalized by neighbouring cells, forming cell-in-cell structures. It typically occurs in non-phagocytic cells and can be observed in various physiological and pathological contexts, including tumour microenvironments. In the scenario described, the presence of entotic cells within the ovarian mass indicates that live cells are being engulfed by neighbouring cells within the ovary. Phagocytosis of apoptotic cells by neighbouring cells (Option A): Phagocytosis involves the clearance of dead or apoptotic cells by neighbouring phagocytic cells such as macrophages. However, entosis involves the engulfment of live cells, not apoptotic cells. Fusion of lysosomes within a cell leading to autophagy (Option C): Autophagy is a cellular process involved in the degradation and recycling of cellular components but no engulfment of neighboring cells. Exocytosis of cellular debris from a damaged cell (Option D): Exocytosis is the process by which cells release molecules or cellular components into the extracellular space, and it does not involve the engulfment of neighboring cells. Emperipolesis v/s Efferocytosis v/s Entosis: Feature Emperipolesis Efferocytosis Entosis Cell State Viable/intact Apoptotic/dying Viable Phagocyte Histiocytes/tumor Professional (macrophages) Neighboring epithelial Fate No degradation, exits Lysosomal digestion Degraded/persists Purpose Dynamic transit Homeostasis Cell competition Pathology Rosai-Dorfman SLE, atherosclerosis Cancer

@Neet_pg_bot

Q11: A 6-month-old male infant presents with recurrent bacterial infections, including otitis media and pneumonia. Laboratory investigations reveal markedly reduced levels of all immunoglobulin classes (IgG, IgA, and IgM). Flow cytometry analysis shows a complete absence of mature B cells in peripheral blood. Which of the following gene mutations is most likely responsible for this condition? (Q845372)

A. BTK gene

B. LYST gene

C. WASP gene

D. ADA gene

Correct Answer: A. BTK gene

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical presentation suggests X-linked agammaglobulinemia (XLA) also known as Bruton's Hypogammaglobulinemia, an X-linked recessive disorder characterized by a complete absence or markedly reduced number of mature B cells in peripheral blood due to mutations in the Bruton tyrosine kinase (BTK) gene located on the X chromosome. B cells are absent or markedly decreased in circulation, but the pre-B cell level is normal in the bone marrow. XLA is characterized by markedly reduced levels of all immunoglobulin classes (IgG, IgA, and IgM), leading to hypogammaglobulinemia and defective Opsonization (due to ↓IgG). It typically presents in infancy with recurrent bacterial infections, particularly affecting the respiratory tract, ears, and sinuses. Replacement therapy with immunoglobulins (IVIG) is the mainstay of treatment. Gene mutation Diseases Findings BTK gene X-linked agammaglobulinemia or Bruton's Hypogammaglobulinemia Hypogammaglobulinemia (low IgG, IgA, IgM); absent B cells on flow cytometry. LYST gene (Option B) Chediak-Higashi syndrome Giant granules in neutrophils are visible in peripheral blood smears. WASP gene (Option C) Wiskott-Aldrich Syndrome Triad: Thrombocytopenia, eczema, and recurrent infections. ADA/IL2RG gene (Option D) Severe Combined Immunodeficiency Profound lymphopenia (primarily T-cells); absent/reduced T & B cells; reduced ADA enzyme activity CD40L gene Hyper IgM Syndrome ↑IgM, ↓IgG/IgA; normal B cells; opportunistic infections (PCP) CYBB/gp91phox gene X-linked Chronic Granulomatous Disease (X-CGD) Recurrent catalase+ infections (Aspergillus, Staph. aureus); NBT/DHR test negative■ ITGB2/CD18 gene Leukocyte Adhesion Deficiency (LAD) Delayed separation of the umbilical cord; absent pus formation ; high neutrophils in blood (but they can't reach the site of infection). AIRE/STAT1 gene Chronic Mucocutaneous Candidiasis Non-invasive Candida infections of skin/nails; normal T/B numbers; anti-IL17 autoantibodies; often associated with autoimmune polyendocrine syndrome

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Which of the following defects is most likely associated with Leukocyte Adhesion Deficiency Type 1 (LAD)-1? (Q845370)

A. Defective synthesis of β2 integrin

B. Defective synthesis of Sialyl Lewis X modified glycoprotein

C. Defective FERMT3 gene

D. Myeloperoxidase deficiency

Correct Answer: A. Defective synthesis of β2 integrin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario suggests Leukocyte Adhesion Deficiency Type 1 (LAD-1) , which is characterized by defective synthesis of the β2 chain of CD11/CD18 integrins (β2 integrin), resulting in defective leukocyte adhesion to endothelium. Leukocyte Adhesion deficiencies (LAD) are rare autosomal recessive disorders LAD-1 LAD-2 LAD-3 Defective synthesis of β2 chain of CD11/CD18 integrins (β2 integrin). (Option A) Defective synthesis of sialyl-Lewis X modified glycoprotein, a ligand for E- and P-selectins. (Option B) Mutations in the FERMT3 genes. (Option C) Clinical manifestations include delayed separation of the umbilical cord stump in newborns, and recurrent bacterial infections. Clinically, LAD 2 patients may exhibit a Bombay Blood group phenotype. Clinical presentation is similar to LAD-1, along with bleeding disorders due to platelet dysfunction. {{caption_text}} Myeloperoxidase deficiency (Option D) is a rare inherited autosomal recessive disorder in which neutrophils lack functional MPO enzymes, impairing their ability to produce reactive oxygen species (ROS) essential for microbial killing. Due to reduced microbicidal activity, these patients are susceptible to recurrent bacterial and fungal infections, especially in mucosal tissues (invasive candida infection).

@Neet_pg_bot

Q13: Which condition is characterized by recurrent catalase positive bacterial, and fungal infections, defective nitroblue tetrazolium (NBT) test results, and deficient

reactive oxygen species production by phagocytes? (Q845366)

A. Leukocyte Adhesion Deficiency

B. Hyper-IgM Syndrome

C. X-linked Agammaglobulinemia

D. Chronic Granulomatous Disease

Correct Answer: D. Chronic Granulomatous Disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical presentation, with recurrent catalase-positive bacterial and fungal infections, negative nitroblue tetrazolium (NBT) test results, and deficient reactive oxygen species production by phagocytes, is due to defective NADPH Oxidase, suggesting Chronic Granulomatous Disease (CGD) . It can be X-linked recessive (75% cases) or autosomal recessive (25% cases). diagnosis: Nitroblue tetrazolium test (NBT) is a screening test commonly used to assess the respiratory burst activity of phagocytes. In CGD, phagocytes fail to reduce NBT to its insoluble form, resulting in a negative NBT test. Dihydrorhodamine test (DHR) is the confirmatory test for CGD done by flow cytometry. Leukocyte Adhesion Deficiency (Option A): Leukocyte Adhesion Deficiency (LAD) is a group of disorders characterized by defects in leukocyte adhesion or migration, leading to impaired immune responses. It is of 3 types: LAD I: Defect in β2 integrin LAD II: Deficiency of sialyl-Lewis X LAD III: Mutation in the FERMT3 gene Hyper-IgM Syndrome (Option B) is a group of primary immunodeficiency disorders marked by elevated IgM levels and decreased levels of other immunoglobulin isotypes, resulting from defects in either the CD40 ligand and the CD40 receptor. X-linked Agammaglobulinemia (Option C) , also known as Bruton’s agammaglobulinemia or Bruton's disease, is caused by mutations in the BTK gene and primarily affecting boys, is characterized by a lack of mature B cells and impaired immunoglobulin production, resulting in recurrent bacterial infections■■■■■.

Robbins and Cotrans pathologic basis of disease, 10th Edition, Page 241.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Which among the following is a cardinal sign of inflammation? (Q845313)

A. Prolonged fever

B. Tissue scarring

C. Abrasions

D. Redness

Correct Answer: D. Redness

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, redness is one of the cardinal signs of inflammation. Cardinal signs of inflammation: Redness (Rubor) is caused by increased blood flow to the affected area due to vasodilation of blood vessels. Heat (Calor): The increased temperature at the site of inflammation due to vasodilation and increased blood flow. Swelling (Tumor): Accumulation of fluid and inflammatory cells, leading to tissue swelling. Pain (Dolor): Sensory nerve stimulation due to tissue damage, increased pressure from swelling, and release of inflammatory mediators. Loss of Function (Functio Laesa): Impairment or loss of normal tissue function. While the 1st four signs were given by Celsus, Functio Laesa was given by Sir Rudolf Virchow. Prolonged fever, Tissue scarring and Abrasions (Option A,B and C) are not cardinal sign of inflammation

@Neet_pg_bot

Q15: Which of the following statements is incorrect regarding Emperipolesis and Phagocytosis? (Q845362)

A. Emperipolesis involves engulfment by any cell depending on disease; Phagocytosis involves engulfment by macrophages, neutrophils, and dendritic cells.

B. Emperipolesis doesn’t involve the killing of the cell; phagocytosis results in the degradation of engulfed cells.

C. Emperipolesis maintains internalized cell membrane integrity; Phagocytosis involves the fusion of engulfed material with lysosomes.

D. Emperipolesis is physiological; phagocytosis is pathological.

Correct Answer: D. Emperipolesis is physiological; phagocytosis is pathological.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Emperipolesis is seen in pathological conditions whereas phagocytosis can be physiological/pathological response. Feature Emperipolesis Phagocytosis Entosis Definition Emperipolesis is a cellular phenomenon characterized by the internalization of one cell within another without causing cell death. Phagocytosis is a cellular process by which certain specialized cells engulf and digest foreign particles, pathogens, dead cells, and cellular debris. Entosis is the internalisation of a live cell by a neighbouring cell, forming a

cell-in-cell structure. Cell Type The large cell dependent on organ/ disease (Option A ruled out) Engulfing cells can be macrophages, neutrophils, and dendritic cells. (Option A ruled out) Typically occurs in non-phagocytic cells (e.g., epithelial or tumor cells). Fate of Internalized Cell No killing of the internalized cell. The engulfed cell often remains viable within the host cell. (Option B ruled out) Typically digest and degrade the engulfed material such as bacteria or cellular debris. (Option B ruled out) The engulfed cell is initially alive , but it is often eventually degraded (cell cannibalism). Mechanism / Integrity The engulfed cell maintains its own membrane integrity. (Option C ruled out) The engulfed material typically fuses with lysosomes for digestion. (Option C ruled out) Driven by actomyosin-mediated contraction; the "loser" cell is internalized by the "winner." Clinical Context It is seen in pathological conditions such as autoimmune diseases, lymphoproliferative disorders, or histiocytic disorders. (Option D) Can be physiological (tissue turnover, apoptotic cells), can be pathological (infection, inflammation). (Option D) Often observed in tumor microenvironments and various physiological/pathological contexts.

Robbins and Cotrans pathologic basis of disease, 10th Edition, Page 80

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 45-year-old male complains of painless bilateral cervical lymphadenopathy for the past six months. Biopsy of a lymph node reveals sheets of large histiocytes with emperipolesis, surrounded by lymphocytes and plasma cells. What is the most likely diagnosis? (Q845360)

A. Hodgkin lymphoma

B. Sarcoidosis

C. Infectious mononucleosis

D. Rosai-Dorfman disease

Correct Answer: D. Rosai-Dorfman disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario and histopathological findings suggest Rosai-Dorfman disease which typically presents with painless bilateral cervical lymphadenopathy and is characterized by the presence of large histiocytes with emperipolesis, where intact lymphocytes are seen within the cytoplasm of histiocytes . Emperipolesis is the phenomenon of one cell residing within another cell, usually a macrophage, without causing death to the cell. The internalized cell is enclosed within the cytoplasmic vacuole of the host cell without fusion of their membranes. This phenomenon is seen in conditions like (Mnemonic - MARC) : Myelodysplastic Syndrome/Myeloproliferative Neoplasm (MDS/MPN) Autoimmune Hepatitis (Lymphocytes and plasma cells

may be seen within the cytoplasm of hepatocytes). Rosai-Dorfman disease Chronic Lymphocytic Leukemia (CLL) {{caption_text}} Hodgkin's lymphoma (Option A) is identified by Reed-Sternberg cells (Owl eye appearance), which are large, multinucleated cells with prominent nucleoli but not associated with emperipolesis. Sarcoidosis (Option B) is characterized by non-caseating granulomas. Infectious mononucleosis (Option C) , caused by the Epstein-Barr virus (EBV), can present with cervical lymphadenopathy, but it typically involves lymphoid hyperplasia with reactive lymphocytes but doesn't show large histiocytes with emperipolesis.

Robbins and Cotrans pathologic basis of disease, 10th Edition, Pages 80, 843

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which of the following statements regarding neutrophil extracellular traps (NETs) is incorrect? (Q845359)

A. NETs are formed in response to infectious pathogens and inflammatory mediators.

B. NETs consist of nuclear chromatin and granule proteins like antimicrobial peptides and enzymes.

C. NET formation is initiated by the release of histones from activated neutrophils.

D. NETs directly phagocytose the invading pathogens.

Correct Answer: D. NETs directly phagocytose the invading pathogens.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Neutrophil extracellular traps (NETs) are extracellular fibrillar structures that localize antimicrobial substances at infection sites and trap microbes, helping to prevent their spread by directly targeting invading pathogens. NETs do not directly phagocytose or engulf the invading pathogens. Instead, they trap pathogens within their structure, immobilizing them and allowing other immune cells, such as macrophages, to recognize and eliminate them. (Option D) They are produced by neutrophils in response to infectious pathogens (mainly bacteria and fungi) and inflammatory mediators (e.g., chemokines, cytokines, complement proteins, and ROS). (Option A ruled out) NET formation starts with ROS-dependent activation of an arginine deaminase that converts arginine to citrulline, leading to chromatin decondensation. NETs are composed of nuclear chromatin and various granule proteins, including antimicrobial peptides and enzymes that help to neutralize and kill pathogens trapped within the NETs. (Option B ruled out) Activated neutrophils release histones into the extracellular space, which helps to unwind and release the DNA, allowing it to combine with granule proteins and form the characteristic web-like structure of NETs. (Option C ruled out) They have been detected in conditions like sepsis, emphasizing their importance in immune protection. The nuclear chromatin in the NETs, which includes histones and associated DNA, has been postulated to be a source of nuclear antigens in systemic autoimmune diseases, particularly lupus, in which individuals react against their own DNA and nucleoproteins. {{caption_text}} {{caption_text}} A neutrophil granulocyte (yellow) has ejected a NET (green) to capture bacteria (purple). A red blood cell (orange) is also trapped in the NET.

@Neet_pg_bot

Q18: A 40-year-old male presents with recurrent bacterial infections. Laboratory tests reveal reduced opsonization activity in his serum. Which of the following processes is primarily affected in this patient? (Q845356)

A. Complement activation

B. Diapedesis

C. Microbial engulfment

D. Leucocyte rolling.

Correct Answer: C. Microbial engulfment

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 40-year-old male presents with recurrent bacterial infections, and laboratory tests show decreased opsonization activity in his serum, indicating that the primary process affected is microbial engulfment. Microbial engulfment refers to the process by which phagocytes engulf and internalize pathogens for destruction. Opsonization plays a critical role in this process by coating pathogens with opsonins that enhance phagocytosis. Reduced opsonization activity in serum directly impacts microbial engulfment, as pathogens are less efficiently recognized and phagocytosed by immune cells. Opsonins are substances that coat pathogens or foreign particles, making them more recognizable and easier for phagocytic cells to engulf. They act as "handles" that bind to both the pathogen and the receptor on the phagocyte. {{caption_text}} Opsonin is divided into 3 Categories: IgG (Most important opsonin) Complement proteins (C 3b , C 4b , C 5b): The most important complement opsonin C 3b Plasma Protein (E.g., Fibrinogen) Effect of reduced opsonization: Phagocytes (macrophages/neutrophils) cannot efficiently engulf microbes Leads to recurrent infections Complement activation (Option A), Diapedesis (Option B), and Leukocyte rolling (Option D) are not affected by reduced opsonization.

Robbins and Cotrans pathologic basis of disease, 10th Edition, Pages 47-48

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 45-year-old man with a history of poorly controlled diabetes presents to the hospital with complaints of fever, productive cough, and chest pain. Chest imaging

reveals the presence of multiple cavitary lesions in the lung parenchyma. Microscopic examination of lung tissue obtained via biopsy demonstrates numerous neutrophils and macrophages surrounding fungal hyphae. Which of the following phenomena is most likely associated with the formation of these cavitary lesions? (Q845347)

A. Activation of complement proteins

B. Release of lysozymes from neutrophils

C. Impaired phagocytosis

D. Formation of neutrophil extracellular traps (NETs)

Correct Answer: C. Impaired phagocytosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 45-year-old man with poorly controlled diabetes presents with fever, productive cough, and chest pain, and chest imaging shows multiple cavitary lesions in the lungs; biopsy reveals fungal hyphae surrounded by neutrophils and macrophages, with the formation of these cavities most likely linked to impaired phagocytosis. In cases of severe infection or in the presence of large pathogen loads, the process of phagocytosis may become ineffective, resulting in incomplete or impaired phagocytosis which is known as ‘ Frustrated Phagocytosis .’ Frustrated phagocytosis: Macrophages cannot engulf large fungal hyphae Leads to the release of lysosomal enzymes Causes tissue necrosis and cavity formation Seen in poorly controlled diabetics with fungal infections Microscopy: Fungal hyphae surrounded by neutrophils and macrophages {{caption_text}} Activation of complement proteins (Option A): Complement opsonizes fungi for phagocytosis but doesn't cause tissue destruction/cavitation; effective in early defense, not lesion formation. Release of lysozymes from neutrophils (Option B) : Lysozymes degrade bacterial peptidoglycan (weak vs. fungal cell walls); ineffective against thick mucormycosis hyphae, so doesn't contribute to necrosis.■ Formation of neutrophil extracellular traps (NETs) (Option D) : NETs trap fungi but are dysregulated in diabetes (excessive/prolonged) and ineffective vs. Mucorales (fungi express enzymes to degrade NETs + high ambient iron blocks NET formation); contribute to inflammation but not primary cavitation mechanism.

@Neet_pg_bot

Q20: Which of the following plays a crucial role in mediating firm adhesion of leukocytes during acute inflammation? (Q845345)

A. CD11a/CD18

B. PECAM 1

C. CD31

D. CD44

Correct Answer: A. CD11a/CD18

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CD11a/CD18 plays a crucial role in mediating firm adhesion of leukocytes during acute inflammation. Adhesion types in inflammation: Rolling & weak adhesion → mediated by selectins Firm adhesion → mediated by integrins β■ integrin (VLA) β■ integrin (LFA-1/MAC-1 = CD11/CD18) → mediates firm adhesion (Option A) PECAM 1 (platelet endothelial cell adhesion molecule 1), also known as CD31 , plays a role in leukocyte transmigration across endothelial junctions. (Options B & C ruled out). CD44 (Option D) is a cell surface glycoprotein that serves as a receptor for hyaluronic acid, a component of the extracellular matrix. It does not involve firm adhesion of transmigration of leukocytes. {{caption_text}} Sequence of Acute Inflamation: Stage Process Key Events 1. Vascular Response Vasodilation & Increased Permeability Transient vasoconstriction followed by rapid vasodilation; increased blood flow causes redness (rubor) and heat (calor). 2. Exudation Fluid Leakage Fluid and proteins move into the interstitial tissue (edema), leading to swelling (tumor). 3. Margination Leukocyte Positioning Blood flow slows (stasis), allowing leukocytes to move from the center of the vessel to the periphery (endothelial surface). 4. Rolling & Adhesion Attachment Leukocytes "roll" along the endothelium via selectins and bind firmly via integrins (e.g., CD18). 5. Transmigration Diapedesis Leukocytes squeeze through endothelial gaps, often at post-capillary venules. 6. Chemotaxis Migration Leukocytes follow a chemical gradient (e.g., C5a, LTB4) to the specific site of injury. 7. Phagocytosis Clearance Specialized cells (macrophages, neutrophils) engulf and digest pathogens or debris. Major mediators of inflammation: Mediator Class Specific Examples Principal Action Vasoactive Amines Histamine, Serotonin Cause immediate vasodilation and increased vascular permeability. Arachidonic Acid Metabolites LTB4 (Leukotriene B4), Prostaglandins LTB4 acts as a potent chemoattractant; Prostaglandins mediate pain and fever. Complement System C5a , C3a C5a is a powerful chemotactic factor; C3b acts as an opsonin for phagocytosis. Cytokines TNF, IL-1, IL-2RG (signaling) Mediate systemic acute-phase responses (fever) and leukocyte activation. Chemokines IL-8 Recruit specific subsets of leukocytes to the inflammatory site. Reactive Oxygen Species NADPH oxidase products Used in the "respiratory burst" to kill engulfed pathogens.

@Neet_pg_bot

Q21: A patient presents with fluid accumulation in the pleural cavity. Which of the following characteristics would be consistent with a diagnosis of exudate rather than a transudate? (Q845336)

A. High LDH

B. Low protein concentration

C. Presence of mainly albumin

D. Low specific gravity

Correct Answer: A. High LDH

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Of the options provided, elevated LDH is a distinguishing feature of an exudate. Features Transudate Exudate Mechanism Ultrafiltrate of plasma due to increased hydrostatic pressure with normal vascular permeability (non-inflammatory process). Inflammatory process with increased vascular permeability Appearance Clear, serous fluid Cloudy/purulent/hemorrhagic Specific gravity (Option D ruled out) Low (<1.018) High (>1.018) Protein (Option B, C ruled out) Low (<2g/dl), mainly albumin High (>2g/dl) Clot Absent Present (Due to high fibrinogen level) Cell count Low High Types of cells Few lymphocytes and mesothelial cells Neutrophils in acute and lymphocytes in chronic inflammation Bacteria Absent Present LDH (Option A) Low High Seen in Congestive cardiac failure Cirrhosis Nephrotic Syndrome Pyogenic infections Malignancy Pancreatitis {{caption_text}} Light's Criteria: To definitively distinguish between the two, clinicians use Light's Criteria . Fluid is classified as an exudate if it meets at least one of the following: Pleural Fluid Protein / Serum Protein ratio > 0.5 Pleural Fluid LDH / Serum LDH ratio > 0.6 Pleural Fluid LDH > 2/3 the upper limit of normal for serum LDH.

@Neet_pg_bot

Q22: Which of the following is considered the hallmark event of acute inflammation? (Q845332)

A. Vasodilation

B. Increased vascular permeability

C. Stasis

D. Leukocyte extravasation

Correct Answer: B. Increased vascular permeability

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Increased vascular permeability, particularly in postcapillary venules, is considered the primary hallmark event of acute inflammation. This process enables the passage of plasma proteins, fluids, and white blood cells from the bloodstream into the tissue. Endothelial contraction is the primary cause of increased Vascular Permeability, particularly in the rapid, transient phase of acute inflammation. Vascular events -> Cellular events Transient vasoconstriction. Vasodilation. Increased vascular permeability. Stasis. Margination. Rolling. Adhesion. Transmigration. Chemotaxis. Opsonization. Phagocytosis.

@Neet_pg_bot

Q23: Which of the following mechanisms primarily contributed to the increased vascular permeability in this patient's with a right knee injury after fall from stairs? (Q845326)

A. Contraction of endothelial cells resulting in the opening of interendothelial gaps

B. Direct damage to endothelial cells

C. Neutrophil-mediated injury to the endothelium

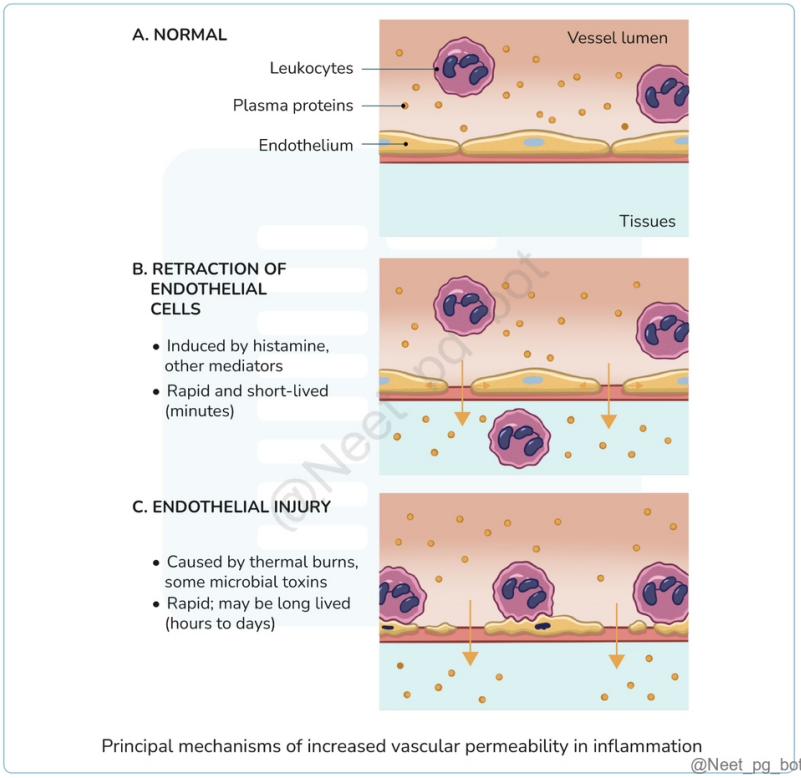
D. Proliferation of lymphatic vessels

Correct Answer: A. Contraction of endothelial cells resulting in the opening of interendothelial gaps

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Increased vascular permeability in this patient with a right knee injury from a fall is mainly caused by endothelial cell contraction, which creates interendothelial gaps. The primary mechanism is the contraction of endothelial cells, leading to the opening of interendothelial gaps. This is mediated by various inflammatory mediators released in response to tissue injury, including histamine, bradykinin, and leukotrienes. Immediate transient response (occurs within minutes and lasts for a short duration) {{caption_text}} Direct damage to endothelial cells (Option B), Neutrophil-mediated injury to the endothelium (Option C), and Proliferation of lymphatic vessels (Option D) do not mediate mechanical injury as given in the scenario.



Principal mechanisms of increased vascular permeability in inflammation

@Neet_pg_bot

Q24: A 30-year-old male presents to the emergency department with sudden onset right lower abdominal pain, accompanied by nausea and fever. On examination, there is tenderness over McBurney's point, and rebound tenderness is noted. Laboratory investigations reveal leukocytosis. Which type of inflammation is most likely to be associated with the following clinical scenario? (Q845322)

A. Serous inflammation

B. Fibrinous inflammation

C. Purulent inflammation

D. Ulcerative inflammation

Correct Answer: C. Purulent inflammation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical findings point towards the diagnosis of acute appendicitis, and purulent inflammation is likely to be associated with this condition. Purulent inflammation is characterized by the production of pus, an exudate consisting of neutrophils, the liquefied debris of necrotic cells, and oedema fluid. Abscesses are localized collections of pus caused by suppuration buried in tissue, organ, or confined space. Examples: Acute appendicitis ; abscesses; bacterial meningitis; lobar pneumonia; empyema. {{caption_text}} Serous inflammation (Option A): Accumulation of fluid in body cavities is called an effusion, which can occur due to increased vascular permeability or local irritation. Examples : Blister from burn; pleural effusion in viral pleuritis; early-stage transudates. Fibrinous inflammation (Option B): Fibrinous inflammation involves the deposition of fibrin in the extracellular space due to increased vascular permeability. Histologically, fibrin appears as an eosinophilic meshwork of threads or an amorphous coagulum. Examples : Fibrinous pericarditis (bread & butter appearance); fibrinous pneumonia); uremic pericarditis. Ulcerative inflammation (Option D): Ulcerative inflammation involves local defects or excavations of an organ or tissue's surface caused by the shedding of inflamed necrotic tissue, which is common in mucosal surfaces, the skin, and subcutaneous tissues. Examples : Peptic ulcers (stomach/duodenum); aphthous ulcers (canker sores); tuberculous ulcer; amebic colitis.

@Neet_pg_bot

Q25: Which of the following features is a characteristic of acute inflammation? (Q845319)

A. Presence of granulomas

B. Proliferation of fibroblasts and angiogenesis

C. The predominance of lymphocytes in the inflammatory infiltrate

D. Accumulation of neutrophils at the site of injury

Correct Answer: D. Accumulation of neutrophils at the site of injury

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, the accumulation of neutrophils at the site of injury is a characteristic of Acute inflammation. Acute inflammation → Predominated by neutrophils Exception: Typhoid → lymphocyte predominance Presence of granulomas (Option A) , Proliferation of fibroblasts and angiogenesis (Option B) , and The predominance of lymphocytes in the inflammatory infiltrate (Option C) are associated with chronic inflammation. Acute v/s Chronic Inflammation: Feature Acute Inflammation Chronic Inflammation Onset Rapid (minutes-hours) Insidious (weeks-months) Duration Short (<2 weeks) Prolonged (>4-6 weeks) Major Cells Neutrophils (PMNs) Lymphocytes, macrophages, plasma cells Mediators Histamine, prostaglandins, LTs, C3a/C5a Cytokines (IL-1, TNF-α), growth factors Vascular Changes Marked vasodilation, ↑permeability Minimal vascular changes Exudate Serous, purulent, fibrinous Minimal exudate; tissue destruction Histology Neutrophils, edema, hyperemia Lymphocytes, fibrosis, angiogenesis Examples Appendicitis, pneumonia, abscess TB, rheumatoid arthritis, atherosclerosis Cause Bacteria, trauma, chemicals Persistent infection, autoimmunity Outcome Resolution, abscess, progression Fibrosis, scarring, organ dysfunction Systemic Signs Fever, leukocytosis (PMN↑) Mild fever, anemia of chronic disease

Robbins and Cotrans pathologic basis of disease, 10th Edition, Page 75

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: A 30-year-old female presents with a history of recent major surgery, deep vein thrombosis (DVT) in the lower extremities, and a family history of thrombotic events. Which of the following components constitute Virchow's triad, predisposing individuals to thrombosis? (Q845316)

A. Endothelial injury, hypercoagulability, and venous stasis

B. Endothelial dysfunction, leukocytosis, and platelet activation

C. Arterial dilation, decreased platelet count, and fibrinolysis

D. Hypothermia, acidosis, and coagulopathy

Correct Answer: A. Endothelial injury, hypercoagulability, and venous stasis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Virchow's triad consists of three primary factors that contribute to thrombosis: Endothelial injury - Triggers platelet adhesion and clot formation. Stasis or turbulent blood flow - Disrupts normal anticoagulant processes, promoting thrombosis. Hypercoagulability of the blood - An increased tendency of blood to clot, often due to genetic or acquired conditions.

Q1: A 50-year-old man developed a small purulent abscess on his shoulder. After appropriate drainage and infection control measures, the wound healed well, leaving a healthy scar. During the early stages of tissue repair, which type of collagen predominates in the provisional matrix? (Q879470)

A. Type I

B. Type II

C. Type III

D. Type IV

Correct Answer: C. Type III

Explanation: Type III collagen is the main collagen deposited in the early provisional matrix. It forms a delicate, flexible scaffold that supports fibroblast migration and granulation tissue formation before being replaced by Type I collagen in later remodelling phases. Incorrect Options: Type I (Option A): Type I collagen is the most abundant collagen in mature scar tissue, appearing later in wound remodelling. Type II (Option B): Type II collagen is primarily found in cartilage and is not involved in skin wound healing. Type IV (Option D): Type IV collagen is a principal component of basement membranes, not the provisional matrix.

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 94.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 45-year-old woman undergoes excision of a sebaceous cyst with primary closure of the wound. During the healing process, angiogenesis is initiated early but reaches its

maximum on which postoperative day? (Q879468)

A. Day 4

B. Day 3

C. Day 5

D. Day 7

Correct Answer: C. Day 5

Explanation: Peak neovascularisation usually occurs around day 5, characterised by maximum formation of new blood vessels to support granulation tissue and fibroblast proliferation essential for wound repair. Incorrect Options: Day 4 (Option A): Day 4 is early in the proliferative phase, but neovascularisation is still developing. Day 3 (Option B): Day 3 mainly involves transition from inflammation to proliferation, with early fibroblast activity, but neovascularisation is not yet at its peak. Day 7 (Option D): By day 7, neovascularisation starts stabilising and the wound begins to mature and remodel.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 97.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: During healing by primary intention, the initial acute inflammatory response is dominated by neutrophils. On which postoperative day do macrophages typically replace neutrophils as the predominant inflammatory cells at the wound site? (Q879467)

A. Day 1

B. Day 2

C. Day 3

D. Day 7

Correct Answer: C. Day 3

Explanation: By day 3, macrophages become the predominant cells in the wound. They clear apoptotic neutrophils through efferocytosis, release growth factors and cytokines to promote tissue repair, and orchestrate the transition from the inflammatory to proliferative phase of healing. Their actions are critical for the progression of effective wound repair. Incorrect Options: Day 1 (Option A): Neutrophils are the main inflammatory cells on day 1,

responsible for initial pathogen clearance and tissue debris removal. Day 2 (Option B): Neutrophils still predominate on day 2; macrophages begin to infiltrate but are not yet dominant. Day 7 (Option D): By day 7, macrophages dominate, and the wound is usually transitioning into the remodelling phase.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 97.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following is NOT true regarding the actions of Transforming Growth Factor Beta (TGF-β)? (Q879464)

A. TGF-β promotes collagen synthesis by fibroblasts

B. TGF-β enhances the breakdown of extracellular matrix proteins

C. TGF-β contributes to tissue fibrosis in organs

D. TGF-β has anti-inflammatory properties

Correct Answer: B. TGF-β enhances the breakdown of extracellular matrix proteins

Explanation: TGF-β stimulates the production of collagen, fibronectin, and proteoglycans and inhibits collagen degradation by decreasing matrix metalloproteinase (MMP) activity and increasing the activity of tissue inhibitors of metalloproteinases (TIMPs). This inhibition stabilises and accumulates matrix proteins, contributing to fibrosis. Incorrect Options: TGF-β promotes collagen synthesis by fibroblasts (Option A): TGF-β stimulates the synthesis of collagen, especially by inducing fibroblast differentiation to myofibroblasts, which are key in fibrosis development in organs. TGF-β contributes to tissue fibrosis in organs (Option C): TGF-β is a pro-fibrotic cytokine involved in the development of fibrosis in the lung, liver, and kidneys in response to chronic inflammation. TGF-β has anti-inflammatory properties (Option D): It acts as an anti-inflammatory cytokine by inhibiting lymphocyte proliferation and the activity of other leukocytes.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following diseases are typically associated with non-caseating granulomas? (Q879462)

A. Leprosy, Sarcoidosis, and Crohn’s disease

B. Tuberculosis and Syphilis

C. Cat-scratch disease only

D. All of the above

Correct Answer: A. Leprosy, Sarcoidosis, and Crohn’s disease

Explanation: Leprosy (Mycobacterium leprae): Non-caseating granulomas with acid-fast bacilli in macrophages. Sarcoidosis: Classic cause of non-caseating granulomas, with abundant activated macrophages. Crohn’s disease: Shows occasional non-caseating granulomas in the intestinal wall. Incorrect Options: Tuberculosis & Syphilis (Option B): Produce caseating granulomas (not non-caseating). Cat-scratch disease (Option C): Produces stellate granulomas with neutrophils, not typical non-caseating.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 91

↑ *Back to this question in Part A*

@Neet_pg_bot

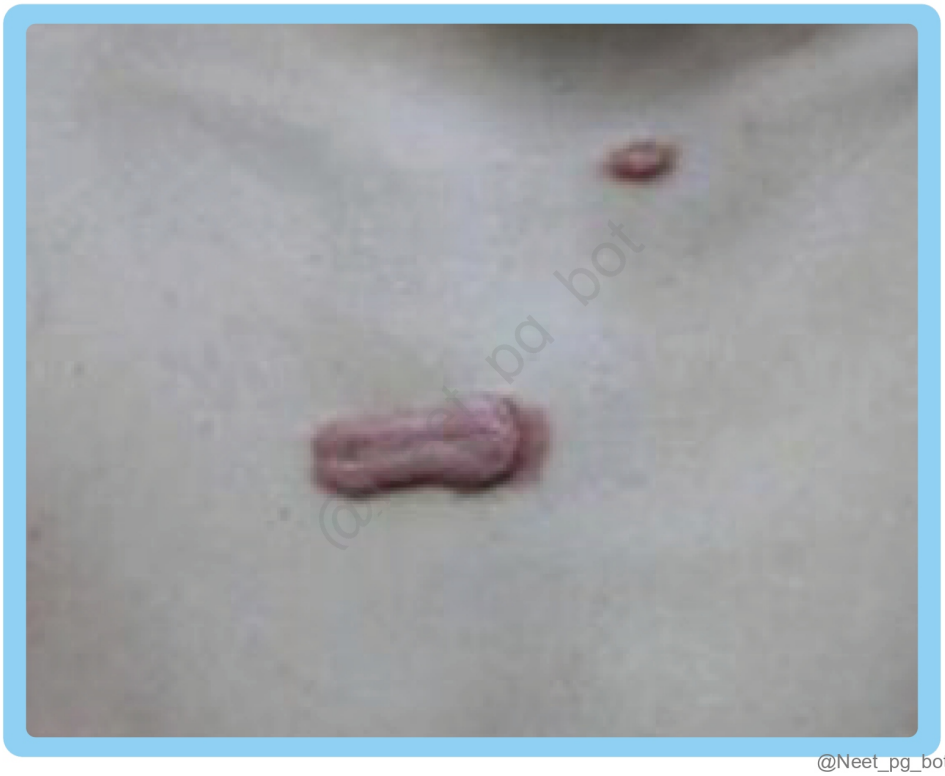
Q6: A 30-year-old man presents to the clinic with a raised scar on his chest. He reports that the scar has been gradually increasing in size since he had a minor injury in that area about a year ago. On examination, the scar extends beyond the original wound margins and appears firm and raised. Which of the following is the most likely diagnosis for the scar on the patient's chest? {{caption_text}} (Q845432)

A. Hypertrophic scar

B. Keloid

C. Exuberant granulation tissue

D. Contracture



Correct Answer: B. Keloid

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The most likely diagnosis for a raised scar on the patient’s chest is Keloid, characterized by abnormal and excessive growth of scar tissue that grows beyond the boundaries of the original wound and does not regress. Scar grows beyond the original wound → unlike hypertrophic scars Firm, raised, pink or reddish Common sites: Sternum, shoulders, upper back, earlobes Cause: Minor or major injury, surgery, burns Functional impact: Can impair mobility if near joints Treatment: Intralesional injection of steroid (triamcenolone) Hypertrophic scar (Option A): While hypertrophic scars are also raised, they typically remain within the boundaries of the original injury. They may regress over time and are less likely to recur after treatment compared to keloids. {{caption_text}} Keloid v/s Hypertrophic Scar: Feature Hypertrophic Scar Keloid Boundaries Confined to the borders of the original wound. Extends beyond the boundaries of the original wound (claw-like projections). Time of Onset Develops soon after injury (usually within 4 weeks). Can develop months or even years after the initial insult. Symptoms Pruritus, pain, growth Pruritus, stiffness (contracture) Evolution Often regresses or flattens over time. Rarely regresses; often continues to grow or recurs after excision. Collagen Type Primarily Type III collagen; organized parallel to skin surface. Primarily Type I and III collagen; organized in thick, disorganized, "glassy" (hyalinized) bundles. Predisposition Associated with wound tension or deep thermal injury. Genetic predisposition; significantly more common in individuals with darker skin tones. Common Sites Areas of high tension (e.g., joints, neck, knees). Earlobes, shoulders, upper back, and precordium (chest). Recurrence after excision High (>50-80%) Low (<10%) Histology Thick, haphazard collagen nodules; no regular pattern Parallel collagen bundles organized along skin tension lines Treatment Response Steroids + 5FU/silicone; poor response Steroids/silicone; good response Genetics Strong familial tendency (Fitzpatrick IV-VI skin) Less genetic predisposition Exuberant granulation tissue (Option C): Exuberant granulation tissue, also known as proud flesh,

refers to excessive amounts of granulation tissue, which protrudes above the level of the surrounding skin and blocks reepithelialization. {{caption_text}} Contracture(Option D): Contractures occur when scar tissue forms and tightens, leading to restricted movement of nearby joints or tissues. They typically occur in case of burns or deep wounds. Contractures may result in deformity and functional impairment. {{caption_text}}

@Neet_pg_bot

@Neet_pg_bot

Q7: Which of the following statements regarding wound healing is true? (Q847861)

A. The wound regains 20% of its normal strength by 1 week.

B. The wound regains 70-80% of its normal strength by 12 weeks.

C. The wound regains its original strength eventually.

D. The initial collagen formed in the process of wound healing is Type-1 collagen.

Correct Answer: B. The wound regains 70-80% of its normal strength by 12 weeks.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The wound regains 70-80% of its normal strength by 12 weeks. Wound Healing At the end of one week, the wound regains 10% of its original strength. (Option A ruled out) The wound regains 70-80% of its normal strength by 12 weeks. (Option B) The wound never reaches 100% of its original strength . (Option C ruled out) The initial collagen formed in the process of wound healing is Type-III collagen. (Option D ruled out) It is replaced by type-1 collagen (strong and has the highest tensile strength). In the end, the ratio of type-1 to type-III collagen is 4:1.

Robbins and Cotrans Pathologic basis of diseases 10th ed. page 108.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 55-year-old man undergoes a minor surgical procedure to remove a small skin lesion from his forearm, and the wound is meticulously closed with sutures. Three days after the surgery, he comes to the OPD for review. Which event of the wound healing process is typically observed in this patient? (Q845437)

A. Platelet and fibrin clot formation

B. Neutrophils start to accumulate

C. Replacement of neutrophils by macrophages

D. Collagen bridging initiation

Correct Answer: C. Replacement of neutrophils by macrophages

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 55-year-old man returns three days after a minor surgical removal of a skin lesion closed with sutures, and at this stage of wound healing, the typical event observed is the replacement of neutrophils by macrophages. Events in wound healing: DAY EVENTS DAY 0 Platelets and Fibrin form blood clots. (Option A ruled out) DAY 1 Blood clot remains and recruitment of neutrophils (acute inflammation). (Option B ruled out) DAY 2 Blood clots remain; neutrophils accumulate, followed by thin epithelial layer formation. DAY 3 Chronic inflammation sets in, and macrophages replace neutrophils. (Option C) Granulation tissue begins (blood vessel formation starts) DAY 5 Maximum granulation tissue (Maximum neovascularization) Collagen bridging starts (Option D ruled out) DAY 21(3RD WEEK) Maximum collagen deposition (Type I collagen.)

Robbins and Cotrans Pathologic basis of diseases 10th ed. page 108

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following cell types is classified as stable cells in terms of their proliferative capacity and turnover rate? (Q845435)

A. Neurons in the brain

B. Hematopoietic cells in bone marrow

C. Stratified squamous epithelia of the skin

D. Endothelial cells in blood vessels

Correct Answer: D. Endothelial cells in blood vessels

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Endothelial cells in blood vessels are classified as stable cells in terms of their proliferative capacity and turnover rate. Classification of cells based on the proliferative capacity and turnover rate: Labile cells Stable cells Permanent cells These cells are continuously being lost and replaced by maturation from tissue stem cells and by the proliferation of mature cells. Labile cells include hematopoietic cells in the bone marrow and the majority of surface epithelia (Option B, C ruled out) They are quiescent and have minimal proliferative activity from progenitor cells. They divide only when required but limited regeneration compared to labile cells. Stable cells constitute the parenchyma of most solid tissues (liver), endothelial cells (Option D) , fibroblasts, and smooth

muscle cells. These cells are considered to be terminally differentiated and nonproliferative in postnatal life. Permanent cells include Neurons (Option A ruled out) and cardiac and skeletal muscle cells.

@Neet_pg_bot

Q11: A 45-year-old woman undergoes a routine elective surgery for the removal of a benign skin lesion on her forearm. The procedure involves making a small incision, excising the lesion, and closing the wound with sutures. Which of the following

statements accurately describes wound healing by primary intention in this scenario? (Q845430)

A. Myofibroblasts play a significant role in wound contraction.

B. The wound is associated with large tissue deficits.

C. Granulation tissue formation is extensive.

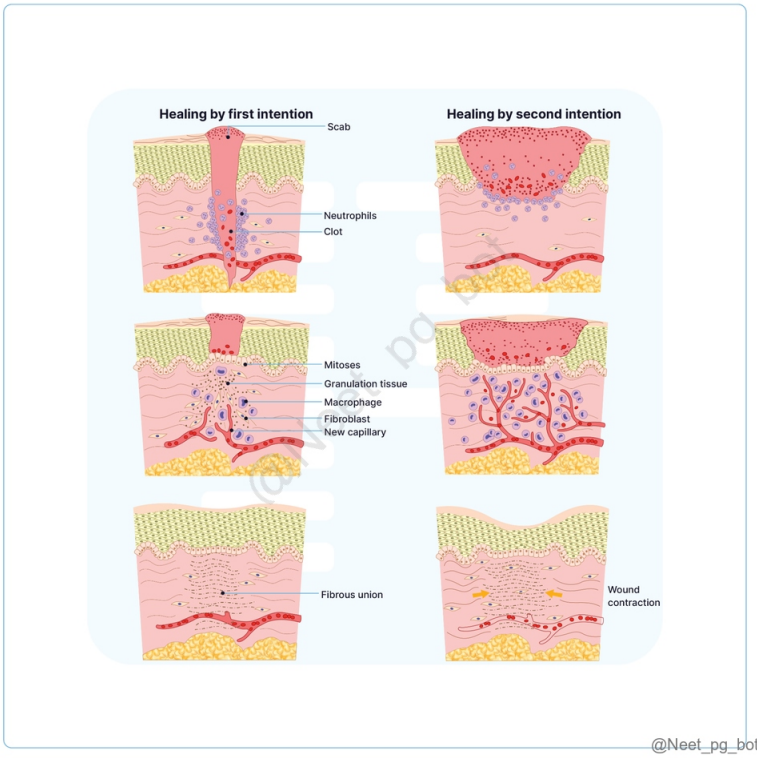
D. The wound is expected to heal with minimal inflammatory response.

Correct Answer: D. The wound is expected to heal with minimal inflammatory response.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this scenario, the wound is expected to heal with minimal inflammation, which is characteristic of healing by primary intention. Primary Intention Healing: Occurs in clean, small surgical wounds Minimal inflammatory response (Option D) Edges approximated → minimal granulation tissue Fast epithelialization, minimal scarring Secondary Intention Healing: Large, open, dirty wounds (Option B ruled out) Requires myocutaneous flaps or contraction (Option A ruled out) Extensive granulation tissue formation (Option C ruled out) Slower healing, more scarring {{caption_text}}



References:

Robbins and Cotrans pathologic basis of diseases 10th edition. page 108

↑ *Back to this question in Part A*

@Neet_pg_bot

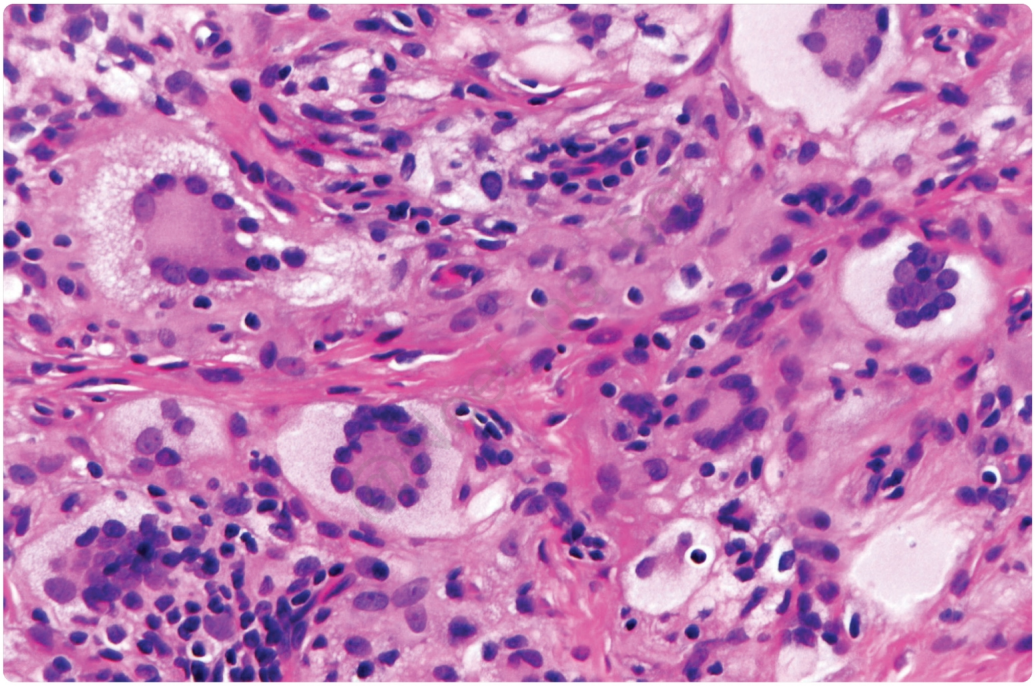
Q12: A 45-year-old male presents with a persistent subcutaneous nodule on his forearm. Biopsy reveals the presence of multinucleated giant cells within the lesion, as shown in the accompanying HPE image. Further analysis indicates a central zone of lipid-laden macrophages surrounded by a wreath-like arrangement of nuclei. Which type of giant cell is most likely to be observed in this scenario? {{caption_text}} (Q845424)

A. Touton giant cells

B. Reed-Sternberg Cells

C. Warthin-Finkeldey giant cells

D. Foreign body giant cells



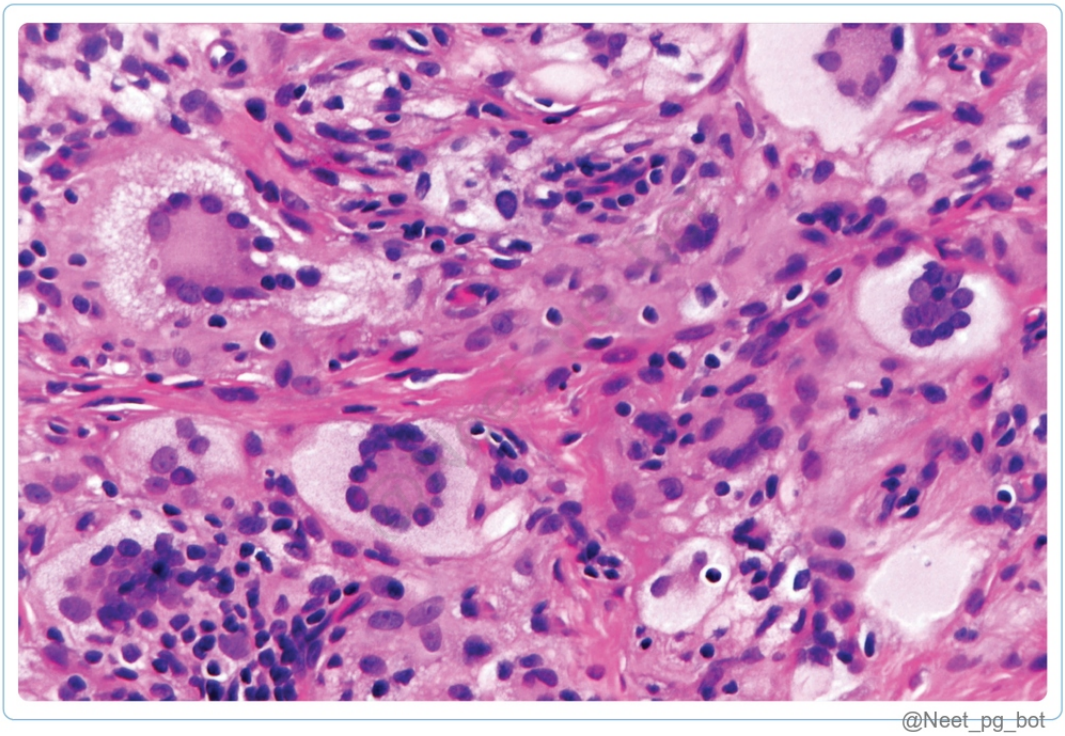
@Neet_pg_bot

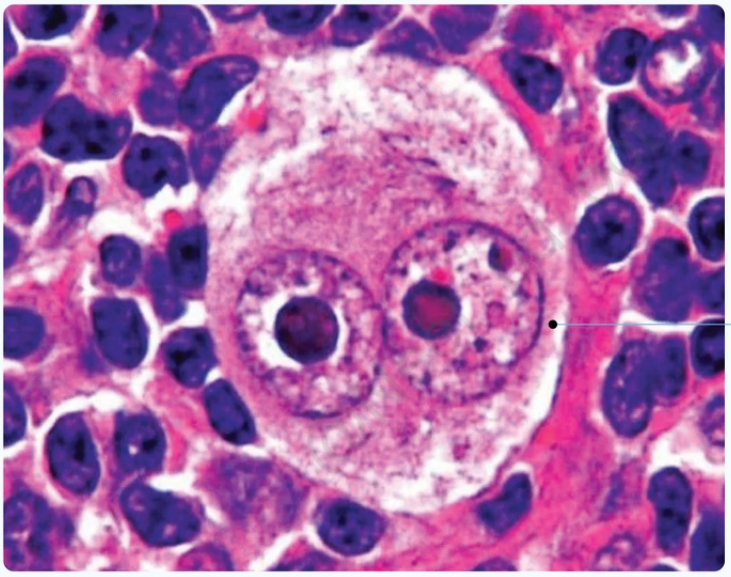
Correct Answer: A. Touton giant cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The multinucleated giant cells described in the scenario, with a central zone of lipid-laden macrophages surrounded by a wreath-like arrangement of nuclei, are characteristic of Touton giant cells. Giant Cell Type Description Seen in Touton Giant Cells (Option A) {{caption_text}} Multinucleated giant cells with a central zone of lipid-laden Macrophages are surrounded by a wreath-like arrangement of nuclei. Xanthogranuloma, xanthoma, fat necrosis Reed-Sternberg Cells (Option B) {{caption_text}} Large, binucleated or multinucleated cells with prominent nucleoli, often with an "owl's eye" appearance (pink nucleoli) (RS cells- also seen in DLBCL, owl’s eye appearance- also seen in CMV infection) Hodgkin lymphoma Warthin-Finkeldey Giant Cells (Option C) {{caption_text}} Large, multinucleated cells with irregularly distributed nuclei and a foamy cytoplasm. May contain intranuclear and intracytoplasmic eosinophilic inclusions. Measles (Rubeola) infection Langhans Giant Cells {{caption_text}} Multinucleated giant cells with nuclei arranged peripherally in a horseshoe-like or semicircular pattern. Tuberculosis, Sarcoidosis Foreign Body Giant Cells (Option D) {{caption_text}} Large, multinucleated cells with multiple nuclei arranged haphazardly. Foreign bodies in tissues like talc, sutures, or crystals





@Neet_pg_bot

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following is not a physiological giant cell? (Q845413)

A. Osteoclast

B. Syncytiotrophoblast

C. Megakaryocytes

D. Langhans cells

Correct Answer: D. Langhans cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Langhans' giant cells are multinucleated giant cells (pathological) formed by the fusion of macrophages. They are often seen in the granulomas formed in response to certain infections or foreign substances. They are typically found associated with tuberculosis. They are characterized by a horseshoe-shaped arrangement of nuclei within the cytoplasm {{caption_text}} Osteoclast (Options A) , Syncytiotrophoblast Options B) , and Megakaryocytes (Options C) are physiological giant cells.

↑ *Back to this question in Part A*

@Neet_pg_bot

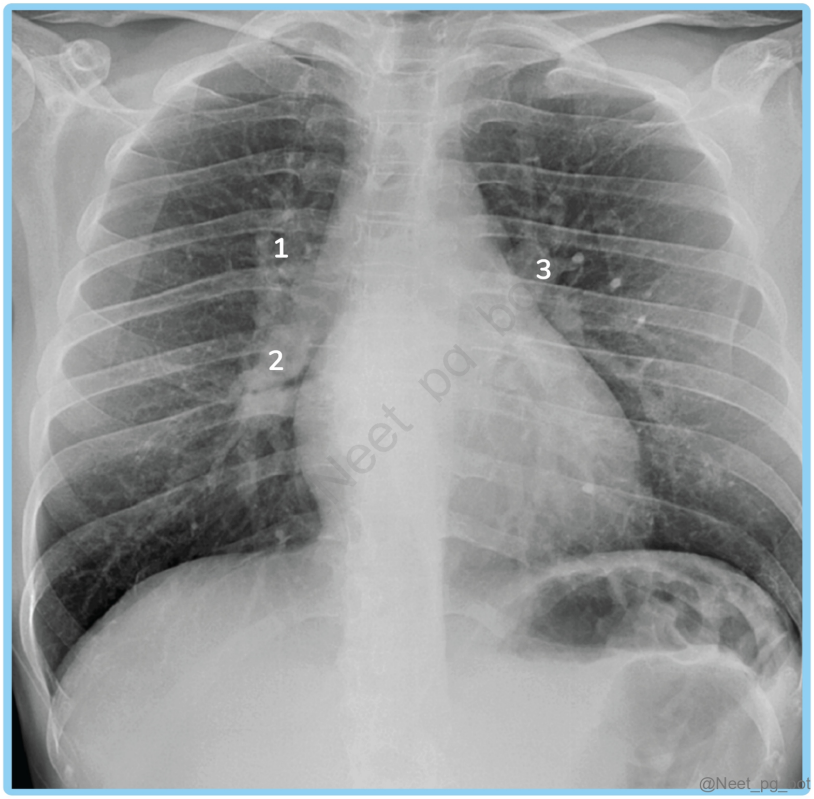
Q14: A 40-year-old woman presents with a persistent dry cough, shortness of breath, and bilateral enlargement of the lymph nodes in her chest, incidentally detected on a routine chest X-ray given below. Physical examination reveals fine crackles in her lung bases. Pulmonary function tests show reduced lung volumes and a decreased diffusion capacity for carbon monoxide. Which type of granuloma is commonly associated with the histopathological findings in this patient? {{caption_text}} (Q845412)

A. Naked granuloma

B. Stellate granuloma

C. Eosinophilic granuloma

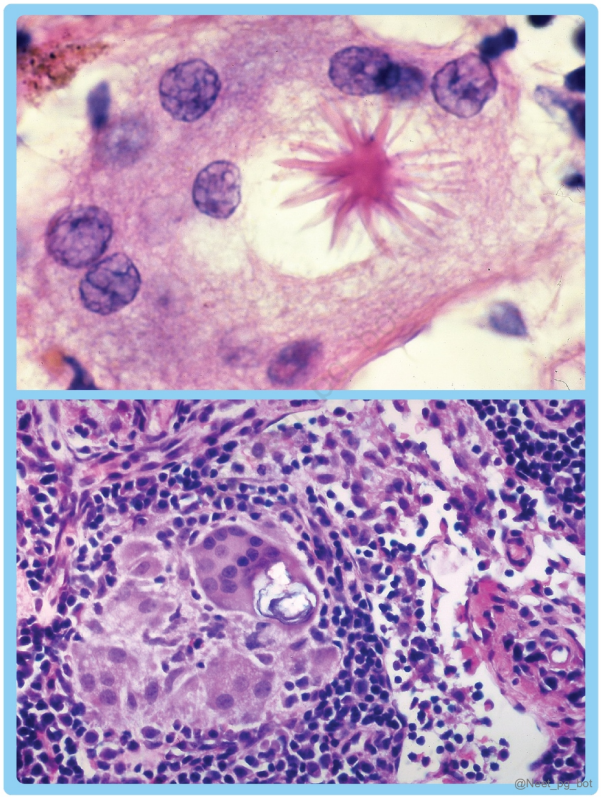
D. Durck granuloma

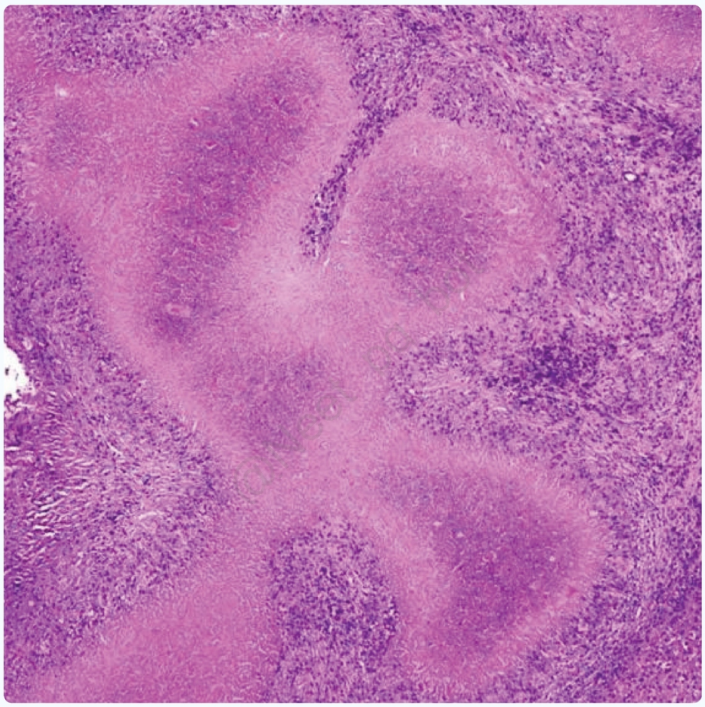


Correct Answer: A. Naked granuloma

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The given clinical presentation suggests Sarcoidosis, a systemic granulomatous disorder characterized by non-caseating granulomas (naked granuloma) composed of epithelioid histiocytes and multinucleated giant cells without associated fibrosis or necrosis. The characteristic histopathological feature of sarcoidosis is "Naked granuloma," which refers to the "absence of lymphocytic collar." Giant cell inclusions like asteroid bodies and Schaumann bodies can be seen. Sarcoidosis is a classic example of a non-infectious cause of granuloma formation. {{caption_text}} Stellate granuloma (Option B) Seen in Cat-scratch disease and lymphogranuloma venereum. {{caption_text}} Eosinophilic granuloma (Option C): Seen in Langerhans cell histiocytosis (LCH) and Churg-Strauss syndrome. Durck granuloma (Option D): Seen in cerebral malaria. {{caption_text}}





Stellate granuloma

Robins and Cotran Pathologic Basis of Disease, 10th Edition, - Pages 100, 101

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following statements about granulomas is incorrect? (Q845408)

A. Granuloma formation is a Type IV hypersensitivity reaction

B. IFN-gamma is an important cytokine involved in this process

C. CD8+ is the type of T lymphocytes involved in this process

D. Epitheloid cells in granuloma are modified macrophages

Correct Answer: C. CD8+ is the type of T lymphocytes involved in this process

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CD4 T cells are involved in the process (Granuloma formation), not CD8+ cells. CD8+ T cells are more commonly associated with cytotoxic responses against infected or abnormal cells rather than granuloma formation. Granulomas Granulomas (Type IV hypersensitivity reaction) typically involve CD4+ T lymphocytes, also known as helper T cells, rather than CD8+ T cells. (Option A ruled out) CD4 T-helper 1 (Th1) cells help activate macrophages and other immune cells, release interferon-gamma (IFN-γ), and maintain granulomas. (Option B ruled out Epithelioid cells in a granuloma are modified macrophages. (Option D ruled out)

References:

Robins and Cotran Pathologic Basis of Disease, 10th Edition, - Pages 100, 101

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which type of macrophages predominantly contributes to tissue repair and resolution of inflammation in patients with chronic obstructive pulmonary disease complicated by pneumonia? (Q845406)

A. M1 macrophages

B. M2 macrophages

C. Both M1 and M2 macrophages

D. Resting macrophages

Correct Answer: B. M2 macrophages

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The predominant type of macrophages contributing to tissue repair and resolution of inflammation in this patient's lungs is M2 type of Macrophages, also known as Alternatively activated macrophages. Macrophages are of two types based on their activation: M1 activation M2 activation Also known as “Classical macrophage activation.” “Alternative macrophage activation.” Stimulus for activation Microbial products (e.g., endotoxin); TLRs (Toll-like receptor) T cell-derived signals (e.g., IFN-γ), Foreign substances (e.g., crystals). IL-4 IL-13. Releases Reactive oxygen species (ROS), lysosomal enzymes, nitric oxide (NO) and Pro-inflammatory cytokines TNF-α IL-1; IL-12; IL-23 Anti-inflammatory cytokines IL-10 TGF-β Function Microbicidal destroys pathogens and amplifies inflammation. Terminates the inflammation and promotes tissue repair (fibrosis).

Q1: In some chronic inflammatory reactions, organized lymphoid follicles resembling lymph nodes may form. These are called tertiary lymphoid structures. Which of the following conditions may show these structures? (Q879461)

A. Synovium in long-standing rheumatoid arthritis

B. Thyroid in Hashimoto thyroiditis

C. Infiltrates around some tumors

D. All of the above

Correct Answer: D. All of the above

Explanation: Tertiary lymphoid structures (TLOs) are clusters of lymphocytes, antigen-presenting cells, and plasma cells forming organized follicles at chronic inflammation sites. Found in the synovium of rheumatoid arthritis, thyroid in Hashimoto thyroiditis, and around some tumors. They may sustain and perpetuate the immune reaction locally The exact pathological significance of TLOs is still not fully established.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 89

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following mediators is not primarily involved in producing fever during inflammation? (Q879460)

A. IL-1

B. Prostaglandins

C. TNF

D. Histamine

Correct Answer: D. Histamine

Explanation: IL-1 and TNF induce fever by stimulating prostaglandin (PGE2) production in the hypothalamus. Prostaglandins act directly on the thermoregulatory center to raise body temperature. Histamine, however, mainly causes vasodilation and increased vascular permeability, not fever.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 77

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following inflammatory mediators are correctly matched with their primary actions? 1. Histamine – arteriolar dilation and ↑ vascular permeability causing hypotension in anaphylaxis 2. Bradykinin – major mediator of pain in inflammation 3. Platelet-activating factor (PAF) – bronchoconstriction via activation of platelets and leukocytes with mediator release 4. Neutrophil lysosomal enzymes – cleavage of C3 and C5 to generate active complement fragments 5. Interleukin-1 (IL-1) mediates vasodilation and bronchoconstriction in asthma (Q879459)

A. 1, 2, 3

B. 1, 3, 5

C. 1, 2, 3, 4

D. 2, 4, 5

Correct Answer: C. 1, 2, 3, 4

Explanation: Histamine causes blood vessels to dilate and become leaky, which can lead to a drop in blood pressure during anaphylaxis. Bradykinin is the primary chemical responsible for producing pain in inflammation; it also dilates vessels and increases their permeability. Platelet-activating factor (PAF) makes the airways narrow (bronchoconstriction) by activating platelets and white blood cells, which then release other inflammatory mediators. Neutrophil lysosomal enzymes break down complement proteins C3 and C5 into active fragments (C3a, C5a) that promote inflammation. Interleukin-1 (IL-1) mainly causes fever; it does not dilate blood vessels or

cause bronchoconstriction, so that match is incorrect.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 77,75,79

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 39-year-old woman with long-standing rheumatoid arthritis presents with fatigue and pallor. Lab tests reveal anemia of chronic disease. Elevated levels of which of the following acute-phase reactants are primarily responsible for this anemia? (Q879458)

A. Fibrinogen

B. C-reactive protein (CRP)

C. Serum amyloid A (SAA)

D. Hepcidin

Correct Answer: D. Hepcidin

Explanation: Hepcidin increases in chronic inflammation and inhibits ferroportin, leading to decreased iron release from macrophages and reduced intestinal absorption, which results in anemia of chronic disease. Fibrinogen, CRP, and SAA (Options A, B, and C) are also positive acute-phase reactants but they do not directly cause anemia.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 92

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: During the acute-phase response in inflammation, which of the following acts as a negative acute-phase reactant by decreasing in serum concentration? (Q879456)

A. Albumin

B. Serum amyloid A (SAA)

C. C-reactive protein (CRP)

D. Fibrinogen

Correct Answer: A. Albumin

Explanation: Albumin is a negative acute-phase reactant - its synthesis falls during inflammation (to conserve amino acids for positive acute-phase proteins). SAA, CRP, and fibrinogen are positive acute-phase reactants -their levels rise in inflammation.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 92

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Fractalkine, a unique chemokine with both membrane-bound and soluble forms, belongs to which chemokine family? (Q879453)

A. C

B. CX3C

C. CXC

D. CC

Correct Answer: B. CX3C

Explanation: CX3 C chemokines contain three amino acids between the first two cysteines. The only known member of this class is called fractalkine (CX3CL1). This chemokine exists in two forms: Cell surface–bound protein induced on endothelial cells by inflammatory cytokines that promotes strong adhesion of monocytes and T cells, and Soluble form derived by proteolysis of the membrane-bound protein that has potent chemoattractant activity for the same cells. Incorrect Options: C (Option A) lacks one of the two cysteines (e.g., lymphotactin). CXC (Option C) neutrophil chemotaxis (e.g., IL-8). CC (Option D) monocyte/eosinophil chemotaxis (e.g., MCP-1, RANTES).

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 81.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following cytokines primarily exhibits anti-inflammatory activity? (Q879452)

A. IL-1

B. IL-4

C. TNF

D. IFN-γ

Correct Answer: B. IL-4

Explanation: IL-4 is anti-inflammatory as it downregulates macrophage activity and promotes Th2 response. IL-1 and TNF are pro-inflammatory, while IFN-γ activates macrophages and enhances inflammation.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 88

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following statements regarding prostaglandins and related eicosanoids is INCORRECT? (Q879451)

A. Thromboxane A2 (TxA2) is the predominant product of platelets

B. Prostacyclin (PGI2) acts as a vasodilator and inhibits platelet aggregation

C. PGD2 is one of the major prostaglandins released from mast cells

D. Vascular endothelium lacks prostacyclin synthase

Correct Answer: D. Vascular endothelium lacks prostacyclin synthase

Explanation: Vascular Endothelium possesses prostacyclin synthase and produces PGI2, which causes vasodilation and inhibits platelet aggregation. Thus, the statement that endothelium lacks prostacyclin synthase is false. ■■■■■■■ Incorrect Options: TxA2 (Option A) promotes vasoconstriction and platelet aggregation; it is the main prostanoid formed in platelets. PGI2 (prostacyclin , endothelium) (Option B) produced by vascular endothelium; causes vasodilation and inhibits platelet aggregation. PGD2 (Option C): Major prostaglandin produced by mast cells, contributes to bronchoconstriction and vasodilation.

@Neet_pg_bot

Q9: Release of arachidonic acid, the precursor of prostaglandins and leukotrienes, is mainly mediated by which of the following enzymes? (Q879449)

A. Phospholipase A1 and C

B. Phospholipase A2 and C

C. Phospholipase B and C

D. Phospholipase A1 and B

Correct Answer: B. Phospholipase A2 and C

Explanation: Phospholipase A2 hydrolyzes membrane phospholipids to release arachidonic acid, the key substrate for eicosanoid synthesis (prostaglandins, thromboxanes, leukotrienes). Phospholipase C generates diacylglycerol (DAG), which can be further converted to arachidonic acid. Phospholipase A1, B play minor roles in lipid metabolism, not the major pathway for arachidonic acid release.

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 77

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following mediators is released immediately during the earliest phase of acute inflammation? (Q879446)

A. Serotonin

B. Interleukins

C. Prostaglandins

D. Bradykinin

Correct Answer: A. Serotonin

Explanation: Serotonin (along with histamine) is stored in pre-formed granules of platelets and mast cells. It is released immediately after injury, making it one of the earliest mediators of inflammation. Incorrect Options: Interleukins (Option B) are cytokines that require new synthesis and act later to sustain inflammation. Prostaglandins (Option C) are synthesized from arachidonic acid after cell activation, so they appear later, not immediately. Bradykinin (Option D) is generated through the kinin cascade and also appears later, mediating pain and vasodilation.

@Neet_pg_bot

Q11: A 25-year-old female presents to the emergency department with sudden-onset swelling of her face, lips, and tongue. She reports a history of similar episodes occurring intermittently since childhood, often triggered by stress or trauma. On examination, she appears anxious and has marked swelling of her lips and tongue, with difficulty speaking and swallowing. There are no signs of urticaria or pruritus. Her vital signs are stable. Which of the following deficiencies is seen in this condition? (Q845600)

A. Deficiency of properdin

B. Deficiency of C1, C2, C3, C4

C. Deficiency of C1 esterase inhibitor

D. Deficiency of C5-C9

Correct Answer: C. Deficiency of C1 esterase inhibitor

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 25-year-old female presents with sudden facial, lip, and tongue swelling without urticaria or pruritus, and a history of similar episodes since childhood; this condition is associated with a deficiency of C1 esterase inhibitor. The entire complement pathway, especially the classical pathway, is controlled by C1 inhibitor, which prevents the initiation of the complement pathway. If C1 esterase inhibitor is missing from the body, it will lead to Hereditary angioneurotic edema , which is a rare autosomal dominant disorder characterised by recurrent episodes of non-pitting, non-pruritic swelling of the skin and mucous membranes. Deficiency of C1 esterase inhibitor leads to elevated plasma levels of bradykinin, leading to angioedema, and excessive activation of C1 results in a decline in plasma C4 and C2 levels. Swelling in HAE commonly affects areas such as the face, lips, tongue, throat, and extremities, and can lead to airway compromise if it involves the upper respiratory tract

(laryngeal edema).

@Neet_pg_bot

Q12: Pain during inflammation is mediated by? (Q845603)

A. Serotonin

B. Leukotrienes

C. Interleukin-1

D. Bradykinin

Correct Answer: D. Bradykinin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Bradykinin mediates pain during an inflammatory response Two main mediators of pain are Prostaglandin E2 and Bradykinin. Functions of bradykinin : Increases vascular permeability Causes smooth muscle contraction Dilates blood vessels Produces pain when injected into the skin Implicated in allergic reactions, including anaphylaxis These effects are similar to those of histamine. The action of bradykinin is short lived because it is quickly inactivated by an enzyme called kininase (Serotonin) (Option A ruled out) It is responsible for vasodilation , increased vascular permeability, and smooth muscle contraction . In the pathogenesis of asthma, it is responsible for bronchoconstriction. It works similarly to histamine. (Leukotrienes) (Option B ruled out) Leukotrienes are lipid mediators synthesized from arachidonic acid metabolism, primarily by the 5-lipoxygenase pathway. Leukotriene B4 is a chemoattractant. Leukotriene C4, D4 and E4 are slow-reacting substances of anaphylaxis playing role in asthma. (Interleukin-1) (Option C ruled out) Interleukin-1 (IL-1) is responsible for fever.

Robbins and Cotran, Pathologic Basis of Disease, 11th edition, Page no. 83.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following deficiencies is seen in paroxysmal nocturnal hemoglobinuria? (Q845602)

A. C5-C9

B. CD59

C. C1

D. Factor H

Correct Answer: B. CD59

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This case is suggestive of paroxysmal nocturnal hemoglobinuria (PNH), which is due to the deficiency of CD55 and CD59. PNH is a rare acquired hematologic disorder characterized by a mutation of the PIG-A gene . This mutation results in a deficiency of glycosylphosphatidylinositol (GPI)- anchored proteins on the surface of blood cells. This deficiency leads to the absence of important complement regulatory proteins, such as CD55 aka DAF (decay-accelerating factor) and CD59 aka RIML (reactive inhibitor of membrane lysis) , which normally protect red blood cells from complement-mediated destruction. Red coloured uring is passed during night Triad: ■■■■■■■ Hemolytic Anemia: Often resulting in dark urine (hemoglobinuria), fatigue, jaundice, and shortness of breath. Thrombosis: Commonly in veins (deep vein thrombosis, Budd-Chiari syndrome), but also in unusual locations. Pancytopenia/Bone Marrow Failure: Leading to infections, anemia, and bleeding. Diagnosis: Flow Cytometry (Gold Standard): Shows a deficiency or absence of GPI-anchored proteins (CD55/CD59) on RBCs or granulocytes. Coombs Test: Characteristically negative (since the hemolysis is not antibody-mediated). Lab Markers: Elevated LDH, low haptoglobin, and reticulocytosis. C5-C9 (Option A) is a composition of Membrane Attack Complex (MAC), and its deficiency makes the patient prone to Neisseria meningitidis infections. C1 (Option C) is associated with autoimmune disorders like SLE. Factor H (Option D) deficiency causes atypical hemolytic uremic syndrome (Atypical HUS) .

@Neet_pg_bot

Q14: A 25-year-old female presents to the emergency department with severe allergic reaction symptoms, including urticaria and hypotension, after ingesting a shrimp. How does the vasoactive mediator involved primarily cause hypotension? (Q845563)

A. Vasodilation and increased vascular permeability

B. Enhancing nitric oxide production and vasodilation

C. Inducing the release of other pro-inflammatory cytokines

D. Inhibiting platelet aggregation and causing clotting

Correct Answer: A. Vasodilation and increased vascular permeability

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The scenario indicates an allergic reaction, where histamine acts as the key vasoactive mediator responsible for hypotension by dilating arterioles and increasing vascular permeability, as seen in severe allergic responses like anaphylaxis. {{caption_text}}

Basis	Histamine	Serotonin (5HT)
Source	Mast cells (richest source) Basophils Platelets	Enterochromaffin cells (EC cells) (richest sourc) Platelets
Precursor	Histidine	Tryptophan
Function	The functions of Histamine And Serotonin are the same. They are • Helps in vasodilation • Increased vascular permeability • Bronchoconstriction

@Neet_pg_bot

Q15: Which of the following is false regarding the alternate complement pathway? (Q845599)

A. Teichoic acid is an initiator of the alternate complement pathway.

B. The first complement protein to be activated is C1.

C. The C3 convertase of the alternate pathway is C3bBb.

D. Properdin is the stabilizer of the alternate pathway.

Correct Answer: B. The first complement protein to be activated is C1.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The first complement protein to be activated is C1 in the classical complement pathway and not in the alternative complement pathway. The complements involved in the alternate pathway are: Free C3 in the serum (alternate complement pathway starts from C3). Factor B. Factor D. Properdin. Activators (Initiators) of the alternate pathway: Pathogens from microbes Non-microbial initiators Gram (-ve) bacteria: Endotoxins or lipopolysaccharides. Gram (+ve) bacteria: Teichoic acid Fungal cells: Yeast cells. Parasites: Trypanosoma. Virus-infected cells. Human antibodies in complexes: IgA, IgD . Tumor cells. Cobra venom factor. Heterologous RBCs from mice, rabbits, and chickens. Anion polymer like dextran sulfate. Pure carbohydrates like agar and inulin. The image below shows the three complement pathways. {{caption_text}}

Q16: Match the following with their correct answers. 1 C3a i Decay accelerating factor 2 C3b ii EBV receptor 3 CR2 iii Anaphylatoxin 4 CD55 iv Opsonin (Q845597)

A. 1-iii, 2-iv, 3-ii, 4-i

B. 1-iii, 2-iv, 3-i, 4-ii

C. 1-iv, 2-iii, 3-i, 4-ii

D. 1-iv, 2-iii, 3-ii, 4-i

Correct Answer: A. 1-iii, 2-iv, 3-ii, 4-i

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Anaphylatoxins: C3a, C4a, and C5a. Opsonins: C3b, C4b, and C5b. Opsonins when coats the bacteria, makes it more tasty for phagocytosis. Overall most important opsonin: IgG Most important complement opsonin: C3b CR2/CD21/C3d: Complement receptor 2 for EBV When EBV enters the body, it attacks the B-cells. To enter into B-cells, it uses CD21/CR2. CD55: Decay-accelerating factor (DAF). CD59: Membrane inhibitor of reactive lysis (MIRL) Missing CD55 and CD59 leads to Paroxysmal nocturnal hemoglobinuria (PNH).

@Neet_pg_bot

Q17: A 45-year-old male presents to the clinic with a high fever, chills, and malaise. He reports feeling unwell for the past few days and has noticed redness and swelling around a cut on his forearm. On examination, the healthcare provider observes a localized area of erythema and induration at the site of the wound. Which of the following events is a crucial step in the activation of the complement system in response to the patient's initial condition? (Q845594)

A. Binding of C1q to antigen-antibody complexes

B. Formation of membrane attack complex

C. Cleavage of C3 into C3a and C3b

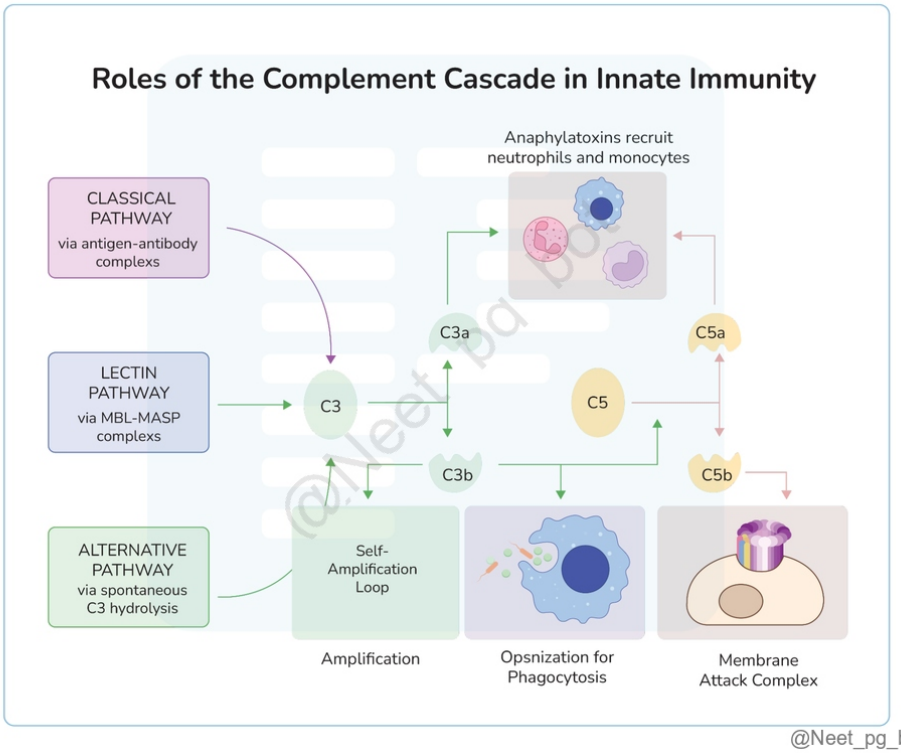
D. Cleavage of C5 by C5 convertase

Correct Answer: C. Cleavage of C3 into C3a and C3b

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 5-year-old male presents with fever, chills, and a swollen, red wound on his forearm; in response to this localized infection, a key step in complement system activation is the cleavage of C3 into C3a and C3b. Complement system It is a plasma-derived mediator of inflammation. The complement system can be activated by three pathways: Classical pathway Alternate pathway Lectin pathway The cleavage of C3 into its active fragments, C3a and C3b , is the critical event in the complement system and serves as a central step in all three complement activation pathways. The image below shows an overview of the complement pathways. {{caption_text}}



References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 90, 91

Essentials of Medical Microbiology, Apurba S Sastry, 3rd edition, Page no. 164-166

@Neet_pg_bot

Q18: Select the correct statements about the complement system. 1) The complement system primarily functions by adaptive immunity. 2) Complement proteins are solely produced in the liver. 3) All complement proteins are synthesized in inactive forms and are activated by proteolysis. 4) Complement activation occurs through three pathways. 5) Complements have two equal fragments. (Q845573)

A. 1,2,3

B. 2,4

C. 2,3,5

D. 3,4

Correct Answer: D. 3,4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The correct statements regarding the complement system are statements 3 and 4. Complement System: The complement proteins function in both innate and adaptive immunity for defense against microbial pathogens. (Statement 1 ruled out) Site of synthesis: (Statement 2 ruled out) Liver (major site). Monocytes. Tissue macrophages. Epithelial cells of GIT and genitourinary tract. Activation of complement proteins occurs by three pathways: (Statement 4) Classical pathway. Alternative pathway. Lectin pathway. Activation of complement pathway: All complement proteins are synthesized in inactive forms and are activated by proteolysis. (Statement 3) E.g.: Inactive C3 splitting into active C3a and C3b Complements have two unequal fragments (small and large fragments). (Statement 5 ruled out) The larger fragments are designated as ‘b’ (e.g., C3b), and the smaller fragments are designated as ‘a' (e.g., C3a) (exception: C2a —larger fragment).

@Neet_pg_bot

Q19: A 20-year-old male is prescribed naproxen for a musculoskeletal injury. What is naproxen’s mechanism of action? (Q845572)

A. Lipoxygenase inhibition

B. COX-2 inhibition

C. Cycloxygenase (COX) 1 and COX-2 inhibition

D. Prostaglandin (PG) F2 inhibition

Correct Answer: C. Cycloxygenase (COX) 1 and COX-2 inhibition

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Naproxen is a non-steroidal anti-inflammatory drug (NSAID). The predominant action of NSAIDs is via COX-1 and COX-2 inhibition, resulting in analgesia and anti-inflammatory effects which is required in this case of musculoskeletal injury. One major adverse effect of NSAIDs is gastric irritation, including ulcers and bleeding. This occurs due to the loss of gastroprotective PGs i.e., PGE2, formed by COX-1. Thus, in patients with previous history of gastric ulcers, selective COX-2 inhibitors may be used - celecoxib, etoricoxib, etc. The Arachidonic Acid Pathway: When cell membranes are injured, phospholipids are converted into arachidonic acid. This acid is then processed via two main enzymatic pathways: the Cyclooxygenase (COX) pathway and the Lipoxygenase (LOX) pathway. Pathway Enzyme Products Inhibitors Effects COX Pathway COX-1 (constitutive) COX-2 (induced) Prostaglandins (PGs), Thromboxane A■ (TXA■), Prostacyclin (PGI■) Naproxen (non-selective NSAID) Celecoxib (COX-2 selective) ↓Inflammation, pain and fever Gastric protection (COX-1) LOX Pathway 5-LOX, 12-LOX, 15-LOX Leukotrienes (LTB■, LTC■) Zileuton (5-LOX) Zafirlukast (LT receptor) Bronchoconstriction, anaphylaxis

@Neet_pg_bot

Q20: Which of the following mediators is responsible for cancer cachexia? (Q845571)

A. TNF-alpha

B. IFN-gamma

C. IL-8

D. TGF-beta

Correct Answer: A. TNF-alpha

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: TNF-alpha is responsible for cancer cachexia. Cancer cachexia means weight loss in cancer patients due to the elevation of TNF-alpha mediators. TNF-alpha also learned as no food appetite, because whenever TNF-alpha is raised in the body (can be due to fever or cancer), appetite of patient decreases and they stop feeling hungry. IFN-gamma (Option B) is responsible for granuloma formation . IL-8 (Option C) is for neutrophil recruitment. TGF-beta (Option D) is the most fibrogenic cytokine.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 90.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 35-year-old male presents with a history of chronic obstructive pulmonary disease (COPD) exacerbation. Which of the following chemokines is primarily responsible for recruiting neutrophils to the airways in COPD exacerbations? (Q845570)

A. IL-8

B. MCP-1

C. SDF-1

D. RANTES

Correct Answer: A. IL-8

Listen (English)

Listen (Hindi)

Explanation: Interleukin-8 (IL-8) is a potent chemokine involved in the recruitment of neutrophils to sites of inflammation, particularly in response to bacterial and other microbial infections. IL-8 belongs to the CXC chemokine family. MCP-1(Option B): Belongs to the CC chemokine family. Primarily recruits monocytes and macrophages to sites of inflammation. RANTES(Option D): Belongs to the CC chemokine family. Primarily recruits T-cells to sites of inflammation. SDF-1(Option C): It is a stromal-derived factor. It primarily recruits lymphocytes, monocytes, and hematopoietic stem cells to sites of inflammation.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no - 90 , 680

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 30-year-old male presents with symptoms of flu-like illness, including fever, sore throat, and fatigue. Further investigation reveals a positive HIV serology. Which of the following chemokine receptors primarily facilitates the entry of HIV into CD4+ T cells? (Q845569)

A. CX3CL1

B. CCR5 , CXCR4

C. CCL11 , MCP-1

D. CXCL8

Correct Answer: B. CCR5 , CXCR4

Listen (English)

Listen (Hindi)

Explanation: Among the given options, CCR5 and CXCR4 are the coreceptors that primarily facilitate HIV entry into CD4+ T cells. Whenever HIV enters the body, it targets CD4 T-cells and macrophages in the body. HIV binds to CD4 T cells and macrophages using glycoproteins: GP120 and GP41. Then, coreceptor binding occurs using

chemokine receptors like CCR5 and CXCR4. CXCR4 coreceptors are predominantly present on CD4 T-cells CCR5 coreceptors are predominantly present on macrophages.

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no - 90

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: All are chemoattractants among the following except : (Q845568)

A. IL-8

B. C5a

C. LTB4

D. C3b

Correct Answer: D. C3b

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, C3b is not a chemoattractant. LTB4, IL-8, and C5a are endogenous chemoattractants. These are primarily involved in neutrophil chemotaxis. Can be learned by a mnemonic: LIC C3b (OPTION D): C3b, C4b, and C5b are opsonins that promote phagocytosis by neutrophils and macrophages. It is not a chemoattractant. Overall best opsonin in Immunoglobulin G (IgG) The best complement opsonin is C3b.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 79.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: Which of the following best describes the mechanism of action of PAF in inducing bronchoconstriction? (Q845567)

A. By binding to seven transmembrane G protein–coupled receptors.

B. Causing smooth muscle constriction by directly stimulating muscarinic receptors

C. Induction of smooth muscle relaxation and bronchodilation

D. Activation of platelets and leukocytes leading to release of inflammatory mediators

Correct Answer: D. Activation of platelets and leukocytes leading to release of inflammatory mediators

Explanation: Activation of platelets and leukocytes leading to release of inflammatory mediators: This statement accurately describes one of the primary actions of PAF. Upon binding to its receptor on platelets and leukocytes, PAF activates these cells, leading to the release of inflammatory mediators such as leukotrienes, prostaglandins, and cytokines. These mediators contribute to bronchoconstriction, increased vascular permeability, and airway inflammation. Platelet-activating factor (PAF) is a phospholipid-derived mediator that was discovered as a factor that caused platelet aggregation, but it is now known to have multiple inflammatory effects. A variety of cell types, including platelets, basophils, mast cells, neutrophils, macrophages, and endothelial cells, can elaborate PAF in both secreted and cell-bound forms. In addition to platelet aggregation, PAF causes vasoconstriction and bronchoconstriction, and at low concentrations it induces vasodilation and increased venular permeability By binding to seven transmembrane G protein–coupled receptors (OPTION A) This is not the mechanism of action of PAF. Chemokines mediate their activities by binding to seven transmembrane G protein–coupled receptors. Chemokines are a family of small proteins that act primarily as chemoattractants for specific types of leukocytes. Causing smooth muscle constriction by directly stimulating muscarinic receptors (OPTION B) This is not the mechanism for PAF Acetylcholine, released from intrapulmonary parasympathetic nerves, causes airway smooth muscle constriction by directly stimulating muscarinic receptors. Induction of smooth muscle relaxation and bronchodilation (OPTION C) : This option suggests a contradictory effect to the actual mechanism of PAF. PAF induces smooth muscle contraction and bronchoconstriction rather than relaxation and bronchodilation.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page - 88, 90, 92

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: Which of the following is the role of neutrophil lysosomal enzymes in acute inflammation? (Q845566)

A. Cleavage of C3 and C5

B. Inhibition of complement proteins

C. Activation of macrophages

D. Degradation of prostaglandins

Correct Answer: A. Cleavage of C3 and C5

Explanation: Neutrophil lysosomal enzymes, especially elastase, cleave C3 and C5 complement proteins into their active C3a/C3b and C5a/C5b forms. These peptides mediate acute inflammation by inducing vasodilation, increased vascular permeability, and leukocyte chemotaxis. Lysosomal enzymes are synthesized in the ER, modified in the Golgi apparatus, and packaged into lysosomes. Enzymes are stored in granules and are released upon cell activation. Azurophil (primary) granules Specific (secondary) granules Myeloperoxidase (MPO) Defensins Acid hydrolases Neutral proteases Elastase Cathepsin G Nonspecific collagenases Proteinase 3 Lysozyme Lysozyme Collagenase Gelatinase Lactoferrin Plasminogen activator Histaminase Enzyme Function Enzyme Function Myeloperoxidase Generates reactive oxygen species for microbial killing Proteinase 3 Degrades proteins in phagolysosomes Defensins Disrupts microbial cell membranes Lysozyme Degrades bacterial cell walls Acid hydrolases Degrades bacteria and debris in phagolysosomes Collagenase Degrades collagen in extracellular matrix Neutral proteases Degrades extracellular matrix components, cleaves complement proteins Gelatinase Degrades gelatin in extracellular matrix Elastase Degrades elastin combats bacterial infections Lactoferrin Binds and sequesters iron due to defects in the alternate pathway. Cathepsin G Degrades proteins in phagolysosomes Plasminogen activator Converts plasminogen to plasmin, fibrinolysis Nonspecific collagenases Degrades collagen in extracellular matrix Histaminase Metabolizes histamine and limits inflammatory response. Inhibition of complement proteins (Option B) Neutrophil lysosomal enzymes do not inhibit complement proteins but rather cleave them to generate bioactive fragments. Activation of macrophages(Option C) Neutrophil lysosomal enzymes primarily act within neutrophils themselves or in the extracellular space, and do not directly activate macrophages. Degradation of prostaglandins(Option D) Neutrophil lysosomal enzymes do not degrade prostaglandins. Prostaglandins are lipid mediators synthesized from arachidonic acid by the action of cyclooxygenases and play a role in inflammation.

@Neet_pg_bot

Q26: Which type of nitric oxide synthase (NOS) is involved in microbial killing and is induced in macrophages by cytokines or microbial products? (Q845565)

A. Endothelial NOS (eNOS)

B. Neuronal NOS (nNOS)

C. Inducible NOS (iNOS)

D. None of the above

Correct Answer: C. Inducible NOS (iNOS)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Inducible nitric oxide synthase (iNOS) is involved in microbial killing. iNOS generates nitric oxide (NO) from Arginine which reacts with superoxide (O2•) to produce peroxynitrite (ONOO–). iNOS works on L-Arginine converting it into Nitric oxide and L-citrulline. Peroxynitrite helps combat infections. Type Constitutive Expression Calcium dependency Function Location Endothelial (eNOS) (Option A ruled out) Constitutive (Low levels) Ca²■-dependent (via calmodulin) Maintains vascular tone (Vasodilation) Endothelial cells (Blood vessels) Neuronal (nNOS) (Option B ruled out) Constitutive (Low levels) Ca²■-dependent (via calmodulin) Functions as a neurotransmitter Neurons/Nerves Inducible (iNOS) (Option C) Inducible (Induced in macrophages by cytokines/microbial products) Ca²■-independent (Tight calmodulin binding) Involved in microbial killing, induced by cytokines or microbial products Macrophages and Inflammatory cells . Essential Co-factors of NOS: NADPH: The primary electron donor that initiates the process. FAD & FMN: The electron bridge that transfers electrons from NADPH to the heme group. Heme (Iron): The catalytic site that activates oxygen (O2) to oxidize L-arginine. Tetrahydrobiopterin (BH4): The stabilizer that ensures "coupling," preventing the production of toxic superoxide. Calmodulin (CaM): The molecular switch that triggers electron flow. Note: Binding is Ca²■-dependent for eNOS/nNOS but Ca²■-independent for iNOS. Zinc (Zn²■): The structural anchor that maintains the enzyme's active dimeric shape.

Q1: Which of the following cytokines does not cause the Jarisch-Herxheimer reaction? (Q855911)

A. TNF alpha

B. IL-6

C. IL-8

D. INF-γ

Correct Answer: D. INF-γ

Explanation: IFN-gamma, produced by activated T cells and NK cells, regulates Th1 immune responses but is not typically involved in the Jarisch-Herxheimer reaction. Instead, TNF-alpha, IL-6, and IL-8 play a key role in this reaction. Jarisch-Herxheimer Reaction: It is a dramatic but self-limited inflammatory response that can occur after the initiation of treatment for syphilis. It is characterized by: Fever Chills Myalgia (muscle pain) Headache Tachycardia (increased heart rate) Increased respiratory rate Elevated circulating neutrophil count Vasodilation with mild hypotension This reaction is believed to be triggered by the release of lipoproteins from dying Treponema pallidum organisms. The reaction occurs in approximately 50% of patients with primary syphilis, 90% of those with secondary syphilis, and in a smaller proportion of individuals with later-stage disease. Symptoms typically subside within 12–24 hours. In patients with secondary syphilis, erythema (redness) and oedema (swelling) of cutaneous lesions may worsen temporarily. TNF alpha (Option A) is a pro-inflammatory cytokine produced by macrophages and T cells , playing a central role in inflammation. It is implicated in the Jarisch-Herxheimer reaction , where cytokine release following antibiotic treatment temporarily worsens symptoms. IL-6 (Option B) is a pro-inflammatory cytokine produced by immune cells, fibroblasts, and endothelial cells , regulating immune responses and inflammation. It contributes to the Jarisch-Herxheimer reaction by amplifying the systemic inflammatory response. IL-8 (Option C) is a chemokine that recruits and activates neutrophils , playing a role in infection and inflammation . It contributes to the Jarisch-Herxheimer reaction by enhancing neutrophil recruitment and activation.

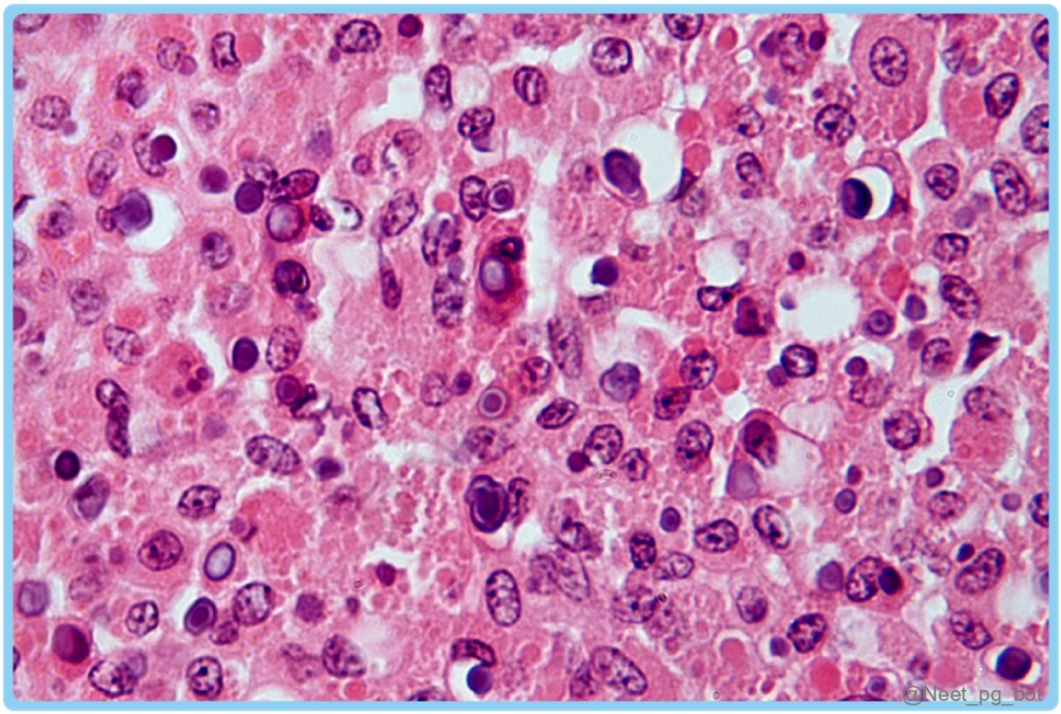
Q2: A patient underwent a cystoscopy, which showed multiple yellow-white plaques in the trigone of the bladder. The histopathology image is given below. What is the diagnosis? (Q855952)

A. Interstitial cystitis

B. Malakoplakia

C. Polypoid cystitis

D. Acute cystitis



Correct Answer: B. Malakoplakia

Explanation: is a common urinary tract infection that presents with dysuria, frequency, and urgency. It does not cause the formation of yellow-white plaques or Michaelis-Gutmann bodies.

@Neet_pg_bot

Q3: All of the following statements regarding neutrophil extracellular trapping (NET) are true, except? (Q855938)

A. It is detected in blood during sepsis

B. It is produced in response to bacterial infection

C. Mitochondrial DNA is seen

D. It is chromatin with antibacterial enzymes

Correct Answer: C. Mitochondrial DNA is seen

Explanation: Neutrophil extracellular traps: They are produced by neutrophils in response to infectious pathogens (mainly bacteria and fungi) and inflammatory mediators (e.g., chemokines, cytokines, complement proteins, and ROS), their presence can be used as a biomarker for sepsis. (Option B ruled out) NET formation starts with ROS-dependent activation of an arginine deaminase that converts arginine to citrulline, leading to chromatin decondensation. NETs are composed of nuclear chromatin and various granule proteins, including antimicrobial peptides and enzymes that help to neutralise and kill pathogens trapped within the NETs. (Option D ruled out) Activated neutrophils release histones into the extracellular space which helps to unwind and release the DNA, allowing it to combine with granule proteins and form the characteristic web-like structure of NETs. NETs do not directly phagocytose or engulf the invading pathogens . Instead, they trap pathogens within their structure, immobilizing them and allowing other immune cells, such as macrophages, to recognize and eliminate them. The nuclear chromatin in the NETs, including histones and associated DNA, has been postulated to be a source of nuclear antigens in systemic autoimmune diseases, particularly lupus, in which individuals react against their DNA and nucleoproteins. {{caption_text}} A neutrophil granulocyte (yellow) has ejected a NET (green) to capture bacteria (purple). A red blood cell (orange) is also trapped in the NET.

@Neet_pg_bot

Q4: A 12-year-old child presented with 15 days of cough. On examination, cervical lymphadenopathy was noted, and the lymph node biopsy showed caseating granulomas. What is the most probable diagnosis? (Q854881)

A. Tuberculosis

B. Leprosy

C. Sarcoidosis

D. Syphilis

Correct Answer: A. Tuberculosis

Explanation: In patients presenting with cervical lymphadenopathy (scrofula) and a prolonged cough, histopathology typically reveals granulomatous inflammation. Caseating granulomas (necrotizing granulomas) are hallmark histopathological findings in tuberculosis. Granulomas are composed of epithelioid cells, Langhans giant cells, and a central area of caseous necrosis. Cervical lymphadenopathy (scrofula) is a common manifestation of extrapulmonary TB in children. Clinical history of prolonged cough supports a tubercular infection. Diagnosis is confirmed by AFB staining, culture, or PCR for Mycobacterium tuberculosis. Note: While predominantly caseating, TB can show both caseating and non-caseating granulomas, with caseating > non-caseating . Similar to TB, sarcoidosis can occasionally show small areas of necrosis, but is typically non-caseating > caseating . Leprosy (Option B): Causes non-caseating granulomas; typically involves skin and peripheral nerves, not cervical lymph nodes with caseation. Sarcoidosis (Option C): Characterized by non-caseating granulomas; more common in adults and usually systemic. Syphilis (Option D): Can cause gummatous lesions but not classic caseating granulomas; cervical lymphadenopathy is usually painless.

@Neet_pg_bot

Q5: During acute inflammation, leukocytes exit the bloodstream and migrate toward the site of tissue injury through several coordinated steps. Arrange the following events in the correct chronological order: Chemotaxis Adhesion Opsonization Rolling Phagocytosis Margination Cytokine-mediated integrin activation Transmigration (Q856703)

A. 1, 2, 3, 4, 5, 6, 7, 8

B. 6, 4, 7, 2, 8, 1, 3, 5

C. 4, 6, 2, 1, 3, 7, 8, 5

D. 2, 1, 4, 3, 5, 6, 7, 8

Correct Answer: B. 6, 4, 7, 2, 8, 1, 3, 5

Explanation: The correct sequence of cellular events of inflammation is as follows: Margination: Due to vasodilation and slowing of blood flow, leukocytes move toward the vessel wall (periphery of the stream). Rolling: Leukocytes transiently attach and detach along the endothelium, mediated by selectins (E-, P-, L-selectin) . Integrin Activation: Chemokines (IL-8, C5a, LTB■) activate leukocyte integrins, converting them from a low- to high-affinity state. Adhesion: Firm binding of leukocytes to the endothelium occurs via integrins (LFA-1, Mac-1) binding to ICAM-1 and VCAM-1 . Transmigration (Diapedesis): Leukocytes squeeze between endothelial cells and cross the basement membrane into the interstitium, mediated by PECAM-1 (CD31) . Chemotaxis: Leukocytes migrate directionally toward the site of injury, guided by gradients of IL-8, C5a, LTB■, and bacterial peptides .

Opsonization: Microbes are coated with opsonins (IgG, C3b) to enhance recognition by phagocytes. Phagocytosis: Leukocytes engulf and destroy pathogens using reactive oxygen species and lysosomal enzymes .

@Neet_pg_bot

Q6: During wound healing, the cells that appear first, due to chemotaxis, at the site of the wound are: (Q857608)

A. Neutrophils

B. Monocytes

C. Macrophages

D. Lymphocytes

Correct Answer: A. Neutrophils

Explanation: Neutrophils are the first cells to migrate to the site of injury due to chemotaxis during the inflammatory response. They are crucial in the initial stages of wound healing, where they help to clear debris, bacteria, and other pathogens. Events in wound healing Day 0 Platelets and Fibrin form blood clots. Day 1 Blood clot remains and recruitment of neutrophils (acute inflammation). Day 2 Blood clots remain; neutrophils accumulate, followed by the formation of a thin epithelial layer. Day 3 Chronic inflammation sets in, and macrophages replace neutrophils. Granulation tissue begins (blood vessel formation starts) Day 5 Maximum granulation tissue (Maximum neovascularisation) Collagen bridging starts Day 21(3rd Week) Maximum collagen deposition (Type I collagen.) {{caption_text}}

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 108

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following molecules helps in the firm adhesion of the leukocyte to the endothelium during inflammation? (Q857101)

A. P-selectin

B. Platelet-activating factor

C. VCAM-1

D. Complements

Correct Answer: C. VCAM-1

Explanation: VCAM-1 (Vascular Cell Adhesion Molecule-1) is involved in the firm adhesion of leukocytes to the endothelium during inflammation. It binds to integrins on the surface of leukocytes, facilitating their migration through the endothelium to the site of injury or infection. Leukocyte Adhesion to Endothelium: In normal blood flow, leukocytes are pushed to the edges of the vessel. In inflammation, stasis causes leukocytes to slow down and interact with endothelial cells. This interaction involves selectins and integrins , which mediate the rolling and firm adhesion of leukocytes. Selectins : These are responsible for the initial rolling interactions . There are three types: L-selectin on leukocytes E-selectin on endothelial cells P-selectin (Option A) on both platelets and endothelial cells The ligands for selectins are sialylated oligosaccharides on mucin-like glycoproteins. Cytokines like TNF and IL-1 upregulate the expression of selectins, promoting leukocyte rolling along the vessel wall. Integrins : After rolling, leukocytes bind more firmly to the endothelium via integrins, such as VLA-4 and LFA-1 (CD11a & CD18) , which interact with endothelial ligands like VCAM-1 and ICAM-1 . This firm adhesion halts the rolling process and allows leukocytes to flatten and spread on the endothelial surface. Migration: Once firmly adhered, leukocytes migrate through the endothelial layer (transmigration), facilitated by adhesion molecules like PECAM-1 (CD31). After exiting the vessel, they follow the chemotactic gradient toward the site of inflammation. Incorrect Options: Platelet-activating factor (PAF) (Option B) is a potent mediator of inflammation, influencing various processes like platelet aggregation, vasodilation, and immune cell activation, but it does not directly contribute to leukocyte adhesion to the endothelium. Complement (Option D) proteins are part of the immune system and are involved in opsonisation, lysis of pathogens, and inflammation. However, they do not directly mediate the adhesion of leukocytes to the endothelium.

@Neet_pg_bot

Q8: Cyclooxygenase plays a role in which of the following pathways? (Q855125)

A. Kreb’s cycle

B. Prostaglandin

C. Leukotriene

D. Vitamin K

Correct Answer: B. Prostaglandin

Explanation: Cyclooxygenase (COX) is an enzyme that plays a key role in the prostaglandin synthesis pathway. It converts arachidonic acid into prostaglandins, which are involved in inflammation, pain, and fever. Arachidonic Acid Metabolites: Arachidonic acid (AA) is a 20-carbon polyunsaturated fatty acid (5,8,11,14-eicosatetraenoic acid). It is stored in membrane phospholipids and released through the action of phospholipase A2 . AA is then converted into lipid mediators, known as eicosanoids, through the action of cyclooxygenases and lipoxygenases. {{caption_text}} Prostaglandins (PGs): Produced by Mast cells, macrophages, endothelial cells, and other cell types. Involved in Vascular and systemic reactions of inflammation. Enzymes : Prostaglandins are synthesized via cyclooxygenase enzymes (COX-1 and COX-2). COX-1 is constitutively expressed and performs homeostatic functions, while COX-2 is induced in response to inflammation. Key Prostaglandins : PGI2 (prostacyclin) is produced by the vascular endothelium and acts as a vasodilator and inhibitor of platelet aggregation. TXA2 is produced by platelets and causes platelet aggregation and vasoconstriction. PGD2 and PGE2 cause vasodilation and increase the permeability of postcapillary venules, promoting oedema formation. PGE2 also contributes to pain and fever during inflammation. Leukotrienes: Produced by : Leukocytes and mast cells through the action of lipoxygenase enzymes, particularly 5-lipoxygenase . Involved in vascular reactions, smooth muscle contraction, and leukocyte recruitment. Key Leukotrienes : LTB4 is a potent chemotactic agent that activates neutrophils and promotes adhesion, generates reactive oxygen species (ROS), and releases lysosomal enzymes. Cysteinyl leukotrienes (LTC4, LTD4, LTE4) cause vasoconstriction, bronchospasm (important in asthma), and increase vascular permeability. Lipoxins: Produced by : Lipoxins are synthesized via the lipoxygenase pathway, involving both neutrophils and platelets for transcellular biosynthesis. Function : Lipoxins suppress inflammation by inhibiting neutrophil chemotaxis and adhesion to the endothelium, thus limiting the inflammatory response. Kreb’s cycle (Option A) is part of cellular respiration and involves the metabolism of carbohydrates, fats, and proteins to generate energy. Cyclooxygenase is not involved in this cycle. Leukotriene (Option C) is another class of eicosanoids derived from arachidonic acid, but it is produced via the 5-lipoxygenase pathway, not the cyclooxygenase pathway. Vitamin K (Option D) is involved in the coagulation cascade and is not related to the action of cyclooxygenase.

@Neet_pg_bot

Q9: Match the following cells with their locations: Cells Locations 1. Kupffer cells a. Stomach 2. Parietal cells b. Liver 3. Dust cells c. Alveoli 4. Clara cells d. Bronchioles (Q855088)

A. 1-a, 2-b, 3-c, 4-d

B. 1-c, 2-d, 3-a, 4-b

C. 1-d, 2-a, 3-d, 4-c

D. 1-b, 2-a, 3-c, 4-d

Correct Answer: D. 1-b, 2-a, 3-c, 4-d

Explanation: Cells Locations Kupffer cells Liver Parietal cells Stomach Dust cells Alveoli Clara cells Bronchioles Kupffer cells are specialized macrophages located in the liver. They are part of the liver's immune system and help filter blood and remove pathogens and debris. Parietal cells are found in the stomach lining and secrete hydrochloric acid and intrinsic factors, which are essential for digestion and absorption of vitamin B12. Dust cells : These are alveolar macrophages located in the lungs, specifically in the alveoli. They play a role in clearing out inhaled particles, bacteria, and debris from the lungs. Clara cells are located in the bronchioles (small air passages in the lungs), protect the lungs from oxidative stress and have a role in detoxification by secreting various substances, including surfactant components. Macrophage Eponyms and Locations: Cell Name Location Primary Role Kupffer cells Liver Specialized macrophages that filter blood and remove pathogens. Dust cells Alveoli (Lungs) Alveolar macrophages that clear inhaled debris and bacteria. Microglia Central Nervous System Act as the primary immune defense in the brain and spinal cord. Langerhans cells Skin (Epidermis) Dendritic cells that act as macrophages to process antigens. Osteoclasts Bone Specialized cells responsible for bone resorption and remodeling. Mesangial cells Kidney (Glomerulus) Regulate filtration and clear immune complexes. Histiocytes Connective Tissue General tissue-resident macrophages. Splenic Macrophages Spleen (Red Pulp) Remove aged or damaged red blood cells (erythrophagocytosis). Hofbauer cells Placenta Protect the fetus from pathogens across the placental barrier. Stem Cells: Stem Cell Type Location Differentiation Potential Hematopoietic Stem Cells Bone Marrow Give rise to all blood cells (RBCs, WBCs, Platelets). Basal cells Skin (Stratum Basale) Continuously produce new keratinocytes to renew the epidermis. Crypt cells (Stem cells) Small Intestine Located in the Crypts of Lieberkühn; renew the intestinal lining every few days. Satellite cells Skeletal Muscle Act as precursors to myoblasts to repair damaged muscle fibers. Oval cells Liver (Canals of Hering) Activated when hepatocytes are unable to regenerate effectively. Neural Stem Cells Subventricular Zone Produce new neurons and glial cells in specific brain regions. Limbal Stem Cells Eye (Corneo-scleral junction) Maintain the transparency and integrity of the corneal epithelium.

@Neet_pg_bot

Q10: Match the cytokines with the effector cells 1. IL-4 a. Eosinophils 2. IL-5 b. Mast cells 3. IL-9 c. B cells 4. IL-13 d. Dendritic cells (Q856029)

A. 1-c, 2-a, 3-b, 4-d

B. 1-a, 2-c, 3-d, 4-b

C. 1-b, 2-d, 3-c, 4-a

D. 1-d, 2-b, 3-a, 4-c

Correct Answer: A. 1-c, 2-a, 3-b, 4-d

Explanation: Cytokine Effector Cell IL-4 B cells IL-5 Eosinophils IL-9 Mast cells IL-13 Dendritic cells Interleukins & functions: Interleukin (IL) Function IL-1 Promotes fever and inflammation and activates T cells and macrophages. IL-2 Stimulates growth and activation of T cells, critical for adaptive immunity. IL-3 Supports growth and differentiation of hematopoietic cells (blood cell precursors). IL-4 Stimulates B cell differentiation and promotes IgE production and Th2 response. IL-5 Stimulates eosinophil differentiation and activation. IL-6 Induces fever and acute-phase reactant production and supports B cell differentiation. IL-7 Essential for T and B cell development and survival. IL-8 (CXCL8) Attracts neutrophils to sites of infection (chemotaxis). IL-9 Promotes mast cell growth and regulates Th2 responses. IL-10 Anti-inflammatory; inhibits Th1 responses and macrophage activity. IL-12 Stimulates Th1 cell differentiation and enhances cytotoxic activity of T and NK cells. IL-13 Modulates immune responses and activates macrophages. IL-17 Promotes inflammation and recruitment of neutrophils, which are involved in autoimmunity. IL-21 Stimulates B cell differentiation, plasma cell generation, and Th17 response. IL-22 Induces antimicrobial peptide production and supports tissue repair. IL-23 Promotes Th17 differentiation and inflammatory responses.

@Neet_pg_bot

Q11: Which of the following molecules helps leukocytes roll over endothelial cells in vessels? (Q856001)

A. Cadherins

B. PECAM-1

C. E-selectin

D. CD11a

Correct Answer: C. E-selectin

Explanation: E-selectin is a molecule expressed on endothelial cells that facilitates the initial rolling of leukocytes along the vessel wall during the inflammatory response. Leukocyte Adhesion to Endothelium: In normal blood flow, leukocytes are pushed to the edges of the vessel. In inflammation, stasis causes leukocytes to slow down and interact with endothelial cells. This interaction involves selectins and integrins , which mediate the rolling and firm adhesion of leukocytes. Selectins : These are responsible for the initial rolling interactions . There are three types: L-selectin on leukocytes E-selectin on endothelial cells P-selectin on both platelets and endothelial cells The ligands for selectins are sialylated oligosaccharides on mucin-like glycoproteins. Cytokines like TNF and IL-1 upregulate the expression of selectins, promoting leukocyte rolling along the vessel wall. Integrins : After rolling, leukocytes bind more firmly to the endothelium via integrins, such as VLA-4 and LFA-1 (CD11a (Option D) & CD18) , which interact with endothelial ligands like VCAM-1 and ICAM-1 . This firm adhesion halts the rolling process and allows leukocytes to flatten and spread on the endothelial surface. Migration: Once firmly adhered,

leukocytes migrate through the endothelial layer in a process called transmigration. It is facilitated by adhesion molecules like PECAM-1 (CD31) (Option B). After exiting the vessel, leukocytes follow the chemotactic gradient toward the site. Cadherins (Option A) are adhesion molecules involved in maintaining cell-cell interactions in tissues, especially in epithelial cells, but they are not directly involved in the rolling of leukocytes on endothelial cells during inflammation.

@Neet_pg_bot

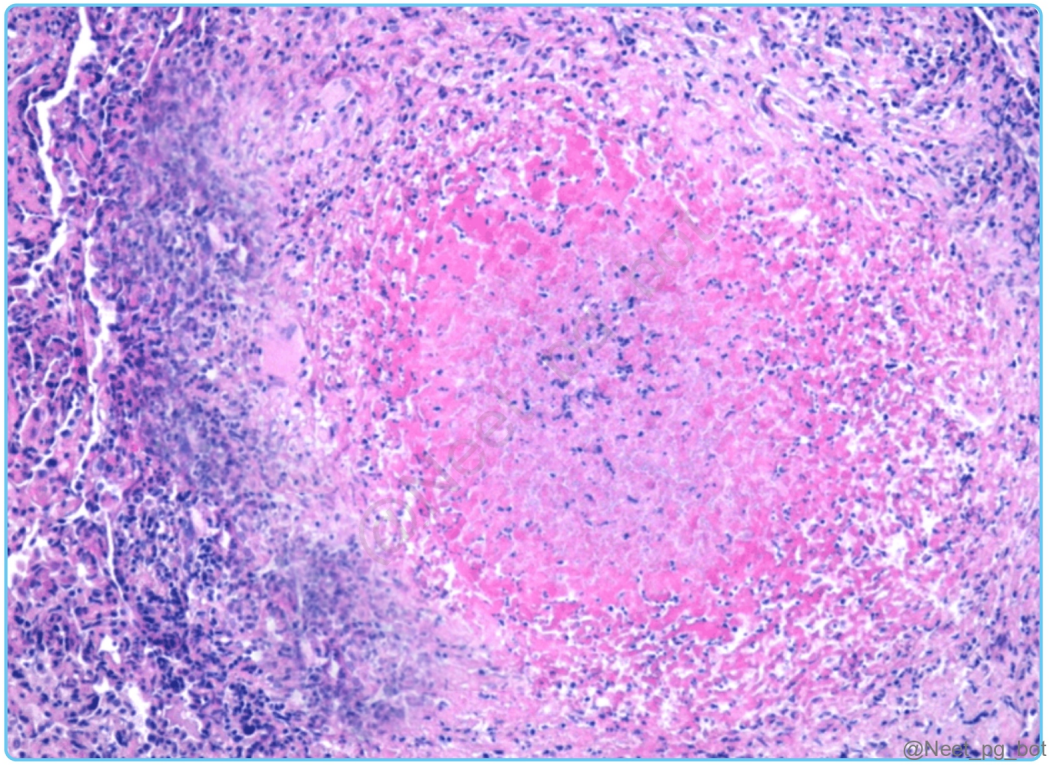
Q13: A patient presents with complaints of cough, night sweats, and fever. A lung biopsy demonstrates the following histological findings. What is the most likely cytokine involved? (Q854700)

A. Interferon-γ

B. Complement C5a

C. Histamine

D. Bradykinin



Correct Answer: A. Interferon-γ

Explanation: The patient's presentation with cough, night sweats, and fever, along with the histological finding of granulomas and multinucleated giant cells, is highly indicative of a granulomatous condition like Tuberculosis (TB) , which is typically driven by the immune response, specifically by the cytokine interferon-γ (IFN-γ) T-lymphocytes release IFN-γ when exposed to M. tuberculosis antigens, which activate macrophages, enhancing their ability to kill intracellular bacteria. Despite IFN-γ activation of macrophages, the bacteria are often not completely eliminated, and they can survive inside the macrophages, evading complete eradication. This results in a chronic infection , leading to continued replication of M. tuberculosis and the formation of granulomas . The granuloma acts as a protective structure around the bacteria, but in some cases, it can break down, leading to active disease and further spread of the infection. Components of Granuloma: Epithelioid Cells: Activated macrophages with abundant cytoplasm that resemble epithelial cells. Multinucleated Giant Cells (Langhans-type): Formed by the fusion of multiple activated macrophages; in TB, nuclei are characteristically arranged in a horseshoe pattern at the periphery. Necrosis: In Tuberculosis, the center of the granuloma often undergoes caseous (cheese-like) necrosis , a hallmark of the disease. Note: TB can show both caseating and non-caseating granulomas, but caseating > non-caseating . Lymphocytic Rim: T-cells surrounding the activated macrophages, providing continuous cytokine signaling (like IFN-γ). Complement C5a (Option B) is a chemotactic factor in the complement system . It helps attract neutrophils and other immune cells to the site of infection. However, it does not directly contribute to granuloma formation or the activation of macrophages needed for multinucleated giant cell formation. Histamine (Option C) is involved in the acute inflammatory response , causing vasodilation and increasing vascular permeability . It does not play a direct role in the formation of granulomas or the differentiation of macrophages into giant cells. Bradykinin (Option D) is part of the acute inflammatory response, not the chronic inflammatory response seen in granulomatous diseases. It does not play a role in granuloma formation.

@Neet_pg_bot

Q14: Which substance plays a role as a mediator in chronic inflammation? (Q830804)

A. IL-1

B. TNF-α

C. TGF-β

D. None

Correct Answer: C. TGF-β

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: TGF-β plays a crucial role in regulating immune responses, cell proliferation, differentiation, and tissue repair. In the context of chronic inflammation, TGF-β is involved in tissue repair and fibrosis. It promotes the production of extracellular matrix components and inhibits the activity of immune cells, contributing to the resolution of inflammation but also leading to tissue remodelling and fibrosis over time. It is important to emphasise that cytokines like IL-1 and TNF-α also take part in chronic inflammation; however, they are primarily associated with the acute phase response . TGF-β is classic for chronic inflammation because of its specific functions in the resolution and repair phases. IL-1 (Option A): IL-1 is a pro-inflammatory cytokine involved in the initial phase of inflammation. IL-1 helps recruit immune cells to sites of infection or damage and promotes the production of other inflammatory mediators. It is associated with acute inflammation. TNF-α (Option B): TNF-α is involved in systemic inflammation and is part of the acute phase response. TNF-α helps mediate the recruitment of immune cells to inflammation sites and stimulates the production of other cytokines and adhesion molecules. TNF-α is associated with acute inflammation.

@Neet_pg_bot

Q15: All of the following are correct about 'Neutrophil extracellular traps' except? (Q860299)

A. May result in SLE

B. Phagocytosis

C. Sepsis

D. Arginine needed

Correct Answer: B. Phagocytosis

Explanation: NETs (Neutrophil Extracellular Traps) do not directly engulf pathogens through phagocytosis but instead trap and immobilise them, allowing other immune cells to clear the infection. They are extracellular fibrillar networks that concentrate antimicrobial substances at sites of infection and trap microbes, helping to prevent their spread. They don't directly phagocytose pathogens but trap and immobilise them, allowing immune cells like macrophages to eliminate them. (Option B) They are produced by neutrophils in response to pathogens and inflammatory mediators. NET formation begins with ROS-induced activation of arginine deaminase, leading to chromatin decondensation. (Option D ruled out) They are composed of nuclear chromatin and granule proteins, including antimicrobial peptides and enzymes. They are implicated in conditions like sepsis (Option C ruled out) and autoimmune diseases like lupus (Option A ruled out) , where they may contribute to autoimmunity. {{caption_text}} {{caption_text}} A neutrophil granulocyte (yellow) has ejected a Neutrophil extracellular trap (green) to capture bacteria (purple). A red blood cell (orange) is also trapped in the Neutrophil extracellular trap.

@Neet_pg_bot

Q17: A 50-year-old female presents with cervical lymphadenopathy. A biopsy has revealed granulomatous necrotising inflammation. Which of the following options is correct? (Q860203)

A. Metastatic calcification with normal serum calcium level

B. Dystrophic calcification with normal serum calcium level

C. Metastatic calcification with increased serum calcium level

D. Dystrophic calcification with increased serum calcium level

Correct Answer: B. Dystrophic calcification with normal serum calcium level

Explanation: The scenario suggests tuberculosis, marked by cervical lymphadenopathy and granulomatous necrotising inflammation, in which Dystrophic Calcification with normal serum calcium levels can be seen. Dystrophic Calcification: It involves the deposition of calcium salts in damaged or abnormal tissues rather than normal tissues . Serum calcium is normal . (Option D ruled out) It is present in the atheromas of advanced atherosclerosis and develops in ageing or damaged heart valves . Macroscopically, the calcium salts appear fine, and white granules or clumps often feel like gritty deposits. Microscopically, calcium salts have a basophilic , amorphous granular, and sometimes clumped appearance. {{caption_text}} Psammoma bodies are small, round, laminated, calcific structures that resemble onion peels . They can be seen in Papillary carcinoma of the thyroid and kidney, Prolactinoma, Serous ovarian carcinoma , Meningioma, and Mesothelioma. Other examples are:

Tuberculosis (Option B) (Option C ruled out) Atheroma Dead parasite Monckeberg Sclerosis Metastatic calcification may occur in normal tissues whenever there is hypercalcemia. (Option A ruled out) There are four principal causes of hypercalcemia: Increased secretion of parathyroid hormone (PTH) : Hyperparathyroidism (parathyroid tumours) and ectopic secretion of PTH-related protein (malignant tumours). Resorption of bone tissue, secondary to primary tumours of bone marrow (e.g., multiple myeloma, leukaemia) or diffuse skeletal metastasis (e.g., breast cancer), accelerated bone turnover (e.g., Paget disease), or immobilisation. Vitamin D–related disorders , including vitamin D intoxication, sarcoidosis, and idiopathic hypercalcemia of infancy (Williams syndrome). Renal failure , which causes retention of phosphate (Secondary hyperparathyroidism). Less common causes include aluminium intoxication, which occurs in patients on chronic renal dialysis, and milk-alkali syndrome, which is due to excessive ingestion of calcium and absorbable antacids such as milk or calcium carbonate. Feature Dystrophic Calcification Metastatic Calcification Definition Calcium deposition in damaged/necrotic tissue Calcium deposition in normal tissues due to hypercalcemia Calcium levels Normal serum Ca^{2}■, PO■^{3}■ Elevated serum Ca^{2}■, PO■^{3}■ Common causes - TB (caseous necrosis) - Fat necrosis - Atherosclerotic plaques - Old hematoma - Degenerating tumors - Hyperparathyroidism - Vitamin D excess - Chronic renal failure - Osteolytic tumors (multiple myeloma) - Milk-alkali syndrome Location - Damaged tissues only - Lungs (TB) - Breast (fat necrosis) - Aorta (atheroma) - Normal tissues - Lung (alveolar septa) - Kidney (basement membranes) - Stomach (mucosa) - Blood vessels Histology/Stain Basophilic deposits; Von Kossa (+) Finely granular; Von Kossa (+) Examples - Calcified TB granuloma - Psammoma bodies - Dystrophic calcification in necrotic tumor - Renal failure → pulmonary calcification - HyperPTH → gastric calcification Clinical Usually asymptomatic Organ dysfunction (renal failure, pulmonary) Clinical Significance Often a sign of previous cell injury ; can cause organ dysfunction (e.g., heart valve stenosis). Sign of an underlying metabolic disorder ; can lead to widespread tissue damage.

@Neet_pg_bot

Q18: Which of the following is the most effective enzyme in Acute inflammation? (Q860193)

A. NADPH oxidase

B. Defensin

C. Catalase

D. MPO

Correct Answer: A. NADPH oxidase

Explanation: NADPH oxidase is the most effective enzyme in acute inflammation. The Phox gene produces it and is the key enzyme involved in phagocytosis. Reactive oxygen species (ROS) are produced through the rapid assembly and activation of NADPH oxidase (phagocyte oxidase) . This enzyme oxidises NADPH , transferring electrons to molecular oxygen and generating superoxide anion (O■•) . Chronic Granulomatous Disease (CGD): Defect: Mutation in NADPH oxidase (often X-linked gp91phox), which prevents the "respiratory burst". Pathophysiology: Neutrophils cannot produce superoxide (O2-) , leading to a failure in generating reactive oxygen species (ROS) for killing microbes. Infections: High susceptibility to catalase-positive organisms (e.g., S. aureus , Serratia , Aspergillus) that neutralize their own H2O2, leaving the host with no oxidative defence. Clinical Sign: Persistent, ineffective inflammation results in widespread granuloma formation. Diagnosis: Determined via Dihydrorhodamine (DHR) flow cytometry (modern) or the Nitroblue Tetrazolium (NBT) dye test (classic). Defensins (Option B) are small antimicrobial peptides that help eliminate pathogens, but they are not the main enzyme involved in acute inflammation. Catalase (Option C) is an enzyme that decomposes hydrogen peroxide (H■O■) to protect cells from oxidative damage, but it is not the primary enzyme involved in the inflammatory response. MPO (Myeloperoxidase) (Option D) is an enzyme present in neutrophils that utilises hydrogen peroxide (produced by NADPH oxidase) to generate hypochlorous acid (HOCl), a potent antimicrobial agent. However, the most critical enzyme in acute inflammation is NADPH oxidase.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 82.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Which of the following parameters decreases in acute inflammation? (Q860161)

A. CRP

B. Hepcidin

C. Fibrinogen

D. Albumin

Correct Answer: D. Albumin

Explanation: During acute inflammation, the liver increases the production of positive acute-phase reactants like C-reactive protein (CRP) (Option A) , hepcidin (Option B) , and fibrinogen (Option C) , which help in immune response and coagulation. However, albumin is a negative acute-phase reactant , meaning its levels decrease during inflammation as the liver prioritises synthesising proteins involved in the inflammatory response. They are plasma proteins, mostly synthesised in the liver, whose plasma concentrations may increase several hundred–fold as part of the response to inflammatory stimuli. Few of these examples are: C-reactive protein (CRP) (Option A ruled out) Fibrinogen (Option C ruled out) Serum amyloid A (SAA) protein. Hepcidin (Option B ruled out) Thrombopoietin These are increased during the process of inflammation. Acute Phase Reactants: Feature Positive Acute Phase Reactants Negative Acute Phase Reactants Serum Level Increase during inflammation. Decrease during inflammation. Physiological Goal To assist in host defense, limit tissue damage, and promote repair. To conserve amino acids for the production of positive reactants. Key Examples C-Reactive Protein (CRP) : Opsonin and complement activator. Fibrinogen : Essential for clotting; increases ESR. Ferritin/Hepcidin : Sequestration of iron to starve microbes. Serum Amyloid A : Immune cell recruiter. Complement (C3, C4) : Opsonization and MAC formation. Albumin : Maintains osmotic pressure; levels drop to save resources. Transferrin : Decreases to prevent iron availability to bacteria. Transthyretin (Prealbumin) : Rapidly falls during acute stress. Antithrombin : Decreases, contributing to a pro-coagulant state. Retinol-Binding Protein : Transport protein that decreases significantly.

@Neet_pg_bot

Q20: All of the following are growth-promoting proto-oncogenes, except? (Q840061)

A. FGF

B. PDGF

C. TGF-α

D. TGF-β

Correct Answer: D. TGF-β

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Correct Option D - TGF-β: Transforming growth factor-beta (TGF-β) is an anti-inflammatory growth factor and is a marker for repair. It is not a growth-promoting oncogene. Incorrect Options: Options A, B, and C: Fibroblast growth factor (FGF), Platelet-derived growth factor (PDGF), and Transforming growth factor-alpha(TGF-α) are growth-promoting oncogenes.

@Neet_pg_bot

Q21: All of the following are correct about NETs except? (Q860511)

A. May result in SLE

B. Phagocytosis

C. Sepsis

D. Arginine needed

Correct Answer: B. Phagocytosis

Explanation: NETs (Neutrophil Extracellular Traps) do not directly engulf pathogens through phagocytosis but instead trap and immobilise them, allowing other immune cells to clear the infection. They are extracellular fibrillar networks that concentrate antimicrobial substances at sites of infection and trap microbes, helping to prevent their spread. They don’t directly phagocytose pathogens but trap and immobilise them, allowing immune cells like macrophages to eliminate them. (Option B) They are produced by neutrophils in response to pathogens and inflammatory mediators. NET formation begins with ROS-induced activation of arginine deaminase, leading to chromatin decondensation. (Option D ruled out) They are composed of nuclear chromatin and granule proteins, including antimicrobial peptides and enzymes. They are implicated in conditions like sepsis (Option C ruled out) and autoimmune diseases like lupus (Option A ruled out) , where they may contribute to autoimmunity. {{caption_text}} {{caption_text}} A neutrophil granulocyte (yellow) has ejected a NET (green) to capture bacteria (purple). A red blood cell (orange) is also trapped in the NET.

[03_Genetics] 010 Genetics- Introduction Mendelian Disorders — Quick Jump

Q1 (p. 1185) *Q2 (p. 1185)* *Q3 (p. 1186)* *Q4 (p. 1187)* *Q5 (p. 1189)* *Q6 (p. 1190)*
Q7 (p. 1192) *Q8 (p. 1193)* *Q9 (p. 1194)* *Q10 (p. 1194)* *Q11 (p. 1195)* *Q12 (p. 1196)*
Q13 (p. 1196)

Q1: Match the following with their correct terms. 1 Exon i Non-coding region 2 Intron ii One of the alternate forms of a single gene occupying a given position in a chromosome 3 Locus iii Coding region 4 Allele iv Location of a gene on the chromosome (Q845099)

A. 1-iii, 2-i, 3-iv, 4-ii

B. 1-iii, 2-i, 3-ii, 4-iv

C. 1-i, 2-iii, 3-iv, 4-ii

D. 1-i, 2-iii, 3-ii, 4-iv

Correct Answer: A. 1-iii, 2-i, 3-iv, 4-ii

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Exon : An exon is a coding region of a gene that contains the genetic information necessary for producing a functional protein. Intron : An intron is a non-coding region of a gene that intervenes between exons. During gene expression, introns are removed from the pre-mRNA molecule through splicing, which allows exons to be joined together to form the final mRNA transcript before translation into a protein. Locus : A locus refers to the specific location of a gene or DNA sequence on a chromosome. Allele : An allele is one of the alternate forms of a single gene occupying a given position in a chromosome , which can lead to different traits or characteristics. Alleles can be dominant or recessive.

Robbins and Cotrans Pathological Basis of Diseases, 10th Edition, Page 459

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 25-year-old male from a tribal area of Madhya Pradesh presents to the clinic with complaints of fatigue and shortness of breath. On examination, he appears pale, and jaundice is noted. Laboratory investigations reveal low hemoglobin levels and increased reticulocyte count. The peripheral blood smear shows numerous sickle-shaped erythrocytes. What is the most likely molecular mechanism underlying the pathogenesis of this patient's condition? (Q845100)

A. Chromosomal translocation

B. Missense mutation

C. Frameshift mutation

D. Nonsense mutation

Correct Answer: B. Missense mutation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of a tribal male with the above-mentioned clinical features and sickle-shaped RBCs in the peripheral smear suggests sickle cell disease. A missense mutation (type of point mutation) is the underlying mechanism in the pathogenesis of this disease. Point mutation: A point mutation is a change in which a single base is substituted with a different base. Sickle cell anaemia. This point mutation involves substituting adenine for thymine at the seventh codon of the β-globin gene (GAG to GTG) , replacing glutamic acid with valine in the β-globin chain of haemoglobin. This single nucleotide change results in the formation of abnormal haemoglobin molecules (HbS) .

Robbins and Cotran Pathological Basis of Diseases, 10th Edition, Pages 142,143

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A couple visits a genetics counselor due to concerns about their baby's blood type. The father has blood type A (genotype I A I A), and the mother has blood type B (genotype I B I B). The counselor explains that blood type is determined by codominant alleles, where both alleles contribute equally to the phenotype in the heterozygous condition. Which of the following best describes codominance? (Q845101)

A. One allele completely masks the expression of the other allele

B. The phenotype of the heterozygote is intermediate between the phenotypes of the homozygotes

C. Only one allele is expressed, while the other remains silent

D. Both alleles contribute to the phenotype equally in the heterozygous condition

Correct Answer: D. Both alleles contribute to the phenotype equally in the heterozygous condition

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Codominance can be defined as a condition in which both the alleles of a gene pair in a heterozygote are equally expressed . Examples: ABO blood group system In the ABO blood group system, the I A and I B alleles are codominant in producing the AB blood group phenotype, in which both A and B-type antigens are produced. The genes responsible for the ABO blood group are located in chromosome 9. The presence of both I A and I B causes the expression of both , forming the AB blood group. HLA gene also shows co dominance One allele completely masks the expression of the other allele (Option A): Complete dominance Example: Mendelian Pea Plants: Purple flowers (P) are dominant over white flowers (p). A Pp plant appears fully purple. The phenotype of the heterozygote is intermediate between the phenotypes of the homozygotes (Option B): Incomplete dominance Example: Snapdragons: Crossing a Red flower (RR) with a White flower (WW) produces a Pink flower (RW). Only one allele is expressed, while the other remains silent (Option C): Epistasis or genomic imprinting Example: Prader-Willi Syndrome: Occurs when specific genes on the paternal chromosome 15 are expressed while the maternal ones are silenced.

Inderbir Singh’s Textbook of Anatomy, Volume 3, 6th edition, Pages 481-484

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 30-year-old man presents to the clinic with a history of tall stature, long limbs, and joint hypermobility. Upon further examination, he also exhibits features such as a high-arched palate, arachnodactyly (long, slender fingers), and aortic root dilation. His father has a similar appearance. Which of the following statements is true regarding the inheritance pattern seen in this condition? (Q845103)

A. Males are more commonly affected than females.

B. Most mutations lead to reduced production of a gene product or give rise to a dysfunctional or inactive protein.

C. Complete penetrance can be seen

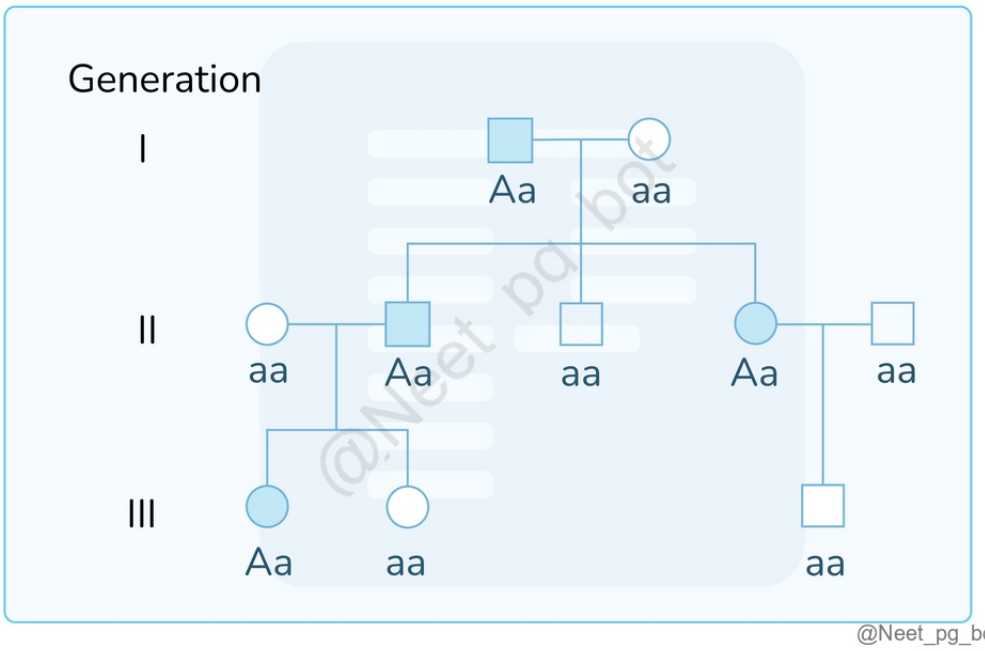
D. The least common mode of inheritance

Correct Answer: B. Most mutations lead to reduced production of a gene product or give rise to a dysfunctional or inactive protein.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario of a male with tall stature , long limbs , joint hypermobility , arachnodactyly , aortic root dilatation , and similar features in his father suggests Marfan's syndrome , an autosomal dominant condition and gene FBN1 (fibrillin-1) on chromosome 15 . The true statement regarding autosomal dominant inheritance is that most proteins lead to reduced production of a gene product or give rise to a dysfunctional or inactive protein. Autosomal dominant inheritance: Autosomal dominant disorders are manifested in the heterozygous state, so at least one parent of an index case is usually affected. It is the most common mode of inheritance. (Option D) Both males and females are affected, and both can transmit the condition. (Option A) They are characterized by: With every autosomal dominant disorder, some proportion of patients do not have affected parents. Clinical features can be modified by variations in penetrance and expressivity: Some individuals inherit the mutant gene but are phenotypically normal. This is referred to as incomplete penetrance . (Option C) If a trait is seen in all individuals carrying the mutant gene but is expressed differently among individuals, the phenomenon is called variable expressivity. In many conditions the age at onset is delayed; symptoms and signs may not appear until adulthood. Pedigree chart: Some examples of autosomal dominant disorders: {{caption_text}}



He - Hereditary Spherocytosis (RBC problem), Hereditary Hemorrhagic Telangiectasia (blood vessel problem), Hereditary Non-Polyposis Colon Cancer (HNPCC / Lynch Syndrome)
Has - Huntington's Disease, Hypertrophic Cardiomyopathy
A - Autosomal Dominant Polycystic Kidney Disease (AD PKD)
Very - Von Willebrand Disease (VWD), Von Hippel Lindau Syndrome (VHL Syndrome- chromosome 3p deleted)
DOMINANT - Muscle Dystonia, Osteogenesis imperfecta, Marfan's Syndrome, Intermittent Porphyria, NF 1 & NF 2, Achondroplasia, Noonam Syndrome, Tuberous Sclerosis.
Powerful - Pseudohypoparathyroidism
FATHER - Familial Adenomatous Polyposis (FAP), Li Fraumeni Syndrome (mutation in p53), Familial hypercholesterolemia.

@Neet_pg_bot

Q5: A 6-month-old male infant presents to the pediatric clinic with failure to thrive, recurrent respiratory infections, and hepatosplenomegaly. Upon further examination, the infant also displays signs of skeletal abnormalities including bowed legs and frontal bossing. Lab investigations reveal pancytopenia with markedly decreased platelet count. Genetic testing confirms a diagnosis of Gaucher disease. What is the pattern of inheritance and underlying genetic defect leading to this disorder? (Q845104)

A. Autosomal Dominant Inheritance, Mutation in the CFTR Gene

B. X-linked Recessive Inheritance, Mutation in the GBA Gene

C. Autosomal Dominant Inheritance, Mutation in the HEXA Gene

D. Autosomal Recessive Inheritance, Mutation in the GBA Gene

Correct Answer: D. Autosomal Recessive Inheritance, Mutation in the GBA Gene

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Gaucher disease is an autosomal recessive inborn error of metabolism caused by mutations in the glucocerebrosidase - GBA1 gene. All lysosomal storage diseases are autosomal recessive Exceptions (X-linked recessive): Fabry disease & Hunter syndrome Autosomal Dominant Inheritance, Mutation in the CFTR Gene (Option A): Cystic fibrosis (CF) is inherited as an autosomal recessive disorder caused by mutations in the CFTR gene. (chromosome 7) X-linked Recessive Inheritance, Mutation in the GBA Gene (Option B): Gaucher disease is not associated with X-linked inheritance; instead, it follows autosomal recessive inheritance. Autosomal Dominant Inheritance, Mutation in the HEXA Gene (Option C) : Tay-Sachs disease is an autosomal recessive disorder caused by mutations in the HEXA gene, resulting in deficient activity of the enzyme β-hexosaminidase A.

Robbins and Cotrans Pathological Basis of Diseases, 10th Edition, Pages 146, 156, 158, 159.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 6-month-old infant presents with hepatosplenomegaly, failure to thrive, and hypotonia. The infant has a cherry-red spot on the macula and exhibits poor startle reflexes on physical examination. Further evaluation reveals foam cells in the bone marrow. What is the diagnosis and associated enzyme deficiency? (Q845105)

A. Diagnosis: Niemann-Pick disease type A, Enzyme Deficiency: Acid sphingomyelinase

B. Diagnosis: Tay-Sachs disease, Enzyme Deficiency: Hexosaminidase A

C. Diagnosis: Gaucher disease, Enzyme Deficiency: Glucocerebrosidase

D. Diagnosis: Metachromatic leukodystrophy, Enzyme Deficiency: Arylsulfatase A

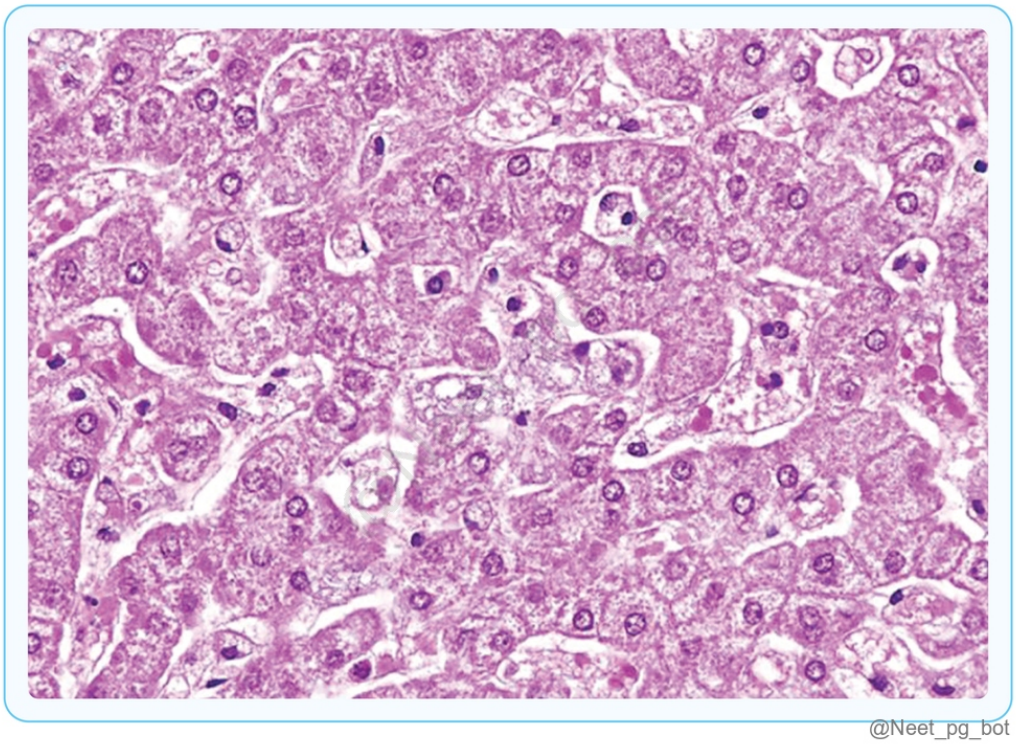
Correct Answer: A. Diagnosis: Niemann-Pick disease type A, Enzyme Deficiency: Acid sphingomyelinase

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Niemann-Pick disease type A is caused by acid sphingomyelinase deficiency , leading to sphingomyelin accumulation in macrophages, producing foam cells . Classic features include: Hepatosplenomegaly Failure to thrive Hypotonia Cherry-red spot on macula Neurodegeneration Type A is the severe infantile form with early death. Image : Niemann-Pick disease in the liver. The hepatocytes and Kupffer cells have a foamy, vacuolated appearance due to the deposition of lipids. Electron microscopy confirms that the vacuoles are engorged secondary lysosomes called zebra bodies. Image : Zebra bodies Tay-Sachs — Hexosaminidase A deficiency (Option B): Cherry-red spot present No hepatosplenomegaly (key differentiator) Accumulation of GM■ ganglioside; “onion-skin lysosomes,” not foam cells Gaucher — Glucocerebrosidase deficiency (Option C): No cherry-red spot Hepatosplenomegaly present Bone crises and Erlenmeyer flask deformity Gaucher cells : “crumpled tissue paper” macrophages, not foam cells Metachromatic leukodystrophy —

Arylsulfatase A deficiency(Option D): Demyelination with ataxia No cherry-red spot No hepatosplenomegaly Accumulation of sulfatides with metachromatic granules



@Neet_pg_bot

Q7: Sarah is a 3-year-old girl who is brought to her pediatrician by her parents due to concerns about her development. Her parents report that Sarah has been experiencing a loss of previously acquired skills, such as hand skills and language, stereotypic hand movements and seizure episodes . What is the mode of inheritance? (Q845106)

A. X-linked dominant

B. X-linked recessive

C. Autosomal recessive

D. Autosomal dominant

Correct Answer: A. X-linked dominant

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical manifestations in the patients point to Rett Syndrome. It has X-linked dominant inheritance. X-linked dominant disorders affect both males and females. All fathers that are affected by an X-linked dominant disorder will have affected daughters but not affected sons. However, if the mother is also affected then sons will have a chance of being affected, depending on whether a dominant or recessive X chromosome is passed on. When the son is affected, the mother will always be affected. Examples of X-linked dominant disorders (Mnemonic : RAVI-C): R ett Syndrome A lport Syndrome (X-linked) V itamin D-dependent rickets I ncontinentia Pigmenti C harcot-Marie-Tooth disease

@Neet_pg_bot

Q8: A 25-year-old male presents with severe hypotonia at birth, joint hypermobility, scoliosis, fragile skin, and ocular fragility. Genetic testing reveals mutations in the gene encoding Lysyl Hydroxylase. Which subtype of Ehlers-Danlos Syndrome (EDS) is most likely present in this patient and its mode of inheritance? (Q845107)

A. Classical EDS - Autosomal Dominant

B. Hypermobility EDS - Autosomal Dominant

C. Kyphoscoliotic EDS - Autosomal Dominant

D. Kyphoscoliotic EDS - Autosomal Recessive

Correct Answer: D. Kyphoscoliotic EDS - Autosomal Recessive

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A young male with severe hypotonia at birth, joint hypermobility, scoliosis, fragile skin, ocular fragility and mutations in the gene encoding Lysyl Hydroxylase points towards Kyphoscoliotic EDS (Type VI), which is Autosomal Recessive.

Type	AKA	Inheritance	Defect
I	Classical EDS	AD (Autosomal Dominant)	Collagen 5
II	Classical EDS	AD	Collagen 5
III	Hypermobile EDS	AD	Free Joints
IV	Vascular type EDS (Flood Blood)	AD	Collagen 3
V	Same as II with a different inheritance	X linked	Collagen 5
VI	Kyphoscoliosis Type	AR (Autosomal Recessive)	LYSYL Hydroxylase
VII A, B	Arthrochalasia Type	AD	Collagen I
VII C	Dermatosparaxis Type	AR	Procollagen Peptidase

@Neet_pg_bot

Q9: What type of inheritance pattern is associated with hypertrichosis pinnae? (Q845108)

A. Autosomal Dominant

B. Autosomal Recessive

C. X-Linked Dominant

D. Holandric

Correct Answer: D. Holandric

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypertrichosis, characterized by excessive hair growth on ears, is a rare genetic condition that can be associated with genes located on the Y chromosome. Since the Y chromosome is only present in males and is passed from fathers to sons, holandric traits are exclusively observed in males and are inherited from fathers.

@Neet_pg_bot

Q10: A 5-year-old boy is brought to the emergency department due to excessive bleeding after a minor injury. His mother reports that his grandfather also had similar bleeding episodes. Laboratory tests reveal a deficiency in factor IX. What is the mode of inheritance for this condition? (Q845109)

A. Autosomal dominant

B. Autosomal recessive

C. X-linked recessive

D. X-linked dominant

Correct Answer: C. X-linked recessive

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Factor IX deficiency, associated with Hemophilia B, is an X-linked recessive disorder that predominantly affects males, as evidenced by the family history. X-Linked Recessive : The gene for Hemophilia B is located on the X chromosome. Males (XY) express the disorder if they inherit the affected X chromosome since they lack a second X for compensation. Females (XX) can be carriers if they inherit one affected X chromosome, often showing no symptoms due to the normal allele on the other X. Affected males cannot pass the disorder to sons but can pass the affected X to daughters, making them carriers. Hemophilia A and B is X linked recessive Hemophilia C is autosomal recessive X-linked Recessive (WISE ABCDEFGH) Wise- Wiskott Aldrich Syndrome AB- Hemophilia A, B B- Bruton's Hypogammaglobulinemia . C- Chronic Granulomatous Disease, Red Green Color Blindness D- DMD, BMD E- Lesch Nyhan Syndrome F- Fabry Disease, Fragile X Syndrome G- G6PD Deficiency H- Hunter Disease

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 10-year-old boy presents to the clinic with a complaint of bone pain. He does not sustain any trauma. He denies a history of fever. On examination, hepatosplenomegaly and bone tenderness are noted. Biopsy specimen from the spleen shows a crumpled tissue paper appearance. Keeping in view the most likely diagnosis, which of the following substance would most likely accumulate in this disorder? (Q882175)

A. Glucocerebroside

B. SphingomyelinSulfatide

C. Sulfatide

D. Ganglioside

Correct Answer: A. Glucocerebroside

Explanation: Option A: Glucocerebroside The boy is most likely suffering from Gaucher disease, in which glucocerebrosides accumulate. Gaucher disease: Aetiology : Autosomal recessive inherited disease Epidemiology Most common lysosomal lipid storage disease Increased incidence of type I in the Ashkenazi Jewish population Pathophysiology : Deficiency of β-glucocerebrosidase → accumulation of glucocerebroside (sphingolipid found in cell membranes that can accumulate in the lysosome of macrophages) in the brain, liver, spleen, and bone marrow Clinical features Vary according to the exact subtype of Gaucher disease Type I: non-neuronopathic Gaucher disease Type II: acute neuronopathic Gaucher disease Type III: chronic neuronopathic Gaucher disease All types Hepatosplenomegaly Bone : bone crises, osteoporosis, avascular necrosis of the femur Blood abnormalities: anaemia, thrombocytopenia, pancytopenia Pulmonary manifestations Growth delays Diagnostics Reduced glucocerebrosidase activity in leukocytes or fibroblasts Accumulation of glucocerebroside in leukocytes or fibroblasts Gaucher cell: lipid-rich macrophages with an enlarged cytoplasm with inclusions that resemble crumpled tissue paper on microscopy Treatment: Enzyme replacement therapy with recombinant glucocerebrosidase or substrate reduction therapy with eliglustat Option B: Sphingomyelin Sphingomyelin accumulation is seen in Niemann-Pick disease. Light microscopy: lipid-laden macrophages (foam cells) in the bone marrow, spleen, and liver Electron microscopy: Zebra bodies (abnormal configuration of myeloid membranes into parallel palisading lamellae in the lysosomal cytoplasm Option C: Sulfatide Arylsulfatase A is deficient in metachromatic leukodystrophy The cerebroside sulfate accumulates The presentation includes demyelination in CNS and PNS, resulting in ataxia and dementia The inheritance is autosomal recessive. Option D: Ganglioside Ganglioside accumulation is seen in Tay Sach disease Hexosaminidase A deficiency → intracellular accumulation of GM2 ganglioside → progressive neurodegeneration

Q1 (p. 1199)	*Q2 (p. 1200)*	*Q3 (p. 1201)*	*Q4 (p. 1204)*	*Q5 (p. 1205)*	*Q6 (p. 1208)*
Q7 (p. 1210)	*Q8 (p. 1211)*	*Q9 (p. 1212)*	*Q10 (p. 1213)*	*Q11 (p. 1215)*	*Q12 (p. 1216)*
Q13 (p. 1217)	*Q14 (p. 1218)*	*Q15 (p. 1220)*	*Q16 (p. 1220)*	*Q17 (p. 1221)*	*Q18 (p. 1222)*

Q1: Fabry disease is an X-linked lysosomal storage disorder caused by a deficiency of which enzyme? (Q879663)

A. Alpha-galactosidase A

B. Beta-glucocerebrosidase

C. Acid alpha-glucosidase

D. Sphingomyelinase

Correct Answer: A. Alpha-galactosidase A

Explanation: Fabry disease: Inheritance: X-linked recessive Enzyme deficiency: Alpha-galactosidase A → accumulation of globotriaosylceramide (Gb3) in lysosomes Clinical features: Angiokeratomas, acroparesthesias, hypohidrosis, renal and cardiac involvement. Maltese cross crystals in the urine because lipids are coming out into the urine. Incorrect Options: Beta-glucocerebrosidase (Option B) : Deficient in Gaucher disease , leading to accumulation of glucocerebroside. Acid alpha-glucosidase (Option C) : Deficient in Pompe disease , causing glycogen accumulation in lysosomes. Sphingomyelinase (Option D) : Deficient in Niemann-Pick disease , leading to sphingomyelin buildup.

@Neet_pg_bot

Q2: Which of the following correctly describes the genetic basis of Myotonic Dystrophy type 1? (Q879658)

A. Autosomal recessive disorder caused by CAG expansion in the HTT gene on chromosome 4

B. Autosomal dominant disorder caused by CTG trinucleotide expansion in the DMPK gene on chromosome 19q13.3

C. X-linked disorder caused by CGG repeat expansion in the FMR1 gene

D. Autosomal dominant disorder caused by GAA trinucleotide expansion in the FXN gene

Correct Answer: B. Autosomal dominant disorder caused by CTG trinucleotide expansion in the DMPK gene on chromosome 19q13.3

Explanation: Myotonic Dystrophy type 1: Inheritance: Autosomal dominant Gene: DMPK (Myotonic Dystrophy Protein Kinase) Chromosome: 19q13.3 Mutation: CTG trinucleotide repeat expansion in the 3′ UTR of the gene Pathogenesis: Toxic gain-of-function RNA sequesters muscle splicing regulators → mis-splicing of genes like CLCN1 → myotonia Other manifestations: Insulin resistance due to splicing changes in insulin receptor isoforms

Incorrect Options: CAG expansion in the HTT gene on chromosome 4 (Option A) : Seen in Huntington disease , not Myotonic Dystrophy. CGG repeat expansion in the FMR1 gene (Option C) : Characteristic of Fragile X syndrome , an X-linked disorder . GAA trinucleotide expansion in the FXN gene (Option D) : Found in Friedreich ataxia , an autosomal recessive condition.

@Neet_pg_bot

Q3: A one-month-old infant presents with developmental delays and physical features such as a prominent occiput, low-set ears, clenched hands with overlapping fingers, and a small mouth with a protruding tongue. Heart murmurs and rocker-bottom foot deformity are also noted. Which syndrome is the most likely cause of these features? (Q845124)

A. Noonan syndrome

B. Down syndrome

C. Patau syndrome

D. Edward syndrome

Correct Answer: D. Edward syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Edward syndrome is caused by the presence of an extra copy of chromosome 18- Trisomy 18. On USG: Strawberry skull is seen: Prominent occiput and small chin. Features: Low birth weight Clenched fists with overlapping fingers Rocker-bottom feet (seen in trisomy 18 and trisomy 13) Microcephaly Micrognathia Macroglosia (Big protruding tongue) Cardiac and renal malformations Mental retardation Noonan syndrome (Option A): Genetic Cause: Autosomal dominant; mutation in the PTPN11 gene (RAS-MAPK pathway); Normal karyotype (Not trisomy). Phenotype: Often called "Male Turner Syndrome" because of similar features (short stature, webbed neck, pectus excavatum). Differentiator: Unlike Turner Syndrome, it affects both males and females and usually presents with Pulmonic Stenosis (rather than Coarctation of the Aorta). Down syndrome (Option B): Genetic Cause: Trisomy 21; most common live-born trisomy. Physical Traits: Flat facies, epicanthal folds , Simian crease (single transverse palmar crease), and gap between 1st and 2nd toes (Sandals-gap deformity) . Comorbidities: Early-onset Alzheimer's, increased risk of ALL/AML, and duodenal atresia ("double bubble" sign). Heart: Atrioventricular septal defects (Endocardial cushion defects) are highly specific. Patau syndrome (Option C): Genetic Cause: Trisomy 13 Mnemonic "The 3 P's": P olydactyly (extra fingers), P alaps (Cleft lip/Palate), and P unced-out scalp lesions (Aplasia cutis congenita). Midline Defects: Often presents with

Holoprosencephaly (failure of brain to divide) and Microphthalmia (small eyes). Heart: Associated with ASD/VSD and PDA.

Robbins and Cotran Pathologic basis of disease, 10th edition, Pages 166-169.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 15-year-old boy presents to the clinic with tall stature and long limbs, along with a history of frequent joint dislocations. Upon physical examination, he exhibits long fingers ,sunken chest, and an echocardiogram shows a dilated aortic root. Considering these clinical features, which of the following genes are commonly mutated in this condition? (Q845130)

A. FBN 1

B. FBN 2

C. FBN 3

D. FBN 4

Correct Answer: A. FBN 1

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 15-year-old boy presents with tall stature, long limbs, joint dislocations, long fingers, a sunken chest, and a dilated aortic root on echocardiogram; these features are consistent with Marfan syndrome , which is commonly caused by mutations in the FBN1 gene An autosomal dominant disorder due to a mutation in the Fibrillin (FBN) 1 Gene on chromosome 15. Clinical Features: Marfan D isease The most common Clinical Manifestation is Skeletal Abnormalities. M itral Valve Prolapse (Most common Cardiac abnormality) A ortic Dissection (Most common cause of death) R etinal Detachment (eye problem) F reely movable Joint (most common Thumb joint) A rachnodactyly (long fingers, spider fingers), High A rched Palate N ine Feet Tall, Pigeon chest (defect in sternum) D islocation of the lens (Ectopia Lentis- Direction of dislocation is Supero Temporal) Steinberg Sign - Positive if the thumb tip extends beyond the palm when folded into a closed fist Walker Sign- Positive if the thumb and fifth finger overlap when you grip your wrist with the opposite hand Homocystinuria: Homocystinuria due to cystathionine beta-synthase (CBS) deficiency is an autosomal recessive disorder causing elevated homocysteine/methionine levels, leading to multisystem involvement. Classic Tetrad (MARFAN-like + Thrombosis) M arfanoid habitus: tall, thin, arachnodactyly, pectus, scoliosis E ctopia lentis (downward dislocation) A therosclerosis/thromboembolism (strokes even in children) R etardation (mild-moderate intellectual disability) Feature Homocystinuria Marfan Syndrome Inheritance Autosomal recessive (CBS gene) Autosomal dominant (FBN1) Lens dislocation Downward Upward Vascular risk Thromboembolism ↑↑ Aortic dilation/rupture Odor Methionine (boiled cabbage) None Mental status Intellectual disability Normal Treatment test Pyridoxine (B6) responsive (~50%) None

Robbins and Cotrans Pathological Basis of diseases, 10th Edition, Page 148, 149

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 3-year-old boy presents with developmental delay, short stature, a heart murmur, and characteristic facial features, as shown in the image below. What is the most likely diagnosis for this patient? (Q845129)

A. Noonan syndrome

B. Down syndrome

C. Williams syndrome

D. Turner syndrome

Correct Answer: A. Noonan syndrome

Explanation: The most likely diagnosis for this patient is Noonan syndrome, which is typically caused by mutations in genes such as PTPN11, SOS1, and RAF1. Noonan syndrome is characterized by distinctive facial features, including wide-set eyes, a large head, a drooping face, short stature, developmental delay, and heart defects. The presence of a heart murmur, along with characteristic facial features and developmental delay, is highly suggestive of Noonan syndrome. Additional clinical factors may include easy bruising or bleeding, dry skin, sensorineural deafness, and lymphedema, which can aid in the diagnosis. Genetic testing can confirm the presence of mutations associated with Noonan syndrome. Down syndrome (Option B) is not the diagnosis due to absence of facial features such as flat face, small nose with a flat bridge, small ears, a short neck, and upward slanting eyes Williams syndrome (Option C) is unlikely due to the absence of characteristic facial features and the uncommon presentation of a heart murmur. Turner syndrome (Option D) is unlikely in a male patient and is characterized by specific physical features not present in this case.

UPTODATE NOONAN SYNDROME

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: An 18-year-old girl presents to the clinic due to the concern that she hasn't started menstruating yet. The girl has a short stature and a webbed neck. Physical examination reveals a broad chest with widely spaced nipples. What is the most likely diagnosis for this patient? (Q845128)

A. Turner syndrome

B. Mullerian agenesis

C. Congenital adrenal hyperplasia

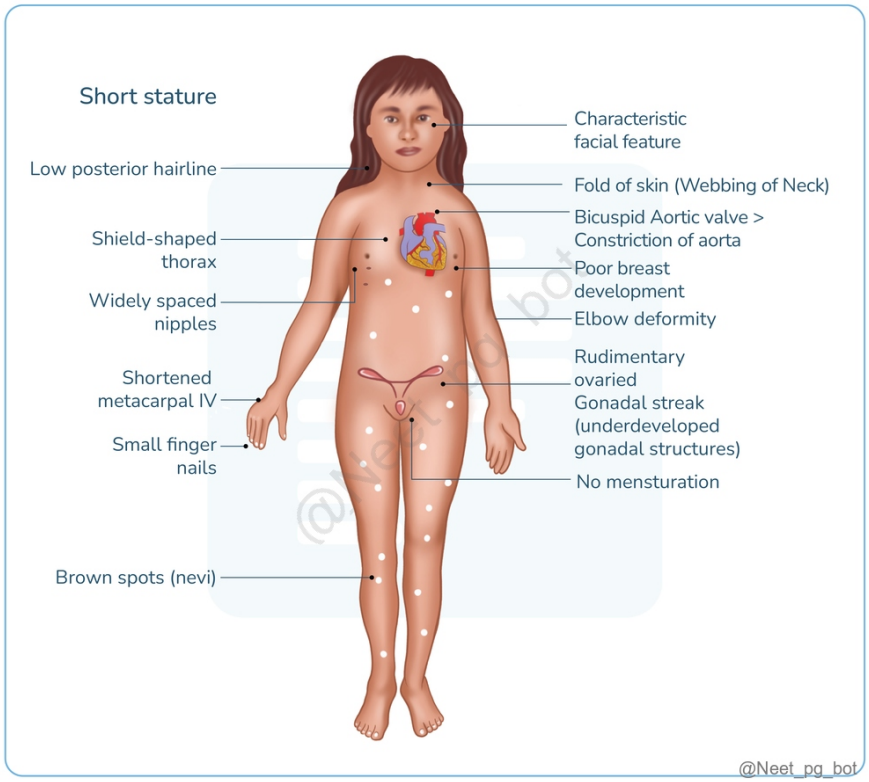
D. 47, XXX syndrome

Correct Answer: A. Turner syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The scenario is diagnosed as Turner syndrome. Genotype: 45 XO Phenotype: Female Improper breast development leading to widely spaced nipples Improper ovarian development: Female presents with streak ovaries and primary amenorrhea (patient will not attain menarche). Physical symptoms: Short stature and webbed neck Cardiac anomalies: Bicuspid aortic valve and Coarctation of aorta. Usually, IQ is normal. The image below shows karyotyping in Turner syndrome. Turner Syndrome vs Noonan Syndrome: Feature Turner Syndrome Noonan Syndrome Genetics 45, X (Monosomy X) Autosomal Dominant (e.g., PTPN11 gene) Gender Females only Males and Females Heart Defect Coarctation of the aorta , Bicuspid aortic valve Pulmonic Stenosis , Hypertrophic cardiomyopathy Chest Shield chest, widely spaced nipples Pectus excavatum/carinatum Gonads Streak ovaries , primary amenorrhea, infertility Males: cryptorchidism; females usually fertile Puberty Delayed/absent, need estrogen Often delayed but usually spontaneous Karyotype Abnormal (missing X) Normal (46, XX or 46, XY) IQ Typically normal Mild intellectual disability possible



References:

Robbins and Cotrans Pathological Basis of diseases, 10th Edition, Page 172

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 30-year-old tall male patient presents to the clinic for fertility treatment. He undergoes testing and is found to have low sperm counts. He has a history of diabetes, and a physical examination reveals gynecomastia, small testes, and minimal facial and body hair. What chromosomal abnormality is most likely causing this condition in the patient? (Q845127)

A. 45,X

B. 47,XXY

C. 47,XXX

D. 47,XYY

Correct Answer: B. 47,XXY

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Klinefelter syndrome is the most common sex chromosome aneuploidy in males, caused by at least one extra X chromosome, leading to hypogonadism and infertility. The classic karyotype is 47, XXY (~90% cases), from meiotic nondisjunction. Mosaics (46, XY/47, XXY) are milder (~10-20%). Clinical features: Initially, the gonads are testes, but because of an extraX chromosome, the testes stay underdeveloped and small (hypogonadism). Physical Appearance: Tall stature with disproportionately long arms and legs. Hypogonadism: Small, firm testes (testicular dysgenesis) and a small penis. Secondary Sex Characteristics: Weak facial and body hair growth; female-type fat distribution (wider hips). Gynecomastia: Development of breast tissue (increases risk of male breast cancer). Fertility: Infertility due to azoospermia (absence of sperm) and atrophy of seminiferous tubules. Cognition: Mild intellectual disability or specific learning disabilities (notably delayed speech). Hormonal profile: Low serum testosterone levels leading to high LH and FSH levels. Marker Level Reason Testosterone Low Leydig cell dysfunction. LH High Loss of negative feedback from low Testosterone. FSH High Loss of negative feedback from low Inhibin B . Estrogen High Increased peripheral conversion of androgens. Most common cancer risk: Male breast cancer (due to high estrogen). Extragonadal Germ Cell Tumors (especially mediastinal). Osteoporosis (due to low testosterone).

Robbins and Cotrans Pathological Basis of diseases, 10th Edition, Page 170

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 6-month-old child has recently passed away after a long ICU stay. Examination reveals microphthalmia and microcephaly. Other known diagnoses included ventricular septal defect, polycystic kidney disease, and omphalocele at birth. What is the chromosome involved? (Q845126)

A. Chromosome 21

B. Chromosome 18

C. Chromosome 13

D. Chromosome Y

Correct Answer: C. Chromosome 13

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given scenario describes Patau syndrome or Trisomy 13. Clinical features and associations include Rocker-bottom feet (Seen in both trisomy 13 and trisomy 18) Severe intellectual disability Keyhole/ Coloboma (eyes) Microphthalmia, microcephaly, holoprosencephaly Cleft lip/palate Polydactyly Congenital heart disease: PDA (Patent Ductus Arteriosus) or VSD (Ventricular Septal Defect) Renal defects-Polycystic kidney disease Umbilical hernia,Omphalocele Trisomy 18 is Edward syndrome: Clinical features include a prominent occiput (Strawberry skull) and rocker-bottom feet (Option B ruled out) Feature Edward (Trisomy 18) Patau (Trisomy 13) Hands Clenched fists with overlapping fingers■ Polydactyly (extra fingers/toes)■ Feet Rocker-bottom ■ Normal or broad Eyes Microphthalmia, short palpebral fissures Microphthalmia + coloboma ■ Face Low-set ears , micrognathia Cleft lip/palate (90%)■ Brain Small cerebellum (Severe intellectual disability) Holoprosencephaly ■ Head Prominent Occiput Scalp defects (Aplasia cutis)

References:

https://www.uptodate.com/contents/congenital-cytogenetic-abnormalities

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 2-year-old boy is brought to the pediatrician by his parents for delayed milestones. Upon examination, the pediatrician notices several physical features, including upward-slanting eyes, a flat facial profile, a protruding tongue, and a single palmar crease. Which type of inheritance is definitely not present in this child? (Q845125)

A. Meiotic nondisjunction of chromosome 21.

B. Robertsonian translocation

C. Mitotic non-disjunction

D. Autosomal recessive inheritance

Correct Answer: D. Autosomal recessive inheritance

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical features are indicative of Down syndrome (Trisomy 21) , which is a chromosomal disorder, so autosomal recessive inheritance is definitely not present . Features: Mongoloid facies: Upward slanting of eyes (because of oblique palpebral fissure) and flat facial profile (because of nasal hypoplasia) Macroglossia (Protruding tongue) Simian crease (single palmar crease) Modes of inheritance of Down syndrome are as follows: Meiotic Nondisjunction of chromosome 21 (~95%) (Option A): ■■■■■■■■■■■■■■■ Cause:

Failure of chromosome 21 to separate during meiosis (usually maternal Meiosis I). Fact: Risk increases significantly with advanced maternal age . Karyotype: 47, XX, +21 or 47, XY, +21. Robertsonian Translocation (4%) (Option B): t(22,14) in mother. Cause: The long arm of chromosome 21 attaches to another chromosome (usually 14 or 21). Inheritance: Can be inherited from a balanced carrier parent. Karyotype: 46, XX, t(14;21) or similar. Note: The t(21;21) Rule: If a parent is a carrier of a 21;21 translocation (where both copies of chromosome 21 are fused), the risk of Down Syndrome in offspring is 100% . This is because the parent can only produce gametes with either "two copies" of 21 (resulting in Trisomy) or "zero copies" (resulting in non-viable Monosomy). Mitotic Nondisjunction (Mosaicism) (~1-2%) (Option C): Cause: Error occurs after fertilization during early cleavage. Presentation: The individual has two cell lines (some 46, some 47): Mosaicism Clinical: Often presents with milder physical and intellectual features. This leads to mosaicism.

Robbins and Cotran Pathological Basis of Diseases, 10th Edition, Pages 166,167.

↑ *Back to this question in Part A*

@Neet_pg_bot

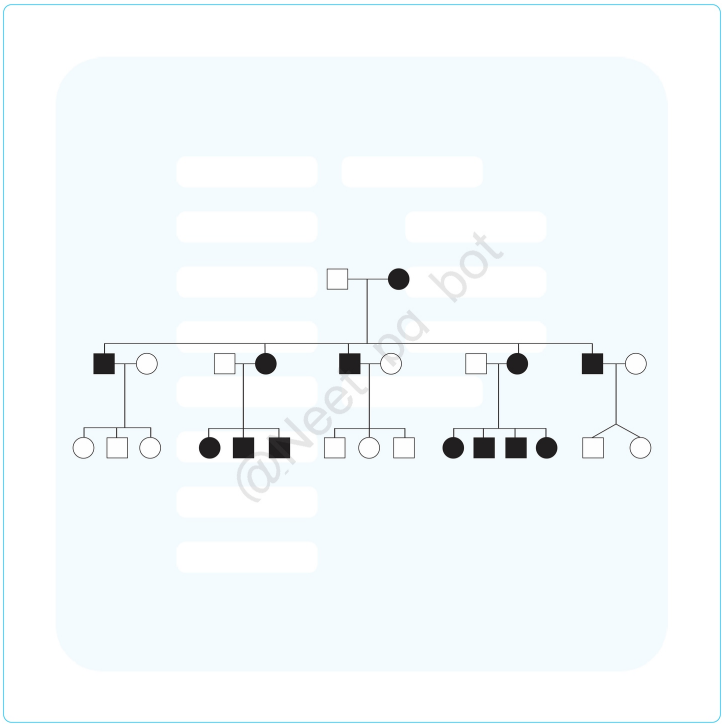
Q10: A young male patient presented with recurrent episodes of acute neurologic dysfunction, cognitive changes, muscle weakness, and lactic acidosis. There is a family history of similar conditions depicted in the pedigree chart below. What is the most likely diagnosis? (Q845115)

A. MELAS

B. MERRF

C. Metachromatic leukodystrophy

D. Adrenoleukodystrophy



@Neet_pg_bot

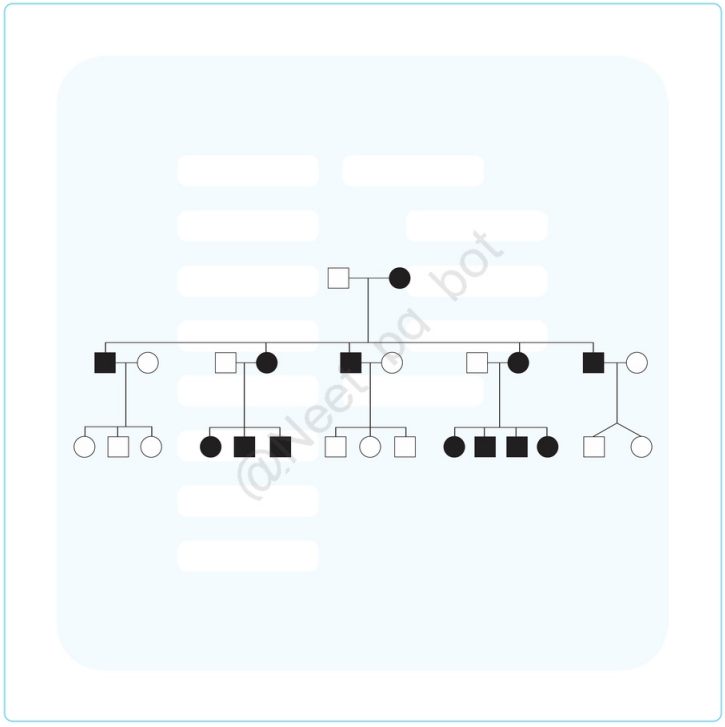
Correct Answer: A. MELAS

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: MELAS -Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes: MELAS follows a unique non-Mendelian pattern of inheritance called maternal inheritance, as mitochondrial DNA is derived entirely from the ovum. Affected mothers and daughters transmit the disease to both male and female children, whereas the affected sons don't transmit the affected DNA. (Mother to all, Father to none.) The most common mitochondrial disease is MELAS. MERRF (Option B): Myoclonic Epilepsy with Ragged Red Fibers presents mainly with myoclonus, generalized seizures, ataxia, ragged■red fibers , not stroke■like episodes with lactic acidosis.■ Metachromatic leukodystrophy (Option C): Autosomal recessive, due to arylsulfatase A deficiency , causes progressive motor and cognitive decline, not maternal inheritance with lactic acidosis and stroke■like events. Adrenoleukodystrophy (Option D): X■linked, affects males only through maternal carrier , with adrenal failure and demyelination; the pedigree would show typical X■linked pattern, not all offspring of an affected mother at risk. Mitochondrial Inheritance (Maternal): Disease Key Features MELAS (Option A) Stroke-like episodes, lactic acidosis, seizures, muscle weakness MERRF (Option B) Myoclonic epilepsy, ragged red fibers, ataxia LHON Leber hereditary optic neuropathy (acute vision loss) NARP Neuropathy, ataxia, retinitis pigmentosa Kearns-Sayre Progressive external ophthalmoplegia, heart block, retinitis Leigh syndrome Encephalopathy, basal ganglia lesions, lactic acidosis X-linked Recessive (Affects males; females carriers): Disease Key Features Adrenoleukodystrophy (ALD) (Option D) Cerebral demyelination, adrenal insufficiency, VLCFA↑ Duchenne MD Proximal weakness, Gower's sign, CK↑↑, dystrophin absent Hunter syndrome MPS II (coarse facies, corneal clouding, cardiac) Hemophilia A/B Factor VIII/IX deficiency, hemarthrosis Fabry disease Angiokeratomas, renal/heart failure, globotriaosylceramide X-linked agammaglobulinemia Absent B cells, recurrent bacterial infections Wiskott-Aldrich Thrombocytopenia, eczema, infections Autosomal Recessive

(Leukodystrophies): Disease Key Features Metachromatic leukodystrophy (MLD) (Option C) Arylsulfatase A def, demyelination, metachromatic granules Krabbe disease Galactocerebrosidase def, globoid cells, spasticity Alexander disease GFAP mutation, Rosenthal fibers, macrocephaly Canavan disease ASPA def, spongy degeneration, megalencephaly Pelizaeus-Merzbacher PLP1 duplication, hypomyelination (XLR but AR forms rare)



@Neet_pg_bot

www.ncbi.nlm.nih.gov/books/NBK560744/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 50-year-old man presents with intentional tremors, cerebellar ataxia, and intellectual disability. His father had similar symptoms at 60 and died due to aortic dissection. The patient's son started showing tremors and has an intellectual disability and aggressive behavior. Additionally males of the family have large ears and mandibles. What condition is most likely affecting him? (Q845123)

A. Fragile X syndrome

B. Huntington's disease

C. Parkinson's disease

D. Alzheimer's disease

Correct Answer: A. Fragile X syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Fragile X Syndrome (FXS) results from CGG trinucleotide repeat disorder. CGG repeats <55: Normal individual Premutation (55–200 CGG repeats): Mechanism: The gene is still active, but produces "toxic" mRNA. Causes Fragile X–associated tremor/ataxia syndrome (FXTAS) Seen in older males Symptoms : Intentional tremor, cerebellar ataxia, cognitive decline Full Mutation (>200 CGG repeats): Fragile X syndrome Mechanism: The massive expansion causes DNA methylation , which "silences" the gene completely. Leads to Fragile X syndrome Due to hypermethylation and silencing of FMR1 gene Symptoms: Severe intellectual disability (IQ 20-60), aggressive behavior, and characteristic physical traits: long face, large ears, large mandible, and macroorchidism. Fragile X syndrome: A very common cause of intellectual disability which is seen in all members of the family. IQ = 20-60 Males are affected more than females; females are carriers, but sometimes females can be mildly affected. Physical phenotype: Includes a long face with a large mandible, large ears, and macroorchidism (enlarged testicles). Investigation of choice: Polymerase chain reaction (PCR) If PCR fails then we go for Southern blotting. Huntington’s disease (Option B): Characterized by chorea, behavioural changes, and adult-onset dementia Parkinson’s disease (Option C): Classic resting tremor, rigidity, bradykinesia. Alzheimer’s disease (Option D): Causes progressive memory loss and cognitive decline, not tremor or ataxia.

Robbins and Cotrans Pathological Basis of diseases, 10th Edition, Pages 174, 176

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A group of researchers studying genetic material noticed the presence of both wild-type and mutated mitochondrial genomes in different mitochondria of the same cells. What does this finding indicate? (Q845122)

A. Copy number variation

B. Heteroplasmy

C. Trinucleotide expansion

D. Imprinting

Correct Answer: B. Heteroplasmy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The presence of both wild-type and mutated mitochondrial genomes in different mitochondria of the same cell is called heteroplasmy. A minimum number of mutant mtDNAs must be present in a cell to give rise to a disease. This is called the “threshold effect.” Homoplasmy: Every single mitochondrion within a cell contains the exact same genetic sequence. Mitochondrial DNA (mtDNA): Maternal Inheritance: mtDNA is inherited exclusively from the mother. Circular Structure: MtDNA is a double-stranded, circular molecule. Encodes 37 Genes: Codes for 13 proteins (OxPhos), 22 tRNAs, and 2 rRNAs. Lack of Introns: It contains almost no non-coding sequences (introns). High Mutation Rate: This is due to a lack of protective histones and constant exposure to Reactive Oxygen Species (ROS) generated during ATP production. Inefficient Repair: Mitochondria have very limited DNA repair mechanisms. Replicative Segregation: During cell division, mitochondria are distributed randomly into daughter cells. This leads to varying proportions of mutant vs. wild-type DNA (Heteroplasmy). Polyplasmy: Each cell contains hundreds of mitochondria, and each mitochondrion contains multiple copies of mtDNA. Threshold Effect: Disease symptoms only appear when the percentage of mutated mtDNA exceeds a certain level (Heteroplasmy). Unique Genetic Code: For example, UGA codes for Tryptophan instead of acting as a "Stop" codon. Copy number variation (Option A): This refers to the number of copies of a particular gene or DNA segment in the nuclear genome (e.g., deletions or duplications). It doesn't describe the mix of mutant and wild-type genomes. Trinucleotide expansion (Option C): This is a mutation where a specific sequence of three nucleotides repeats excessively (e.g., Huntington’s disease or Fragile X syndrome). Imprinting (Option D): This involves the epigenetic silencing of one parental allele in the nuclear genome, not the mixture of mitochondrial DNA.

Robbins and Cotrans Pathological Basis of diseases, 10th Edition, Pages 1291, 178, 143

www.ncbi.nlm.nih.gov/pmc/articles/PMC8640565/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following explains a single mutant gene leading to different end effects in sickle cell anemia? (Q845121)

A. Variable expressivity

B. Variable penetrance

C. Pleiotropy

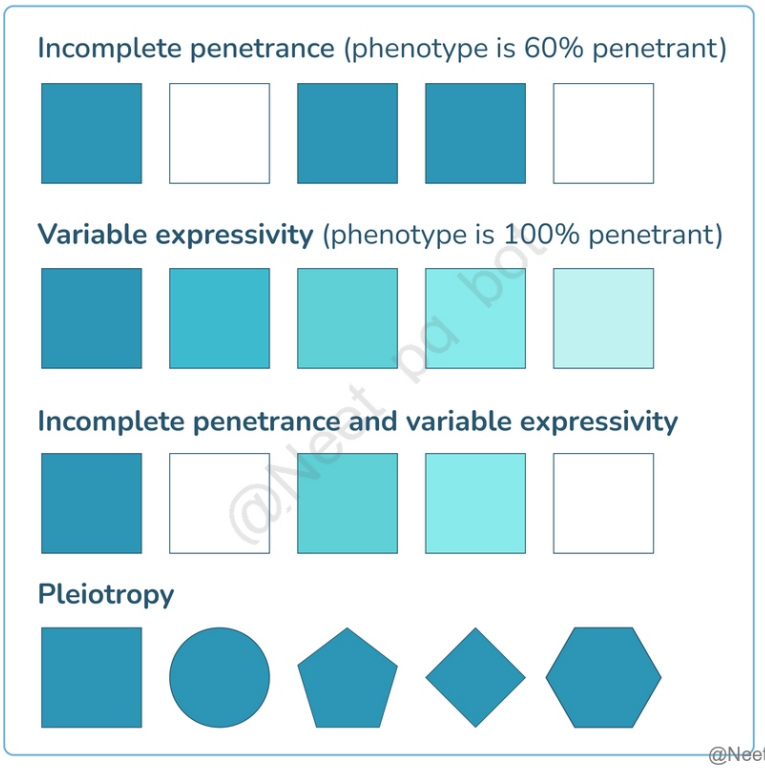
D. Genetic heterogeneity

Correct Answer: C. Pleiotropy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A single mutant gene leading to many end effects is called pleiotropism , whereas mutations at several genetic loci producing a similar phenotypic effect are called genetic heterogeneity. Sickle cell anemia is an example of pleiotropy with a single gene mutation causing multiple physical effects: Mutation at beta-7 position: Glutamic acid is replaced by valine. The mutation produces hemoglobin S (HbS) , which makes red blood cells prone to hemolysis. Additionally, it can lead to complications like splenic fibrosis, organ infarcts, and bone pains. Variable expressivity (Option A) : It refers to the phenomenon where individuals with the same genetic mutation display different levels and types of symptoms or traits. Variable penetrance (Option B) : It refers to a condition where individuals inherit the mutant gene but are phenotypically normal. It is a binary phenomenon where the genotype either causes the disease or it doesn't. Genetic heterogeneity (Option D): Mutations at several genetic loci producing a similar phenotypic effect.



References:

1. Robbins and Cotran Pathological Basis of Diseases, 10th Edition, Page 144. 2. www.ncbi.nlm.nih.gov/pmc/articles/PMC9380816/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 4-year-old girl is brought to the pediatrician's office for evaluation of developmental delay and seizures. She is very jovial, has microcephaly and is diagnosed with happy puppet syndrome. What is the genetic basis for this child's diagnosis? (Q845120)

A. Imprinting

B. Robertsonian translocation

C. Trinucleotide repeats

D. Monosomy

Correct Answer: A. Imprinting

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario likely describes Angelman syndrome. Classical symptom of Angelman syndrome: Happy puppet syndrome (inappropriate laughter). 2 main disorders of genomic imprinting: Angelman syndrome (AS): Paternal 15q11-q13 region is imprinted, while the maternal region is deleted Prader-Willi syndrome (PWS): Paternal deletion and maternal imprinting on chromosome 15. Feature Angelman Syndrome Prader-Willi Syndrome Genetic Cause Loss of maternal UBE3A expression (deletion 70%, UPD 3-7%, mutation 10%, imprinting defect 3%) Loss of paternal genes (e.g., SNORD116) (deletion 65-75%, maternal UPD 20-30%, imprinting defect 1-3%) Intellectual Disability Severe/profound; absent speech Mild-moderate; speech delay Behavior Happy demeanor, frequent laughter, hand-flapping, hyperactivity Hyperphagia, temper tantrums, obsessive-compulsive, skin picking Motor Issues Ataxia, jerky gait, tremulous movements Neonatal hypotonia; later normal gait Feeding Poor suck in infancy Poor suck in infancy → hyperphagia/obesity after age 2 Seizures Common (>80%, onset <3 years) Rare■ Physical Features Microcephaly, wide mouth, protruding tongue Short stature, small hands/feet, almond eyes Other Sleep disturbance, hypopigmentation Hypogonadism, scoliosis Other important genomic imprinting syndromes: Disorder Chromosome Imprinting Error Primary Features Beckwith-Wiedemann Syndrome (BWS) 11p15.5 Over-expression of paternal genes (IGF2) Overgrowth : Macrosomia (large birth size), macroglossia (large tongue), and increased risk of childhood tumors (Wilms tumor). Silver-Russell Syndrome (SRS) 11p15.5 or Chr 7 Under-expression of paternal genes (opposite of BWS) Growth restriction : Small stature, triangular face, prominent forehead, and body asymmetry. Temple Syndrome 14q32 Excess maternal contribution Low birth weight, hypotonia, early puberty, and short stature. Kagami-Ogata Syndrome 14q32 Excess paternal contribution Skeletal abnormalities (bell-shaped thorax), polyhydramnios (excess amniotic fluid), and developmental delays. Transient Neonatal Diabetes Mellitus (TNDM) 6q24 Over-expression of paternal genes Severe hyperglycemia in the first weeks of life that typically resolves within months, though it may return later. Pseudohypoparathyroidism (Type 1a) 20q13 Loss of maternal expression (GNAS gene) Resistance to parathyroid hormone, short stature, and round face (Albright hereditary osteodystrophy).

References:

Robbins and Cotrans Pathological Basis of Diseases, 10th Edition, Page 178.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 25-year-old male presents with brief, abrupt, involuntary movements of his arms and face for the last 2 months. A history of Huntington's disease in his father, who was diagnosed at 40 years of age and passed away at the age of 50, is found. What is the mechanism behind this patient's earlier presentation? (Q845119)

A. Anticipation

B. Mosaicism

C. Imprinting

D. Non-penetrance

Correct Answer: A. Anticipation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: HD is a CAG trinucleotide repeat disorder, seen in the axon region of a gene present on chromosome 4. HD is characterised by the Anticipation/Sherman Paradox. The number of repeats increases with every generation, leading to early and more severe presentation in the next generation. HD features psychiatric disturbances and choreoathetosis early on, with cognitive disturbance and death later. Examples of diseases showing anticipation include: Autosomal Dominant Autosomal Recessive Multiple spinocerebellar ataxias Huntington's disease – CAG repeats Myotonic dystrophy – CTG Congenital dyskeratosis – TTAGGG (telomere repeating sequence) Friedreich's ataxia – GAA X-linked Fragile X Syndrome – CGG Others Crohn's disease Behcet's disease Mosaicism (Option B) refers to the presence of multiple genetically different cell lines in the same individual. Imprinting (Option C) refers to a gene silencing. Non-penetrance (Option D): It means that the Gene is received from parents but no symptoms are seen in patient.

Q16: Match the following Disease Trinucleotide repeats a. Fragile X syndrome 1. CAG b. Friedreich ataxia 2. CTG c. Myotonic dystrophy 3. GAA d. Huntington disease 4. CGG (Q845118)

A. a-2, b-1, c-4, d-3

B. a-4, b-3, c-2, d-1

C. a-3, b-2, c-1, d-4

D. a-4, b-1, c-3, d-2

Correct Answer: B. a-4, b-3, c-2, d-1

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The below-mentioned disorders are trinucleotide repeat disorders where there is excessive repetition of trinucleotides. In Introns/ Non coding region: Fragile X syndrome - CGG Friedreich ataxia - GAA Myotonic dystrophy -CTG In Exons/ Coding region: Huntington's disease - CAG (Mnemonic- Hunter in a Cage) Fragile X Syndrome (CGG): Inheritance: X-linked dominant; it is the most common cause of inherited intellectual disability. Clinical Scenario: Look for a male child with a long face, large everted ears , and macroorchidism (enlarged testes) post-puberty. Pathophysiology: Caused by hypermethylation of the FMR1 gene, which silences its expression. Friedreich Ataxia (GAA): Inheritance: Autosomal recessive. Clinical Scenario: An adolescent presenting with progressive ataxia, loss of vibratory sense/proprioception , and muscle weakness . Systemic Involvement: Frequently associated with Hypertrophic Cardiomyopathy (the most common cause of death) and Diabetes Mellitus . Pathophysiology: Repeat expansion in the FXN gene leads to decreased frataxin , causing mitochondrial dysfunction. Myotonic Dystrophy Type 1 (CTG): Inheritance: Autosomal dominant; exhibits anticipation (symptoms become more severe/earlier in successive generations). Clinical Scenario: An adult with myotonia (difficulty releasing grip after a handshake), frontal balding , cataracts , and gonadal atrophy . Pathophysiology: Expansion in the DMPK gene leads to abnormal RNA processing. Huntington Disease (CAG): Inheritance: Autosomal dominant with 100% penetrance; also shows anticipation (primarily via paternal transmission). Clinical Scenario: A middle-aged patient (30–50 years) presenting with chorea (involuntary jerky movements), aggression, depression, and progressive dementia. Neuroimaging: Classically shows atrophy of the caudate nucleus and putamen, leading to "boxcar ventricles."

@Neet_pg_bot

Q17: Which of the following does not show the same pattern of inheritance as Leber hereditary optic neuropathy? (Q845117)

A. MERRF

B. MELAS

C. Fragile-X syndrome

D. NARP

Correct Answer: C. Fragile-X syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Fragile-X syndrome shows X-linked Recessive > X-linked dominant inheritance. Leber hereditary optic neuropathy (LHON) is characterized by permanent loss of vision in young men due to progressive, bilateral optic neuropathy. LHON demonstrates mitochondrial inheritance. Some other examples of mitochondrial inheritance disorders are: Chronic progressive external ophthalmoplegia (CPEO)/ Kearns-Sayre syndrome (KSS) Leigh syndrome Mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) (Option B ruled out) Myoclonic epilepsy with ragged red fibers (MERRF) (Option A ruled out) Neuropathy, ataxia, and retinitis pigmentosa (NARP) (Option D ruled out) Primary coenzyme Q10 (CoQ10) deficiency

Q19 (p. 1247)

Q1: Which of the following chromosomal aberrations results in a change in the amount of genetic material? (Q879652)

A. Balanced reciprocal translocation

B. Inversion

C. Deletion

D. Paracentric inversion

Correct Answer: C. Deletion

Explanation: Aberrations involving changes in genetic material: Deletion – Loss of a chromosome segment. Can be: Interstitial: Between two breaks → loss of material. Terminal: Single break → fragment lost. Effect: Usually abnormal phenotype due to missing genes. Ring chromosome – Breaks at both ends and fusion; loss of genetic material may occur → abnormal phenotype. Isochromosome – Loss of one arm and duplication of the other → monosomy for lost arm genes and trisomy for duplicated arm genes. Trisomy / Monosomy – Numerical change in chromosomes → gain or loss of genetic material. Incorrect Options: Balanced reciprocal translocation (Option A) : No loss or gain of genetic material - just exchange of segments between nonhomologous chromosomes. Inversion (Option B) : A chromosome segment is reversed end to end, but no genetic material is gained or lost. Paracentric inversion (Option D) : Involves inversion of a segment not including the centromere - no change in total genetic content.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 145-146

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following chromosomal aberrations and mechanisms is correctly matched? (Q879646)

A. Trisomy – caused by deletion of a chromosome segment.

B. Balanced reciprocal translocation – inversion of a chromosome segment without change in gene copy number.

C. Isochromosome formation – fusion of chromosome ends after breaks.

D. Ring chromosome – breaks at both ends of a chromosome with fusion of the damaged ends.

Correct Answer: D. Ring chromosome – breaks at both ends of a chromosome with fusion of the damaged ends.

Explanation: A ring chromosome occurs when breaks happen at both ends of a chromosome and the broken ends fuse, often resulting in phenotypic abnormalities. Incorrect Options: Trisomy (Option A): Caused by nondisjunction, not deletion Balanced reciprocal translocation (Option B): Exchange of segments without loss, not inversion. Isochromosome formation (Option C): Loss of one arm and duplication of the other, not fusion of ends.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 145-146

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: In cytogenetic notation, what does Xp21.2 represent? (Q879644)

A. Long arm of the X chromosome, region 21, band 1, sub-band 2

B. Short arm of the X chromosome, region 2, band 1, sub-band 2

C. Short arm of the X chromosome, region 21, band 2, sub-band 1

D. Long arm of the X chromosome, region 1, band 2, sub-band 1

Correct Answer: B. Short arm of the X chromosome, region 2, band 1, sub-band 2

Explanation: Chromosome arms: p = short arm (petit), q = long arm. Numbering system: Regions are numbered outward from the centromere (1, 2, 3…). Bands and sub-bands: Each region is divided into bands → further subdivided into sub-bands. Example: Xp21.2 = X chromosome, short arm, region 2, band 1, sub-band 2.

@Neet_pg_bot

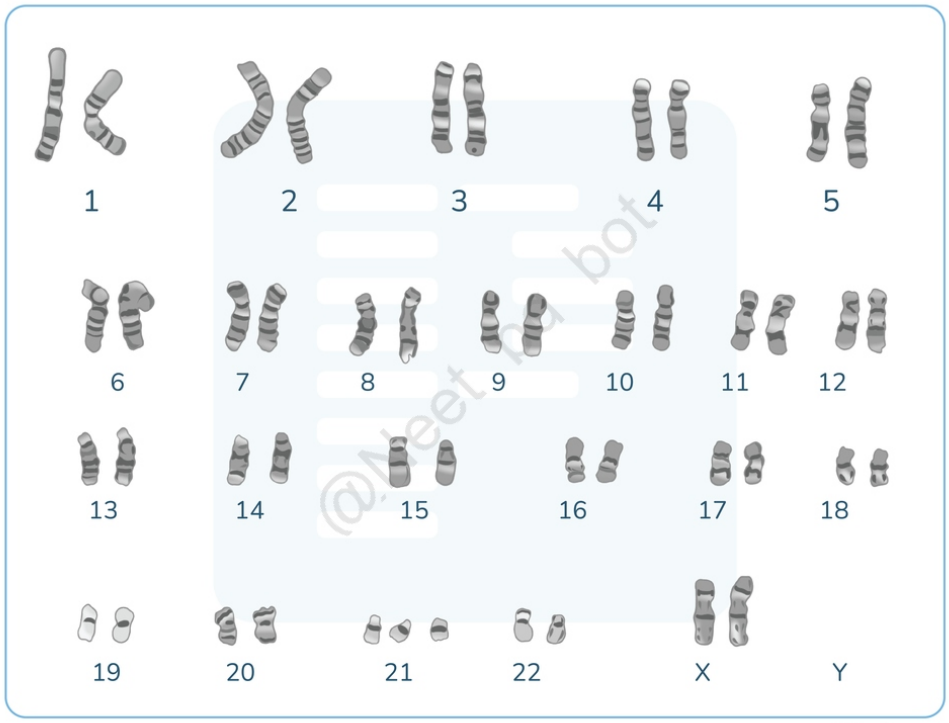
Q4: A 35-year-old pregnant woman presents for prenatal screening due to advanced maternal age. She undergoes amniocentesis, and chromosome analysis is performed on the fetal cells to assess for chromosomal abnormalities . The results indicate Down syndrome. From the below chromosomal analysis, which of the following results is most likely associated with this case? (Q845185)

Correct Answer: Unknown

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: B demonstrates the result as trisomy of chromosome 21, as along with two normal chromosomes, one extra chromosome is present, indicating trisomy 21 or Down’s syndrome as a diagnosis. TRISOMY 21: DOWN SYNDROME Karyotypes: Trisomy 21 type: 47,XX, +21 Translocation type: 46,XX,der(14;21)(q10;q10),+21 Mosaic type: 46,XX/47,XX, +21 The given image represents a normal karyotype. (Option A): The given image represents trisomy 18 – Edward syndrome (Option C) The given image represents two X chromosomes and one Y chromosome – Klinefelter’s syndrome (Option D)



@Neet_pg_bot

Q5: Arrange the following steps of karyotyping in the correct sequence: Staining/Banding Sample collection Fixative Arrangement of chromosomes Arrest Interpretation (Q847860)

A. 2, 5, 3, 1, 4, 6

B. 2, 3, 5, 1, 4, 6

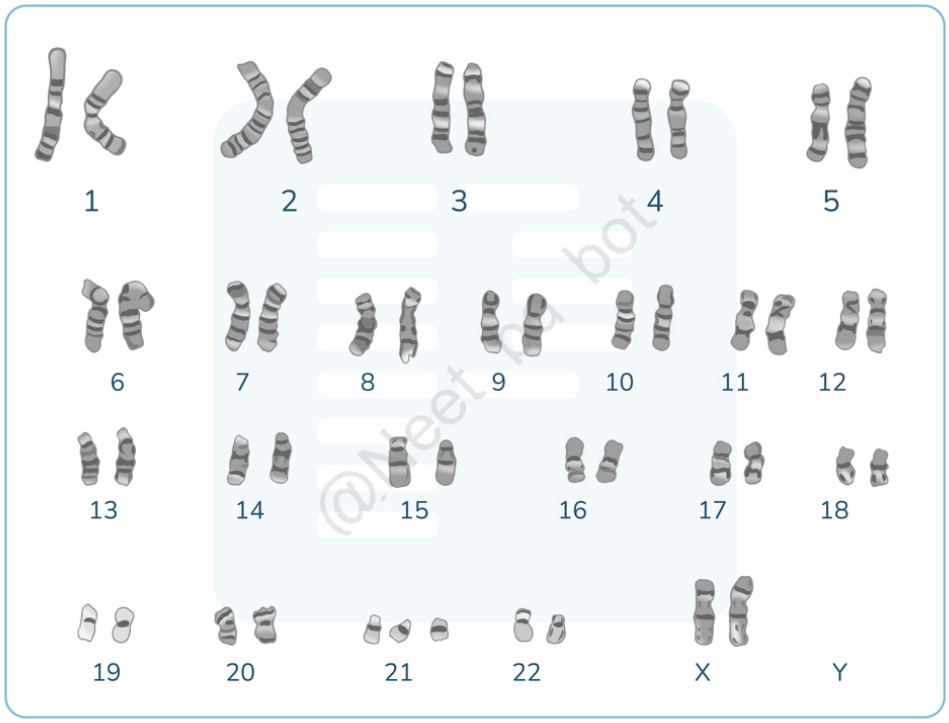
C. 1, 2, 3, 5, 4, 6

D. 3, 5, 2, 4, 1, 6

Correct Answer: A. 2, 5, 3, 1, 4, 6

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Karyotyping is the study of chromosomes. Sample collection: Patient type Sample type Pregnant woman Amniocentesis Chorionic villous sampling 10 year old boy Lymphocyte blood sample (preferred) Fibroblast skin sample 2.Arrest: It is carried out in metaphase using colchicine. 3.Fixative: Using Carnoy fixative (Methanol: Glacial acetic acid in 3:1 ratio) 4.Staining/ Banding: Chromosome has dark (AT nucleotides rich) and light (CG nucleotides rich) bands. 5.Arrangement of Chromosomes: According to length in descending order. Shortest chromosome is chromosome 21. 6. Interpretations: Trisomy 21 (Down’s syndrome) Trisomy 18 (Edwards syndrome) 47 XXY (Klinefelter syndrome)



@Neet_pg_bot

Q6: A researcher wants to analyze gene expression levels in a sample using a PCR technique that quantifies the amount of DNA produced after each amplification cycle. Which type of PCR is most suitable for this purpose? (Q845190)

A. Real-time PCR

B. Nested PCR

C. Reverse Transcription PCR (RT-PCR)

D. Multiplex PCR

Correct Answer: A. Real-time PCR

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: DNA amplification is measured after each cycle using fluorescent dyes or probes Can quantify initial template levels, making it ideal for gene expression analysis. When combined with RT-qPCR, it quantifies mRNA expression accurately Types of PCR: Type of PCR Characteristics Real-time PCR (qPCR) (Option A) Quantitative measurement of DNA amplification in real-time. Allows for gene expression analysis, viral load determination, and quantitative DNA/RNA analysis. Nested PCR (Option B) Two rounds of PCR amplification using two sets of primers. Improves specificity and sensitivity compared to conventional PCR. PCR (RT-PCR) (Option C) Enables gene expression analysis by amplifying RNA targets. Multiplex PCR (Option D) Simultaneous amplification of multiple DNA targets in a single reaction. Reduces time and cost by amplifying multiple targets together. Highly accurate for determining gene expression levels, viral load, and copy number variations. Digital PCR Divides the sample into thousands of individual reactions, allowing for absolute quantification of DNA targets. Provides high precision and sensitivity for rare target detection. Used in rare allele detection, copy number variation analysis, and precise quantification of nucleic acids. Hot Start PCR Minimizes non-specific amplification and primer-dimer formation by activating the DNA polymerase after an initial denaturation step. Prevents background noise and false-positive results. Polymerase Chain Reaction (PCR) involves three main steps: Denaturation , where the DNA double-strand separates into two single strands at 94 degrees Celsius. Annealing , where primers bind to the target DNA sequence at 54 degrees Celsius. Amplification , where DNA polymerase extends the primers to replicate the target sequence at 72 degrees Celsius. Ligation, which is the process of joining DNA fragments together, is not a step in PCR. Multiplex Ligation-dependent Probe Amplification in which ligation is done Key Components of PCR: DNA Template: The sample containing the target sequence. Primers: Two short, synthetic DNA fragments that flank the region to be amplified. Enzyme (DNA Polymerase): Most commonly Taq Polymerase , derived from the bacterium Thermus aquaticus . It is used because it is thermostable and does not denature at high temperatures. dNTPs: Deoxynucleotide triphosphates (A, T, C, G), the building blocks for the new DNA. Buffer & Mg^{2}■: Magnesium ions act as a necessary cofactor for DNA polymerase activity. Low Mg → Poor yield (no cofactor) High Mg → Nonspecific (stabilizes mismatches) Optimal = 1.5-2.5 mM

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 181

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 35-year-old female undergoes genetic testing due to a family history of Cystic Fibrosis. The test reveals a suspected deletion in the CFTR gene. Which technique is most suitable for confirming large deletions or duplications in the CFTR gene? (Q845189)

A. Polymerase Chain Reaction (PCR)

B. Comparative Genomic Hybridization (CGH)

C. Multiplex Ligation Dependent Probe Amplification (MLPA)

D. Sanger sequencing

Correct Answer: C. Multiplex Ligation Dependent Probe Amplification (MLPA)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: While PCR and Sanger sequencing are excellent for detecting small point mutations, they often fail to detect large heterozygous deletions or duplications (copy number variations). MLPA is the gold standard for this purpose. Multiplex Ligation Dependent Probe Amplification (MLPA) (Option C): Best for: Detecting copy number variations (CNVs) such as large deletions or duplications in a single gene (like CFTR , DMD , or BRCA1). Mechanism: Two probes hybridize to adjacent target DNA sequences. They are then ligated together and amplified. The amount of amplified product is proportional to the number of target DNA copies present. Key Advantage: Can analyze up to 50 different genomic DNA sequences in a single reaction. Polymerase Chain Reaction (PCR) (Option A): Best for: Detecting small deletions, insertions, or counting trinucleotide repeats (e.g., Fragile X). Limitation: Standard PCR may miss a large deletion on one chromosome because the primer will still amplify the "normal" allele on the other chromosome, masking the loss. Enzyme: Uses Taq Polymerase , a thermostable enzyme. Comparative Genomic Hybridization (CGH) (Option B): Best for: Detecting large chromosomal imbalances (deletions/duplications) across the entire genome . Limitation: It is generally used for whole-genome screening rather than specific, high-resolution analysis of a single gene like CFTR unless an array-CGH is specifically designed for it. Sanger Sequencing (Option D): Best for: Identifying point mutations (single nucleotide changes) and very small indels. Limitation: Like PCR, it cannot accurately quantify the number of gene copies, making it unreliable for detecting large heterozygous deletions. Technique Primary Use Case Sanger Sequencing "Gold standard" for point mutations . PCR Amplifying DNA; detecting repeat expansions . MLPA Detecting large deletions/duplications in specific genes. Southern Blot Detecting large expansions or structural changes if PCR fails. Microarray (CGH) Screening the whole genome for gains/losses.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. Page 181

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which technique is specifically designed to detect copy number variations (CNVs) in the genome by comparing patient DNA with a reference DNA sample? (Q845188)

A. PCR

B. Comparative Genomic Hybridization (CGH)

C. DNA sequencing

D. Southern blotting

Correct Answer: B. Comparative Genomic Hybridization (CGH)

Explanation: Comparative Genomic Hybridization (CGH) is a molecular cytogenetic technique used to detect copy number variations (CNVs) in the genome, including microdeletions and microduplications. It involves comparing the patient's DNA with a reference DNA sample, often labelled with different fluorescent dyes, to identify gains or losses of genetic material. Schematic for Comparative Genomic Hybridization : Uses of Comparative Genomic Hybridization: Detection of Copy Number Variations (CNVs) : Identifies gains and losses of DNA segments. Diagnosis of Genetic Disorders : Detects chromosomal abnormalities (e.g., microdeletions, microduplications) linked to developmental and congenital disorders (e.g., Williams, DiGeorge syndrome). Cancer Genomics : Identifies chromosomal imbalances in cancer cells, including gene amplifications or deletions (e.g., in breast cancer, and gliomas). Prenatal Screening : Detects chromosomal abnormalities in fetuses, such as Down syndrome and other congenital defects. Assessment of Structural Variations : Identifies larger structural changes (e.g., duplications, deletions, inversions, translocations). Neurodevelopmental Disorders : Identifies CNVs linked to conditions like autism spectrum disorders. Genomic Research : Provides insights into the genetic basis of diseases by identifying recurrent CNVs in patient populations. Personalized Medicine : Identifies genetic alterations that guide targeted therapies, particularly in cancer. PCR: Polymerase Chain Reaction (PCR) is used for amplifying specific DNA sequences and is not specifically designed to detect CNVs. (Option A) DNA sequencing: DNA sequencing is used to determine the precise order of nucleotides in a DNA molecule and is not primarily focused on detecting CNVs. (Option C) Southern blotting: Southern blotting is a technique used to detect specific DNA sequences, often related to gene expression or mutations, but it is not tailored for CNV detection. (Option D)

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 181

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which steps are NOT involved in the Polymerase Chain Reaction (PCR) process? (Q845187)

A. Denaturation

B. Annealing

C. Amplification

D. Ligation

Correct Answer: D. Ligation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Polymerase Chain Reaction (PCR) involves three main steps: Denaturation , where the DNA double-strand separates into two single strands at 94 degrees Celsius. Annealing , where primers bind to the target DNA sequence at 54 degrees Celsius. Amplification , where DNA polymerase extends the primers to replicate the target sequence at 72 degrees Celsius. Ligation, which is the process of joining DNA fragments together, is not a

step in PCR. Multiplex Ligation-dependent Probe Amplification in which ligation is done Key Components of PCR: DNA Template: The sample containing the target sequence. Primers: Two short, synthetic DNA fragments that flank the region to be amplified. Enzyme (DNA Polymerase): Most commonly Taq Polymerase , derived from the bacterium Thermus aquaticus . It is used because it is thermostable and does not denature at high temperatures. dNTPs: Deoxynucleotide triphosphates (A, T, C, G), the building blocks for the new DNA. Buffer & Mg^{2}■: Magnesium ions act as a necessary cofactor for DNA polymerase activity. Low Mg → Poor yield (no cofactor) High Mg → Nonspecific (stabilizes mismatches) Optimal = 1.5-2.5 mM PCR Types: Type Purpose Clinical Application Reverse Transcriptase (RT-PCR) Uses RNA as a template to create cDNA before amplification. Detecting RNA viruses (e.g., HIV, SARS-CoV-2). Real-Time PCR (qPCR) Measures DNA amplification in real-time using fluorescent dyes. Quantifying "viral load" or gene expression levels. Nested PCR Uses two sets of primers in two successive runs. Increases sensitivity and specificity for low-abundance DNA. Multiplex PCR Uses multiple primer sets in a single reaction tube. Screening for multiple pathogens or mutations at once. Digital PCR (dPCR) Partitions the sample into thousands of droplets for absolute quantification. Detecting rare mutations or "liquid biopsies" in cancer.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no.181

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: In a cytogenetics laboratory, a technician is tasked with preparing chromosomes obtained from a patient's blood sample for analysis under a light microscope. The patient has been experiencing unexplained developmental delays, and the physician suspects a potential chromosomal abnormality. To aid in the identification and analysis of individual chromosomes, which technique will the technician employ to produce distinct banding patterns? (Q845186)

A. G-banding

B. C-banding

C. Q-banding

D. R-banding

Correct Answer: A. G-banding

■ *Listen to Audio 1*

Explanation: G-banding involves staining chromosomes with Giemsa dye, which results in characteristic dark and light bands along the length of each chromosome. G-banding is the most widely used cytogenetic technique to visualize distinct banding patterns on chromosomes. It helps in: Identifying individual chromosomes Detecting structural abnormalities (e.g., deletions, duplications, translocations) Diagnosing chromosomal disorders linked to

developmental delays It allows karyotyping with high accuracy. Each chromosome has a unique banding pattern , making it easier to detect abnormalities like trisomy, deletions, or rearrangements Karyotyping: Step-by-Step Process: Cell Collection: Usually performed using peripheral blood (T-lymphocytes) , but can also use skin fibroblasts, amniotic fluid, or bone marrow. Stimulation: Cells are stimulated to divide using a mitogen , most commonly Phytohemagglutinin (PHA) . Arrest: Cells are arrested in Metaphase using Colchicine or Colcemid. Mechanism: Colchicine inhibits microtubule polymerization (spindle fiber formation), preventing the cell from moving past metaphase where chromosomes are most condensed. Hypotonic Treatment: Cells are placed in a hypotonic solution (typically $0.075 M$ KCl). Purpose: This causes the cells to swell, which spreads the chromosomes apart so they don't overlap on the slide. Fixation: The "fixative" used is Carnoy's Fixative , which is a 3:1 mixture of Methanol and Glacial Acetic Acid . Staining: The slides are prepared and stained, most commonly with G-banding (Giemsa) . C-banding (Option B) selectively stains the centromeric regions Q-banding (Option C) also known as quinacrine staining, involves staining chromosomes with quinacrine mustard, which fluoresces under ultraviolet light R-banding (Option D) or reverse banding, is the reverse of G-banding . it produces light bands where G-banding shows dark, and vice versa.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 45-year-old woman has been newly diagnosed with breast cancer. Histopathological analysis of the tumour reveals invasive ductal carcinoma. Given the aggressive nature of her tumour, the oncologist wants to determine if the patient's cancer is HER2-positive. Which diagnostic method is most appropriate for detecting HER2/neu amplification in this patient? (Q845184)

A. Immunohistochemistry (IHC)

B. Fluorescence In Situ Hybridization (FISH)

C. Polymerase Chain Reaction (PCR)

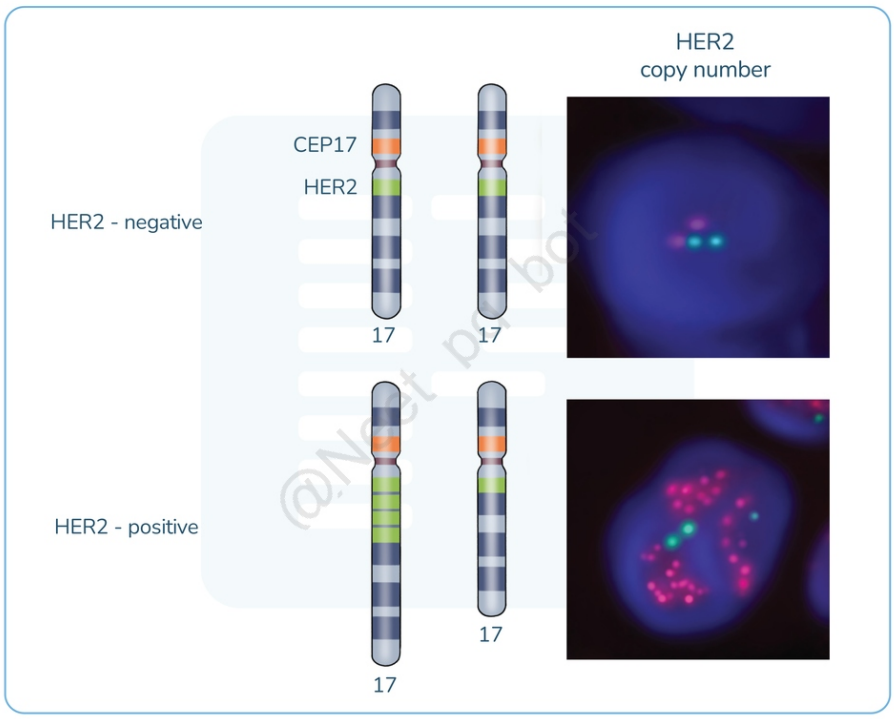
D. Western Blotting

Correct Answer: B. Fluorescence In Situ Hybridization (FISH)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: FISH uses DNA probes that recognize sequences specific to particular chromosomal regions. In the case of HER2 testing, FISH directly visualizes HER2 gene amplification by labelling the HER2 gene with a fluorescent probe. HER2 protein overexpression is virtually always caused by amplification of the region of chromosome 17q that contains the HER2 gene. The increase in HER2 gene copy number is detected by fluorescence in situ hybridization using a HER2-specific probe (red signal), which is typically co-hybridized to tumour cell nuclei with a second probe specific for the centromeric region of chromosome 17 (green signal), allowing the chromosome 17 copy number to be determined. Scoring / Interpretation: Positive (+1 / +2 / +3 or equivocal): HER2/CEP17 ratio >2.0 → HER2 amplified → positive HER2/CEP17 ratio 1.8–2.0 → equivocal → repeat testing or IHC correlation HER2/CEP17 ratio <2.0 → negative FISH can be used for testing: Chromosomal translocations Deletions Amplifications FISH cannot detect point mutations. Immunohistochemistry (IHC): (Option A) IHC involves staining tissue samples with antibodies specific to HER2/neu protein. While widely used for HER2 testing, it does not directly measure gene amplification Polymerase Chain Reaction (PCR) (Option C) PCR amplifies DNA sequences, including the HER2 gene, from tumour samples. It can detect gene amplification but It is not commonly used for HER2 testing in breast cancer patients. Western Blotting (Option D) Western blotting detects specific proteins in a sample but does not directly measure gene amplification. It is not commonly used for HER2 testing in breast cancer patients.



@Neet_pg_bot

Q13: Which of the following statements regarding gonadal mosaicism is true? (Q845183)

A. It is associated with autosomal recessive disorders.

B. It occurs due to a pre-zygotic mutation during early embryonic development.

C. It can be associated with osteogenesis imperfecta.

D. It follows the laws of Mendelian inheritance.

Correct Answer: C. It can be associated with osteogenesis imperfecta.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The true statement regarding gonadal mosaicism is that it can be associated with osteogenesis imperfecta. GONADAL MOSAICISM/GERMLINE MOSAICISM The parent's sperm and ova are genotypically normal. On the fusion of normal sperm and normal ova, a normal zygote isformed. Post Zygotic mutation results in the disease. Gonadal mosaicism can be seen in: Osteogenesis imperfecta. Tuberous sclerosis. Achondroplasia

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 180

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 25-year-old male has been complaining of painless, progressive central vision loss in both eyes over the past few months. He reports a family history of similar visual problems, with his maternal grandfather and maternal uncle experiencing sudden vision loss in their 20s. On examination, the ophthalmologist notes bilateral optic disc pallor and central scotomas on visual field testing. The patient denies any systemic symptoms or significant medical history. What is the inheritance pattern seen in this condition? (Q845182)

Correct Answer: Unknown

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation, along with the family history of sudden vision loss in multiple maternal relatives, is highly suggestive of Leber hereditary optic neuropathy (LHON) , a maternally inherited mitochondrial disorder affecting the optic nerves. Mitochondrial inheritance: A unique feature of mitochondrial DNA (mtDNA) is maternal inheritance. This peculiarity exists because ova contain numerous mitochondria within their abundant cytoplasm, whereas spermatozoa contain few, if any. Hence the mtDNA complement of the zygote is derived entirely from the ovum. Thus, mothers transmit mtDNA to all their offspring , male and female. Father does not transmit mitochondrial DNA → none of his children affected Daughters transmit the DNA to their further progeny. Most common mitochondrial disease: MELAS, Leber hereditary optic neuropathy (LHON) All generations of the family are affected in a vertical pattern with equal male and female involvement. Hence it shows autosomal dominant inheritance.(OPTION A) The mother has transmitted the defective gene to both her son and daughter. But, in the second generation, the father has transmitted the disease only to females. Hence it shows an X-linked dominant inheritance pattern.(OPTION B) The females are carriers in all generations, and only the males are affected by the disease. Hence, it shows an X-linked recessive inheritance pattern.(OPTION C)

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 177,178

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Hairy pinna is associated with which type of Mendelian inheritance? (Q845181)

A. Autosomal dominant

B. X-linked recessive

C. Mitochondrial inheritance

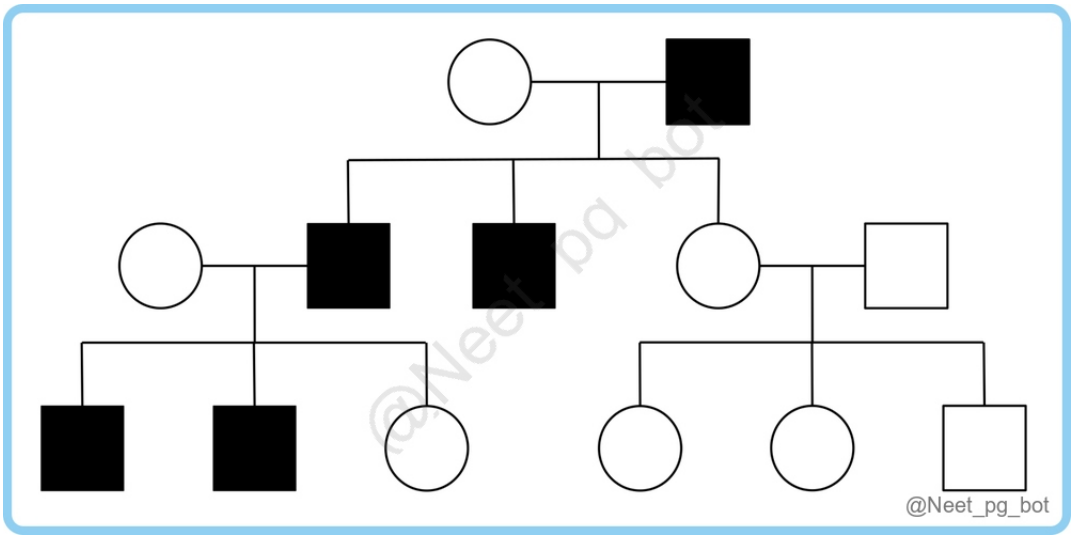
D. Y-linked inheritance

Correct Answer: D. Y-linked inheritance

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hairy pinna (hypertrichosis of pinna) is associated with Y-linked inheritance/ Holandric inheritance. Other examples: Webbed toes Porcupine man The image below shows a pedigree chart of Y-linked inheritance. Only males are affected, and transmission occurs only to the sons.



References:

Inderbir Singh's Human Embryology, 11th edition, Page no. 17,18

↑ *Back to this question in Part A*

@Neet_pg_bot

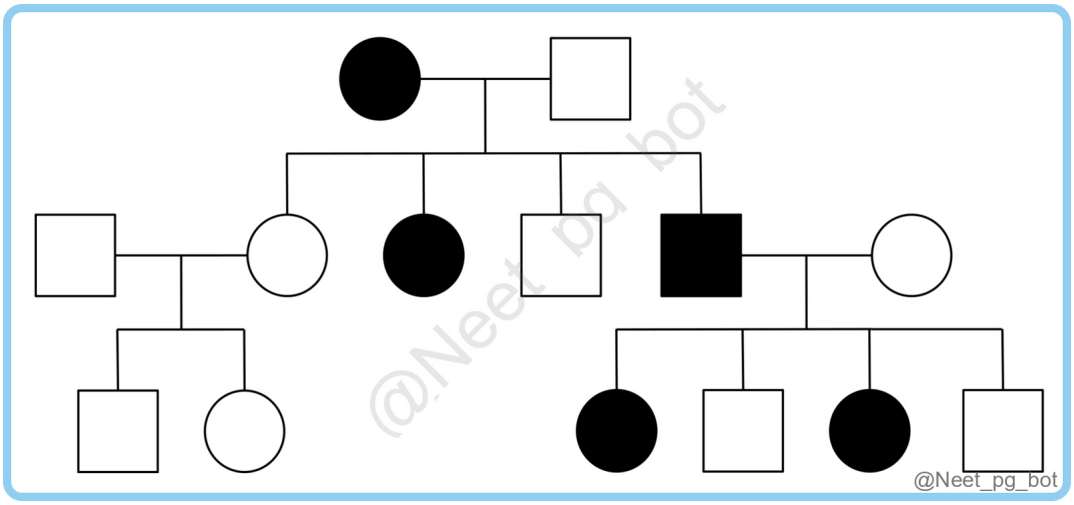
Q16: In which of the following conditions can you see this pedigree chart? (Q845180)

A. Fabry disease

B. Albinism

C. Reye syndrome

D. Alport syndrome



Correct Answer: D. Alport syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: An affected male will transmit the disease to all his daughters but not sons. An affected female can transmit the disease to both daughters and sons. Conditions with X-linked dominant inheritance: Rett syndrome. Alport syndrome (M/C inheritance pattern is X-linked dominant). Vitamin D-resistant rickets. Incontinentia pigmenti. Alport syndrome ■■■■■■is X-linked Dominant in inheritance. The "Can't see, can't pee, can't hear a high-C" triad: Eye: Anterior lenticonus (conical lens) and retinopathy. Renal: Progressive hereditary nephritis (hematuria, proteinuria, and renal failure). Ear: Sensorineural deafness. Pathology: Defect in Type IV Collagen (basement membrane). EM Finding: "Basket-weave" appearance of the glomerular basement membrane. Fabry's disease (Option A) is X-linked recessive in inheritance. Deficiency: α-galactosidase A. Accumulation: Ceramide trihexoside. Triad: Episodic peripheral neuropathy, angiokeratomas (reddish-purple skin spots), and hypohidrosis (decreased sweating). Late Complications: Progressive renal failure and cardiovascular disease. Albinism (Option B) is autosomal recessive in inheritance (ocular albinism: X-linked recessive) Mechanism: Deficiency of Tyrosinase or defective tyrosine transporters. Presentation: Absence of pigment in skin, hair, and eyes. Risk: Highly increased risk of skin cancers (Squamous Cell Carcinoma). Reye syndrome (Option C): Acquired/Environmental It is a rare but serious condition primarily affecting children and teenagers Mechanism: Hepatic encephalopathy and fatty liver following aspirin use during a viral infection (e.g., VZV, Influenza). Pathology: Mitochondrial damage leading to decreased β-oxidation. Key Lab: Elevated ammonia and ALT/AST with a microvesicular fatty liver.

@Neet_pg_bot

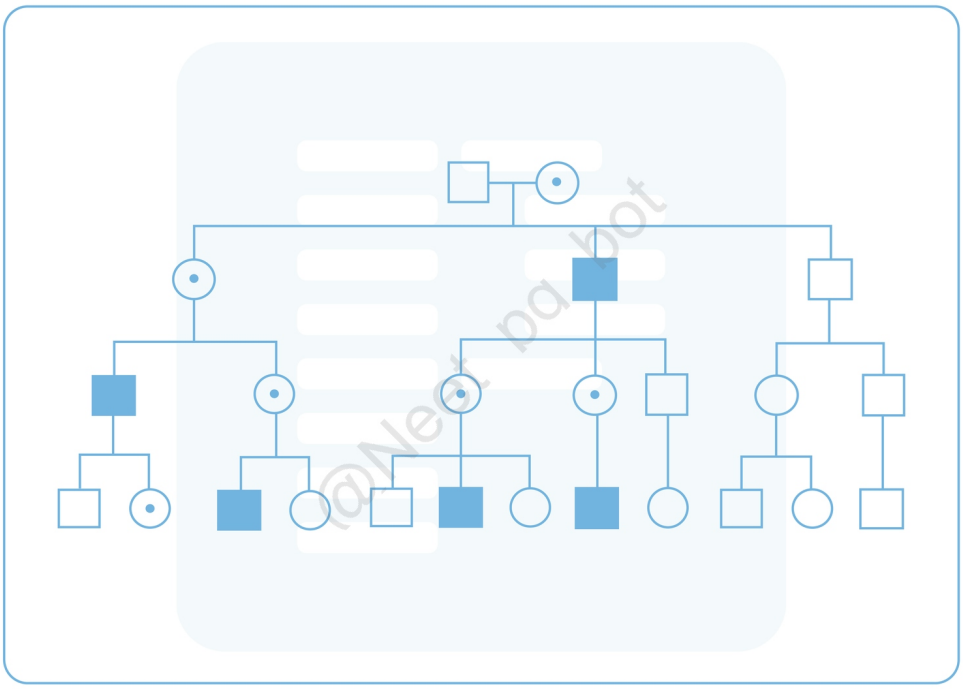
Q17: A 6-year-old boy presents to the clinic with complaints of muscle weakness and difficulty walking. His parents report a family history of similar symptoms. A detailed history was obtained, and a pedigree analysis was done, which is shown below. What is the most likely diagnosis and the inheritance pattern seen in this condition? (Q845179)

A. Dystonia myotonica, autosomal dominant

B. Dystonia myotonica, X-linked recessive

C. Duchenne muscular dystrophy, autosomal recessive

D. Duchenne muscular dystrophy, X-linked recessive



@Neet_pg_bot

Correct Answer: D. Duchenne muscular dystrophy, X-linked recessive

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Duchenne muscular dystrophy is an X-linked recessive disease. X-linked recessive disorders: Females (XX) are carriers. Males are affected by the disease. Duchenne Muscular Dystrophy (DMD): X-linked recessive (DMD gene mutation → absent dystrophin <5%) Boys, onset 2-3years : Gowers sign , calf pseudohypertrophy , toe-walking, waddling gait Diagnosis : Genetic testing > biopsy Treatment : Steroids (prolong ambulation), exon-skipping (eteplirsen) Myotonic Dystrophy (DM1) Autosomal dominant (DMPK CTG repeat expansion) – anticipation (worse in kids) Myotonia (can't release grip), hatchet face , frontal baldness, ptosis Congenital : Hypotonia, tented mouth, respiratory failure, MR Multi-system : Cataracts, arrhythmias, diabetes, hypogonadism Diagnosis : EMG (myotonia), genetic (CTG >50) Feature DMD Myotonic Dystrophy Inheritance X-linked Recessive Autosomal Dominant Age of Onset Early Childhood (~3–5 yrs) Adulthood (~20–30 yrs) Mutation Type Frameshift (Deletion) CTG Trinucleotide Repeat Primary Sign Proximal weakness (Gower's) Myotonia (Handshake stiffness) Heart Issues Dilated Cardiomyopathy Conduction defects (Arrhythmia) Associated Signs Calf pseudohypertrophy Balding, Cataracts, Gonadal atrophy Examples of X-linked recessive disorders: Mnemonic Diseases Wise Wiskott-Aldrich syndrome AB Hemophilia A, B Ocular albinism B Bruton’s agammaglobulinemia Becker muscular dystrophy C Chronic granulomatous disease Color blindness (Red-green) D Duchenne Muscular dystrophy E Lesch Nyhan syndrome F Fabry disease Fragile-X syndrome (X-linked recessive > X-linked recessive) G G-6-PD deficiency H Hunter’s disease

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 10-year-old boy presents to the clinic with complaints of unsteady gait and frequent falls. Upon further inquiry, it is revealed that he has experienced progressive difficulty with coordination and balance over the past few years. His parents report a similar history in his older sister, who is now 15 years old. Interestingly, the parents are both asymptomatic, but the boy's maternal uncle was diagnosed with a similar condition in his late 20s. What is the most likely inheritance pattern seen in this condition? (Q845178)

A. Autosomal Dominant

B. X linked dominant

C. X linked recessive

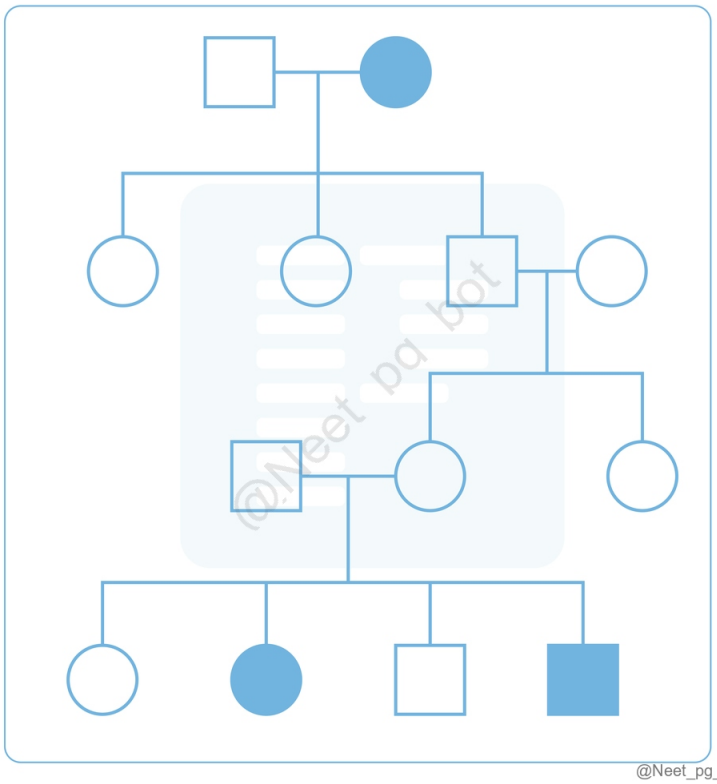
D. Autosomal Recessive

Correct Answer: D. Autosomal Recessive

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The progressive difficulty with coordination and balance in both siblings, along with the maternal uncle's being affected, suggests Friedreich's ataxia, a pattern consistent with autosomal recessive inheritance. In this scenario, both parents are likely carriers of a defective gene responsible for Friedreich's ataxia, and each sibling has inherited two copies of the defective gene , resulting in the development of this disorder. Friedrich Ataxia (FRDA): It is an autosomal recessive trinucleotide repeat disorder that causes progressive damage to the nervous system and heart. Genetics: GAA repeat expansion in the FXN gene (Chromosome 9). Pathophysiology: Deficiency in Frataxin (a mitochondrial protein) leads to iron overload and oxidative stress. Neurological: Ataxia: Progressive gait instability (spinocerebellar tract). Sensory: Loss of vibration/proprioception (dorsal columns). Motor: Muscle weakness (corticospinal tract) with absent reflexes . Skeletal: Pes cavus (high-arched feet) and kyphoscoliosis . Cardiac/Metabolic: Hypertrophic cardiomyopathy (most common cause of death) and Diabetes Mellitus . Mnemonic (GAA): G ait ataxia, A rched feet, A rrhythmia. Examples of autosomal recessive disorders: Mnemonic Disease Pasta P henylketonuria A lkaptonuria S ickle cell anemia T halassemi a Fried F riedrich’s ataxia: Chawal C ystic fibrosis, C ongenital adrenal hyperplasia H emophilia C, H omocystinuria, H emochromatosis A lpha-1-antitrypsin deficiency W ilson’s disease A lbinism L ysosomal storage disorders, g l ycogen storage disorders DNA repair defects Big B loom syndrome Fax F anconi’s anemia A taxia telangiectasia X eroderma pigmentosum X-linked recessive (Option C) is less likely because the sister is affected (females are usually carriers). X-linked dominant (Option B) and autosomal dominant (Option A) are unlikely since parents are asymptomatic , and dominant conditions usually show up in at least one parent.



References:

Inberbir Singh’s Embryology, 11th edition, Page no. 17

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 145,146

↑ *Back to this question in Part A*

@Neet_pg_bot

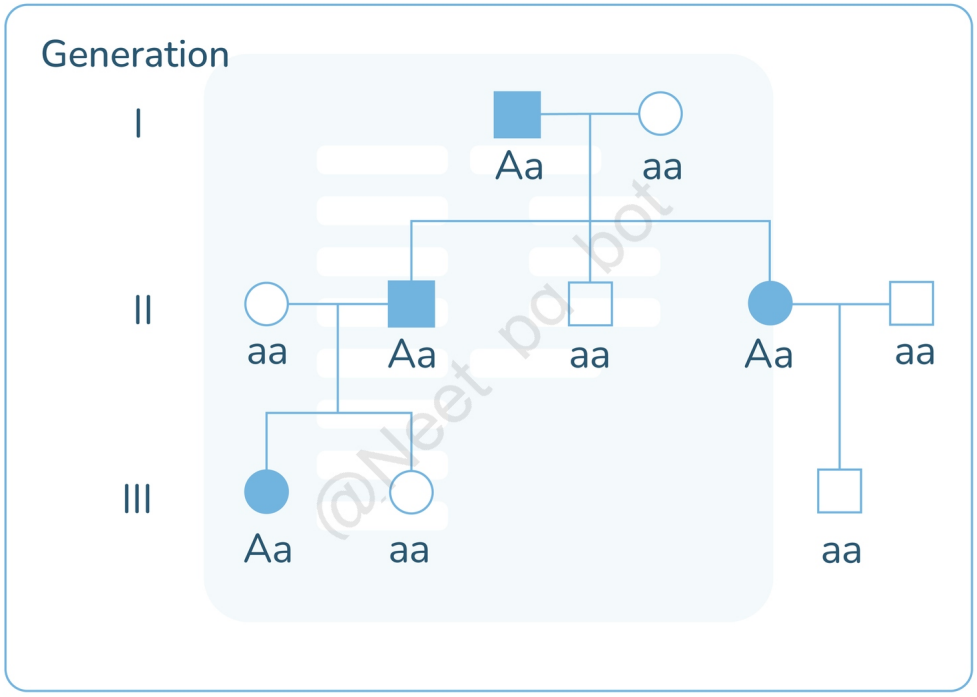
Q19: A couple seeks medical advice after their daughter presents with frequent nosebleeds and easy bruising. Lab investigations reveal prolonged bleeding time, prolonged aPTT, and a normal PT. A detailed history and a pedigree analysis were obtained, suspecting a genetic disorder. Based on the pedigree chart, what is this condition's most likely inheritance pattern? (Q845177)

A. Autosomal recessive

B. Autosomal dominant

C. X linked recessive

D. X linked dominant



@Neet_pg_bot

Correct Answer: B. Autosomal dominant

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The clinical presentation of a female with frequent nosebleeds, easy bruising, prolonged bleeding time & aPTT, and normal PT is suggestive of Von Willebrand disease. Platelet Function & Factor VIII – 1-Molybdenum Deficiency: Platelet Adhesion: Factor VIII is part of the intrinsic coagulation pathway 1-Molybdenum deficiency → defective platelet adhesion → bleeding time ↑ Coagulation Defect: Factor VIII cannot function normally → factor VIII activity ↓ Leads to prolonged APTT (activated partial thromboplastin time) The pedigree chart shows a vertical transmission pattern with no skipping of generations and is suggestive of autosomal dominant inheritance. Autosomal dominant inheritance pattern: The mode of transmission is vertical . An affected person has an affected parent. There is a 50% chance of the dominant trait being transmitted to offspring. Both males and females are equally affected.

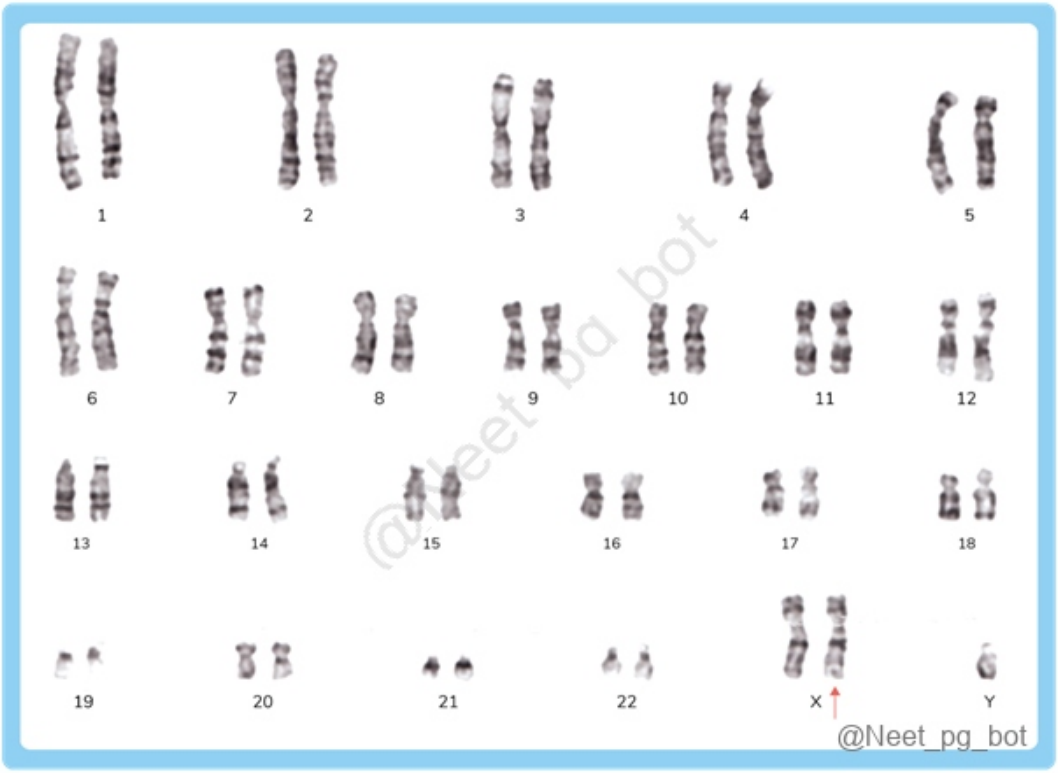
Q1: A karyotyping image is given below. What are the clinical features most likely to be expected in such patients? (Q856714)

A. Gynecomastia and long limbs

B. Flat occiput

C. Webbing of neck and lymphedema

D. Cleft lip and polydactyly



Correct Answer: A. Gynecomastia and long limbs

Explanation: The karyotype image reveals an additional X chromosome, confirming the presence of Klinefelter Syndrome (47, XXY), a condition often associated with features like gynecomastia and longer limbs. It is male hypogonadism resulting from two or more X chromosomes and one or more Y chromosomes. It is an important genetic cause of reduced spermatogenesis and male infertility. Karyotype: The most common is 47, XXY, from meiotic nondisjunction; some have mosaic patterns (e.g., 46, XY/47, XXY). X chromosome genes: Some genes escape inactivation, leading to uneven dosage compensation and overexpression. Clinical features of Klinefelter syndrome: Gynecomastia (breast development) Long limbs Infertility (most common cause of male hypogonadism and infertility). Flat occiput (Option B) is a feature of Down syndrome (Trisomy 21), a genetic condition caused by an extra chromosome 21, leading to intellectual disability, developmental delays, and physical traits like a flat face and almond-shaped eyes. It's linked to heart defects, hearing loss, and other health issues. Webbing of the neck and lymphedema (Option C) are features of Turner's syndrome, a genetic condition that occurs when a female is born with only one full X chromosome (45, X instead of the usual 46, XX). It leads to short stature, infertility, and sometimes heart defects, kidney problems, and hearing loss. Individuals may also have learning difficulties, particularly with spatial reasoning. Cleft lip and polydactyly (Option D) are features of Patau syndrome (Trisomy 13), a genetic disorder caused by an extra copy of chromosome 13. It leads to severe intellectual disability, cleft lip and palate, polydactyly (extra fingers or toes), heart defects, and brain abnormalities. Most affected infants have a short life expectancy, often not surviving beyond the first year.

Robbins & Cotran Pathologic Basis of Disease,10th Edition, Page 170-171.

↑ *Back to this question in Part A*

@Neet_pg_bot

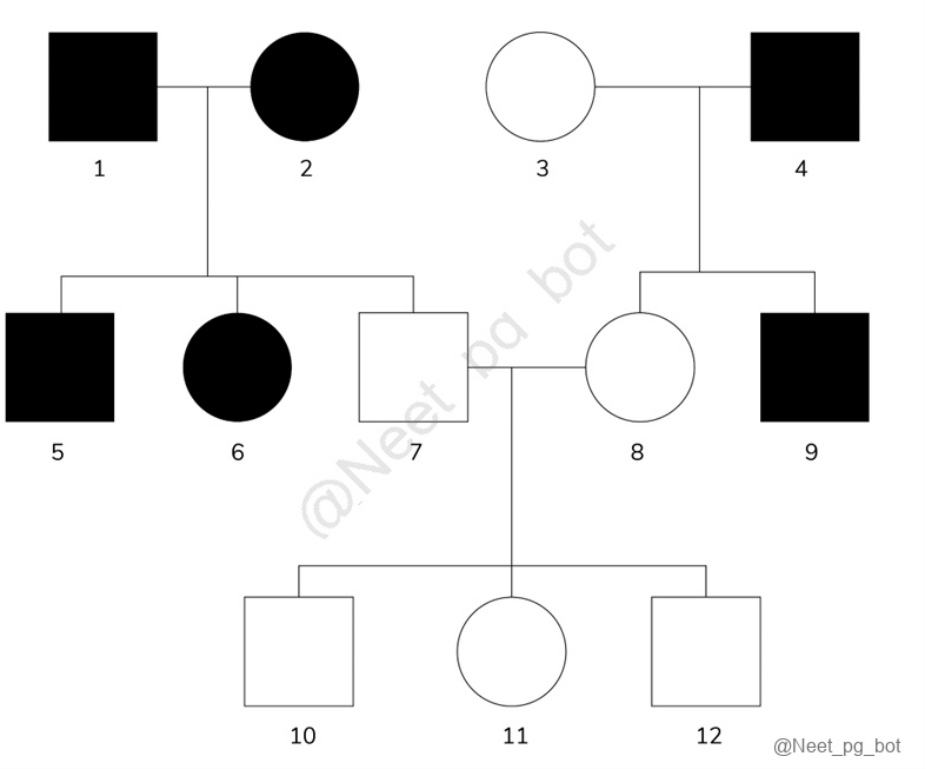
Q2: Identify the type of inheritance? (Q820500)

A. Autosomal Dominant

B. Autosomal Recessive

C. X-linked dominant

D. X-linked recessive



Correct Answer: A. Autosomal Dominant

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Correct Option A - Autosomal Dominant Inheritance: In autosomal dominant inheritance, a single copy of the mutated gene from one parent is enough to cause the trait or disorder. The trait or disorder will be present in every generation, as affected individuals pass the mutated gene to their offspring. Individuals with one affected parent have a 50% chance of inheriting the trait. For example, if a parent has a dominant genetic disorder like Huntington's disease, there's a 50% chance their child will inherit the disorder. Incorrect Options: Option B - Autosomal Recessive Inheritance: In autosomal recessive inheritance, two copies of the mutated gene (one from each parent) are required to manifest the trait or disorder. Carriers of a single mutated gene are usually healthy but can pass on the mutation to their offspring. The trait or disorder might skip generations if carriers do not have affected children. When two carriers have a child, there's a 25% chance the child will have the disorder, a 50% chance of being a carrier, and a 25% chance of having neither the disorder nor being a carrier. An example is cystic fibrosis. Option C - X-Linked Dominant Inheritance: X-linked dominant inheritance involves a mutated gene on the X chromosome. A single copy of the mutated gene on one of the X chromosomes is sufficient to cause the trait or disorder in females (since they have two X chromosomes) and in males (who have one X chromosome). Affected fathers pass the disorder to all their daughters, but not to their sons. Affected mothers have a 50% chance of passing the disorder to both sons and daughters. An example is Rett syndrome. Option D - X-Linked Recessive Inheritance: X-linked recessive inheritance also involves a mutated gene on the X chromosome. Males are more commonly affected because they have only one X chromosome. Carrier mothers (with one normal and one mutated X chromosome) can pass the mutation to their sons (who get their X chromosome from the mother) and to half of their daughters (who inherit the mutated X chromosome). Carrier fathers pass the mutated gene only to their daughters, who become carriers. An example is color blindness.

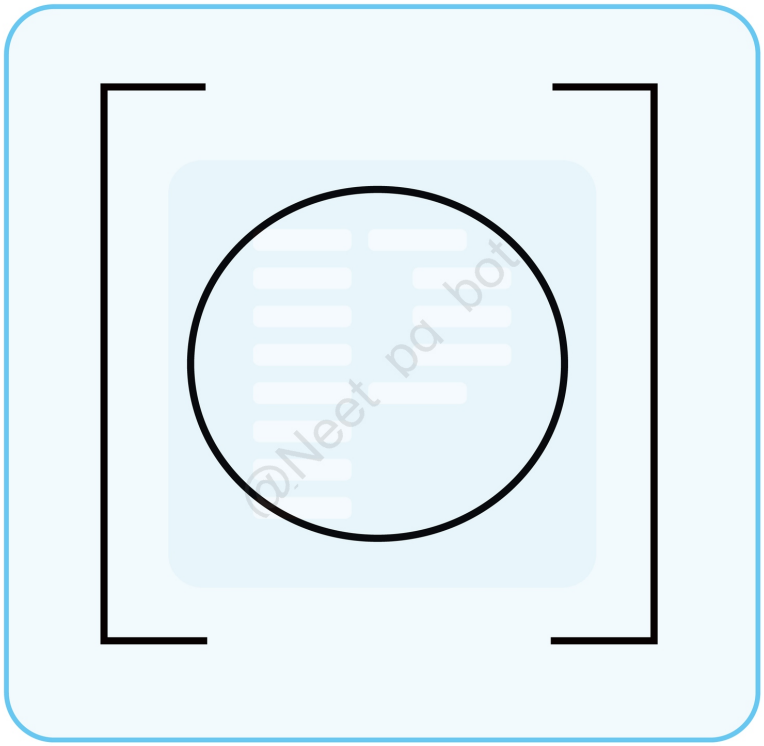
Q3: What is the status of the marked individual? (Q866668)

A. Adopted from another family

B. Has a disease of chronic origin

C. Curable disease

D. Twin



Correct Answer: A. Adopted from another family

Explanation: In standard pedigree notation: An individual marked with brackets around the symbol indicates adoption. If the brackets are dashed, it usually means adopted in (from another family). If the brackets are solid, it usually means adopted out (given to another family). Has a disease of chronic origin / Curable disease (Option B, C): would be indicated by shading or other symbols, not brackets. Twin (Option D) : represented by two siblings connected by a triangle or horizontal bar, not brackets.

@Neet_pg_bot

Q4: Which of the following statements regarding Mendelian (single-gene) disorders is correct? (Q855359)

A. X-linked dominant disorders are the most common type of Mendelian disorders.

B. Autosomal recessive disorders always appear in every generation of a family.

C. Y-linked disorders are extremely rare because few genes are present on the Y-chromosome.

D. In autosomal dominant disorders, two defective alleles are required for the disease to manifest.

Correct Answer: C. Y-linked disorders are extremely rare because few genes are present on the Y-chromosome.

Explanation: Y-linked disorders are extremely rare because the Y-chromosome contains very few functional genes. Most Y-linked traits involve male sexual development, so pathogenic mutations are uncommon. Since the Y-chromosome is passed strictly from father to son, any Y-linked disorder shows strict male-to-male inheritance. Because so few Mendelian diseases follow this pattern, Y-linked disorders are among the least common modes of inheritance. Incorrect Options: Option A) X-linked dominant disorders are the most common type : False - they are rare ; autosomal disorders (dominant or recessive) are far more common. Option B) Autosomal recessive disorders appear in every generation : False - they typically skip generations because carriers are asymptomatic. Option D) Autosomal dominant disorders require two defective alleles : False - only one mutant allele is needed for disease expression.

Q5: A 30-year-old pregnant woman who has the thalassemia trait visits the clinic for genetic counselling. Her husband is also confirmed to have the thalassemia trait.

Considering their genetic background, what is the likelihood of their next offspring having thalassemia? (Q858074)

A. 100%

B. 50%

C. 75%

D. 25%

Correct Answer: D. 25%

Explanation: There is a 25% chance that their child will inherit the genotype β■/β■, corresponding to β-thalassemia major . Mother's Genotype: β/β■ (carrier for β-thalassemia) Father's Genotype: β/β■ (carrier for β-thalassemia) Punnett Square Analysis β β■ β β/β β/β■ β■ β/β■ β■/β■ Possible Outcomes: β/β (Normal): 25% β/β■ (Carrier): 50% β■/β■ (β-thalassemia major): 25%

@Neet_pg_bot

Q6: Which of the following correctly represents the effect of the mutation causing sickle cell anaemia? (Q858078)

A. Glutamate by valine at the 6th position

B. Valine by glutamate at the 6th position

C. Glutamate by valine at the 5th position

D. Valine by glutamate at the 5th position

Correct Answer: A. Glutamate by valine at the 6th position

Explanation: Sickle cell anaemia is caused by a point mutation that involves substituting adenine for thymine at the sixth codon of the β-globin gene (GAG to GTG) , replacing glutamic acid (glutamate) with valine in the β-globin chain of haemoglobin. This single nucleotide change results in the formation of abnormal haemoglobin molecules (HbS) . After deoxygenation, HbS molecules polymerize to form bundles. These polymer bundles cause erythrocytes to adopt a sickle shape and also promote hemolysis of erythrocytes, releasing cell-free Hb into circulation.

@Neet_pg_bot

Q7: B cells express IgM and IgD antibodies at the same time. Which phenomenon is it due to? (Q856008)

A. Somatic hypermutation

B. Alternative RNA splicing

C. Affinity maturation

D. Allelic exclusion

Correct Answer: B. Alternative RNA splicing

Explanation: B cells express IgM and IgD antibodies simultaneously due to alternative RNA splicing . This process allows the same gene for the heavy chain to be spliced in different ways to produce both IgM and IgD isotypes. The IgM and IgD are both produced from the same heavy chain gene but are differentiated through this splicing mechanism. During this process, the RNA transcript for the heavy chain is spliced in two different ways, one to produce IgM and the other to produce IgD . Both these antibodies have the same antigen-binding specificity but differ in their constant regions, which define their isotypes. Somatic hypermutation (Option A) occurs after antigen exposure and increases antibody affinity, but it does not affect the simultaneous expression of IgM and IgD. Affinity maturation (Option C) is a process that occurs during the immune response to improve the affinity of antibodies, not to generate multiple antibody classes at the same time. Allelic exclusion (Option D) ensures that only one allele of the immunoglobulin gene is expressed in a B cell at any given time, which helps in maintaining clonal specificity, but it does not explain the co-expression of IgM and IgD.

@Neet_pg_bot

Q8: Differential expression of a gene depending upon the parent of origin is a feature of: (Q855071)

A. Gonadal mosaicism

B. Genomic imprinting

C. Anticipation

D. Incomplete penetrance

Correct Answer: B. Genomic imprinting

Explanation: Genomic imprinting refers to the phenomenon where the expression of a gene depends on which parent the gene was inherited from. In imprinted genes, one allele is silenced depending on the parent of origin, leading to differential expression. Genomic imprinting: Inheritance : We inherit two copies of each autosomal gene, one from each parent, but functional differences can exist between the maternal and paternal alleles. Mechanism: Imprinting is an epigenetic process that selectively inactivates either the maternal or paternal allele. Maternal imprinting silences the maternal allele, while paternal imprinting silences the paternal allele. Imprinting occurs in the ovum or sperm before fertilization. The imprinting pattern is stably transmitted to somatic cells through mitosis. Imprinting is linked to disorders like Prader-Willi syndrome and Angelman syndrome. Prader-Willi syndrome Chromosome 15q SNORP gene Paternal deletion Maternal imprinting Angelman syndrome Chromosome 15q UBE3A gene Maternal deletion Paternal imprinting Gonadal mosaicism (Option A) refers to a condition where some of an individual's gametes (eggs or sperm) carry a mutation that is not present in the somatic cells. It does not involve differential expression based on the parent of origin, which is specific to genomic imprinting. Anticipation (Option C) refers to the phenomenon where a genetic disorder becomes more severe or appears at an earlier age with each successive generation. It is seen in trinucleotide repeat disorders. Incomplete penetrance (Option D) refers to situations where an individual with a disease-causing genotype does not show the expected phenotype. Example: BRCA1 gene mutations , which increase the risk of breast and ovarian cancer. Some individuals with the mutation never develop cancer despite carrying the gene.

@Neet_pg_bot

Q9: Which of the following disorders is inherited in an X-linked dominant pattern? (Q855075)

A. Rett syndrome

B. Duchenne muscular dystrophy

C. Huntington’s disease

D. Tuberous sclerosis

Correct Answer: A. Rett syndrome

Explanation: Rett syndrome is inherited in an X-linked dominant pattern, primarily affecting females. X-linked dominant inheritance: The gene responsible for the concerned trait or disorder is present on the X chromosome and can express itself both in homozygous and heterozygous conditions. It is more commonly seen in females than males since females have two X chromosomes. An affected male will transmit the disease to all his daughters but not sons. An affected female can transmit the disease to both daughters and sons. Conditions with X-linked dominant inheritance: Rett syndrome . Alport syndrome Vitamin D-resistant rickets. Incontinentia pigmenti. The pedigree chart below shows an X-linked dominant pattern: The affected mother of the first generation transmitted the disease to both son and daughter. The affected father of the second generation transmitted the disease only to the daughters. {{caption_text}} Duchenne muscular dystrophy (Option B) follows an X-linked recessive inheritance pattern. Huntington's disease (Option C) follows an autosomal dominant inheritance pattern. Tuberous sclerosis (Option D) is inherited in an autosomal dominant pattern. Learning Objective: X-linked dominance is more common in females. Affected males transmit the disease only to their daughters. Affected females transmit the disease to both daughters and sons.

@Neet_pg_bot

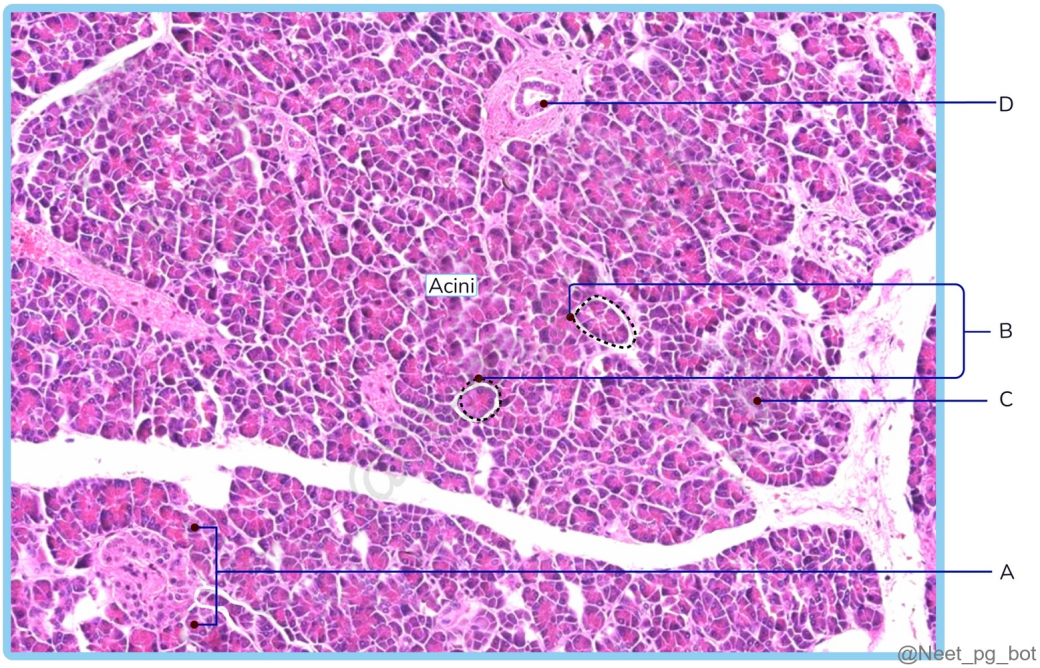
Q10: In cystic fibrosis, which of the following structures is affected in the pancreas? (Q855391)

A. A

B. B

C. C

D. D



Correct Answer: B. B

Explanation: "B" represents the acini, the functional units of the exocrine pancreas that produce and secrete digestive enzymes into the pancreatic ducts, and these are affected in Cystic Fibrosis, an autosomal recessive genetic disorder. Pathogenesis: It is caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene, resulting in a defect in the production or function of the CFTR protein. This leads to thick, sticky mucus forming in various organs, including the pancreas. In the pancreas, the defective CFTR protein affects the secretion of chloride ions and water, dehydrating pancreatic secretions. This thickened mucus obstructs the pancreatic ducts, preventing the proper flow of digestive enzymes from the acini into the duodenum. (Option B) Consequently, there is a reduction in the production and release of pancreatic enzymes, leading to impaired digestion and malabsorption of nutrients. Clinical features: Respiratory system Gastrointestinal and hepatic Others Progressive airway obstruction Infective exacerbations of bronchiectasis Respiratory failure Spontaneous pneumothorax Haemoptysis Lobar collapse due to secretions Pulmonary hypertension Nasal polyps Malabsorption and steatorrhoea Distal intestinal obstruction syndrome Biliary cirrhosis Portal hypertension, varices, and splenomegaly Gallstones Diabetes Delayed puberty, Male infertility Stress incontinence due to repeated forced cough Psychosocial problems Osteoporosis Arthropathy Cutaneous vasculitis A (Option A) is the islets of Langerhans, responsible for the production and secretion of hormones such as insulin and glucagon. It is not the target of cystic fibrosis. C (Option C) is the intralobular duct, which is part of the pancreatic duct system and plays a role in transporting pancreatic enzymes. It is not the target of cystic fibrosis. D (Option D) is the interlobular duct that transports pancreatic secretions and is not the target of cystic fibrosis.

@Neet_pg_bot

Q12: A girl presents with short stature, a webbed neck, thick calves, a shield-shaped chest, swelling of the ankle, and an increased carrying angle. What is the likely diagnosis? (Q856105)

A. Turner syndrome

B. Down syndrome

C. Patau syndrome

D. Edward syndrome

Correct Answer: A. Turner syndrome

Explanation: The clinical features described are characteristic of Turner syndrome , which is a genetic condition caused by the partial or complete absence of one of the X chromosomes (45 XO karyotype). It leads to hypogonadism in phenotypic females. Features of Turner Syndrome: Down syndrome (Option B) results from Trisomy 21. It is associated with features such as intellectual disability , epicanthal folds , flat facial profile , and congenital heart defects but does not include the specific skeletal and physical features seen in Turner syndrome. Patau syndrome (Option C) occurs due to trisomy 13 , and its clinical features include microphthalmia, microcephaly, rocker bottom feet, polycystic kidney disease, and congenital heart disease , none of which are consistent with the features described in the question. Edward syndrome (Option D) is caused by the presence of an extra copy of chromosome 18 (Trisomy 18) and is characterized by severe developmental delay, clenched fists , rocker-bottom feet , and heart defects , which differ significantly from the features seen in Turner syndrome.

@Neet_pg_bot

Q13: Which of the following statements is correct about Huntington's chorea? (Q854894)

A. It is a trinucleotide repeat disorder

B. There is a loss of function type of mutation

C. There are abnormal length repeats of CUG

D. Abnormality is seen due to a defect in chromosome 6

Correct Answer: A. It is a trinucleotide repeat disorder

Explanation: Huntington's chorea is a trinucleotide repeat disorder caused by the expansion of the CAG repeat in the HTT gene on chromosome 4. Huntington's disease: HD is an autosomal dominant disorder caused by the

degeneration of striatal neurons, leading to a progressive movement disorder and dementia. Symptoms include chorea , bradykinesia, and rigidity. It is relentlessly progressive and fatal, typically over 15 years. Pathogenesis: HD is a trinucleotide repeat expansion disease caused by a CAG repeat (Option C) in the HTT gene on chromosome 4p16.3 (Option D) , encoding huntingtin protein . Normal HTT genes have 6 to 35 CAG repeats , while pathogenic mutations have expanded repeats, leading to earlier disease onset with paternal transmission causing anticipation & the toxic gain-of-function (Option B) of mutant huntingtin is believed to be the primary pathogenic mechanism. Morphology: The brain exhibits atrophy of the caudate nucleus and putamen , along with ventricular dilation . There is a loss of striatal neurons , particularly affecting GABAergic neurons in the caudate and putamen. Gliosis is more extensive than usual due to neuronal loss. Clinical features: The loss of striatal neurons results in increased motor activity, causing choreoathetosis . Cognitive decline follows, with symptoms such as forgetfulness and dementia . The disease usually manifests in the fourth or fifth decade , and motor symptoms typically precede cognitive symptoms . The leading cause of death is often pneumonia , especially in advanced stages. Suicide rates are higher in HD patients.

@Neet_pg_bot

Q14: Premature ageing in Werner syndrome is due to: (Q858514)

A. Increased telomerase activity

B. Defects in DNA helicase

C. Increase in length of telomere due to decrease in telomerase activity

D. Decreased telomerase activity

Correct Answer: B. Defects in DNA helicase

Explanation: Werner syndrome , a rare autosomal recessive disorder, is characterised by premature ageing and accelerated development of age-related diseases. It results from mutations in the WRN gene, which encodes a DNA helicase involved in DNA repair and maintenance of genomic stability. Chromosomal damage accumulates rapidly due to the defective enzyme. This damage mimics normal ageing at a faster rate, leading to premature ageing. Similar conditions like Bloom syndrome and ataxia-telangiectasia also involve mutations in genes responsible for DNA repair . These disorders result in genetic instability and accelerated ageing due to impaired DNA repair mechanisms. Incorrect Options: Increased telomerase activity (Option A) is typically seen in some cancers, where it allows cells to maintain telomere length and avoid senescence. Increase in length of telomere due to decrease in telomerase activity (Option C) and Decreased telomerase activity (Option D) : In Werner syndrome, telomere shortening occurs due to DNA repair defects rather than telomere maintenance problems. Telomerase activity is not significantly altered.

@Neet_pg_bot

Q15: What is the mode of inheritance in a patient suffering from colour blindness? (Q859300)

A. AD

B. AR

C. XLR

D. XLD

Correct Answer: C. XLR

Explanation: The mode of inheritance in a patient suffering from colour blindness is X-linked recessive (XLR). X-Linked Recessive : The gene for Color blindness is located on the X chromosome. Males (XY) express the disorder if they inherit the affected X chromosome since they lack a second X for compensation. Females (XX) can be carriers if they inherit one affected X chromosome, often showing no symptoms due to the normal allele on the other X. Affected males cannot pass the disorder to sons but can pass the affected X to daughters, making them carriers. X-linked Recessive (WISE ABCDEFGH) Wise- Wiskott Aldrich Syndrome AB- Hemophilia A, B B- Bruton's Hypogammaglobulinemia . C- Chronic Granulomatous Disease, Red Green Color Blindness D- DMD, BMD E- Lesch Nyhan Syndrome F- Fabry Disease, Fragile X Syndrome G- G6PD Deficiency H- Hunter Disease Incorrect Options: Autosomal Dominant (AD) (Option A) disorders affect both sexes equally , and only one mutated allele is required for the disease to manifest. Examples: Marfan syndrome, Achondroplasia, Familial hypercholesterolemia . Autosomal Recessive (AR) (Option B) disorders require both alleles to be mutated for disease manifestation. Examples: Cystic fibrosis, Sickle cell disease, Phenylketonuria (PKU) . Colour blindness is inherited in an X-linked pattern, not AR. X-linked Dominant (XLD) (Option D) affects both males and females , but females more commonly due to having two X chromosomes. Examples: Rett syndrome, Fragile X syndrome, and Hypophosphatemic rickets . Colour blindness is X-linked recessive, not dominant.

@Neet_pg_bot

Q16: A female is heterozygous for an autosomal recessive mitochondrial disorder. What does this involve? (Q879194)

A. Skeletal muscle and immune system

B. Skeletal muscle and cardiac muscle

C. Skeletal muscle and neural tissue

D. Gastric and respiratory tissue

Correct Answer: C. Skeletal muscle and neural tissue

Explanation: Mitochondrial disorders most severely affect tissues with the highest energy (ATP) demand, such as skeletal muscle and neural tissue. Skeletal muscle: High energy requirement Rich in mitochondria ("red fibres") Classic site for mitochondrial myopathies Shows ragged red fibres on biopsy Neural tissue (CNS and peripheral nerves): The brain consumes ~20% of the body's ATP Neurons rely heavily on oxidative phosphorylation Mitochondrial defects cause seizures, hearing loss, neuropathy, and encephalopathy. This is why most mitochondrial syndromes (MELAS, MERRF, LHON, Leigh disease) involve muscle weakness, exercise intolerance, seizures, ataxia and developmental delay. Skeletal muscle and immune system (Option A): The immune system is not the classical target in mitochondrial diseases, and energy demand is lower compared to the CNS or muscle. Skeletal muscle and cardiac muscle (Option B): Cardiac muscle can be involved, but not as characteristically as the CNS in autosomal recessive mitochondrial disorders. Gastric and respiratory tissue (Option D): GI dysmotility can occur in some mtDNA diseases (e.g., MNGIE), but the respiratory epithelium has lower mitochondrial dependence than neural/muscle tissue.

References:

Mitochondrial Disorders

@Neet_pg_bot

Q17: A 3-year-old child presents with unilateral proptosis and leukocoria. Histopathology demonstrates Flexner–Wintersteiner rosettes. Regarding this condition, which of the following statements is false? It is always unilateral Called the guardian of the genome The RB protein is hypophosphorylated in the inactive state Oncogenesis is due to a loss-of-function mutation (Q879199)

A. 1,2,3

B. 1,2,3,4

C. 3,4

D. 2,3

Correct Answer: A. 1,2,3

Explanation: A 3-year-old child presents with unilateral proptosis and leukocoria, and histopathology reveals Flexner–Wintersteiner rosettes , which are diagnostic of Retinoblastoma , a malignant intraocular tumor of the retina in young children. It can be unilateral or bilateral . (Statement 1 ruled out) Sporadic form: usually unilateral. Hereditary form: often bilateral and multifocal. RB is known as the “governor of the cell cycle” . (Guardian is p53) (Statement 2 ruled out) The RB protein is active when hypophosphorylated , binding to E2F transcription factors and suppressing cell cycle progression from the G1 to S phase . When phosphorylated (hyperphosphorylated), RB becomes inactive , releasing E2F and allowing cell cycle progression. (Statement 3 ruled out) Tumor development arises from loss-of-function mutations in the RB1 tumor suppressor gene, which disables its cell cycle regulatory function and leads to uncontrolled cell proliferation. (Statement 4)

Robbins & Cotran, Pathologic Basis of Diseases, 10th Edition, Page 293-294.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Which of the following statements regarding Gaucher disease are correct? Enzyme defect: Sphingomyelinase Enzyme defect: β-glucocerebrosidase Presence of foamy macrophages Macrophages exhibit a “crumpled tissue paper” appearance (Q879204)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 2, 4

D. 1, 3, 4

Correct Answer: B. 2, 3, 4

Explanation: Gaucher’s Disease is an autosomal recessive inborn error of metabolism caused by mutations in the β-glucocerebrosidase - GBA1 gene. (Option 2) Glucocerebrosides accumulate massively within phagocytic cells throughout the body, forming distended foamy macrophages known as Gaucher cells. (Option 3) These cells, found in various organs including the spleen, liver, bone marrow, and lungs, exhibit a fibrillar cytoplasm resembling crumpled tissue paper. (Option 4) They stain intensely positive with periodic acid–Schiff staining. Wright stain - Crumpled tissue paper Enzyme defect sphingomyelinase (Option 1) is a feature of Niemann–Pick disease.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: What are the steps involved in the polymerase chain reaction (PCR)? (Q879217)

A. Denaturation - Annealing - Extension

B. Denaturation - Annealing - Extension - Hybridization

C. Annealing - Extension - Denaturation

D. Extension - Denaturation - Annealing

Correct Answer: A. Denaturation - Annealing - Extension

Explanation: The correct order of the sequence is Denaturation - Annealing - Extension. Polymerase Chain Reaction (PCR) Step 1 Denaturation Double-stranded DNA is heated to around 95°C to separate into 2 single strands. Step 2 Annealing Addition of two primers, which anneal the flanking sequence of the desired fragments. An optimal temperature (5 degrees less than the average melting temperature of the primers) should be maintained to avoid non-specific amplification. Step 3 Elongation Enzyme used is thermostable Taq (Thermus Aquaticus) DNA polymerase. DNA polymerase elongates new strands in 5'3' direction, and the optimal temperature required for elongation is 72°C. If PCR goes through 'n' number of cycles, then '2n' number of products are formed.

Harper's Biochemistry, 32nd Edition, Page 452, 453.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A boy with karyotype 46,XY del(15)(q11–13) presents with obesity and elevated ghrelin levels. What is the most likely diagnosis? (Q879225)

A. Prader-Willi syndrome

B. Angelman syndrome

C. Cri du chat syndrome

D. Fragile X syndrome

Correct Answer: A. Prader-Willi syndrome

Explanation: Prader-Willi syndrome Explanaation: The boy with karyotype 46,XY del(15)(q11–13), obesity, and elevated ghrelin levels most likely has Prader-Willi syndrome (PWS). It results from paternal deletion of chromosome 15q11–13 . Maternal allele in this region is normally imprinted (silenced), so loss of the paternal copy → loss of gene expression. Features: Hypotonia and poor feeding in infancy → obesity in childhood Hyperphagia and elevated ghrelin levels Short stature, hypogonadism Mild to moderate intellectual disability Incorrect Options: Angelman syndrome (Option B): Due to maternal deletion of 15q11–13 . It features “happy puppet” phenotype with laughter, seizures, and ataxia. Cri du chat syndrome (Option C): Deletion of short arm of chromosome 5 (5p). It features cat-like cry, microcephaly. Fragile X syndrome (Option D): Due to CGG repeat expansion in the FMR1 gene (X chromosome). It features macroorchidism, large ears, intellectual disability.

Robbins & Cotran, Pathologic Basis of Diseases, 10th Edition, Page 178,179

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: An adult tall male presents with subluxation of the lens, long arm span, pectus excavatum, and cardiac abnormalities. What is the most likely protein found to be defective? (Q844234)

A. Elastin

B. Collagen

C. Fibrillin

D. Laminin

Correct Answer: C. Fibrillin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Correct Option C – Fibrillin: The clinical presentation of the patient is highly suggestive of Marfan syndrome. It is caused by mutations in the FBN1 gene, leading to defective fibrillin, a protein essential for connective tissue integrity. Incorrect Options: Options A, B, and D are not affected by Marfan syndrome.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 25-year-old man presents with headaches, visual disturbances, and hypertension. MRI brain shows a cerebellar hemangioblastoma, and abdominal imaging reveals multiple cysts in the kidneys along with a solid renal mass suggestive of renal cell carcinoma. His father had similar findings and died from a brain tumor in his 40s.Which of the following chromosomal abnormalities is most likely associated with his condition? (Q866733)

A. Deletion on chromosome 13q

B. Deletion on chromosome 17p

C. Deletion on chromosome 3p

D. Trisomy of chromosome 12

Correct Answer: C. Deletion on chromosome 3p

Explanation: The most likely diagnosis is Von Hippel-Lindau (VHL) disease , a hereditary condition characterised by the development of multiple cysts in the kidneys, pancreas, and other organs. Genetics and pathogenesis: Inheritance : Autosomal dominant Gene : VHL tumour suppressor Chromosomal location: 3p25–26 Pathogenesis: The VHL gene product is part of a complex that degrades hypoxia-inducible factor (HIF) under normal oxygen levels. Mutation or deletion → HIF is not degraded → ↑ VEGF, PDGF → abnormal angiogenesis and tumour formation. Classic tumours/cysts: CNS : Hemangioblastomas (esp. cerebellum, retina, spinal cord) Kidneys : Simple cysts, clear cell RCC Adrenal glands: Pheochromocytoma - headaches, palpitations, and sweating Pancreas: Cysts, neuroendocrine tumours Inner ear: Endolymphatic sac tumours 13q deletion (Option A): RB1 gene loss → retinoblastoma, osteosarcoma. 17p deletion (Option B): TP53 loss → Li-Fraumeni syndrome (sarcomas, breast cancer, brain tumors, adrenal carcinoma). Trisomy 12 (Option D) : common cytogenetic change in CLL.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: FBN1 gene mutation is seen in which of the following genetic disorders? (Q866750)

A. Ehlers-Danlos syndrome

B. Marfan syndrome

C. Homocystinuria

D. von Hippel-Lindau syndrome

Correct Answer: B. Marfan syndrome

Explanation: Marfan syndrome is commonly associated with mutations in the FBN1 gene, which encodes the connective protein fibrillin on chromosome 15q21 . Pathophysiology: Abnormal fibrillin-1 → defective microfibrils → weakened elastic fibres. This leads to increased TGF-β activity , which contributes to the characteristic features of the syndrome. Mode of inheritance: Autosomal dominant. Multisystem disorder with involvement of the connective tissues. Clinical features: Skeletal abnormalities: Tall, thin build with long limbs (dolichostenomelia) Arachnodactyly Chest wall abnormalities like pectus excavatum/Pectus carinatum Thumb sign(On folding the thumb, it will protrude beyond the ulnar border of palm) or wrist sign is positive Increased joint laxity Scoliosis CVS abnormalities: Aortic root dilation → aortic regurgitation Risk of aortic aneurysm and dissection Mitral valve prolapse Arrhythmias Eye abnormalities: Ectopia lentis or subluxation of the lens of the eye Blindness, Myopia Pulmonary involvement: Increased risk of pneumothorax Diagnosis: Marfan syndrome is clinically diagnosed using the Ghent criteria Ehlers-Danlos syndrome (Option A): Usually due to collagen synthesis defects (type III or type V collagen), not FBN1. Homocystinuria (Option C): Due to cystathionine β-synthase deficiency → high homocysteine levels; may have marfanoid habitus but with downward lens dislocation and thrombosis risk. Von Hippel–Lindau syndrome (Option D): Due to VHL gene mutation on chromosome 3p, not FBN1; characterized by hemangioblastomas, renal cell carcinoma, and pheochromocytomas.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: Which of the following is not an aneuploidy? (Q865426)

A. Bloom syndrome

B. Trisomy 13

C. Trisomy 21

D. Klinefelter syndrome

Correct Answer: A. Bloom syndrome

Explanation: Aneuploidy refers to a numerical abnormality in chromosomes — gain or loss of whole chromosomes. Normal human chromosome number: 46 (2n) Trisomy = 2n + 1 (47 chromosomes) Monosomy = 2n – 1 (45 chromosomes) Bloom Syndrome: Genetic defect : Mutation in BLM gene on chromosome 15. Autosomal recessive disorder caused by loss-of-function mutations in a DNA helicase that is required for homologous recombination repair in DNA repair. Result: Defective DNA repair → Chromosomal instability → Predisposition to cancer. Chromosome number is normal (46) - it's a chromosomal instability disorder , not a numerical abnormality. Condition Description Chromosome Count Aneuploidy Type Trisomy 13 (Option B) Patau syndrome 47 2n + 1 Trisomy 21 (Option C) Down syndrome 47 2n + 1 Klinefelter syndrome (Option D) 47,XXY (extra X chromosome in males) 47 2n + 1 (sex chromosome)

Robbins and Cotran's Pathologic Basis of Disease, 10th Edition, Page 314.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A lymphoma characterised by the presence of centrocytes and centroblasts, along with BCL2 positivity and CD10 expression, is most commonly associated with which chromosomal translocation? (Q866357)

A. t(2;5)

B. t(8;14)

C. t(14;18)

D. t(11;14)

Correct Answer: C. t(14;18)

Explanation: The given HPE findings of the presence of centrocytes and centroblasts are consistent with Follicular lymphoma, which is associated with BCL2- gene translocation and CD10+; the chromosomal translocation associated with it is t(14:18). Follicular lymphoma (FL) is a malignant neoplasm originating from germinal centre B-cells, characterised by the t(14;18) translocation leading to overexpression of BCL2. Clinically, it presents with painless lymphadenopathy and may include systemic symptoms. Histopathologically, FL exhibits a nodular growth pattern with centrocytes(Small cells with cleaved nuclei and scanty cytosol) and centroblasts(Larger cells with open nuclear chromatin, several nucleoli) Immunohistochemistry shows positivity for CD10/19/20, BCL2, and BCL6, and negativity for CD5. Management focuses on palliative approaches due to its indolent but incurable nature. Incorrect Options: t(2;5) (Option A): This translocation is associated with Anaplastic large cell lymphoma. It is seen in children or young adults. It is associated with an ALK gene mutation on chromosome 2. Histopathology reveals large anaplastic cells with horseshoe-shaped nuclei and voluminous cytoplasm (Hallmark cells/Doughnut cells). It usually presents with soft tissue involvement (mimicking metastatic carcinoma). t(8;14) (Option B): This translocation is associated with Burkitt's lymphoma. Histopathological examination reveals numerous mitotic and apoptotic cells, nuclear remnants phagocytosed by benign macrophages with abundant clear

cytoplasm, creating a characteristic "starry sky" pattern. Immunohistochemistry shows positivity for IgM, CD19, CD20, CD10, and BCL6, but negativity for BCL2. t(11;14) (Option D): This translocation is associated with Mantle cell lymphoma. Immunohistochemistry shows positivity for Cyclin D1, CD19, CD20, surface immunoglobulins (usually IgM and IgD), and CD5, but CD23 is negative and HPE shows small lymphoid cells with irregular nuclear outlines, condensed chromatin, and scanty cytoplasm

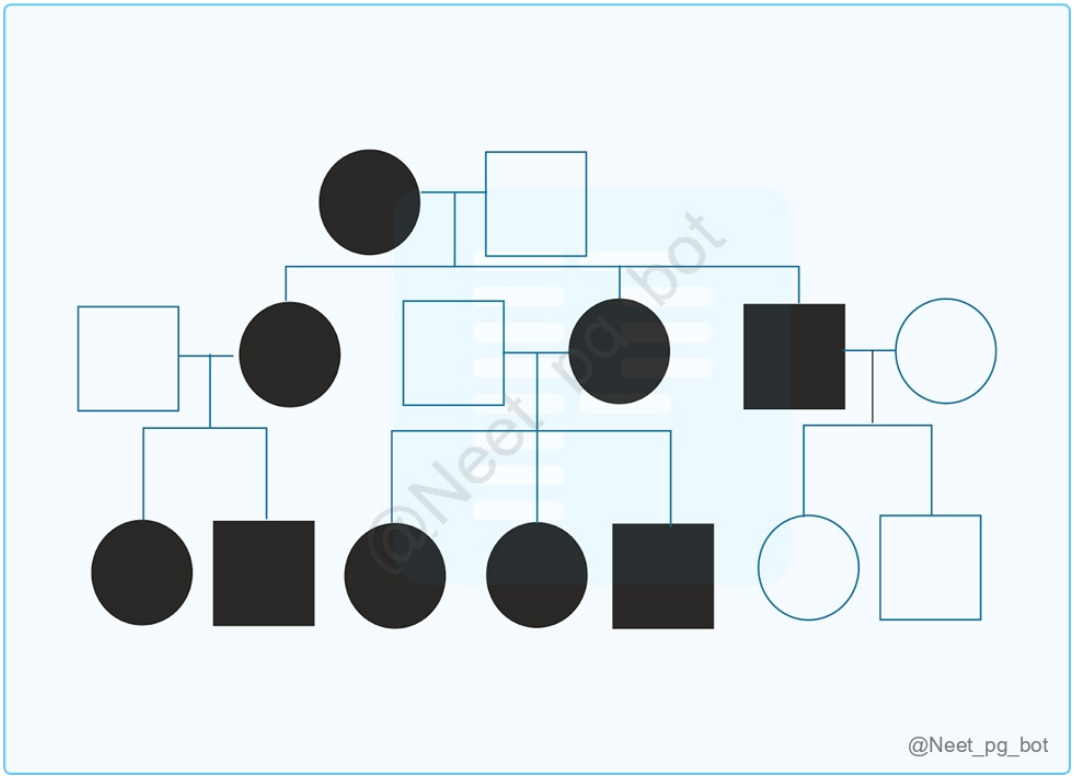
Q26: Which of the following diseases exhibits the inheritance pattern shown? (Q866378)

A. Kearns-Sayre syndrome

B. Williams syndrome

C. Achondroplasia

D. Cystic fibrosis



Correct Answer: A. Kearns-Sayre syndrome

Explanation: Kearns-Sayre syndrome follows mitochondrial inheritance, which matches the pedigree pattern shown. Key features of mitochondrial inheritance: Inherit exclusively through the maternal line Affected mothers pass the trait to ALL of their children (both male and female) Affected fathers pass the trait to NONE of their children The trait appears in every generation through maternal lines Both sexes can be affected, but only females transmit the condition Incorrect Options Option C) Achondroplasia - Incorrect ; Inheritance pattern: Autosomal dominant. While autosomal dominant traits do appear in every generation, they show transmission from BOTH affected mothers and affected fathers to their children. In this pedigree, the pattern specifically shows maternal-only transmission, which rules out autosomal dominant inheritance. Option B) Williams Syndrome -

Incorrect; Inheritance pattern: Typically sporadic (de novo deletions on chromosome 7). Williams syndrome is rarely inherited in a familial pattern. It usually occurs as a new mutation in an individual, not passed through multiple generations as shown in this pedigree. The consistent multi-generational pattern here is inconsistent with sporadic occurrence. Option D) Cystic Fibrosis - Incorrect; Inheritance pattern: Autosomal recessive. Autosomal recessive conditions skip generations and typically show two unaffected parents producing affected children. This pedigree shows affected individuals in consecutive generations with clear vertical transmission, which is incompatible with recessive inheritance.

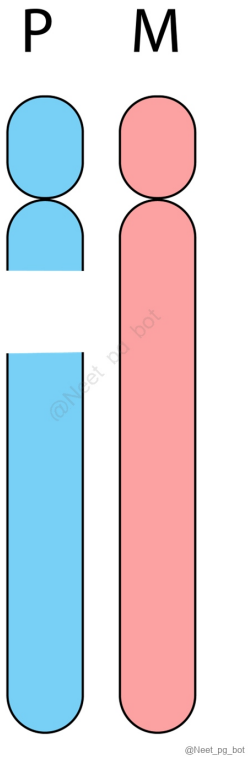
Q28: Identify the syndrome associated with the following chromosomal pattern on chromosome number 15 : (Q843980)

A. Angelman syndrome

B. Prader-Willi syndrome

C. Rett syndrome

D. Cri-du-chat syndrome



Correct Answer: B. Prader-Willi syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given image shows a part of paternal chromosome 15 deleted, which is seen in Prader-Willi syndrome. Prader Willi Syndrome In Prader-Willi syndrome, maternal imprinting is done, and paternal deletion

happens. Clinical features: Mental Retardation Short Stature Obesity/hyperphagia (because of an increase in the hormone called Ghrelin) Incorrect Options: Angelman syndrome (Option A): In Angelman syndrome, the maternal region of chromosome 15 is deleted. Rett Syndrome (Option C): Caused by mutation in the MECP2 gene Chromosomal Location: X chromosome (Xq28) Type of Abnormality: Single-gene mutation (not a chromosomal structural abnormality) Cri du Chat Syndrome (Option D): Cause: Deletion of the short arm of chromosome 5 Chromosomal Abnormality: 46,XX or 46,XY, del(5p)

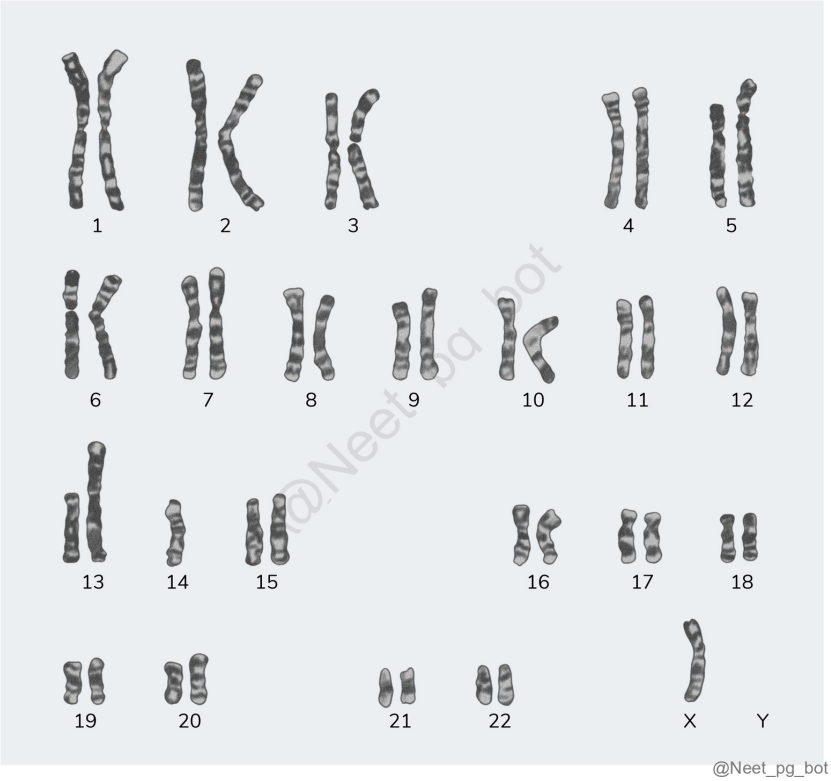
Q29: A 23-year-old female with a height of 4 feet has a karyotype, as shown in the image below. Which of the following conditions is the most likely etiology? (Q844074)

A. Turner syndrome

B. Klinefelter syndrome

C. Mayer-Rokitansky-Küster-Hauser syndrome (MRKHS)

D. Edwards syndrome



Correct Answer: A. Turner syndrome

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The given karyotype shows an absence of the Y chromosome and monosomy of the X chromosome, which is seen in Turner syndrome. Turner's Syndrome Pathogenesis: Either 45 X0 (deleted) or 46 Xr(X) (Ring Chromosome) In Turner's Syndrome, the IQ is normal. Patients with higher webbing of the neck have higher chances of cardiac symptoms. Clinical features: Incorrect Options: Klinefelter syndrome (Option B): In Klinefelter syndrome, an extra X chromosome is present. Mayer-Rokitansky-Küster-Hauser syndrome (MRKHS) (Option C): Mayer-Rokitansky-Küster-Hauser syndrome is characterized by the failure of the uterus and the vagina to develop properly in women who have normal ovarian function and normal external genitalia. Edwards syndrome (Option D): In Edwards syndrome, there is trisomy of chromosome 18.

@Neet_pg_bot

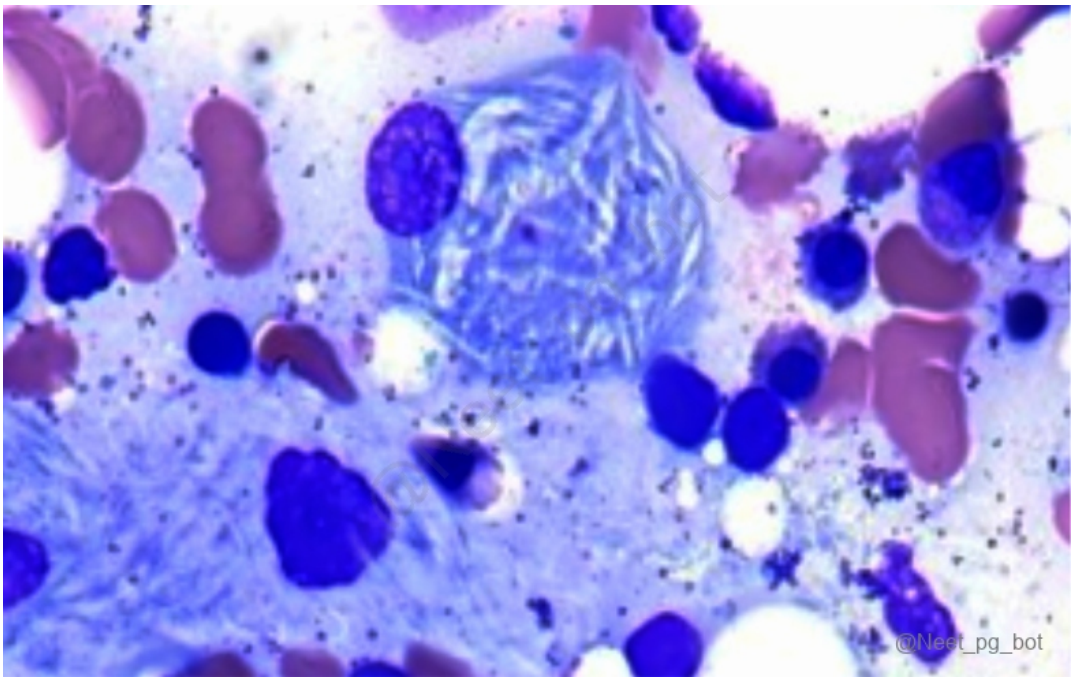
Q30: Identify the disease associated with the image provided: (Q844143)

A. Gaucher's disease

B. Tay-Sachs disease

C. Sandhoff's disease

D. Fabry's disease



Correct Answer: A. Gaucher's disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The image shows a Gaucher cell, which is a lipid-laden macrophage. Cytoplasm has a crumpled tissue paper appearance, characteristic of Gaucher's disease. It is caused by deficiency of β-glucocerebrosidase. This leads to accumulation of glucocerebroside in macrophages. Common sites:Bone marrow, spleen, liver. Clinical features include hepatosplenomegaly, anemia,bone pain. Incorrect Options: Option B) Tay-Sachs disease: Shows cherry-red spot on macula, no hepatosplenomegaly. Neurons are affected, not macrophages. Option C) Sandhoff's disease: Similar to Tay-Sachs but with hepatosplenomegaly. Still no Gaucher cells or tissue-paper macrophages. Option D) Fabry's disease: X-linked disorder with angiokeratomas and renal failure. No characteristic macrophages in bone marrow.

@Neet_pg_bot

Q32: The SRY gene is present on: (Q857449)

A. Y-chromosome short arm

B. Y-chromosome long arm

C. X-chromosome short arm

D. X-chromosome long arm

Correct Answer: A. Y-chromosome short arm

Explanation: The SRY (Sex-determining Region Y) gene is crucial for male sex determination. It is located on the distal short arm of the Y chromosome. Yp11.3 is the precise genetic locus where "Yp" refers to the short arm ("p") of the Y chromosome. Mutations in this gene can lead to disorders of sex development (DSDs), such as Swyer syndrome (46, XY gonadal dysgenesis) . Y-chromosome long arm (Option B) is rich in genes related to male reproductive functions, but the SRY gene is located on the short arm (Yp). X-chromosome short arm (Option C) & X-chromosome long arm (Option D): The X chromosome plays no role in initiating male sex determination . Instead, it carries genes like DAX1 (Xp21), which antagonizes SRY function , and XIST (Xq13), which regulates X-inactivation .

@Neet_pg_bot

Q33: Which mutation is linked to the Philadelphia chromosome? (Q860544)

A. Inversion

B. Deletion

C. Reciprocal translocation

D. Insertion

Correct Answer: C. Reciprocal translocation

Explanation: The Philadelphia Chromosome is a reciprocal translocation involving chromosomes 9 and 22 that is commonly identified in CML (chronic myeloid leukaemia). The two chromosome breaks lie within: ABL gene on chromosome 9 BCR (breakpoint cluster region) gene on chromosome 22. Nonhomologous end-joining causes a reciprocal translocation , resulting in the formation of an oncogenic BCR-ABL fusion gene on the derivative chromosome 22, known as the Philadelphia chromosome. BCR-ABL fusion genes encode chimeric BCR-ABL proteins with constitutive tyrosine kinase activity. Inversion (Option A): In an inversion, a segment of a chromosome is flipped within the same chromosome but remains in its original location. Example of inversion-related disorder: Hemophilia A (due to intrachromosomal inversion in the F8 gene). Deletion (Option B) involves the loss of a chromosome segment, leading to missing genetic material. Example of deletion-related disorder: Cri-du-chat syndrome (chromosome 5p deletion) Insertion (Option D) occurs when a segment of one chromosome is inserted into another chromosome without reciprocal exchange. Example of insertion-related disorder: Some cases of hereditary cancer syndromes due to gene insertions.

@Neet_pg_bot

Q34: A teenager was brought to the OPD with complaints of delayed fertility and primary amenorrhea. Physical examination reveals a webbed neck and widely spaced nipples. Which karyotype is associated with a given condition? (Q860555)

A. 45, X

B. 47, XXY

C. 47, XXX

D. 47, XYY

Correct Answer: A. 45, X

Explanation: The teenager presenting with delayed fertility, primary amenorrhea, a webbed neck, and widely spaced nipples is diagnosed with Turner Syndrome , which is characterised by the karyotype 45, X (monosomy X) . It is characterised by complete or partial monosomy of the X chromosome, leading to hypogonadism in phenotypic females. Clinical features: Short stature, webbed neck, lymphedema, and primary amenorrhea. The image below shows karyotyping in Turner syndrome. {{caption_text}} 47, XXY (Option B) is Klinefelter syndrome , which occurs in males with an extra X chromosome, leading to hypogonadism, small testes, gynecomastia, reduced body/facial hair, and infertility. While it is associated with tall stature and sometimes mild intellectual disabilities, it does not present with features like a webbed neck, widely spaced nipples, or primary amenorrhea, which are characteristic of Turner syndrome. 47, XXX (Option C) is Triple X Syndrome , which occurs in females with an extra X chromosome. It is usually asymptomatic or causes mild developmental delays but does not present with primary amenorrhea or webbed neck, which are typical of Turner syndrome. 47, XYY (Option D) is Jacob's Syndrome , which occurs in males with an extra Y chromosome, leading to tall stature and mild intellectual disabilities, but it does not cause primary amenorrhea, webbed neck, or widely spaced nipples, which are characteristic of Turner syndrome.

@Neet_pg_bot

Q35: Which of the following is not a feature of G6PD deficiency? (Q840016)

A. Males and females are equally affected

B. Oxidative stress

C. Absence of NADPH

D. Presence of Heinz's bodies

Correct Answer: A. Males and females are equally affected

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Correct Option A - Males and females are equally affected: G6PD deficiency, being a recessive X-linked trait, puts males at a significantly higher risk of symptomatic disease compared to females. T Incorrect Options: Option B, C, and D: In G6PD deficiency, NADPH does not form, and the glutathione pathway does not occur. This leads to an increase in the concentration of free radicals (oxidative stress). Oxidative stress causes the denaturation of hemoglobin and leads to the formation of Heinz bodies.

@Neet_pg_bot

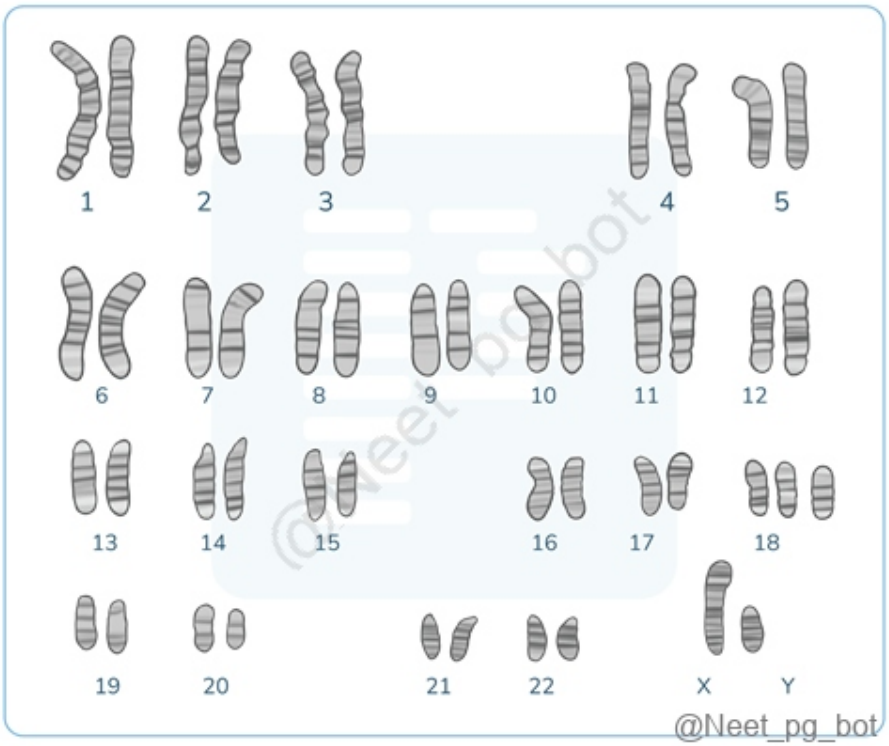
Q36: A child with a strawberry skull, mental retardation, and the given karyotype suggests which diagnosis? (Q860199)

A. Patau syndrome

B. Edward syndrome

C. Prader-Willi syndrome

D. Angelman syndrome



Correct Answer: B. Edward syndrome

Explanation: A child with a "strawberry skull," intellectual disability, and the given karyotype likely has trisomy 18 , indicating a diagnosis of Edwards Syndrome . It is caused by the presence of an extra copy of chromosome 18. Clinical features: Low birth weight Strawberry skull (small chin & prominent occiput/back side of the head). Closed fists with overlapping fingers Rocker-bottom feet Microcephaly Micrognathia Cardiac and renal malformations Mental retardation 95% of cases die in the 1st year of life Patau syndrome (Option A) , caused by trisomy 13 , is characterised by features such as polydactyly (extra fingers), cleft lip and palate, keyhole-shaped pupils/coloboma, intellectual disability, and patent ductus arteriosus (PDA), among others. Prader-Willi syndrome (Option C) occurs when there is maternal disomy of chromosome 15, leading to the absence of the paternal allele. Key features include intellectual disability (MR), short stature, and obesity/hyperphagia due to elevated levels of the hormone ghrelin. Angelman syndrome (Option D), often referred to as "Happy Puppet" syndrome , arises when there is a paternal disomy of chromosome 15, leading to the absence of the maternal allele. Key features include seizures, ataxia, intellectual disability (MR), and inappropriate laughter.

@Neet_pg_bot

Q37: All of the following are used to detect abnormal gene sequences, except? (Q857421)

A. FISH

B. RFLP analysis

C. Pyrosequencing

D. Flow cytometry

Correct Answer: D. Flow cytometry

Explanation: Flow cytometry is not used to detect abnormal gene sequences . Flow cytometry is a technique primarily used to measure the physical and chemical properties of cells, such as cell size, granularity, and protein

expression. It has numerous uses in genomic studies, with a high focus on monitoring cell cycle phases and cell viability, and is more often employed for immunophenotyping and cell sorting. Fluorescence in situ Hybridization (FISH) (Option A) detects DNA sequence alterations like translocations, deletions, and amplifications using fluorescent probes to bind specific DNA regions, identifying chromosomal abnormalities. RFLP analysis (Option B) (Restriction Fragment Length Polymorphism) detects DNA sequence variations by analyzing the lengths of restriction enzyme-digested DNA fragments. Pyrosequencing (Option C) is a type of DNA sequencing technology that can directly read DNA sequences by measuring the release of pyrophosphate during nucleotide incorporation. It allows for the detection of mutations, SNPs, and other genetic alterations.

@Neet_pg_bot

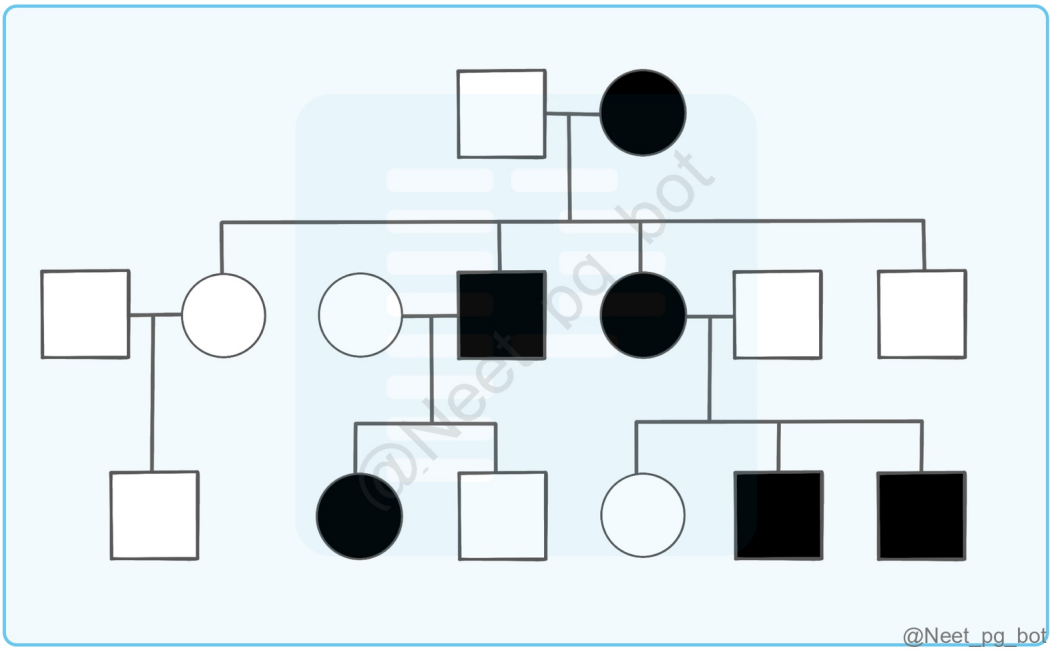
Q38: What is the interpretation of the given pedigree chart? (Q857425)

A. Incomplete penetrance

B. Autosomal dominant

C. Autosomal recessive

D. Pseudo-dominance



Correct Answer: B. Autosomal dominant

Explanation: The interpretation of the pedigree chart given reveals Autosomal dominant inheritance , which means that an individual only needs one copy of the mutated gene to express the condition. The affected individuals appear in every generation, as one parent passes on the mutated gene to their offspring. Both males and females can be affected equally because the gene is located on one of the autosomes . If an affected person has children, there is a 50% chance that each child will inherit the mutated gene and be affected. Incomplete penetrance (Option A) refers to a situation where some individuals inherit the mutant gene but are phenotypically normal. Autosomal Recessive (Option C) inheritance requires two copies of the mutation for the trait to be expressed. It typically shows horizontal transmission and can skip generations. Pseudo dominance (Option D) occurs when a recessive allele appears to be expressed in the heterozygous condition due to the limited number of crossovers between linked genes.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q39: Match the following genetic abnormalities with their disorders. A. Trinucleotide repeat Patau syndrome B. Trisomy 18 2. Huntington C. Trisomy 13 3. Sickle cell anemia D. Hb beta chain Glu 4. Edward syndrome (Q857437)

A. A-1, B-3, D-4, D-2

B. A-1, B-2, C-3, D-4

C. A-2, B-4, C-1, D-3

D. A-2, B-1, C-4, D-3

Correct Answer: C. A-2, B-4, C-1, D-3

Explanation: Trinucleotide repeat Huntington Trisomy 18 Edward syndrome Trisomy 13 Patau syndrome Hb beta chain Glu Sickle cell anemia Trinucleotide repeat disorders : These are caused by the expansion of specific three-nucleotide sequences in genes. They are characterized by the instability of repeat numbers, which can increase across generations or even within an individual’s lifetime, a key feature of these conditions. Examples of Trinucleotide repeat and the disease-associated are: Huntington's disease: CAG Fragile X syndrome: CGG Myotonic dystrophy type 1: CTG Trisomy 18 (Edward syndrome): Features include Low birth weight Closed fists with overlapping fingers Rocker-bottom feet Microcephaly Micrognathia Cardiac and renal malformations Mental retardation 95% of cases die in the 1st year of life Trisomy 13 (Patau Syndrome): Features include Rocker-bottom feet Severe intellectual disability Keyhole/ Coloboma (eyes) Microphthalmia, microcephaly, holoprosencephaly Cleft lip/palate Polydactyly Congenital heart disease Renal defects-Polycystic kidney disease Umbilical hernia, Omphalocele Hb beta chain Glu This mutation is seen in sickle cell anaemia and produces haemoglobin S (HbS), making red blood cells prone to hemolysis. This leads to complications such as splenic fibrosis, organ infarcts, and bone pain due to HbS polymerization and vaso-occlusion.

@Neet_pg_bot

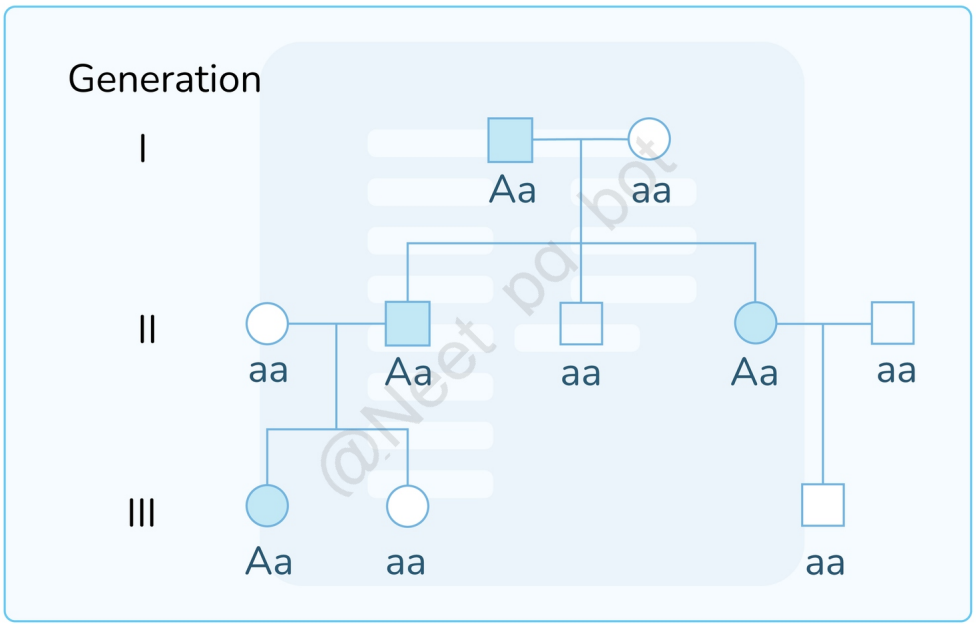
Q40: The family pedigree chart is given below. Identify the mode of inheritance of this condition. (Q854889)

A. Autosomal dominant

B. Autosomal recessive

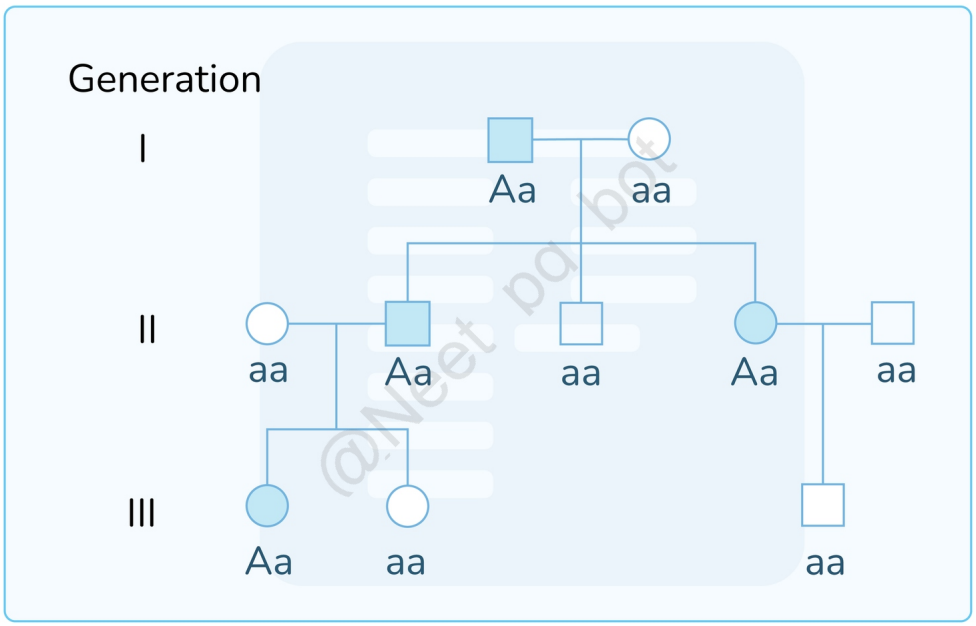
C. X-linked dominant

D. X-linked recessive



Correct Answer: A. Autosomal dominant

Explanation: The disorder appears in every generation, showing vertical transmission, which strongly suggests an autosomal dominant pattern. Both males and females are affected, excluding sex-linked patterns. An affected father passing the condition to his son rules out X-linked inheritance (X-linked disorders cannot show father-to-son transmission). The pedigree shows affected individuals as Aa, a classic representation for heterozygous dominant. {{caption_text}} Incorrect Options: Option B) Autosomal recessive - Usually skips generations (affected parents often unaffected carriers), which the pedigree does not show; here affected individuals appear in every generation. Option C) X-linked dominant - Would show mother-to-child transmission from affected mothers to sons and daughters, but an affected father passing to a son (seen here) rules this out. Option D) X-linked recessive - Typically more males affected and affected males usually inherit from carrier mothers; here both sexes are similarly affected and the pattern is vertical, not the expected X-linked recessive pattern.



@Neet_pg_bot

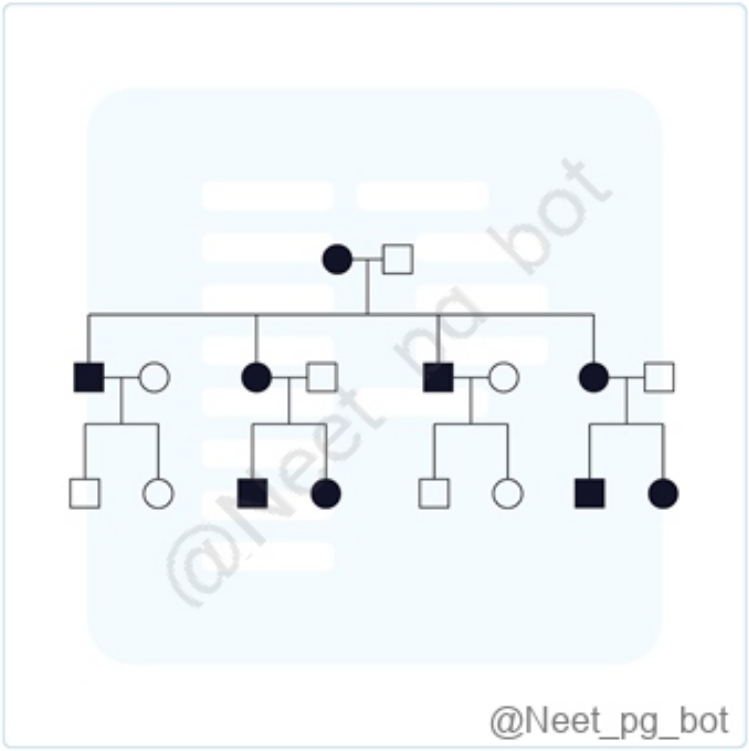
Q42: What does the given pedigree chart indicate? (Q860176)

A. Autosomal Dominant (AD)

B. Autosomal Recessive (AR)

C. Mitochondrial Disorder

D. X-linked Recessive (XLR)



Correct Answer: C. Mitochondrial Disorder

Explanation: The given pedigree suggests a Mitochondrial Disorder , where a defect in maternal mtDNA is inherited by all offspring, while a defect in paternal mtDNA is not passed on to any offspring. They involve

defects in the mitochondria, which are responsible for producing energy in the form of ATP through oxidative phosphorylation. Mitochondrial DNA (mtDNA) is inherited exclusively from the mother (females with pathogenic mtDNA can pass the disease to their offspring). They affect organs with prominent aerobic metabolism (commonly skeletal muscle (myopathy) and nervous system). Some examples are: Leber hereditary optic neuropathy (LHON) Chronic progressive external ophthalmoplegia (CPEO)/ Kearns-Sayre syndrome (KSS) Leigh syndrome Mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) Myoclonic epilepsy with ragged red fibres (MERRF) Neuropathy, ataxia, and retinitis pigmentosa (NARP) Primary coenzyme Q10 (CoQ10) deficiency The most common mitochondrial disease is MELAS. The most common mitochondrial Myopathy is CPEO (Chronic Progressive External Ophthalmoplegia). Autosomal Dominant (AD) (Option A) inheritance follows a vertical transmission pattern , where an affected individual has an affected parent, and there is a 50% chance of passing the dominant trait to offspring, with both males and females equally affected. Autosomal Recessive (AR) (Option B) inheritance shows horizontal transmission , with the trait appearing in siblings while parents are unaffected, often in consanguineous marriages. Carriers have a 25% chance of an affected child, and males and females are equally affected. It includes most inborn errors of metabolism. X-linked Recessive (XLR) (Option D) inheritance means females (XX) are carriers, while males are affected by the disease.

@Neet_pg_bot

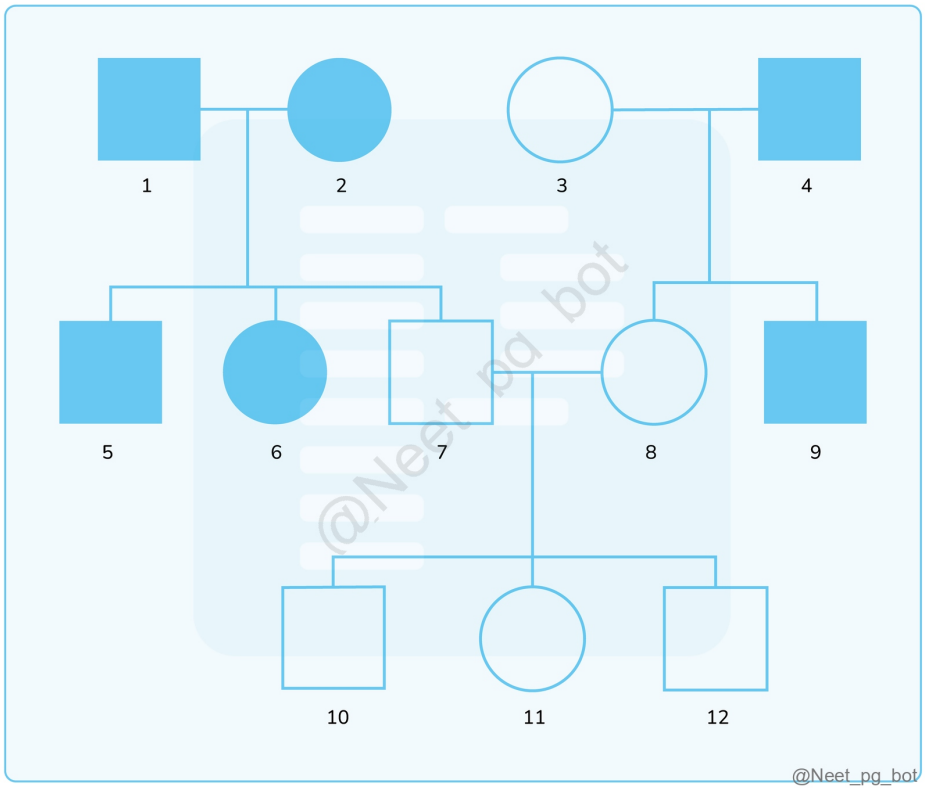
Q43: What is the interpretation of the given pedigree chart? (Q858065)

A. Autosomal dominant

B. Autosomal recessive

C. X-linked recessive

D. X-linked dominant



Correct Answer: A. Autosomal dominant

Explanation: The interpretation of the pedigree chart given reveals Autosomal dominant inheritance , which means that an individual only needs one copy of the mutated gene to express the condition. Affected individuals appear in every generation, as one parent passes on the mutated gene to their offspring. Both males and females can be affected equally because the gene is located on one of the autosomes . If an affected person has children, there is a 50% chance that each child will inherit the mutated gene and be affected. Autosomal Recessive (Option B) inheritance is where the Individuals usually do not express the trait unless they inherit two copies of the mutation . This inheritance pattern typically has horizontal transmission and skip generations in between. X-linked recessive (Option C) disorders affect males more than females because males have only one X chromosome. Females need

two copies of the mutation to be affected. Additionally, X-linked recessive disorders often show a pattern where affected males pass the mutated gene to all their daughters but none of their sons. X-linked dominan t (Option D) inheritance means an affected female can pass the condition to both sons and daughters, while an affected male passes it to all daughters but none of his sons. The question contradicts this pattern, so X-linked dominant is not the correct answer.

Q1: A biopsy from a rapidly enlarging thigh mass in a 35-year-old man reveals a malignant tumor composed of spindle-shaped cells arising from mesenchymal tissue. Which of the following is the most appropriate designation for this neoplasm? (Q879697)

A. Adenocarcinoma

B. Lymphoma

C. Sarcoma

D. Papilloma

Correct Answer: C. Sarcoma

Explanation: Since the origin is mesenchymal, the neoplasm is a sarcoma Sarcomas are malignant tumors that arise from solid mesenchymal tissues (e.g., bone, cartilage, fibrous tissue, muscle, fat, blood vessels). Naming pattern: The cell/tissue of origin is prefixed (e.g., fibrosarcoma from fibrous tissue, chondrosarcoma from cartilage). Spread: Sarcomas typically spread hematogenously (via blood) Incorrect Options: Adenocarcinoma (Option A) and Papilloma (Option D) have epithelial origin. Lymphoma (Option B) has a lymphoid cell origin

https://www.ncbi.nlm.nih.gov/books/NBK519533/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following statements best characterizes a hamartoma? (Q879693)

A. Malignant neoplasm composed of immature, non-native cells

B. Disorganized but benign proliferation of mature, native cells within an organ

C. Developmental cyst always present from birth and never clonal

D. Metastatic lesion that reproduces the normal architecture of the tissue

Correct Answer: B. Disorganized but benign proliferation of mature, native cells within an organ

Explanation: Hamartomas are disorganized masses of mature cells and tissues native to the organ of origin, but lacking the normal architecture. Once thought to be developmental malformations, many are now recognized as benign neoplasms with clonal chromosomal aberrations. Examples: hemangiomas, lymphangiomas, rhabdomyomas, adenomas of the liver, and some developmental cysts. Despite being benign, they can cause clinical problems depending on their size and location.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 238, 432

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 4-year-old child presents with an abdominal mass. Biopsy shows a poorly differentiated neoplasm composed of uniform, undifferentiated cells with scant cytoplasm and hyperchromatic nuclei, giving a “small round blue cell” appearance. Which of the following tumors is not typically classified under the group of small round blue cell tumors of childhood?’ (Q879691)

A. Neuroblastoma

B. Wilms tumor

C. Medulloblastoma

D. Hepatoblastoma

Correct Answer: D. Hepatoblastoma

Explanation: Hepatoblastoma is not a small round blue cell tumor; it shows epithelial and/or mixed epithelial-mesenchymal differentiation rather than primitive undifferentiated cells. The classic group of small round blue cell tumors of childhood includes neuroblastoma, Wilms tumor , lymphoma, rhabdomyosarcoma, Ewing sarcoma, medulloblastoma, and retinoblastoma. They are called so because of their primitive histologic appearance. HPE of Wilms Tumor

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 434

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following statements about adenomas is correct? (Q879679)

A. Adenoma refers only to benign epithelial tumors that form true glandular structures.

B. Adenoma can refer to benign epithelial tumors of glandular origin, even if they do not form glands

C. Adenoma is a term used for malignant tumors of glandular epithelium

D. Adenoma refers exclusively to tumors of the adrenal cortex

Correct Answer: B. Adenoma can refer to benign epithelial tumors of glandular origin, even if they do not form glands

Explanation: Adenoma is a benign epithelial neoplasm derived from glandular tissue. Tumor cells do not need to form true glandular structures to be called adenomas. Examples: Renal tubular adenoma: Forms tightly clustered

glands. Adrenal cortical adenoma: Grows as a solid sheet without forming glands. The classification depends on the origin from glandular epithelium, not the microscopic appearance. Adenomas are non-invasive and do not metastasize, distinguishing them from adenocarcinomas (malignant glandular tumors).

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 237

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 55-year-old patient is diagnosed with a tumor. Histopathology shows uncontrolled proliferation, invasion into adjacent structures, and the presence of cells with variable differentiation. Which of the following features is the most definitive indicator of malignancy in this tumor? (Q879673)

A. Presence of mitotic figures

B. Tissue of origin identifiable as epithelial

C. Ability to invade surrounding tissues

D. Formation of glandular patterns in some areas

Correct Answer: C. Ability to invade surrounding tissues

Explanation: While mitotic figures, tissue type, and differentiation patterns provide supportive information, the defining feature of malignancy is the ability of the tumor to invade adjacent structures.. Malignancy features: Invasion of adjacent structures - Malignant tumors can infiltrate and destroy nearby tissues. Metastasis - Ability to spread to distant sites. Uncontrolled growth - Rapid and disorganized proliferation of cells. Variable differentiation - Cells may resemble the tissue of origin (well-differentiated) or may lose normal features (poorly differentiated/undifferentiated).

@Neet_pg_bot

Q7: Which of the following is true regarding the Sentinel lymph node? (Q845146)

A. The first lymph node to receive metastasis from a secondary tumour.

B. Also helpful in identifying metastasis in Melanoma.

C. Commonly involved in skip metastasis

D. The presence of cancer cells indicates a good prognosis

Correct Answer: B. Also helpful in identifying metastasis in Melanoma.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Sentinel lymph node (SLN): The first lymph node to receive drainage from a primary tumor site. Example: In breast cancer, usually axillary lymph node is the first lymph node where the lymphatics are drained. Hence, it is the sentinel lymph node. Sometimes, cancer may bypass the sentinel lymph node and spread directly to other lymph nodes. This can occur in patients who have received radiotherapy, as radiation can cause fibrosis and blockage of the lymphatic channels. If the pathway to the sentinel node is obstructed, tumour cells are diverted to alternative routes, resulting in what is known as skip metastasis . Tumors where SLN biopsy is validated are Breast cancer, Melanoma, Vulvar cancer, and Colon cancer. Sentinel Lymph Node (SLN) identification techniques: Gold Standard: Dual Technique (Radioisotope + Blue Dye) – 95-98% detection rate 1. Radioactive Tracer (Lymphoscintigraphy): Agent: A radioactive isotope, most commonly Technetium-99m labeled sulfur colloid. Procedure: The tracer is injected peritumorally or intradermally near the biopsy site. Detection: A handheld gamma probe is used during surgery to locate the "hot" node emitting the highest radioactivity. Pre-operative Imaging: Static images (lymphoscintigrams) are often taken before surgery to map the lymphatic flow and the approximate location of the nodes. 2. Blue Dye Visualization: Agent: Isosulfan blue or Methylene blue . Procedure: The dye is injected near the tumor site shortly before or during the start of the operation. Detection: The surgeon visually inspects the lymphatic channels during dissection; the sentinel node will be stained blue . 3. Combined Technique (The "Gold Standard") : The use of both the radioactive tracer and the blue dye is the preferred method, as it provides both an auditory/numerical guide (the gamma probe) and a visual guide (the blue color). A node is considered "sentinel" if it is: Blue-stained. "Hot" (radioactivity >10% of the most radioactive node). Palpably suspicious (firm or enlarged, even if not hot or blue). Step-by-Step Intraoperative Dual Technique (Breast/Melanoma): Preoperative lymphoscintigraphy (99mTc) Intraop: Inject blue dye peritumorally Incise over "hot spot" (gamma probe) Dissect along blue channel → first blue + hot node Confirm: Probe counts drop >90% after excision The first lymph node to receive metastasis from a secondary tumour (Option A): Sentinal lymph node is the first lymph node to receive drainage from a primary tumor site. Commonly involved in skip metastasis (Option C): Skip metastasis is not a very common phenomenon; it's rather rare. The presence of cancer cells indicates a good prognosis (Option D): Cancer spreading to the sentinel or any other lymph node is always a bad prognosis.

@Neet_pg_bot

Q8: Which of the following tumors do not follow lymphatic route of spread? (Q845145)

A. Rhabdomyosarcoma

B. Krukenberg tumor

C. Follicular thyroid carcinoma

D. Synovial sarcoma

Correct Answer: C. Follicular thyroid carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hematogenous spread Lymphatic spread Transcoelomic spread Veins are more prone to invasion than arteries due to their thinner walls. Tumours use existing lymphatic vessels at their margins. Follows natural routes of lymphatic drainage. Invades the serosal wall of the coelomic cavity, releasing tumour fragments into coelomic fluid, which is implanted elsewhere in the body cavity. Seen in most of the sarcomas. Seen in most carcinomas. Krukenberg tumour is a metastatic tumour to the ovary that can show lymphatic or transcoelomic spread. (Option B) Exceptions: Synovial sarcoma (Option D) Rhabdomyosarcoma (Option A) These tumours are spread by the lymphatic route. Exceptions: HCC RCC Follicular carcinoma of the thyroid (Option C) These tumours are spread by a hematogenous route.

References:

Robbins and Cotrans Pathologic basis of disease 10th edition, page 274, 275

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following tumours do not typically exhibit direct seeding of body cavities? (Q845144)

A. Pseudomyxoma peritonei

B. Gastric carcinoma

C. Hepatocellular carcinoma

D. Medulloblastoma

Correct Answer: C. Hepatocellular carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hepatocellular carcinoma typically exhibits metastasis by hematogenous spread rather than direct seeding of body cavities. Direct Seeding of Body Cavities or Surfaces: Pseudomyxoma peritonei (Option A) is

characterized by the presence of a gelatinous neoplastic mass filling the peritoneal cavity arising from the rupture of mucin-secreting adenocarcinoma of the appendix (most common cause) or mucin-secreting adenocarcinoma of ovarian. Gastric carcinoma (Option B) can spread to the distal end of the peritoneal cavity (Pouch of Douglas) and is known as the 'Blummer shelf.' Medulloblastoma (Option D) from the cerebellum spreads to the spinal cord by 'Drop metastasis.'

Robbins and Cotrans Pathologic basis of disease, 10th edition, Pages 273, 274

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 45-year-old female presents with a palpable lump in her left breast which is freely mobile and painless. A biopsy of the lump was performed, and a histopathological examination was done. Which feature from the biopsy report is most likely to differentiate between benign and malignant breast lesions? (Q845134)

A. Presence of well-defined glandular structures

B. Evidence of invasion into surrounding tissues

C. Low mitotic rate

D. Presence of fibrous stroma

Correct Answer: B. Evidence of invasion into surrounding tissues

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: We differentiate benign and malignant tumours based on whether the basement membrane is intact or broken: In benign tumours: The basement membrane is completely intact and normal. In malignant tumours: The basement membrane is broken, so the cancer cells can invade surrounding tissues. Feature Benign Lesions Malignant Lesions Growth Localised Invasive (Option B) Microscopic Appearance Resemble normal tissue and maintain differentiated features. (Option A) Cellular atypia , mitotic figures, loss of tissue organisation. Macroscopic Appearance Well-defined borders Irregular borders, necrosis, hemorrhage. Histological Features Cells are typically uniform in size and shape, with minimal nuclear atypia and low mitotic rate. (Option C) Cells may display pleomorphism, increased nuclear-to-cytoplasmic ratio, high mitotic rate, and evidence of invasion or metastasis.

Robbins and Cotran's Pathologic basis of disease 10th edition, page 268

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following characteristics distinguishes hemangiomas from other benign tumors? (Q845141)

A. Rapid growth rate

B. Presence of extracellular matrix (ECM) deposited by stromal cells

C. Easily resected by excision

D. Unencapsulated

Correct Answer: D. Unencapsulated

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A hemangioma is a benign vascular tumour caused by an abnormal overgrowth of blood vessels that is distinguished from other benign tumours by: Lack of well-defined capsule (Hemangiomas are uncapsulated). Tendency to permeate the site of origin making it difficult for surgical excision. Rapid growth rate (Option A): The rapid growth rate is a feature of malignant tumors, not benign tumors which grow slowly and localized to the site of origin. Presence of extracellular matrix (ECM) deposited by stromal cells (Option B): Benign tumours usually has a capsule, which consists of an extracellular matrix (ECM) deposited by stromal cells such as fibroblasts. Since hemangioma is unencapsulated, it is not associated with the deposition of extracellular matrix by stromal cells. Easily resected by excision (Option C): Encapsulation makes benign tumours easily resectable but since hemangiomas are unencapsulated ,they permeate site of origin making it difficult to resect. Some important exceptions: Feature General Rule Exceptions (The Outliers) Capsule Benign tumors are encapsulated. Hemangiomas , Lipomas (occasionally), and Leiomyomas (of the uterus) are often unencapsulated or poorly circumscribed. Metastasis Malignant tumors metastasize. Basal Cell Carcinoma (skin) and Gliomas (brain) are highly invasive but rarely metastasize. Growth Rate Benign is slow; Malignant is fast. Leiomyomas (benign) can grow rapidly during pregnancy due to estrogen; some low-grade cancers grow very slowly. Well-Defined Malignant tumors are poorly defined/invasive. Follicular Thyroid Carcinoma can appear well-encapsulated, making it hard to distinguish from an adenoma without seeing capsular invasion.

Q12: Which of the following statements is/are True? The basement membrane remains intact in dysplasia. Dysplasia is always irreversible. Pleomorphism is observed in metaplasia. Myositis ossificans is an example of dysplasia. (Q845140)

A. 1, 3 and 4

B. 1 only

C. 2 and 4

D. 1, 2 and 3

Correct Answer: B. 1 only

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Feature Metaplasia Dysplasia Anaplasia Definition Differentiated cell type (epithelial or mesenchymal) is replaced by another cell type Disordered growth and loss of architectural orientation of cells Lack of cellular differentiation and organisation Nature (Statement 2) Adaptive response to stress or injury Preneoplastic Associated with malignant transformation Reversibility Reversible Reversible in early stages (irreversible if whole the epithelium is involved) Irreversible Pleomorphism (Statement 3) Absent Present in low-grade Present in high-grade Nuclear-to-cytoplasmic ratio Normal (1:4 to 1:6) Increased (↑) Increased (↑↑↑) Mitotic figures Absent/minimal at normal places Typical mitotic figures present at abnormal places Atypical, bizarre mitotic figures present at abnormal places Basement membrane integrity Intact Intact Breached Example (Statement 4) Barret's oesophagus, myositis ossificans Cervical dysplasia of squamous cells Carcinoma of the cervix, carcinoma oesophagus

References:

Robbins and Cotrans Pathologic basis of disease 10th edition, Page 270-272

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following features is not a characteristic of anaplasia? (Q845139)

A. Pleomorphism

B. Loss of polarity

C. Increased nuclear-to-cytoplasmic ratio

D. Intact basement membrane

Correct Answer: D. Intact basement membrane

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Differentiation between precancer and cancer is based on the basement membrane. If the basement membrane is intact: Precancer/Dysplasia If the basement membrane is broken or breached: Cancer cells can invade into surrounding tissue and spread anywhere: Cancer/Anaplaisa Image showing Mitosis: Mercedes Benz sign Image showing Mitosis: Starburst mitosis Anaplasia and Dysplasia common points: Pleomorphism: Both conditions exhibit cells that vary in size and shape. Nuclear Abnormalities: Both show hyperchromatic (darkly staining) nuclei that are larger than normal. Increased Mitosis: Both demonstrate a higher-than-normal rate of cell division. Atypical Morphology: Both involve a loss of the normal, organized appearance of the tissue of origin. Anaplasia and Dysplasia differentiating points: Feature Dysplasia Anaplasia Definition Disordered growth and maturation of an epithelium. Total lack of differentiation; a "formative backward" state. Clinical Status Pre-malignant (may or may not progress). Malignant (diagnostic hallmark of cancer). Reversibility Potentially reversible if the inciting stress is removed. Irreversible . Basement Membrane The basement membrane remains intact . Often associated with invasion through the basement membrane. N:C Ratio Increased, but usually less severe than anaplasia. Extreme increase; can approach a 1:1 ratio . Mitotic Figures Frequent, but usually follow normal spindle patterns. Atypical/Bizarre mitoses (e.g., tripolar or multipolar spindles). Examples CIN, Barrett's dysplasia Anaplastic carcinoma, sarcoma

@Neet_pg_bot

Q14: A 55-year-old man presents with chronic heartburn and difficulty swallowing. Upon examination, the physician suspects gastroesophageal reflux disease (GERD) and orders an upper GI endoscopic biopsy, which reveals the presence of columnar epithelium in the lower oesophagus, replacing the normal squamous epithelium. Which of the following terms describes the observed cellular change? (Q845138)

A. Metaplasia

B. Dysplasia

C. Anaplasia

D. Desmoplasia

Correct Answer: A. Metaplasia

- *Listen (English)*
- *Listen (Hindi)*

Explanation: This specific clinical scenario describes Barrett’s Esophagus , where chronic acid reflux causes the esophageal lining to transform to withstand the acidic environment. Metaplasia: Metaplasia is a reversible change in which one adult cell type (epithelial or mesenchymal) is replaced by another adult cell type. Mechanism: It is not a direct "transformation" of existing cells, but rather a reprogramming of stem cells to differentiate along a new pathway. Barrett's Esophagus: Chronic acid reflux causes the squamous lining to become columnar (intestinal metaplasia). Barrett's esophagus is a precancerous condition, and if not treated, it may turn into Adenocarcinoma of esophagus. Squamous Metaplasia: Occurs in the respiratory tract of chronic smokers, where ciliated columnar epithelium is replaced by stratified squamous epithelium. While tougher, this new tissue loses the ability to clear mucus. Connective Tissue Metaplasia: Formation of bone within soft tissue (e.g., myositis ossificans) following injury. Dysplasia (Option B): Dysplasia refers to disordered growth and is typically encountered in epithelial linings. Characteristics: It involves a loss of architectural uniformity and cellular orientation. Cells show pleomorphism (variation in size and shape) and have large, hyperchromatic nuclei. Mitotic Activity: Mitoses are more frequent than normal and may appear in unusual locations within the epithelium (e.g., in the upper layers of the skin). Pre-cancerous Nature: While dysplasia does not necessarily progress to cancer, it is often a precursor. If it involves the entire thickness of the epithelium but does not penetrate the basement membrane, it is termed Carcinoma in situ . Anaplasia (Option C): Anaplasia is defined as a lack of differentiation and is a hallmark of malignancy . Morphological Hallmarks: Pleomorphism: Extreme variation in cell size and shape. Abnormal Nuclear Morphology: Nuclei are disproportionately large, with a nuclear-to-cytoplasmic (N:C) ratio approaching 1:1 (normal is 1:4 or 1:6). Atypical Mitoses: Bizarre, tripolar, or multipolar mitotic spindles. Clinical Significance: The degree of anaplasia determines the grade of the tumor; highly anaplastic tumors are "high-grade" and typically very aggressive. Desmoplasia (Option D): Desmoplasia refers to the stromal (connective tissue) response rather than the epithelial cells themselves. Definition: It is the proliferation of non-neoplastic connective tissue (fibrosis) triggered by certain malignant tumors. Clinical Presentation: This reaction results in a "stony" or "scirrhous" consistency of a tumor. Classic Example: Invasive ductal carcinoma of the breast often shows a strong desmoplastic response, making the lump feel very hard and fixed on palpation.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 30-year-old female presents with pelvic pain and irregular menstrual cycles. She undergoes surgical resection of the mass, and histopathological examination reveals a tumour composed of mature tissues derived from multiple germ layers, including hair, teeth, and sebaceous material. Based on the histopathological findings described, which of the following tumours is the most likely diagnosis? (Q845137)

A. Teratoma

B. Serous cystadenoma

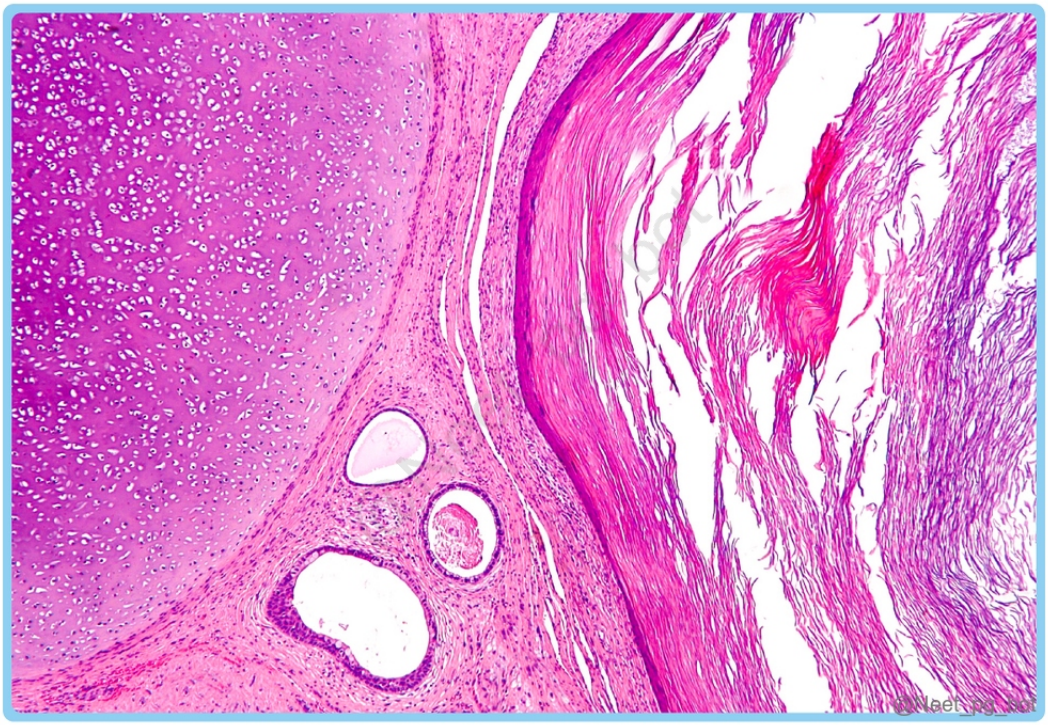
C. Mucinous cystadenoma

D. Granulosa cell tumour

Correct Answer: A. Teratoma

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Teratomas arise from 2 or more germ layers Teratomas are commonly seen in the ovaries, but can also be seen in other organs of the body. Teratomas are of 2 types: Mature teratoma: Benign and has all the mature tissues Immature teratoma: Has neuroepithelial cells and has the potential to cause cancer. Mature Cystic Teratoma (Dermoid Cyst): Origin: Derived from all three germ layers: Ectoderm (skin, hair, teeth), Mesoderm (muscle, bone), and Endoderm (gut tissue). Epidemiology: Most common germ cell tumor; typically occurs in young women (ages 20–30). Gross Appearance: Often contains a "Rokitansky protuberance" (a solid nodule from which hair or teeth originate). Complications: * Torsion: The most common complication due to the weight of the mass. Struma Ovarii: A specialized teratoma composed entirely of thyroid tissue, which can lead to hyperthyroidism. Malignant Transformation: Rare (<1%), usually into Squamous Cell Carcinoma. Serous Cystadenoma (Option B): Origin: These arise from the surface epithelium of the ovary rather than germ cells. Histology: They are typically unilocular cysts lined with ciliated columnar epithelium , resembling the lining of the fallopian tube. Key Distinction: They do not contain teeth, hair, or sebum; they are filled with clear, watery (serous) fluid. Note: If these become malignant (Serous Cystadenocarcinoma), they often display Psammoma bodies (concentric lamellated calcifications). Mucinous Cystadenoma (Option C): Origin: Another surface epithelial tumor. Histology: These are often very large, multiloculated masses lined by mucus-secreting cells (resembling endocervical or intestinal mucosa). Key Distinction: Instead of solid tissue like hair or bone, these are filled with thick, gelatinous mucoid material. Clinical Complication: If a mucinous tumor ruptures, it can lead to Pseudomyxoma peritonei , where the abdominal cavity fills with "jelly-like" mucinous ascites. Granulosa Cell Tumor (Option D): Origin: This is a Sex Cord-Stromal tumor , not a germ cell tumor. Function: These tumors are "functional," meaning they secrete Estrogen . Clinical Presentation: * In children: Causes precocious puberty . In adults/postmenopausal women: Causes postmenopausal bleeding and increases the risk of endometrial hyperplasia or cancer. Histology: Characterized by Call-Exner bodies (small, gland-like follicles filled with eosinophilic material) and "coffee-bean" nuclei. Key Distinction: It lacks the multiple germ layers (hair/teeth) found in teratomas.



@Neet_pg_bot

Q16: What is the most likely diagnosis of a patient with a painless, slowly enlarging mass in the right parotid gland region that is well-defined and heterogeneous, with both epithelial and mesenchymal components present in the biopsy? (Q845136)

A. Pleomorphic adenoma

B. Mucoepidermoid carcinoma

C. Acinic cell carcinoma

D. Warthin tumour

Correct Answer: A. Pleomorphic adenoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Benign Salivary Gland Tumors: 1. Pleomorphic Adenoma (Mixed Tumor): Pleomorphic adenoma is the most common benign tumour of the salivary glands, often found in the parotid gland. Composition: Pleomorphic adenoma, also known as a mixed tumour, typically contains epithelial components (such as glandular cells) and mesenchymal components (such as myxoid stroma, islands of cartilage, or bone). Pleomorphic adenoma is more commonly found in females. Clinical: Painless, slow-growing, mobile, and firm mass. It has a high recurrence rate if not widely excised because it often has microscopic "finger-like" projections (pseudopods) that extend through the capsule. Treatment: Superficial parotidectomy (facial nerve preservation); recurrence if enucleation only Complication: Can undergo malignant transformation into Carcinoma ex Pleomorphic Adenoma , which usually presents as sudden rapid growth of a long-standing stable mass. 2. Warthin Tumor (Papillary Cystadenoma Lymphomatosum) (Option D): The second most common benign parotid tumor. Demographics: Almost exclusively found in the parotid gland ; highly associated with smoking and older males. Histology: Double layer of oncocytic (eosinophilic) epithelial cells surrounding a dense lymphoid stroma with germinal centers. Key Feature: Often found in the tail of the parotid and is bilateral in about 10% of cases. Malignant Salivary Gland Tumors: 1. Mucoepidermoid Carcinoma (Option B): The most common malignant salivary gland tumor in both adults and children. Composition: A mixture of squamous (epidermoid) cells, mucus-secreting cells, and intermediate cells. Clinical: Can range from low-grade (slow-growing) to high-grade (aggressive). 2. Adenoid Cystic Carcinoma: Histology: Classic "Swiss cheese" appearance (cribriform pattern). Clinical: Very high tendency for perineural invasion . This is a major clue in board exams; if a patient has a parotid mass and facial nerve palsy (pain or weakness) , think of this first. Prognosis: Slow-growing but relentless; it can metastasize many years after initial treatment. 3. Acinic Cell Carcinoma (Option C): Features: Consists of cells resembling normal serous acini (granular cytoplasm). Clinical: Generally low-grade with a relatively good prognosis compared to other malignancies. Tumor Category High-Yield Buzzword Clinical Clue Pleomorphic Adenoma Benign Mixed Tumor / Mesenchymal stroma Most common; mobile mass Warthin Tumor Benign Smoking / Oncocytic / Lymphoid Bilateral; older males Mucoepidermoid Ca Malignant Mucus-secreting cells Most common malignancy Adenoid Cystic Ca Malignant Swiss Cheese / Perineural invasion Painful / Facial nerve palsy

@Neet_pg_bot

Q17: Which of the following tumour is of mesenchymal origin? (Q845135)

A. Adenoma

B. Papilloma

C. Seminoma

D. Leiomyoma

Correct Answer: D. Leiomyoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Leiomyoma is a benign tumour of mesenchymal origin, originating from the smooth muscles of the uterus. Adenoma (Option A): Arises from gland: Epithelial Tumour Papilloma (Option B): Usually arises from surfaces like skin: Epithelial Tumour Seminoma (Option C): Germ cell tumour in testes: Epithelial Tumour Mesenchymal Tumours Epithelial Tumours Origin Connective tissues and derivatives Blood and lymph vessels Hematopoietic stem cells and lymphoid tissue Meninges Mesothelium Smooth muscles and Skeletal muscles Stratified squamous epithelium Melanocytes and basal cells of the skin Glandular epithelium and epithelium of ducts Respiratory, Hepatic, Renal, Transitional, Testicular, Placental epithelium Examples Leiomyosarcoma Lipoma Osteosarcoma Rhabdomyosarcoma Fibrosarcoma Meningioma Synovial sarcoma Adenocarcinoma Squamous cell carcinoma Adenoma Papilloma Seminoma Hepatocellular carcinoma Transitional cell carcinoma Markers Vimentin Desmin S100 Protein Fibronectin Myogenin Cytokeratin Epithelial Membrane Antigen (EMA) E-Cadherin P63, P40 Carcinoembryonic Antigen (CEA)

Q1: Which of the following conditions is most likely associated with vinyl chloride exposure? (Q845149)

A. Hepatocellular carcinoma

B. Hepatic angiosarcoma

C. Cholangiocarcinoma

D. Focal nodular hyperplasia

Correct Answer: B. Hepatic angiosarcoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Vinyl chloride exposure is associated with hepatic angiosarcoma (cancer that arises from the blood vessels). 3 chemicals cause hepatic angiosarcoma: Vinyl chloride Arsenic Thorotrast Hepatocellular carcinoma (Option A) : Typically associated with cirrhosis, chronic hepatitis B or C infections due to HBV or HCV, alcohol abuse, or non-alcoholic fatty liver disease. Cholangiocarcinoma (Option C): Cholangiocarcinoma (carcinoma of the biliary duct in the liver) includes Primary sclerosing cholangitis (PSC), liver fluke infections such as Clonorchis and Opisthorchis, or certain biliary tract disorders. Focal nodular hyperplasia (Option D) : FNH is more prevalent in women and is associated with hormonal imbalances.

@Neet_pg_bot

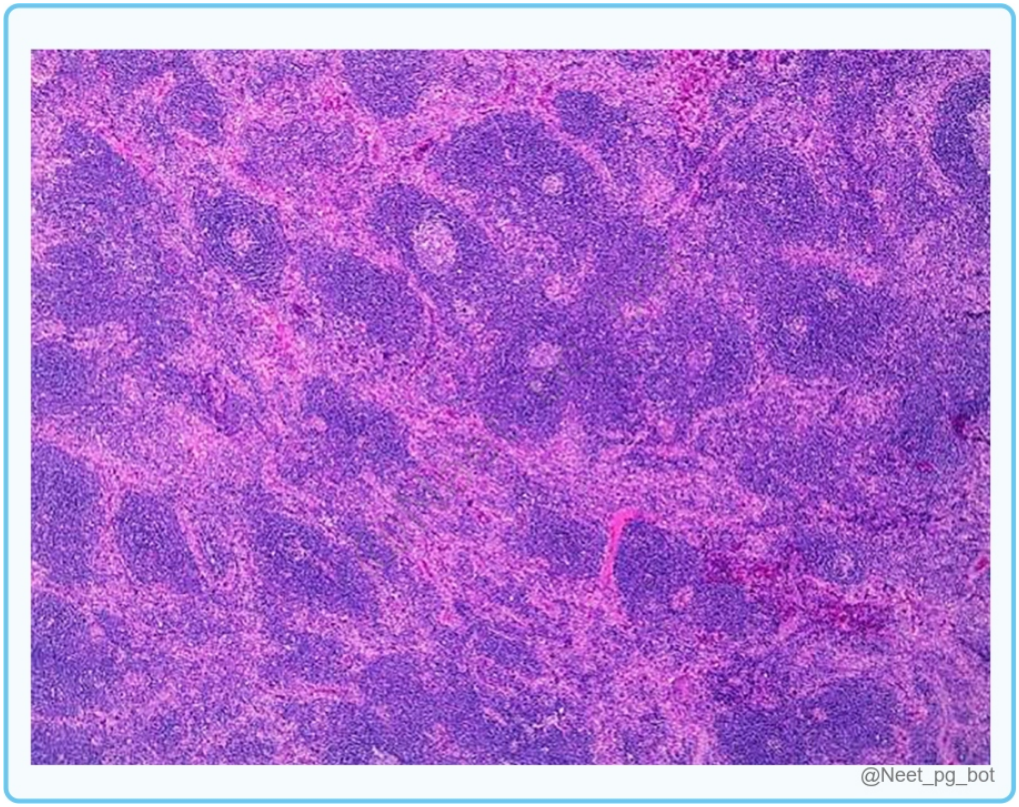
Q2: A 35-year-old man presents with painless enlarged lymph nodes in the neck and intermittent low-grade fever. Laboratory studies show normal peripheral blood counts. A biopsy of the lymph node reveals enlarged follicles with prominent vascular proliferation and increased plasma cells. Which of the following is the most likely diagnosis? (Q879869)

A. Angiolymphoma

B. Hodgkin's lymphoma

C. IgG4-related disease

D. Castleman disease



Correct Answer: D. Castleman disease

Explanation: Castleman disease is characterized by enlarged lymph nodes with prominent vascular proliferation and increased plasma cells, often presenting with painless lymphadenopathy and systemic symptoms like low-grade fever. Histopathology: Hyaline-vascular type: small, hyalinized follicles with prominent vascular proliferation ("lollipop" appearance) Plasma-cell type: sheets of plasma cells in interfollicular areas Incorrect Options: Angiolymphoma (Option A) is a benign vascular tumor, usually in the form of subcutaneous nodules in the extremities Hodgkin's lymphoma (Option B): Presence of Reed-Sternberg cells , different morphology IgG4-related disease (Option C) is a systemic fibroinflammatory condition; lymph nodes show dense IgG4 plasma

cells but not classic CD morphology

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.228.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A teenager is diagnosed with infectious mononucleosis, confirmed by a positive Monospot (heterophile antibody) test. The virus responsible for this condition is also linked to several malignancies. Which of the following cancers is least likely to be associated with this viral infection? (Q879867)

A. Burkitt lymphoma

B. Hodgkin's lymphoma

C. Nasopharyngeal carcinoma

D. Follicular lymphoma

Correct Answer: D. Follicular lymphoma

Explanation: The teenager has infectious mononucleosis, caused by Epstein–Barr virus (EBV). EBV is associated with: Burkitt lymphoma Hodgkin's lymphoma Nasopharyngeal carcinoma Follicular lymphoma (Option D) arises due to the t(14;18) translocation, leading to overexpression of the BCL2 gene. It is a B-cell non-Hodgkin lymphoma that is not linked to Epstein-Barr virus (EBV) infection.

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 544,228

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Infection with Human T-lymphotropic virus type 1 (HTLV-1) is most strongly associated with which of the following hematologic malignancies? (Q879844)

A. Adult T-cell leukemia/lymphoma

B. Enteropathy-associated T-cell lymphoma

C. Diffuse large B-cell lymphoma

D. B-cell lymphomas

Correct Answer: A. Adult T-cell leukemia/lymphoma

Explanation: HTLV-1 is a retrovirus that infects CD4+ T cells, causing adult T-cell leukemia/lymphoma (ATLL) . Clinical features of ATLL: lymphadenopathy, skin lesions, hepatosplenomegaly, and hypercalcemia. Incorrect Options: Enteropathy-associated T-cell lymphoma (Option B) is linked to celiac disease , not HTLV-1 Diffuse large B-cell lymphoma (Option C) is associated with EBV or genetic factors , not HTLV-1 B-cell lymphomas (Option D) is unrelated to HTLV-1

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.289

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following cancers is least likely to be linked to an infectious etiology? (Q879840)

A. Burkitt lymphoma

B. Castleman’s disease

C. Adenocarcinoma of the lung

D. Primary effusion lymphoma

Correct Answer: C. Adenocarcinoma of the lung

Explanation: Adenocarcinoma of the lung → primarily caused by tobacco smoke, environmental exposures, and genetic mutations, not by microbial infection. Incorrect Options: Burkitt lymphoma (Option A) is associated with Epstein–Barr virus (EBV) infection. Castleman’s disease (Option B), especially the multicentric type, can be associated with HHV-8 infection. Primary effusion lymphoma (Option D) is strongly associated with HHV-8, often in immunocompromised patients.

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 228,246,290,291

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 52-year-old construction worker with a history of chronic sun exposure presents for a routine skin examination. Which of the following skin conditions are considered UV-induced premalignant or malignant lesions? 1. Squamous cell carcinoma 2. Basal cell carcinoma 3. Seborrheic keratosis 4. Actinic keratosis (Q879835)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 3, 4

D. 1, 2, 4

Correct Answer: D. 1, 2, 4

Explanation: Chronic sun exposure is a major risk factor for: Squamous cell carcinoma (SCC) – UV-induced DNA damage, especially in fair-skinned individuals. (Option 1) Basal cell carcinoma (BCC) is the most common skin cancer, associated with UV exposure. (Option 2) Actinic keratosis (AK) – pre-malignant lesion caused by cumulative UV exposure; can progress to SCC. (Option 4) Seborrheic keratosis (Option 3) : Benign epidermal tumor not related to sun exposure ; arises spontaneously with age.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following compounds acts as a direct-acting carcinogen, meaning it does not require metabolic conversion to become carcinogenic? (Q879831)

A. Cyclophosphamide

B. Benzidine

C. 3-Methylcholanthrene

D. Dimethylaminoazobenzene

Correct Answer: A. Cyclophosphamide

Explanation: Cyclophosphamide is a direct-acting alkylating agent that can interact directly with DNA without requiring metabolic conversion. Incorrect Options: Benzidine (Option B), 3-methylcholanthrene (Option C), and Dimethylaminoazobenzene (Option D) are procarcinogens that require hepatic metabolic activation to become DNA-reactive and carcinogenic.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.287

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following neoplasms is considered the prototype for studying the multi-step process of carcinogenesis? (Q879825)

A. Colon carcinoma

B. Melanoma

C. Thyroid carcinoma

D. Breast carcinoma

Correct Answer: A. Colon carcinoma

Explanation: Colon carcinoma is the classic model of multi-step carcinogenesis, explained by the adenoma–carcinoma sequence . This sequence demonstrates how the accumulation of multiple genetic alterations (both oncogenes and tumor suppressor genes) drives tumor progression. Key genetic events: APC mutation – the earliest change, leading to dysplasia in colonic epithelium. KRAS mutation – promotes the growth of adenomas. Loss of DCC/SMAD genes – progression to advanced adenoma. TP53 mutation – final step to invasive carcinoma. Other tumors (melanoma, thyroid carcinoma, breast carcinoma) also require multiple mutations, but colon carcinoma is the best documented and most extensively studied model .

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.286.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following immune checkpoint interactions is correctly matched with its inhibitory effect on T-cell activation? (Q879809)

A. CTLA-4 binding to B7 molecules on APCs – prevents costimulatory signaling via CD28

B. PD-1 binding to PD-L1/PD-L2 on tumor cells – enhances T-cell cytotoxic activity

C. CD28 binding to B7 molecules on APCs – induces long-lived unresponsiveness of T cells

D. PD-1 blockade – reduces T-cell function in the tumor microenvironment

Correct Answer: A. CTLA-4 binding to B7 molecules on APCs – prevents costimulatory signaling via CD28

Explanation: CTLA-4 competes with CD28 for B7 binding → neutralizes costimulation and may induce T-cell unresponsiveness. PD-1 engagement by PD-L1/PD-L2 activates inhibitory signaling (via phosphatases) → suppresses T-cell activation. Checkpoint blockade therapy (anti-CTLA-4, anti-PD-1, anti-PD-L1) removes these "brakes" to restore antitumor T-cell responses. Incorrect Options: PD-1 binding to PD-L1/PD-L2 on tumor cells – enhances T-cell cytotoxic activity (Option B): PD-1–PD-L1 interaction inhibits, not enhances, T-cell cytotoxicity. CD28 binding to B7 molecules on APCs – induces long-lived unresponsiveness of T cells (Option C): CD28–B7 normally provides positive costimulatory signals, not unresponsiveness. PD-1 blockade – reduces T-cell function in the tumor microenvironment (Option D): Blocking PD-1 restores (not reduces) T-cell function.

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page. 278-279

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Deletion of which microRNAs is most commonly associated with increased BCL2 expression in chronic lymphocytic leukemia? (Q879806)

A. miR-15 and miR-16

B. miR-155 and miR-21

C. miR-34a and miR-200

D. miR-17 and miR-92

Correct Answer: A. miR-15 and miR-16

Explanation: MicroRNAs (miRs) are small noncoding RNAs (~22 nucleotides) that regulate gene expression by sequence-specific inhibition of mRNAs. Tumor-suppressive miRs normally restrain the translation of oncogenic proteins. Loss of these miRs can increase oncogene expression. In chronic lymphocytic leukemia (CLL), deletion of miR-15 and miR-16 leads to upregulation of BCL2, an anti-apoptotic protein, enhancing tumor cell survival. Onco-miRs are microRNAs whose overexpression promotes tumorigenesis, e.g., miR-155, which indirectly upregulates proliferation-promoting genes like MYC. Altered miR expression in cancer can result from

amplifications or deletions of miR loci and contributes to dysregulated cell growth, survival, and differentiation. Incorrect Options: miR-155 and miR-21 (Option B): These are oncogenic microRNAs commonly upregulated in cancers but not involved in BCL2 suppression in CLL. miR-34a and miR-200 (Option C): These tumor-suppressive microRNAs regulate p53 and EMT pathways, not BCL2 in CLL. miR-17 and miR-92 (Option D): Part of an oncogenic cluster linked to cell proliferation, but not directly associated with BCL2 regulation in CLL.

@Neet_pg_bot

Q11: Which of the following genes is most frequently mutated in malignant rhabdoid tumors? (Q879801)

A. SNF5

B. ARID1A

C. PBRM1

D. DNMT3A

Correct Answer: A. SNF5

Explanation: Malignant Rhabdoid Tumors are aggressive pediatric cancers characterized by mutations in genes involved in nucleosome positioning and chromatin remodeling. SNF5 is a core component of the SWI/SNF chromatin remodeling complex, mutated in 100% of malignant rhabdoid tumors. Gene(s) Function Tumor (Approximate Frequency of Mutation) DNMT3A (Option D ruled out) DNA methylation Acute myeloid leukemia (20%) KMT2A Histone methylation Acute leukemia in infants (90%) KMT2D Follicular lymphoma (90%) CREBBP / EP300 Histone acetylation Diffuse large B-cell lymphoma (40%) ARID1A (Option B ruled out) Nucleosome positioning/chromatin remodeling Ovarian clear cell carcinoma (60%), Endometrial carcinoma (30–40%) SNF5 Malignant rhabdoid tumor (100%) PBRM1 (Option C ruled out) Renal carcinoma (30%) H3F3A, HIST1H3B Histone H3 variants (nucleosome components) Pediatric gliomas (30–80%, depending on anatomic location)

@Neet_pg_bot

Q12: Which type of circulating blood cell shows the greatest resistance to radiation damage? (Q879733)

A. Lymphocytes

B. Granulocytes

C. Platelets

D. Erythrocytes

Correct Answer: D. Erythrocytes

Explanation: Mature erythrocytes (RBCs) are non-dividing, enucleated cells, hence the least radiosensitive Lymphocytes are the most radiosensitive blood cells; even small doses of radiation can destroy them. Granulocytes and platelets are moderately radiosensitive.

@Neet_pg_bot

Q13: Which of the following cancers is most strongly associated with excessive alcohol use? (Q879729)

A. Carcinoma of lip

B. Carcinoma of larynx

C. Carcinoma of pancreas

D. Carcinoma of stomach

Correct Answer: B. Carcinoma of larynx

Explanation: Alcohol increases the risk of oropharyngeal carcinoma (excluding the lip), laryngeal carcinoma , oesophagal carcinoma, and via cirrhosis → hepatocellular carcinoma. The risk of upper airway and digestive tract cancers is markedly higher when combined with tobacco smoking. Incorrect Options: Carcinoma of lip (Option A) : More commonly linked to sun exposure and tobacco , not strongly associated with alcohol. Carcinoma of pancreas (Option C) : Primarily associated with smoking and chronic pancreatitis , not directly with alcohol alone. Carcinoma of stomach (Option D) : Linked to H. pylori infection , dietary factors , and smoking - alcohol plays a

minor role.

@Neet_pg_bot

Q14: The Notch signaling pathway in angiogenesis is mainly involved in? (Q879725)

A. ECM degradation

B. Vasodilation

C. Regulating sprouting and branching of new vessels

D. Endothelial cell proliferation

Correct Answer: C. Regulating sprouting and branching of new vessels

Explanation: Notch ensures orderly spacing and prevents excessive or chaotic angiogenesis. Angiogenesis promoters / regulators: VEGF (especially VEGF-A) - stimulates endothelial migration, proliferation, capillary sprouting, vasodilation (Option B ruled out) , lumen formation. FGF-2 (Fibroblast Growth Factor-2) - endothelial cell proliferation (Option D ruled out) , macrophage/fibroblast migration, epithelial migration (wound healing). Angiopoietin-1 & Angiopoietin-2 - vessel formation and structural maturation. PDGF (Platelet-Derived Growth Factor) - recruits smooth muscle cells to stabilize vessels. TGF-β (Transforming Growth Factor-beta) - stabilizes vessels Notch signaling pathway - regulates vessel sprouting, branching, and spacing (Option C) . ECM proteins - provide scaffold for vessel growth. MMPs (Matrix Metalloproteinases) - degrade ECM (Option A ruled out) , allow remodeling and extension of vessels.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 60-year-old man who has worked in the zinc mines presents to his urologist with urinary symptoms, including increased frequency, hesitancy, and nocturia. During a digital rectal examination, he is found to have an enlarged prostate with a palpable nodule. Which environmental exposure is most likely associated with his

prostate cancer risk? (Q845148)

A. Zinc

B. Benzopyrene

C. Arsenic

D. Cadmium

Correct Answer: D. Cadmium

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Occupational exposure to cadmium, commonly found in industries such as zinc mining, smelting of zinc ores, and battery manufacturing, has been associated with an increased risk of prostate cancer. Zinc (Option A): Excessive zinc exposure does not have a direct association with prostate cancer. Benzopyrene (Option B): It is associated with increased risks of lung cancer, bladder cancer, skin cancer, and other malignancies. Arsenic (Option C): It is associated with an increased risk of angiosarcoma of the liver.

@Neet_pg_bot

Q16: A 16-year-old girl presents with a clear-cell vaginal tumour. Upon further inquiry, it was revealed that her mother has a history of taking medication during pregnancy to prevent premature labour. Which medication is most likely associated with the development of this tumour in the daughter? (Q845150)

A. DES (Diethylstilbestrol)

B. Thalidomide

C. Tamoxifen

D. Medroxyprogesterone acetate

Correct Answer: A. DES (Diethylstilbestrol)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: DES (Diethylstilbestrol) , a synthetic estrogen previously administered to pregnant women to prevent miscarriages and pregnancy complications, has been associated with a significantly increased risk of clear cell adenocarcinoma of the cervix or vagina in daughters exposed to it in utero. Thalidomide (Option B): Causes severe birth defects like limb deformities (phocomelia), blindness, deafness, heart issues, and brain damage in babies. It is a teratogen, not a carcinogen. Tamoxifen (Option C): Tamoxifen is a selective estrogen receptor modulator used in the treatment of ER-positive breast cancer. Medroxyprogesterone acetate (Option D): Long-term use or high doses of MPA, particularly in combination with estrogen, may increase the risk of breast cancer.

@Neet_pg_bot

Q17: Which of the following is not an indirect-acting carcinogen? (Q845151)

A. Griseofulvin

B. Azo dyes

C. Nitrosoureas

D. Betel nuts

Correct Answer: C. Nitrosoureas

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Nitrosoureas are a direct-acting carcinogenic agent. Characteristic Direct-Acting Carcinogens Indirect-Acting Carcinogens Mode of action Directly damage DNA, leading to mutations Require metabolic conversion to become active (ultimate carcinogens) Carcinogenic potency Typically weak More potent Endogenous enzymes involved None Cytochrome P-450 Examples Alkylating agents (Anti-cancer drugs) like nitrosoureas, cyclophosphamide Acylating agents Aromatic hydrocarbons like benzo[a]pyrene Aromatic Amines, Amides, Azo Dyes (Option B ruled out) Natural Plant and Microbial Products like Aflatoxin B1, Griseofulvin, and Betel nuts (Options A, D ruled out) Insecticides, fungicides

@Neet_pg_bot

Q18: Which of the following radiations is the most common cause of skin cancer? (Q845152)

A. UV-A radiation

B. UV-B radiation

C. UV-C radiation

D. UV-D radiation

Correct Answer: B. UV-B radiation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: UV-B radiation is the major cause of sunburn and skin cancer. Wavelengths: 280-320 nm It is responsible for inducing the formation of pyrimidine dimers within DNA, leading to mutations that can result in various types of skin cancer: Squamous cell carcinoma Basal cell carcinoma Malignant melanoma. Basal Cell Carcinoma (BCC): This is the most common skin cancer worldwide. It arises from the basal layer of the epidermis. Clinical Appearance: Typically presents as a "pearly" or waxy papule with prominent, dilated subepidermal blood vessels (telangiectasias). Key Feature: Often exhibits a central ulceration with "rolled" or "peaded" borders (sometimes called a Rodent Ulcer). Histology: Shows nests of "basaloid" cells with peripheral palisading (nuclei at the edge of the nest align in a row). Metastasis: It is highly locally invasive but rarely metastasizes . Treatment: MOHS surgery, imiquimod, vismodegib (Hedgehog pathway) Squamous Cell Carcinoma (SCC): The second most common skin cancer; it arises from the malpighian (prickly) layer of the epidermis. Clinical Appearance: Usually appears as a firm, red, scaling plaque or a nodule with an ulcerated center . Precursor Lesion: Often preceded by Actinic Keratosis (a rough, scaly patch caused by sun damage). Histology: Characterized by Keratin pearls and intercellular bridges (desmosomes). Unique Risk Factors: Associated with chronic non-healing wounds (Marjolin ulcer), arsenic exposure, and immunosuppression Treatment: Excision, Radiotherapy (If elderly/inoperable) Malignant Melanoma: The most aggressive and deadly form of skin cancer; it arises from melanocytes . Identification (ABCDE Criteria): A symmetry B orders (irregular or notched) C olor (variegated/multiple shades) D iameter (usually >6 mm) E volving (changing in size, shape, or color) Prognostic Factor: The Breslow depth (measured in millimeters from the granular layer of the epidermis to the deepest tumor cell) is the most important predictor of metastasis and survival. Markers: Tumor cells are typically positive for S-100 , HMB-45 , and Melan-A . Treatment: Wide excision + SLNB, immunotherapy (anti-PD1), targeted (BRAF) UV-A radiation (Option A): Wavelengths: 320-400 nm. They primarily cause skin ageing. UV-A radiation, particularly in combination with UV-B, can increase the risk of skin cancer. UV-C radiation (Option C): These shorter wavelengths (200-280 nm) are extremely potent in terms of DNA damage, but they are largely filtered out by the Earth's ozone layer and do not reach the surface in significant amounts. UV-D radiation (Option D): The UV spectrum typically consists of UV-A, UV-B, and UV-C and no UV-D radiation.

Robbins and Cotrans Pathologic basis of disease 10th edition,Page 323

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 55-year-old female radiology technician with 25 years of occupational exposure to diagnostic X-rays and fluoroscopy presents with a three-month history of increasing fatigue, unintentional weight loss, and frequent infections. Which cancer type is most likely associated with her occupational history? (Q845153)

A. Acute Myeloid Leukemia

B. Pancreatic cancer

C. Medullary thyroid cancer

D. Chronic Lymphocytic Leukemia

Correct Answer: A. Acute Myeloid Leukemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Acute Myeloid Leukemia (AML) is a type of blood cancer commonly associated with prolonged exposure to ionizing radiation, such as X-rays and γ-rays, placing affected individuals at increased risk of developing the disease The most common thyroid cancer associated with ionising radiations: Papillary carcinoma thyroid Cancer which is never associated with ionising radiations: CLL

Robbins and Cotrans Pathologic basis of disease 10th edition, Page 323

↑ *Back to this question in Part A*

@Neet_pg_bot

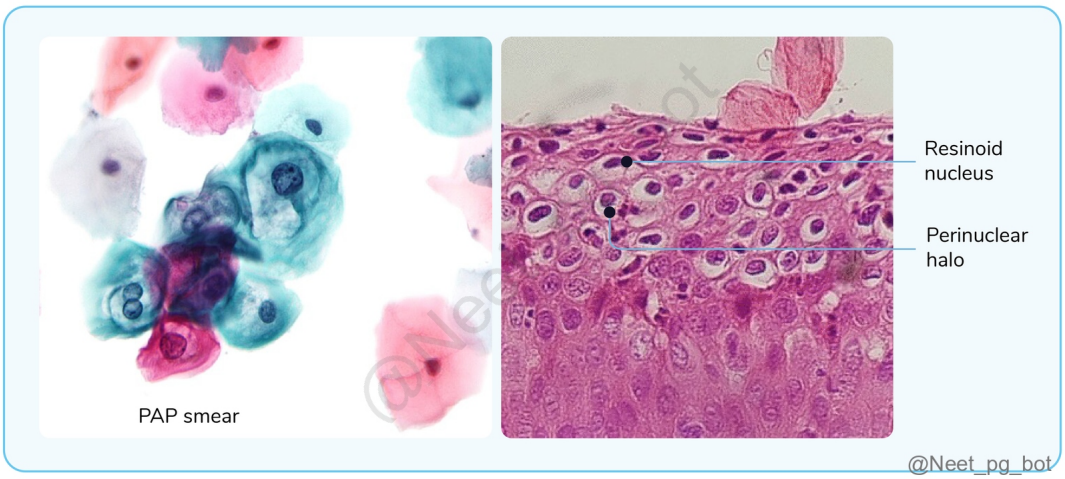
Q20: A 35-year-old woman presents for a routine gynaecological examination. Her Pap smear and biopsy reveals abnormal cells suggestive of cervical dysplasia. Further, HPV testing indicates the presence of specific HPV types associated with cervical cancer. Which HPV types are most commonly linked to an increased risk of cervical cancer in this patient? (Q845154)

A. Low-risk 6, 11

B. High-risk 6, 11

C. Low-risk 16, 18

D. High-risk 16, 18



Correct Answer: D. High-risk 16, 18

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The abnormal cells in the pap smear and biopsy are known as Koilocytes, characterised by a raisinoid nucleus and a perinuclear halo, which indicates HPV infection. High-Risk HPV (Types 16 and 18): Clinical Condition: Cervical Intraepithelial Neoplasia (CIN) and invasive Cervical Cancer . Mechanism: These types produce two critical oncoproteins: E6: Inhibits p53 (prevents apoptosis). E7: Inhibits Rb (promotes uncontrolled cell cycle progression). Other Cancers: Also strongly linked to vulvar, vaginal, penile, anal, and oropharyngeal cancers. Low-Risk HPV (Types 6 and 11): Clinical Condition: Condyloma Acuminatum (Anogenital warts) and Laryngeal Papillomas . Oncogenic Potential: Very low. They rarely lead to invasive cancer but cause significant physical morbidity. Other Notable Types: HPV 1, 2, 4: Cause Verruca Vulgaris (common skin warts). HPV 3, 10: Cause Verruca Plana (flat warts). HPV 31, 33, 45, 52, 58: Other high-risk types included in the 9-valent vaccine (Gardasil 9) . Risk Group HPV Types Conditions Caused LOW RISK 6, 11, 40, 42, 43, 44, 54, 61, 72 Genital warts (90%), recurrent respiratory papillomatosis HIGH RISK (14 types) 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, 68 Cervical dysplasia/Ca (99%) , anal/oropharyngeal/vulvar/penile/vaginal Ca Oncogenic Microbes & Associated Cancers: Microbe Cancer Mechanism HPV 16/18 Cervical (99%), oropharyngeal E6/E7 → p53/Rb inactivation HBV/HCV Hepatocellular carcinoma Chronic inflammation → cirrhosis EBV Burkitt Lymphoma, Nasopharyngeal Carcinoma, Hodgkin Lymphoma B-cell proliferation H. pylori Gastric adenocarcinoma , MALToma Chronic gastritis → atrophy HHV-8 Kaposi sarcoma Angiogenesis (AIDS) HTLV-1 Adult T-cell leukemia/lymphoma T-cell transformation Schistosoma Bladder Ca (squamous) Chronic inflammation Opisthorchis Cholangiocarcinoma Biliary inflammation

References:

Robbins and Cotrans Pathologic basis of disease 10th edition, page 324

↑ *Back to this question in Part A*

@Neet_pg_bot

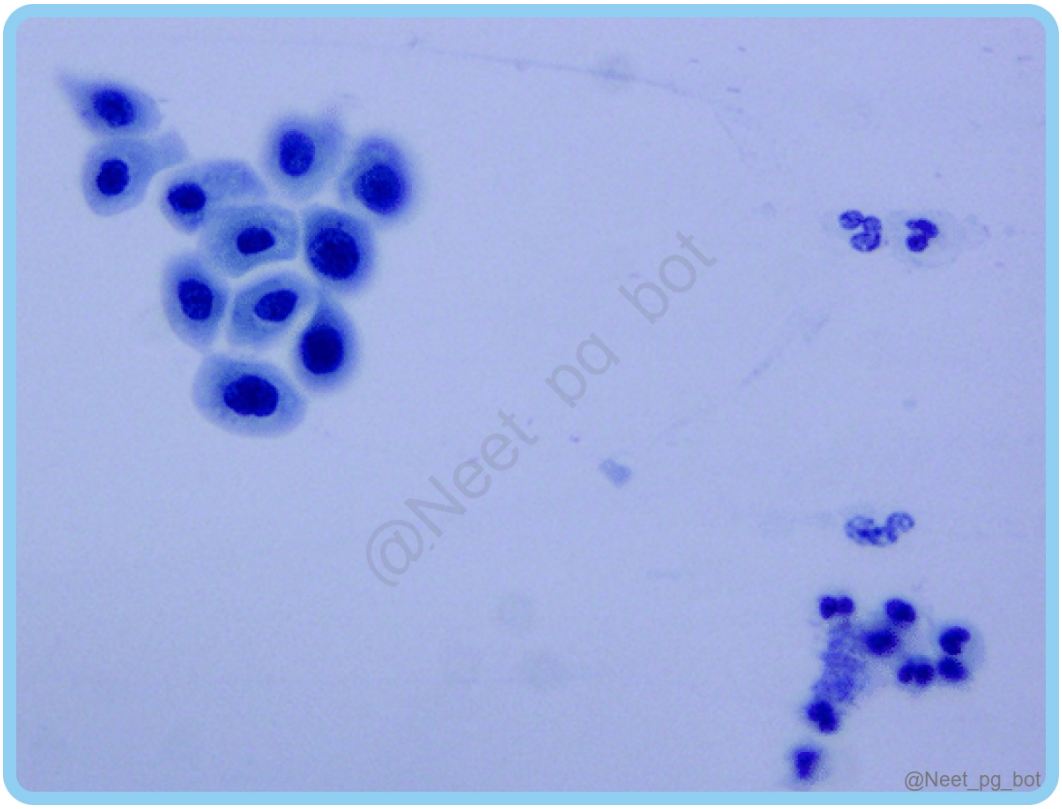
Q21: A 35-year-old woman with regular menstrual cycles undergoes routine Pap smear screening, which reveals a high-grade squamous intraepithelial lesion (HSIL) of the cervix. Further testing confirms infection with high-risk HPV type 16. Which of the following mechanisms regarding the oncogenic activity of E6 and E7 of HPV is correct? (Q845155)

A. E6 protein inhibits the degradation of p53.

B. E6 stimulates the expression of TERT.

C. E7 activates CDK inhibitors.

D. E7 can inactivate cyclins A and E



Correct Answer: B. E6 stimulates the expression of TERT.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: E6 and E7 proteins from high-risk HPV types exhibit increased affinity for key cellular regulatory proteins (e.g., p53, RB) compared to low-risk HPV types. Oncogenic Activities of E6 Protein Oncogenic Activities of E7 Protein Binds to and promotes degradation of p53 (policeman of the cell) → Impairs cell growth and apoptosis regulation (Option A ruled out). Stimulates expression of TERT (telomerase reverse transcriptase)

→ Facilitates cellular immortalisation by maintaining telomere length. Disrupts interaction between RB gene (governor of genome) and E2F transcription factors Inactivates CDK inhibitors (e.g., p21 and p27) (Option C ruled out). Activates cyclins A and E (Option D ruled out) All these mechanisms enhance cell cycle progression and cellular proliferation in HPV infections.

References:

Robbins and Cotrans Pathologic basis of disease 10th edition, page 324-325

↑ *Back to this question in Part A*

@Neet_pg_bot

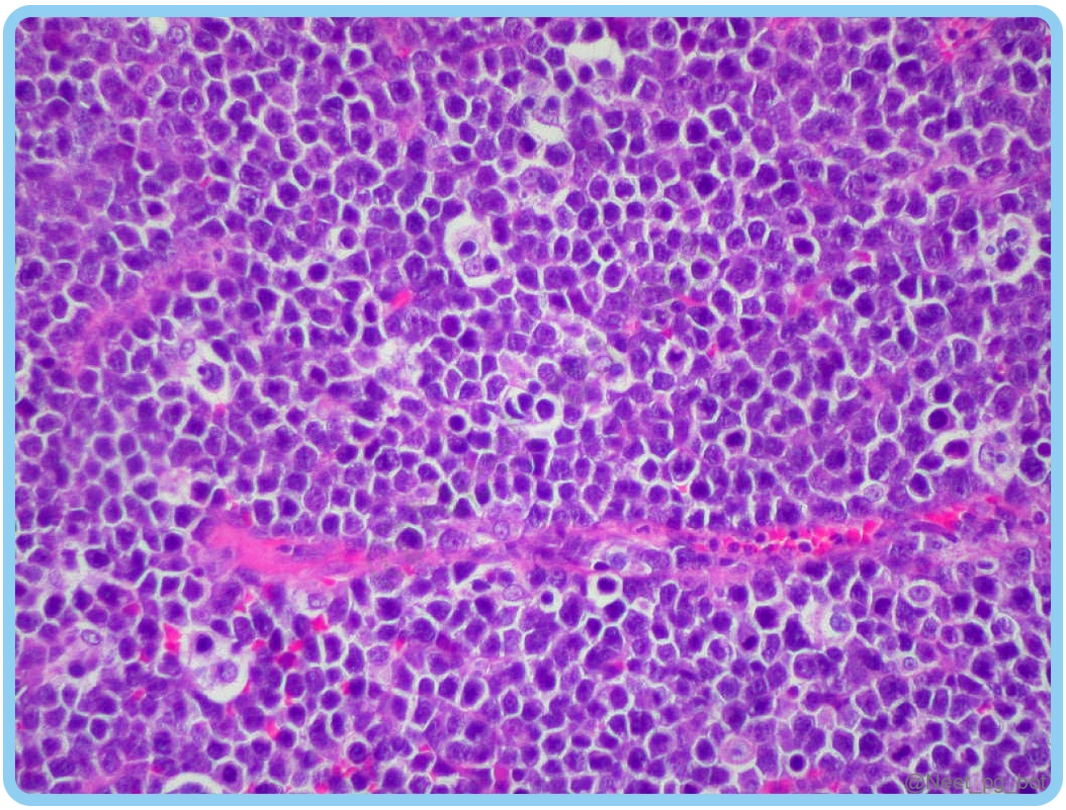
Q22: A 10-year-old girl presents with rapidly growing jaw swelling and pain. Further examination reveals bilateral enlargement of the mandible and maxilla. Biopsy suggests the presence of a starry-sky appearance as shown in the image. Which of the following infectious agents is most commonly associated with the pathogenesis of this malignancy? (Q845156)

A. EBV

B. HTLV-1

C. HHV-8

D. Aspergillus flavus



Correct Answer: A. EBV

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The image displays a characteristic "starry sky" appearance , which is typically seen in Burkitt's lymphoma , a type of aggressive B-cell non-Hodgkin lymphoma commonly associated with Epstein-Barr virus (EBV) infection. The ‘starry sky pattern’ of histopathology represents scattered macrophages with phagocytosed cell debris among proliferating lymphoma cells is characteristic of Burkitt lymphoma . Stars (Lighter cells): Macrophages Sky (dark blue cells in background): Tumorous cells of Burkitt lymphoma Burkitt Lymphoma: It is a highly aggressive B-cell non-Hodgkin lymphoma characterized by the fastest doubling time of any human tumor. Pathogenesis: Driven by the translocation of the c-myc proto-oncogene from chromosome 8 to the Ig heavy chain locus on chromosome 14 [t(8;14)]. This leads to the constitutive expression of myc, a potent transcriptional activator that promotes cell cycle progression. Clinical Variants: Endemic (African): Strongly associated with EBV (nearly 100% of cases). Typically presents as jaw or facial bone swelling in children. Sporadic: Occurs worldwide. EBV association is lower (approx. 15–20%). Usually presents as an abdominal mass (ileocecal region). Immunodeficiency-related: Seen in HIV/AIDS patients; often the first manifestation of AIDS. Epstein-Barr Virus (EBV): EBV (Human Herpesvirus 4) is a ubiquitous virus that infects B-cells via the CD21 receptor (CR2). Clinical Conditions Caused by EBV : EBV is associated with both benign proliferative disorders and various malignancies: Infectious Mononucleosis (Glandular Fever): Presentation: Fever, sore throat, lymphadenopathy, and splenomegaly. Diagnosis: Positive Monospot test (heterophile antibodies) and presence of atypical T-lymphocytes (Downey cells) on peripheral blood smear. Nasopharyngeal Carcinoma: A malignant tumor of the head and neck, common in Southern China and East Africa. Hodgkin Lymphoma: Specifically the "Mixed Cellularity" and "Lymphocyte Depleted" subtypes. Oral Hairy Leukoplakia: Non-malignant white, corrugated patches on the lateral borders of the tongue, primarily seen in immunocompromised (HIV) patients. 5.

Primary CNS Lymphoma: An AIDS-defining illness. HTLV-1 (Human T-cell Lymphotropic Virus-1) (Option B): Target Cells: Specifically infects CD4+ T-lymphocytes . Associated Malignancy: Adult T-cell Leukemia/Lymphoma (ATLL) . Differentiating Features: Unlike the B-cell origin of Burkitt lymphoma, ATLL presents with "flower cells" (lymphocytes with highly leaf-like, multilobulated nuclei) in the peripheral blood. Often presents with skin lesions, lymphadenopathy, and lytic bone lesions with hypercalcemia. HHV-8 (Human Herpesvirus 8) (Option C): Also Known As: Kaposi Sarcoma-associated Herpesvirus (KSHV). Target Cells: Endothelial cells. Associated Malignancy: Kaposi Sarcoma , Primary Effusion Lymphoma, and Multicentric Castleman Disease. Differentiating Features: It typically presents as purplish-red skin nodules or plaques, especially in patients with HIV/AIDS . Histology: Shows a proliferation of spindle cells forming slit-like vascular spaces containing red blood cells. Aspergillus flavus (Option D): Nature: This is a fungus , not a virus. Mechanism: It produces Aflatoxins (specifically B1), which contaminate stored grains and nuts. Associated Malignancy: Hepatocellular Carcinoma (HCC) . Differentiating Features: Aflatoxin acts as a dietary carcinogen that causes a specific mutation in the p53 tumor suppressor gene (at codon 249). It does not cause jaw swelling or "starry sky" patterns.

Robbins and Cotrans Pathologic basis of disease, 10th edition, Pages 321-327

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: Infection with Helicobacter pylori is linked to the development of several gastrointestinal diseases. Which of the following conditions is least likely to be associated with H. pylori infection? (Q845158)

A. Peptic ulcer disease

B. Barrett's esophagus

C. Gastric adenocarcinoma

D. Mucosa-associated lymphoid tissue (MALT) lymphoma

Correct Answer: B. Barrett's esophagus

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: H. pylori infection causes chronic gastritis leading to decreased acid production in the stomach. Reduced gastric acid secretion lowers the incidence of gastroesophageal reflux disease (GERD). Since GERD is the primary cause of Barrett's esophagus, H. pylori indirectly protects against this condition. Barrett's esophagus results from chronic acid injury to the lower esophagus, not from H. pylori infection. Therefore, it is not associated with H. pylori. Studies show an inverse relationship between H. pylori and Barrett's esophagus. Hence, Barrett's esophagus is the least likely condition linked to H. pylori. Peptic ulcer disease (Option A): Strongly associated with H. pylori, especially in duodenal and gastric ulcers due to mucosal inflammation and increased acid exposure. Gastric adenocarcinoma (Option C) : Chronic H. pylori infection causes atrophic gastritis → intestinal metaplasia → dysplasia → gastric cancer. MALT lymphoma (Option D) : H. pylori stimulates lymphoid proliferation in the stomach, directly leading to MALT lymphoma , which often regresses with eradication therapy.

@Neet_pg_bot

Q25: A 60-year-old man who has worked in the zinc mines presents to his urologist with urinary symptoms, including increased frequency, hesitancy, and nocturia. During a digital rectal examination, he is found to have an enlarged prostate with a palpable nodule. Which environmental exposure is most likely associated with his prostate cancer risk? (Q845484)

A. Benzene

B. Benzopyrene

C. Arsenic

D. Cadmium

Correct Answer: D. Cadmium

Explanation: Occupational exposure to cadmium, commonly found in industries such as zinc mining, smelting of zinc ores, and battery manufacturing, has been associated with an increased risk of prostate cancer. The body accumulates cadmium through inhalation of dust and fumes containing cadmium particles. Benzene (Option A) Benzene is a carcinogen that disrupts normal blood cell production and is associated with higher risks of developing acute myeloid leukaemia (AML), myelodysplastic syndromes (MDS), and non-Hodgkin lymphoma (NHL). Benzopyrene (Option B) Benzopyrene, a polycyclic aromatic hydrocarbon (PAH) present in tobacco smoke and combustion products, is associated with increased risks of lung cancer, bladder cancer, skin cancer, and other malignancies. Arsenic (Option C) Prolonged exposure to arsenic can occur through contaminated water, soil, and food, commonly by the use of arsenic-based pesticides and herbicides. It is associated with an increased risk of developing skin, lung, bladder, and liver cancers.

@Neet_pg_bot

Q27: Which of the following conditions is most likely associated with vinyl chloride exposure? (Q845485)

A. Hepatocellular carcinoma

B. Hepatic angiosarcoma

C. Cholangiocarcinoma

D. Focal nodular hyperplasia

Correct Answer: B. Hepatic angiosarcoma

Explanation: Hepatic angiosarcoma is a high-grade vascular malignancy and is the most common sarcoma arising in the liver, especially in those with significant exposure to Vinyl chloride. It is more common in men and occurs in the elderly. Some other risk factors include arsenic, anabolic steroids, radiation, and thorium dioxide (Thorotrast). Hepatocellular carcinoma (Option A) Hepatocellular carcinoma is the most common primary liver cancer and is typically associated with cirrhosis, chronic hepatitis B or C infections due to HBV or HCV, alcohol abuse, or non-alcoholic fatty liver disease and not associated with exposure to vinyl chloride. Cholangiocarcinoma (Option C) Cholangiocarcinoma (carcinoma of the biliary duct in the liver) includes conditions that lead to chronic inflammation of the bile ducts, such as Primary sclerosing cholangitis (PSC), liver fluke infections such as Clonorchis and Opisthorcis, or certain jbiliary tract disorders. It is not associated with vinyl chloride exposure . Focal nodular hyperplasia (Option D) Focal nodular hyperplasia (FNH) is the second most common benign liver lesion after hepatic hemangioma. It consists of hyperplastic hepatocytes surrounding a central scar, which can result from altered blood flow. FNH is more prevalent in women and is associated with hormonal imbalances but not with vinyl chloride exposure.

@Neet_pg_bot

Q28: A 16-year-old girl presents with a clear-cell vaginal tumour. Upon further inquiry, it was revealed that her mother has a history of taking medication during pregnancy to prevent premature labour. Which medication is most likely associated with the development of this tumour in the daughter? (Q845486)

A. DES (Diethylstilbestrol)

B. Thalidomide

C. Tamoxifen

D. Medroxyprogesterone acetate

Correct Answer: A. DES (Diethylstilbestrol)

Explanation: In the given scenario, the clear cell vaginal tumour in the daughter is most likely linked to DES (Diethylstilbestrol). DES, a synthetic estrogen previously administered to pregnant women to prevent miscarriages and pregnancy complications, has been associated with a significantly increased risk of clear cell adenocarcinoma of the cervix or vagina in daughters exposed to it in utero. Thalidomide (Option 2): Thalidomide, once used to treat morning sickness in pregnant women, caused severe birth defects like limb deformities (phocomelia), blindness, deafness, heart issues, and brain damage in their babies. It is a teratogen, not a carcinogen. Tamoxifen (Option 3): Tamoxifen is a selective estrogen receptor modulator used in the treatment of ER-positive breast cancer. While it is associated with an increased risk of endometrial cancer in women who take it for breast cancer treatment, it's not linked to clear cell vaginal tumours in their daughters. Medroxyprogesterone acetate (Option 4): It is a synthetic progestin commonly used in hormonal therapies and contraceptives. Long-term use or high doses of MPA, particularly in combination with estrogen, may increase the risk of breast cancer. However, maternal use of it is not typically associated with vaginal tumours in daughters.

@Neet_pg_bot

Q30: Which of the following statements regarding H. pylori infection and its association with malignancies is correct ? (Q845493)

A. Gastric lymphomas associated with H. pylori infection are primarily of B-cell origin.

B. H. pylori strains associated with gastric adenocarcinomas contain the cytotoxin-associated B gene.

C. VacA, a toxin from H. pylori, causes gastric cell apoptosis, reducing cancer risk.

D. MALT lymphomas associated with t(11;18) translocation respond to anti-H.Pylori therapy.

Correct Answer: A. Gastric lymphomas associated with H. pylori infection are primarily of B-cell origin.

Explanation: H. pylori, the first bacterium classified as a carcinogen, is associated with gastric adenocarcinomas and lymphomas, including MALT lymphomas of B-cell origin. (Option A is correct) Gastric adenocarcinomas arise due to increased epithelial cell proliferation in chronic inflammation caused by H. pylori infection. Pathogenicity genes like CagA (cytotoxin-associated A) trigger uncontrolled growth factor pathways. (Option 2) H. pylori produces a bacterial toxin VacA, inducing apoptosis in gastric epithelial cells and influencing cancer development. (Option 3) Chronic H. pylori infection leads to polyclonal B-cell proliferation triggered by H. pylori-reactive T cells, which contribute to the development of MALT lymphomas. Antibiotic therapy can eradicate H. pylori and "cure" MALT lymphomas by removing the antigenic stimulus for T cells . But, MALT lymphomas associated with t(11;18) translocation are resistant to anti-H.Pylori therapy. (Option 4)

@Neet_pg_bot

Q31: A 10-year-old girl presents with rapidly growing jaw swelling and pain. Further examination reveals bilateral enlargement of the mandible and maxilla. Biopsy suggests the presence of a starry-sky appearance. What is the characteristic chromosomal translocation associated with this tumor? (Q845492)

A. t(8;14)

B. t(15;17)

C. t(9;22)

D. t(11;14)

Correct Answer: A. t(8;14)

Explanation: The ‘starry sky pattern’ of histopathology represents scattered macrophages with phagocytosed cell debris among proliferating lymphoma cells, characteristic of Burkitt lymphoma. An aggressive B-cell non-Hodgkin lymphoma. Characterized by the translocation t(8;14)(q24;q32) , involving the MYC gene on chromosome 8q24 and the immunoglobulin heavy chain (IGH) locus on chromosome 14q32. It is most commonly associated with Epstein-Barr virus (EBV) infection, which is endemic in central Africa and New Guinea, where it is the most common childhood tumour. t(15;17) (Option B): Acute promyelocytic leukemia (PML::RARA fusion). t(9;22) (Option C): Chronic myeloid leukemia and some cases of ALL (BCR::ABL fusion, Philadelphia chromosome). t(11;14) (Option D): Mantle cell lymphoma (Cyclin D1 overexpression).

↑ *Back to this question in Part A*

@Neet_pg_bot

Q32: A 35-year-old woman with regular menstrual cycles undergoes routine Pap smear screening, which reveals a high-grade squamous intraepithelial lesion (HSIL) of the cervix. Further testing confirms infection with high-risk HPV type 16. Which of the following mechanisms regarding the oncogenic activity of E6 and E7 of HPV is correct? (Q845491)

A. E6 protein inhibits the degradation of p53.

B. E6 stimulates the expression of TERT.

C. E7 activates CDK inhibitors.

D. E7 can inactivate cyclins A and E.

Correct Answer: B. E6 stimulates the expression of TERT.

Explanation: E6 and E7 proteins from high-risk HPV types exhibit increased affinity for key cellular regulatory proteins (e.g., p53, RB) compared to low-risk HPV types. This enhanced affinity allows high-risk HPV-infected cells to evade tumour suppressor mechanisms, dysregulate cell cycle control, and promote oncogenic transformation. Oncogenic Activities of E6 Protein Oncogenic Activities of E7 Protein Binds to and promotes degradation of p53 → Impairs cell growth and apoptosis regulation (Option 1). Stimulates expression of TERT (telomerase reverse transcriptase) → Facilitates cellular immortalisation by maintaining telomere length. Disrupts interaction between RB protein and E2F transcription factors Inactivates CDK inhibitors (e.g., p21 and p27) (Option 3). Activates cyclins A and E (Option 4) All these mechanisms enhance cell cycle progression and cellular proliferation in HPV infections.

Robbins and Cotrans Pathologic basis of disease 10th edition, pg 324-325

↑ *Back to this question in Part A*

@Neet_pg_bot

Q33: A 35-year-old woman presents for a routine gynaecological examination. Her Pap smear and biopsy reveals abnormal cells suggestive of cervical dysplasia. Further, HPV testing indicates the presence of specific HPV types associated with cervical cancer. Which HPV types are most commonly linked to an increased risk of cervical cancer in this patient? (Q845490)

A. Low-risk 6, 11

B. High-risk 6, 11

C. Low-risk 16, 18

D. High-risk 16, 18

Correct Answer: D. High-risk 16, 18

Explanation: The abnormal cells in the pap smear and biopsy are known as Koilocytes characterised by a raisinoid nucleus and a perinuclear halo, which indicates HPV infection. High-risk HPV types like HPV 16 and HPV 18 are strongly linked to a higher risk of cervical cancer, including high-grade cervical dysplasia and invasive cancer. Low-risk HPV types such as HPV 6 and HPV 11 are often associated with genital warts such as condyloma

acuminatum and low-grade changes in cervical cells (Option 1). Integration of viral DNA within the E1/E2 open reading frame disrupts the E2 viral repressor gene, leading to increased expression of the HPV E6 and E7 oncogenes. Integration of high-risk HPV DNA is a critical step in the oncogenic process, distinguishing it from low-risk HPV infections.

References:

Robbins and Cotrans Pathologic basis of disease 10th edition, pg 324

↑ *Back to this question in Part A*

@Neet_pg_bot

Q34: A 55-year-old female radiology technician with 25 years of occupational exposure to diagnostic X-rays and fluoroscopy presents with a three-month history of increasing fatigue, unintentional weight loss, and frequent infections. Which cancer type is most likely associated with her occupational history? (Q845489)

A. Acute Myeloid Leukemia

B. Pancreatic cancer

C. Medullary thyroid cancer

D. Chronic Lymphocytic Leukemia

Correct Answer: A. Acute Myeloid Leukemia

Explanation: Due to prolonged exposure to ionising radiation the patient is at an increased risk of developing Acute Myeloid Leukemia (M/C cancer in individuals with exposure to ionising radiation). Ionising radiation, which includes electromagnetic (x-rays, γ rays) and particulate (α particles, β particles, protons, neutrons) radiations, is carcinogenic. It can cause cancer by directly damaging cellular DNA, leading to mutations that disrupt normal gene function and structure. Leukaemia often has a relatively short latent period, typically around 7 years or less after exposure to certain factors like radiation or chemicals. Solid tumours like breast, colon, thyroid, and lung cancers generally have longer latent periods compared to leukaemia. Pancreatic cancer (Option 2) Risk of Pancreatic cancer is more associated with cigarette smoking, heavy alcohol drinking, obesity, and diet (high intake of saturated fat and/or meat, particularly smoked or processed meats). Medullary thyroid cancer (Option 3) Medullary thyroid cancer is primarily associated with genetic factors, specifically mutations in the RET proto-oncogene, rather than radiation exposure. However, the risk of Papillary carcinoma of the thyroid and Follicular carcinoma of the thyroid have a high association with radiation exposure. Chronic Lymphocytic Leukemia (Option 4) Chronic Lymphocytic Leukemia (CLL) is the only leukaemia not associated with radiation exposure.

References:

Robbins and Cotrans Pathologic basis of disease 10th edition, Pg 323

↑ *Back to this question in Part A*

@Neet_pg_bot

Q35: Which of the following radiations is the most common cause of skin cancer? (Q845488)

A. UV-A radiation

B. UV-B radiation

C. UV-C radiation

D. UV-D radiation

Correct Answer: B. UV-B radiation

Explanation: UV-B radiation is the major cause of sunburn and skin cancer. These medium wavelengths (280-320 nm) primarily affect the outer layers of the skin and are highly mutagenic. It is responsible for inducing the formation of pyrimidine dimers within DNA, leading to mutations that can result in various types of skin cancer, including squamous cell carcinoma, basal cell carcinoma, and melanoma. Fair-skinned individuals are at higher risk. UV-A radiation (Option 1): UV-A rays are longer wavelengths (320-400 nm) and penetrate deeper into the skin. They primarily cause skin ageing. UV-A radiation, particularly in combination with UV-B, can increase the risk of skin cancer. UV-C radiation (Option 3) These shorter wavelengths (200-280 nm) are extremely potent in terms of DNA damage, but they are largely filtered out by the Earth's ozone layer and do not reach the surface in significant amounts. UV-D radiation (Option 4): The UV spectrum typically consists of UV-A, UV-B, and UV-C and no UV-D radiation.

Q19 (p. 1371)	*Q20 (p. 1372)*	*Q21 (p. 1373)*			

Q1: Which of the following best describes the change in the nuclear-to-cytoplasmic ratio seen in malignant cells compared to normal cells? (Q879702)

A. Decreased ratio due to abundant cytoplasm

B. Increased ratio due to larger nuclei and scant cytoplasm

C. No change; ratio remains constant across benign and malignant cells

D. Decreased ratio due to nuclear shrinkage (pyknosis)

Correct Answer: B. Increased ratio due to larger nuclei and scant cytoplasm

Explanation: Normal cells:N: C ratio ≈ 1:4 to 1:6 (small nucleus, abundant cytoplasm). Malignant/anaplastic cells:N: C ratio increases to 1:1 or higher, because nuclei become large, hyperchromatic, and cytoplasm is relatively scant. Diagnostic importance: High N: C ratio is a hallmark of anaplasia and malignancy; used in cytology (e.g., Pap smear, FNAC) to identify malignant cells.

https://pubmed.ncbi.nlm.nih.gov/35977407/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following markers is not used to identify gastrointestinal stromal tumors (GISTs)? (Q879908)

A. KIT

B. SDH

C. PDGFRA

D. NRG-1

Correct Answer: D. NRG-1

Explanation: NRG-1 is not used to identify Gastrointestinal stromal tumors (GISTs) → mesenchymal tumors of the GI tract. Markers used for diagnosis: KIT (CD117): Expressed in ~95% of GISTs; key diagnostic marker. PDGFRA mutations: Found in a subset of KIT-negative GISTs; also drives tumor growth. SDH (succinate dehydrogenase): Loss of SDH subunits is seen in SDH-deficient GISTs , a distinct subgroup.

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.253,709

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following is not classified as an oncofetal tumor marker? (Q879907)

A. Alpha-fetoprotein

B. Carcinoembryonic antigen

C. Prostate-specific antigen

D. Both A and B

Correct Answer: C. Prostate-specific antigen

Explanation: Alpha-fetoprotein and carcinoembryonic antigen are classic Oncofetal Tumor Markers expressed during fetal development and certain cancers, while prostate-specific antigen is a tissue-specific marker unrelated to fetal proteins. Oncofetal antigens are proteins expressed during fetal life and re-expressed in certain malignancies. Examples: Alpha-fetoprotein (AFP): (Option A ruled out) Normally produced by the fetal liver and yolk sac. Reappears in hepatocellular carcinoma, yolk sac tumors, some GI carcinomas . Carcinoembryonic antigen (CEA): (Option B ruled out) Produced in fetal gut, pancreas, liver. Seen in colorectal carcinoma, pancreatic carcinoma, gastric carcinoma, breast carcinoma .

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.300

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following tumor markers is most useful for diagnosing pheochromocytoma? (Q879906)

A. Calcitonin

B. Catecholamine

C. Alpha-fetoprotein

D. Carcinoembryonic antigen

Correct Answer: B. Catecholamine

Explanation: Pheochromocytomas are tumors of chromaffin cells of the adrenal medulla (or extra-adrenal paraganglia). They characteristically produce catecholamines (epinephrine, norepinephrine, dopamine) . Diagnosis is confirmed by measuring catecholamines and their metabolites (metanephrines, VMA) in plasma or urine. Incorrect Options: Calcitonin (Option A): Marker for medullary thyroid carcinoma, not pheochromocytoma. Alpha-fetoprotein (AFP) (Option C): Elevated in hepatocellular carcinoma, yolk sac tumors, and non-seminomatous germ cell tumors. Carcinoembryonic antigen (Option D): Marker for colorectal carcinoma and pancreatic carcinoma , not pheochromocytoma.

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.300.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 48-year-old man develops recurrent, painful, red, tender nodules that appear and disappear on his arms and legs over several weeks. This clinical picture suggests migratory thrombophlebitis. Which of the following cancers is not commonly associated with this condition? (Q879904)

A. Uterine carcinoma

B. Pancreatic carcinoma

C. Bronchogenic carcinoma

D. Bladder carcinoma

Correct Answer: D. Bladder carcinoma

Explanation: The condition described is Migratory Superficial Thrombophlebitis , which results from tumor-induced hypercoagulability; however, bladder carcinoma is not associated with this manifestation. Most common tumor associations: Pancreatic adenocarcinoma (classic) (Option B ruled out) Bronchogenic carcinoma (Option C ruled out) Uterine carcinoma (Option A ruled out)

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.294

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 55-year-old man presents with headache, dizziness, and blurred vision. He has a ruddy complexion and mild hypertension. Labs show hemoglobin 19.2 g/dL and hematocrit 60%. Secondary polycythemia from ectopic erythropoietin is suspected. Which tumor is least likely to be responsible? (Q879901)

A. Melanoma

B. Renal cell carcinoma

C. Cerebellar hemangioma

D. Hepatocellular carcinoma

Correct Answer: A. Melanoma

Explanation: Melanoma is not associated with polycythemia. Paraneoplastic polycythemia occurs due to ectopic production of erythropoietin (EPO) by certain tumors. Tumors commonly associated with increased EPO and secondary polycythemia include: Renal cell carcinoma (Option B ruled out) Cerebellar hemangioblastoma (Option C ruled out) Hepatocellular carcinoma (Option D ruled out)

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.294

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Based on the image and clinical presentation of this 58-year-old obese female, which of the following tumors is not commonly associated with this dermatologic condition? (Q879896)

A. Gastric carcinoma

B. Bladder carcinoma

C. Uterine carcinoma

D. Thymoma

Correct Answer: B. Bladder carcinoma

Explanation: The image is consistent with Acanthosis Nigricans - Bladder carcinoma is not a recognized cause. It may be: Benign - associated with obesity and insulin resistance. Malignant (paraneoplastic) - most often associated with gastric carcinoma , and less frequently with uterine carcinoma and thymic tumors . (Option A, B, C ruled out)

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no.294

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 55-year-old patient presents with generalized fatigue, muscle weakness, and bone pain. Laboratory tests reveal a serum calcium level of 14.2 mg/dL. Which type of lung cancer is most commonly associated with this hypercalcemia? (Q879874)

A. Squamous cell carcinoma

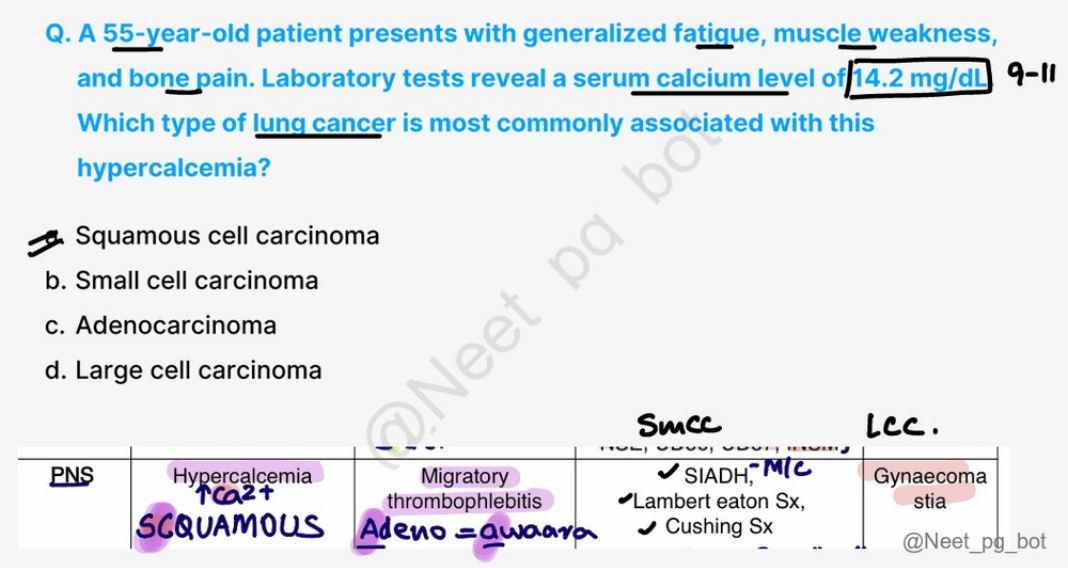
B. Small cell carcinoma

C. Adenocarcinoma

D. Large cell carcinoma

Correct Answer: A. Squamous cell carcinoma

Explanation:



References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 294

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which subtype of acute myeloid leukemia is characteristically linked to disseminated intravascular coagulation (DIC) as a paraneoplastic syndrome? (Q879871)

A. AML minimally differentiated

B. Acute promyelocytic leukemia

C. Acute myelomonocytic leukemia

D. Acute megakaryoblastic leukemia

Correct Answer: B. Acute promyelocytic leukemia

Explanation: Acute promyelocytic leukemia (APL, AML-M3) is characterized by the t(15;17)(q22;q12) translocation, leading to the PML-RARA fusion gene. DIC as a paraneoplastic manifestation: APL blasts contain primary granules rich in tissue factor and procoagulants . Upon lysis (spontaneous or chemotherapy-induced), these trigger massive activation of the coagulation cascade , resulting in DIC. Incorrect Options: AML minimally differentiated (Option A): Rare, lacks specific features of DIC Acute myelomonocytic leukemia (M4) (Option C) can present with leukostasis or organ infiltration, but DIC is uncommon Acute megakaryoblastic leukemia (M7) (Option D): More often associated with myelofibrosis and thrombocytopenia , not classic DIC

References:

Robbins and Cotran, Pathologic Basis of Disease, 11th Edition, Page no. 294

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Choose the correct option regarding tumor invasion and metastasis: Assertion (A): All tumors that show invasive properties eventually metastasize. Reason (R): The ability to invade allows tumor cells to penetrate blood vessels or lymphatics, facilitating spread to distant organs. (Q879708)

A. Both A and R are true, and R correctly explains A

B. Both A and R are true, but R does not explain A

C. A is false, but R is true

D. A is true, but R is false

Correct Answer: C. A is false, but R is true

Explanation: Invasion is a hallmark of malignancy, but not all invasive tumors metastasize (e.g., basal cell carcinoma of the skin invades locally but rarely metastasizes). The reason is true: invasive ability allows tumors to enter lymphatics or blood vessels, which is a prerequisite for metastasis.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 242

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A biopsy from a liver mass in a 60-year-old man reveals clusters of malignant epithelial cells forming irregular glands. The surrounding liver architecture is compressed but not invaded by native hepatocytes. Which histological feature most strongly suggests that this mass represents a metastatic carcinoma rather than a primary liver tumor? (Q879705)

A. Presence of malignant epithelial cells with atypia

B. Lack of normal organ-specific architecture within the tumor

C. Presence of mitotic figures in tumor cells

D. Hyperchromatic nuclei with increased nuclear-to-cytoplasmic ratio

Correct Answer: B. Lack of normal organ-specific architecture within the tumor

Explanation: Key Histological Features of Metastatic Cancer: Tumor cells often do not reproduce the normal architecture of the host organ. Histology resembles the primary site (e.g., breast adenocarcinoma metastasis showing ductal/glandular patterns in bone/liver). Disruption or replacement of native tissue. Atypia, pleomorphism, abnormal mitoses, high N:C ratio (features of malignancy, but not specific for metastasis). Sometimes multiple nodules at the metastatic site. Incorrect Options: Presence of malignant epithelial cells with atypia (Option A) : This indicates malignancy but does not differentiate primary from metastatic tumors. Presence of mitotic figures in tumor cells (Option C) : Shows proliferation but is not specific to metastasis. Hyperchromatic nuclei with increased nuclear-to-cytoplasmic ratio (Option D) : Feature of malignancy, not specific for metastatic vs primary.

https://pmc.ncbi.nlm.nih.gov/articles/PMC10165727/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Which of the following is used in immunohistochemical (IHC) staining as a chromogen to diagnose tumours of unknown origin? (Q845495)

A. Diaminobenzidine

B. Congo Red

C. Masson's Trichrome

D. Mucicarmine

Correct Answer: A. Diaminobenzidine

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: 3,3′ Diaminobenzidine (DAB) is a chromogen used in histochemical and IHC staining. In IHC, DAB is a substrate for a peroxidase enzyme coupled to a primary or secondary antibody. It is oxidised and converted to an insoluble polymer, precipitating as a dark brown pigment, which allows visualisation of the target molecule. Congo red can stain (Option B) amyloid fibres in red and orange. When viewed under polarised light in a microscope, Congo-red-stained tissues high in amyloid will show bright apple-green birefringence . Masson's Trichrome stain (Option C) is a three-color stain that highlights collagen in blue, muscle in red, and nuclei in blue-black. It helps identify fibrosis in the heart, lungs, and kidney . Mucicarmine stains (Option D) mucin, a secretion produced in epithelial and connective tissue and capsule of Cryptococcus . IHC Markers for Tumors: Marker Type Marker Name Associated Tumor / Tissue Epithelial Cytokeratins (CK) Carcinomas (e.g., Lung, Breast, Colon) Mesenchymal Vimentin Sarcomas Melanocytic S100, HMB-45, Melan-A Melanoma Leukocyte CD45 (LCA) Lymphomas Muscle Desmin, Myogenin Rhabdomyosarcoma, Leiomyosarcoma Neural NSE, Synaptophysin, Chromogranin Neuroendocrine tumors (Small cell CA, Carcinoid) Vascular CD31, ERG Angiosarcoma Prostate PSA Prostate Adenocarcinoma Germ Cell AFP, β-hCG Yolk sac tumor, Choriocarcinoma

www.ncbi.nlm.nih.gov/pmc/articles/PMC5775208/

www.ncbi.nlm.nih.gov/books/NBK557663/

↑ *Back to this question in Part A*

@Neet_pg_bot

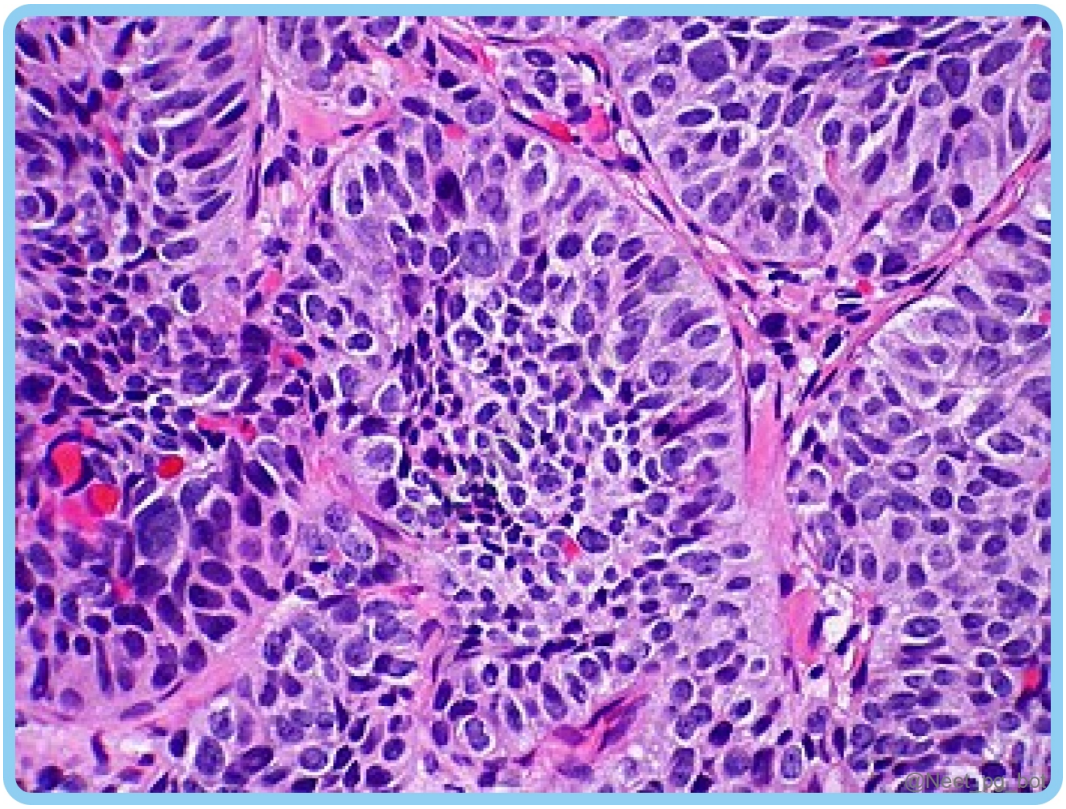
Q13: An appendix specimen, whose HPE is shown below, had a 2 cm submucosal nodule identified. Electron microscopy showed numerous neurosecretory granules in the cytoplasm. Twenty-four-hour urine analysis showed an elevation of 5-hydroxy indoleacetic acid (5-HIAA). Which of the following would not be seen in this condition? (Q845506)

A. Flushing

B. Diarrhea

C. Valvular heart disease

D. Bronchodilation



Correct Answer: D. Bronchodilation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A submucosal nodule with neurosecretory granules on electron microscopy and elevated 5-HIAA confirms a neuroendocrine (carcinoid) tumor of the appendix, typically at the tip, and it is not associated with bronchodilation Common Microscopic features of Neuroendocrine tumors: The "Salt-and-Pepper" Nuclei: The most diagnostic feature is the chromatin . It appears as a mix of fine and coarse clumps, creating a "speckled" or grainy look (similar to spilled salt and pepper) within a round, uniform nucleus. Organoid Growth Patterns: The cells don't grow in random clumps; they arrange themselves in organized, gland-like structures: Nests: Solid clusters of cells. Trabeculae: Long, thin ribbons or cords. Rosettes: Cells arranged in a circle around a central point. Granular Cytoplasm: The cells typically have an eosinophilic (pink) , granular cytoplasm. These granules represent the storage of hormones or neurotransmitters. Key Markers (IHC): To confirm the diagnosis, pathologists stain for specific proteins: Synaptophysin (Most sensitive) Chromogranin A (Most specific) {{caption_text}} Image showing cells arranged in the form of a rosette (cells in nests) {{caption_text}} Image showing salt and pepper chromatin Carcinoid tumors: Cell of Origin: Derived from Argentaffin cells (also known as Kulchitsky cells). Vasoactive Mediators: While serotonin (5-HT) is primary, these tumors also secrete kallikrein, bradykinin, histamine, and prostaglandins . Primary Locations: Most common in the midgut (ileum, appendix). They are also found in the bronchi and ovaries. Clinical features: S - S ystemic fibrosis H - H epatomegaly, H eart disorders (valvular heart disorders - tricuspid regurgitation) (Option C ruled out) I - I ntestinal motility increases (diarrhoea, abdominal cramping) (Option B ruled out) V - V asodilation (flushing, pruritus)

(Option A ruled out) A - A sthma-like features - wheezing, dyspnea (bronchoconstriction) (Option D) The "Liver Rule": GI carcinoid tumors only cause systemic syndrome after they metastasize to the liver , as the liver normally metabolizes serotonin before it reaches systemic circulation. Biochemical Marker: The gold standard for screening is the 24-hour urine collection for 5-HIAA (5-hydroxyindoleacetic acid), a metabolite of serotonin. Dietary Interference: Students should know that eating walnuts, pecans, or bananas can falsely elevate 5-HIAA levels. Vitamin Deficiency: Chronic carcinoid syndrome can lead to Pellagra (Niacin/B3 deficiency) because the tumor uses up all the body's Tryptophan to make serotonin.

@Neet_pg_bot

Q14: Which of the following paraneoplastic syndrome is not associated with lung cancer? (Q845504)

A. Dermatomyositis

B. Acanthosis nigricans

C. Myasthenia

D. Red cell aplasia

Correct Answer: D. Red cell aplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Red cell aplasia is associated with thymic neoplasms and not lung cancer. Paraneoplastic syndromes associated with lung cancer are as follows: Cushing syndrome (Ectopic ACTH) Small cell carcinoma of the lung , Pancreatic tumours SIADH (Inappropriate ADH) Small cell carcinoma of the lung , CNS tumors Hypercalcemia (PTHrP) Squamous cell carcinoma of the lung Myasthenia (Lambert-Eaton) (Option C) Bronchogenic carcinoma Acanthosis nigricans (Option B) Adenocarcinoma lung, Gastric adenocarcinoma Dermatomyositis (Option A) Bronchogenic carcinoma Hypertrophic osteoarthropathy and clubbing of the fingers Adenocarcinoma lung Venous thrombosis (Trousseau phenomenon Pancreatic carcinoma, Bronchogenic carcinoma Polycythemia (Ectopic EPO) Renal cell carcinoma , Hepatocellular carcinoma, Hemangioblastoma Nonbacterial Thrombotic Endocarditis Advanced Adenocarcinomas (esp. Pancreatic) Opsoclonus-myoclonus syndrome Neuroblastoma (children), Small cell lung cancer (adults) Pure Red Cell Aplasia Thymoma Hypoglycemia Hepatocellular carcinoma , Mesothelioma, Insulinomas

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 60-year-old male was diagnosed with a lung malignancy two months ago. He now came with complaints of malaise, abdominal pain, bone pain, lethargy, and confusion. The intern suspects a condition related to lung cancer and decides to send a blood test. Which of the following would be the appropriate test? (Q845503)

A. Erythropoietin

B. Adrenocorticotrophic hormone

C. Parathyroid hormone-related protein

D. Antidiuretic hormone

Correct Answer: C. Parathyroid hormone-related protein

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario indicates paraneoplastic hypercalcemia likely linked to lung cancer, and the appropriate diagnostic test is parathyroid hormone-related protein (PTHrP). Paraneoplastic syndrome: Refers to signs and symptoms that cannot be explained by the tumour's anatomic distribution or hormones indigenous to the tumour tissue. These occur in about 10% of patients with cancer It may be the earliest manifestation of an occult neoplasm. It may mimic metastatic disease and confound treatment. PTHRP leads to hypercalcemia, which can present as Nausea, vomiting, Abdominal pain (groans) , Bone pain (bones) , Renal stones (stones) , Fatigue malaise (moans) , Polyuria, polydipsia, Constipation (thrones) , Lethargy, confusion, depression, Memory loss (psychic overtones). PTHRP is also associated with Squamous cell carcinoma of the lung Breast carcinoma Renal carcinoma Adult T-cell leukaemia/lymphoma Erythropoietin (Option A) levels can be checked in polycythemia, which associated with renal carcinoma, cerebellar hemangioma, and hepatocellular carcinoma . Adrenocorticotropic hormone(ACTH) (Option B) levels can be checked in Cushing’s syndrome which is associated with small cell carcinoma of the lung, pancreatic carcinoma, and neural tumours . Antidiuretic hormone (Option D) levels can be checked in Syndrome of inappropriate antidiuretic hormone secretion(SIADH) which is associated with small cell carcinoma of the lung and intracranial neoplasms .

@Neet_pg_bot

Q16: Match the given neoplasias with their respective immunohistochemistry markers. 1. Carcinoma A. S100 2. Sarcoma B. Leucocyte common antigen 3.

Lymphoma C. Cytokeratin 4. Melanoma D. Vimentin (Q845502)

A. 1-C, 2-A, 3-B, 4-D

B. 1-A, 2-C, 3-B, 4-D

C. 1-C, 2-D, 3-B, 4-A

D. 1-A, 2-D, 3-B, 4-C

Correct Answer: C. 1-C, 2-D, 3-B, 4-A

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The correctly matched pair of neoplasias and their respective immunohistochemistry(IHC) markers are: Carcinoma (epithelial origin/squamous cell carcinoma) Cytokeratin Cytokeratin 1, cytokeratin 10 Sarcoma Vimentin, desmin(skeletal muscle) Lymphoma Leucocyte common antigen, CD 45 Melanoma S100, HMB45 , Melan A

References:

Robbins Pathology 10th edition: Page no 332

www.ncbi.nlm.nih.gov/pmc/articles/PMC3439132/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 45-year-old female presents with a breast lump. On biopsy, the tissue shows anaplastic cells without any differentiation. Immunohistochemistry (IHC) staining is performed to characterise the tumour further. Which marker would be most appropriate to confirm the epithelial origin of the tumour cells in breast cancer? (Q845500)

A. CD20

B. p63

C. TTF-1

D. CK7

Correct Answer: D. CK7

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In a female with a breast lump and presence of anaplastic cells, CK7 (cytokeratin 7) is the most appropriate marker to confirm the epithelial origin of the tumor, as cytokeratins are commonly expressed in all carcinomas. In I mmunohistochemistry (IHC) , a CK7 and CK20 profile is commonly used to help determine the tumor origin. Most female-origin cancers (breast, endometrial, thyroid, cervical) typically show a CK7-positive and CK20-negative pattern. (Option D) ER (estrogen receptor), PR (progesterone receptor), and HER2 (human epidermal growth factor receptor 2) are other markers that can be positive in breast cancer, which help in deciding management. CD20 (Option A) is a B-cell marker that is typically positive in B-cell lymphomas, including non-Hodgkin lymphoma (NHL). Pp3 (Option B) is a marker positive in squamous cell carcinoma in the lung. TTF-1(thyroid transcription factor-1) (Option D) is a marker positive in the adenocarcinoma of the lung.

References:

Robbins Pathology 10th edition - Pg- 993, 719, 593, 1056,718 Panels of immunohistochemical markers help determine primary sites of metastatic adenocarcinoma - PubMed (nih.gov)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Which of the following conditions is FNAC helpful in establishing diagnosis ? (Q845499)

A. Follicular adenoma of the thyroid

B. Testicular cancer

C. Hydatid cyst

D. Medullary thyroid carcinoma

Correct Answer: D. Medullary thyroid carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: FNAC serves as an initial diagnostic tool for medullary thyroid carcinoma (MTC), often revealing pinkish amyloid material alongside malignant cells—findings that are highly suggestive of MTC. Limitations of FNAC: Cystic changes cannot be identified. Inadequate cell sampling may require repeated procedure Indications Contraindications /limitations Thyroid disorders Follicular disorders of the thyroid (Limitation) (Option A ruled out) Breast lesions Infections, septicemia Lymph node evaluation Bleeding disorders Pancreatic malignancy Hydatid cyst- Risk of anaphylaxis (Option C ruled out) Most solid organ masses accessible via FNAC Testicular cancer- Increased risk of spread of cancer (Option B ruled out) Follicular adenoma of the thyroid (Option A): FNAC cannot definitively diagnose follicular neoplasms, as the key distinction between benign and malignant forms lies in detecting capsular and vascular invasion. This assessment isn't possible with FNAC, as the thin

needle doesn't allow evaluation of tissue architecture.

@Neet_pg_bot

Q19: What needle size is typically employed for Fine Needle Aspiration Cytology (FNAC) procedures? (Q845498)

A. 18-gauge needle

B. 22-gauge needle

C. 25-gauge needle

D. 30-gauge needle

Correct Answer: C. 25-gauge needle

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The appropriate needle size commonly used for FNAC procedures is the 25-27-gauge needle. Fine Needle Aspiration Cytology (FNAC): FNAC is a rapid, minimally invasive diagnostic technique used to investigate lumps or masses. A slender needle is used to extract cells for cytological examination. Needle Size: The typically employed size is a 25–27 gauge needle . This provides effective sample collection while minimizing patient discomfort and tissue damage. Thinner needles (higher gauge) are often preferred for vascular organs like the thyroid gland to reduce the risk of hematoma or complications. Procedure: The lesion is identified via palpation or imaging (ultrasound, CT, or MRI). The needle is inserted into the lesion, and gentle suction is applied to draw cells into the syringe. Multiple passes are often made to ensure a sufficient sample volume. Material is smeared onto glass slides or preserved in a fixative solution for analysis. Contraindications (C/I) for FNAC: While generally safe, FNAC should be avoided or performed with extreme caution in the following scenarios: Bleeding Diathesis: Patients with severe coagulopathy or those on high-dose anticoagulants (risk of uncontrollable hematoma). Suspected Pheochromocytoma: Needle entry can trigger a massive release of catecholamines, leading to a hypertensive crisis. Suspected Echinococcal (Hydatid) Cyst: Aspiration can lead to fluid leakage, potentially causing life-threatening anaphylactic shock or peritoneal seeding. Lack of Safe Access: If the lesion is located behind major blood vessels or vital structures that cannot be avoided. Critical Diagnostic Limitations: ■■■■■■■ Follicular Adenoma vs. Carcinoma: FNAC cannot differentiate between a follicular adenoma and a follicular carcinoma of the thyroid. Distinction between the two requires observing capsular or vascular invasion , which can only be seen on formal histology (biopsy), not on a cell smear. Non-Diagnostic Samples: Highly cystic lesions or very hard, fibrotic tumors may yield "inadequate" or "pauci-cellular" samples.

@Neet_pg_bot

Q20: Which of the following is used to determine treatment response in patients with colorectal cancer? (Q845497)

A. Alpha-fetoprotein

B. Carcinoembryonic antigen

C. Human Chorionic Gonadotropin

D. Calcitonin

Correct Answer: B. Carcinoembryonic antigen

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Carcinoembryonic antigen (CEA) can be used to assess responsiveness to treatment in colorectal cancers. Persistent elevation of CEA after successful tumor resection suggests residual or recurrent disease and warrants further investigation. It is associated with the following cancers: (Mnemonic: C K a P i L SH arma) C - CEA K - Colon cancer P - Pancreatic cancer L - Lung cancer S - Stomach cancer H - Heart tumors
Alpha-fetoprotein (Option A) is associated with yolk sac tumours and hepatic tumors (hepatocellular carcinoma, hepatoblastoma). Human Chorionic Gonadotropin (Option C) is elevated in choriocarcinoma and non-seminomatous germ cell tumors. Calcitonin (Option D) is a tumor marker for Medullary thyroid carcinoma.

@Neet_pg_bot

Q21: Which of the following is a marker for breast cancer? (Q845496)

A. CA-19-9

B. CA-125

C. CA-15-3

D. β - HCG

Correct Answer: C. CA-15-3

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CA-15-3 is the tumour marker seen in breast cancer. Tumor marker Associated conditions Alpha-fetoprotein (AFP) Hepatocellular carcinoma (HCC) Hepatoblastoma Yolk sac tumour (endodermal sinus tumour) Nonseminomatous germ cell tumour of testis ↑ AFP: abdominal wall defects, neural tube defects ↓ AFP: associated with trisomy 21, 18, and 13 β-HCG (Option D ruled out) Nonseminomatous testicular germ cell tumours (choriocarcinoma, embryonal cell carcinoma, mixed germ cell tumour, seminoma) Ovarian cancer: choriocarcinoma (gestational trophoblastic disease) Carcinoembryonic antigen (CEA) Colorectal cancer Pancreatic cancer Breast cancer Lung cancer (especially in non-small cell cancers) Gastric cancer Prostate-specific antigen (PSA) Prostate cancer Benign prostatic hyperplasia Prostatitis Calcitonin Medullary thyroid cancer (both sporadic and associated with MEN 1 and MEN 2) Alkaline phosphatase Metastases to bone or liver Paget disease of the bone Placental alkaline phosphatase Seminoma Lactate dehydrogenase Ovarian cancer (dysgerminoma) Testicular germ cell tumours (both seminoma and nonseminoma) Lymphomas Ewing's sarcoma Neuron specific enolase (NSE) Neuroendocrine tumors Small cell lung cancer Carcinoid tumour Neuroblastoma CA 19–9 (Option A ruled out) Pancreatic adenocarcinoma Colon cancer Cholangiocarcinoma CA 15–3 and CA 27–29 (Option C) Breast cancer CA 125 (Option B ruled out) Ovarian carcinoma Other gynecologic malignancies S-100 protein (S100A) and (S100B) Malignant melanoma SMRP Mesothelioma

Q1: What is the consequence of the RB protein being in its hypophosphorylated (active) state? (Q879748)

A. Cell cycle is halted at the G2 phase

B. Cell cycle is arrested at the G1 phase

C. RB protein’s phosphorylation status does not impact the cell cycle

D. Cell cycle continues normally, leading to cell division

Correct Answer: B. Cell cycle is arrested at the G1 phase

Explanation: Hypophosphorylated RB binds E2F transcription factors, blocking progression into S phase. RB (Retinoblastoma) is a tumor suppressor protein encoded by the RB1 gene . RB is a key negative regulator of the G1/S transition, acting as a “governor” of cell proliferation Hypophosphorylated RB: Active, binds and inhibits E2F transcription factors → prevents G1/S progression. (Option B) Hyperphosphorylated RB: Inactive, releases E2F → allows S-phase entry and cell cycle progression. RB mutations are linked to retinoblastoma, osteosarcoma, and somatic mutations in glioblastoma, lung, breast, and bladder cancers. Incorrect Options: Cell cycle is halted at the G2 phase (Option A): RB controls the G1 to S transition, not G2. RB protein’s phosphorylation status does not impact the cell cycle (Option C): RB phosphorylation is essential for G1/S progression. Cell cycle continues normally, leading to cell division (Option D): Hypophosphorylated RB inhibits E2F, preventing S-phase entry.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following disorders is unrelated to defects in homologous recombination-mediated DNA repair pathways? (Q879792)

A. Bloom syndrome

B. Ataxia-telangiectasia

C. Fanconi anemia

D. Li-Fraumeni syndrome

Correct Answer: D. Li-Fraumeni syndrome

Explanation: Li-Fraumeni syndrome is caused by germline TP53 mutations; it is associated with defective p53-mediated cell cycle control and apoptosis, not directly with homologous recombination repair. Homologous Recombination (HR) repair is a critical pathway for repairing DNA double-strand breaks and cross-links. Disorders caused by defects in HR factors include: Bloom syndrome: Caused by loss-of-function mutations in a helicase required for HR, associated with developmental anomalies and increased cancer risk. (Option A ruled out) Ataxia-telangiectasia: Caused by ATM defects; patients show impaired DNA double-strand break repair via HR, immunodeficiency, and cancer predisposition. (Option B ruled out) Fanconi anemia: Mutations in Fanconi pathway genes disrupt HR-mediated repair of DNA cross-links, leading to bone marrow failure and leukemia. (Option C ruled out)

Robbins, Cotran & Kumar's Pathologic Basis of Disease, 11th Edition, Page. 282

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following oncogenes, when mutated, can give rise to neoantigens recognized by the immune system? (Q879786)

A. KRAS

B. TP53

C. CDKN2A

D. PTEN

Correct Answer: A. KRAS

Explanation: KRAS is an oncogene; point mutations produce altered proteins that can serve as tumor neoantigens. Neoantigens are protein antigens produced from genes bearing driver or passenger mutations. Mutated oncogenes

such as KRAS encode variant proteins that have never been seen by the immune system and can therefore be recognized as non-self by CD8+ cytotoxic T cells. These neoantigens contribute to protective antitumor immunity and are often associated with tumors having high mutational loads. Incorrect Options: TP53 (Option B): Tumor suppressor gene; mutations generally do not produce oncogenic proteins recognized as neoantigens. CDKN2A (Option C): Tumor suppressor involved in cell cycle regulation; loss-of-function mutations do not generate neoantigens. PTEN (Option D): Tumor suppressor regulating PI3K signaling; mutations are typically inactivating and do not produce immunogenic neoantigens.

Robbins, Cotran & Kumar's Pathologic Basis of Disease, 11th Edition, Page. 277

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following changes does not convert a proto-oncogene into an oncogene? (Q879784)

A. Gene amplification

B. Point mutation

C. Chromosomal translocation

D. Gene deletion

Correct Answer: D. Gene deletion

Explanation: Gene deletion typically results in loss of function and therefore does not convert a proto-oncogene into an oncogene. Proto-oncogenes→ Normal cellular genes that, when altered, promote excessive cell growth. They can be activated into oncogenes by multiple mechanisms: Gene amplification (Option A ruled out) ERBB2 (HER2) - Breast carcinoma FGF3 - Stomach, bladder, breast cancers NMYC - Neuroblastoma CCND1 - Breast and esophageal cancers. Point mutations (Option B ruled out) KRAS - Colon, lung, and pancreatic tumors HRAS - Bladder and kidney tumors NRAS - Melanomas BRAF - Melanomas, leukemias, and colon carcinoma JAK2 - Myeloproliferative neoplasms. Chromosomal translocations (Option C ruled out) MYC - Burkitt lymphoma CCND1 - Mantle cell lymphoma and multiple myeloma ABL (BCR-ABL) - Chronic myeloid leukemia and ALL ALK - Lung adenocarcinoma and some lymphomas NOTCH1 - Leukemias and lymphomas.

Robbins, Cotran & Kumar's Pathologic Basis of Disease, 11th Edition, Page. 253

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following is a receptor tyrosine kinase, rather than a nonreceptor tyrosine kinase? (Q879766)

A. ABL

B. BCR-ABL

C. JAK2

D. EGFR

Correct Answer: D. EGFR

Explanation: EGFR is a receptor tyrosine kinase located at the plasma membrane. Nonreceptor tyrosine kinases are cytoplasmic or nuclear enzymes that become oncogenic through translocations, rearrangements, or point mutations. ABL (Option A ruled out) and JAK2 (Option C ruled out) fall into this group. BCR-ABL (Option B) represents a fusion protein with constitutive activity.

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page no. 255- 256

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which gene plays a key role in promoting epithelial-mesenchymal transition (EMT) in carcinomas? (Q879764)

A. E-cadherin

B. SNAIL

C. Vimentin

D. Smooth muscle actin

Correct Answer: B. SNAIL

Explanation: SNAIL is a transcription factor that promotes Epithelial-mesenchymal transition (EMT) by downregulating epithelial markers and upregulating mesenchymal markers, thereby facilitating tumor invasion and metastasis. Epithelial cells lose their polarity and adhesion properties and acquire mesenchymal traits (enhancing motility and invasiveness). Dissociation of cancer cells is often due to loss of intercellular adhesion. E-cadherin mediates epithelial cell-cell adhesion; its loss facilitates EMT. EMT is controlled by transcription factors SNAIL

and TWIST. Involves downregulation of epithelial markers (E-cadherin) and upregulation of mesenchymal markers (vimentin, smooth muscle actin). EMT contributes to a promigratory phenotype, aiding metastasis in carcinomas like breast and prostate cancers. Incorrect Options: E-cadherin (Option A): A cell adhesion molecule; its loss occurs during EMT but it does not drive the transition. Vimentin (Option C): A mesenchymal marker upregulated during EMT, not a transcriptional regulator. Smooth muscle actin (Option D): Another mesenchymal marker; indicates EMT but does not initiate it.

Robbins, Cotran & Kumar's Pathologic Basis of Disease, 11th Edition, Page. 274

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following mechanisms is commonly used by cancer cells to evade apoptosis? (Q879763)

A. Overexpression of pro-apoptotic BAX and BAK proteins

B. Loss of TP53 function and overexpression of anti-apoptotic BCL2 family proteins

C. Increased activation of caspase-9

D. Enhanced release of cytochrome c from mitochondria

Correct Answer: B. Loss of TP53 function and overexpression of anti-apoptotic BCL2 family proteins

Explanation: Loss of TP53 and overexpression of BCL2 block apoptosis and allow tumor survival. The intrinsic (mitochondrial) pathway is the main regulator of apoptosis in cancer. BH3-only proteins (BIM, BAD, BID, PUMA) promote apoptosis by neutralizing anti-apoptotic BCL2 members. Loss of p53 or BCL2 overexpression allows resistance to chemotherapy and radiation. Incorrect Options: Overexpression of BAX and BAK (Option A): Promotes apoptosis rather than preventing it. Increased caspase-9 activation (Option C): Caspase-9 activation triggers apoptosis, so this does not help cancer cells evade death. Enhanced cytochrome c release (Option D): Promotes apoptosis; cancer cells inhibit this process to survive.

Robbins, Cotran & Kumar's Pathologic Basis of Disease, 11th Edition, Page. 270-271

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following statements about BRCA mutations is correct? (Q879762)

A. BRCA1 and BRCA2 are involved in DNA repair via homologous recombination

B. BRCA proteins primarily use nonhomologous end-joining (NHEJ) for DNA repair

C. BRCA1 mutations are not associated with ovarian cancer

D. BRCA2 mutations cause only breast cancer

Correct Answer: A. BRCA1 and BRCA2 are involved in DNA repair via homologous recombination

Explanation: BRCA1 and BRCA2 are essential for DNA repair by homologous recombination, maintaining genomic stability (Option A) (Option B ruled out) Defects in this pathway shift cells to error-prone NHEJ, leading to chromosomal aberrations. BRCA1 mutations: increase risk of breast, ovarian (Option C ruled out) , and prostate cancers. BRCA2 mutations: associated with breast (male & female), ovary, prostate, pancreas, stomach, bile ducts, melanoma, and B-cell malignancies (Option D ruled out)

References:

Robbins, Cotran & Kumar's Pathologic Basis of Disease, 11th Edition, Page. 282

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 45-year-old man presents with progressive abdominal discomfort and weight loss. Endoscopy reveals a gastric mass, and biopsy confirms diffuse gastric carcinoma. Which protein responsible for maintaining cell-to-cell adhesion and inhibiting cell motility is most likely mutated in this condition? (Q879760)

A. p63

B. p53

C. E-cadherin

D. Integrin

Correct Answer: C. E-cadherin

Explanation: Loss-of-function mutations in E-cadherin (CDH1 gene) are strongly associated with diffuse gastric carcinoma and lobular breast carcinoma. Role: Maintains cell–cell adhesion; binds β-catenin; mediates contact inhibition of growth. Pathogenesis: Loss of adhesion → increased motility and invasiveness; β-catenin release → nuclear translocation → activation of Wnt target genes → increased proliferation Syndromes (Germline Mutations): Familial gastric carcinoma (autosomal dominant) Associated Sporadic Tumors: Gastric carcinoma

(diffuse type), lobular breast carcinoma, esophageal carcinoma, colon carcinoma, ovarian carcinoma, prostate carcinoma. Incorrect Options: p63 (Option A) is important for epithelial differentiation, not cell adhesion in gastric cancer. p53 (Option B) regulates apoptosis and DNA repair, not adhesion. Integrin (Option D) mediates cell-extracellular matrix interactions, not the main defect here.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 259, 265, 267

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 19-year-old woman presents with recurrent episodes of abdominal pain and melena. On physical examination, she has dark-blue to brown macules on her lips and buccal mucosa. Genetic testing reveals germline loss-of-function mutations in the STK11 gene. What is the most likely diagnosis? (Q879758)

A. HNPCC

B. Gorlin syndrome

C. von Hippel-Lindau syndrome

D. Peutz-Jeghers syndrome

Correct Answer: D. Peutz-Jeghers syndrome

Explanation: In Peutz-Jeghers Syndrome , STK11 germline loss-of-function mutations cause hamartomatous GI polyps, mucocutaneous pigmentation, and increased cancer risk. Gene: STK11 (also called LKB1 – Liver kinase B1) Protein function: Activator of the AMPK family of kinases; suppresses cell growth under low nutrient and energy conditions. Pathogenesis: Germline loss-of-function mutations → failure to suppress growth under nutrient/energy stress → tumorigenesis. Features: Hamartomatous GI polyps, GI cancers, mucocutaneous pigmentation, increased risk of pancreatic carcinoma, and other carcinomas. Incorrect Options: HNPCC (Option A) is associated with mismatch repair gene mutations and colorectal cancer, without mucocutaneous pigmentation. Gorlin syndrome (Option B) is caused by PTCH1 mutations, characterized by basal cell carcinomas and jaw cysts. von Hippel-Lindau syndrome (Option C) is caused by VHL gene mutations, associated with hemangioblastomas and renal cell carcinoma.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 259

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following is the etiology of Gorlin syndrome? (Q879757)

A. Germline loss-of-function mutation in STK11

B. Germline missense mutation in SDHB

C. Germline loss-of-function mutation in WT1

D. Germline loss-of-function mutation in PTCH1

Correct Answer: D. Germline loss-of-function mutation in PTCH1

Explanation: PTCH1 mutations cause Gorlin Syndrome (nevoid basal cell carcinoma syndrome) , resulting in multiple basal cell carcinomas, jaw keratocysts, and skeletal anomalies. Gene: PTCH (Patched) Pathogenesis: Germline loss-of-function mutations → constitutive Hedgehog pathway activation → tumor formation Protein function: Tumor suppressor Regulates cell proliferation by controlling Hedgehog signaling Features: Basal cell carcinoma, medulloblastoma, various benign tumors Incorrect Options: Germline loss-of-function mutation in STK11 (Option A): Causes Peutz-Jeghers syndrome. Germline missense mutation in SDHB (Option B) is associated with hereditary paraganglioma-pheochromocytoma syndrome. Germline loss-of-function mutation in WT1 (Option C) is linked to Wilms tumor.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 259

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 25-year-old woman experiences progressive balance issues and bilateral sensorineural hearing loss. Imaging reveals tumors affecting both vestibular nerves. This clinical picture is characteristic of a hereditary condition involving a mutation in which protein that plays a role in linking the cytoskeleton to the cell membrane? (Q879756)

A. Neurofibromin

B. Merlin

C. PATCHED

D. RB protein

Correct Answer: B. Merlin

Explanation: Merlin is the NF2 gene product, involved in cytoskeletal stability and tumor suppression; mutation causes bilateral vestibular schwannomas (neurofibromatosis type 2) . Gene: NF2; Chromosome 22q12 Inheritance: Autosomal dominant Protein function: Tumor suppressor Cytoskeletal stability Activator of the Hippo signaling pathway Integrates cytoskeletal signals Features: Bilateral acoustic schwannomas, meningiomas, and other schwannomas Associated Disorders: Neurofibromatosis type 2 Incorrect Options: Neurofibromin (Option A): NF1 gene product, regulates RAS, associated with neurofibromatosis type 1. PATCHED (Option C): Receptor in Hedgehog signaling, associated with basal cell nevus syndrome. RB protein (Option D): Regulator of G1/S cell cycle, associated with retinoblastoma.

@Neet_pg_bot

Q13: A 35-year-old woman presents with multiple trichilemmomas on her face, a history of breast cancer, and the recent discovery of endometrial hyperplasia. She also reports that her father had colon polyps. Germline loss-of-function mutations of which gene are most likely responsible for her condition? (Q879753)

A. CDKN2A

B. SMAD2

C. APC

D. PTEN

Correct Answer: D. PTEN

Explanation: The scenario is Cowden Syndrome caused by a Germline loss-of-function mutation of the PTEN gene. Gene: PTEN (Phosphatase and Tensin Homologue) - Chromosome 10q23 Inheritance: Autosomal dominant Pathogenesis: Germline loss-of-function mutations → dysregulated PI3K/AKT pathway → uncontrolled cell growth Clinical features: Benign follicular appendage tumors (trichilemmomas), lipomas Hamartomatous/inflammatory intestinal polyps, ganglioneuromas; generally no increased risk of GI cancers Benign growths in the CNS Increased risk of breast, endometrial, and thyroid carcinoma; diverse cancers, particularly carcinomas and lymphoid tumors Incorrect Options: CDKN2A (Option A) is associated with familial melanoma and pancreatic cancer. SMAD2 (Option B) is involved in TGF-β signaling, not this syndrome. APC (Option C) is associated with familial adenomatous polyposis (FAP), but not with skin lesions or breast/endometrial cancers.

@Neet_pg_bot

Q14: Which of the following statements about p53 is true? (Q879752)

A. p53 is rarely altered in cancers

B. p53 is induced by DNA damage

C. p53 promotes cell cycle progression by downregulating p21

D. p53 inhibits apoptosis by suppressing BAX

Correct Answer: B. p53 is induced by DNA damage

Explanation: p53 is a tumor suppressor protein that is altered in the majority of human cancers (Option A ruled out) It is activated in response to DNA damage (Option B) and plays a crucial role in maintaining genomic stability. It causes cell cycle arrest by upregulating the cyclin-dependent kinase inhibitor p21, allowing time for DNA repair (Option C ruled out) It can induce apoptosis by upregulating BAX and other pro-apoptotic genes when the damage is irreparable (Option D ruled out)

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 257

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Which of the following statements about Knudson’s two-hit hypothesis for retinoblastoma is true? (Q879746)

A. Both familial and sporadic cases require two somatic mutations in the same retinoblast

B. In familial cases, one defective RB allele is inherited in the germline, and the second hit occurs somatically

C. Sporadic cases are caused by inheritance of one defective RB allele and a spontaneous second hit

D. Only one mutation is sufficient to cause retinoblastoma in any case

Correct Answer: B. In familial cases, one defective RB allele is inherited in the germline, and the second hit occurs somatically

Explanation: Knudson’s hypothesis states that: Two loss-of-function mutations (“hits”) of both RB alleles are required to cause retinoblastoma. In familial cases, one defective RB allele is inherited (first hit), and the second hit occurs somatically in a retinoblast. In sporadic cases, both RB alleles undergo independent somatic mutations in the same cell. This explains why retinoblastoma is more common in familial cases and rare in sporadic cases. Incorrect Options: Both familial and sporadic cases require two somatic mutations in the same retinoblast (Option A): Familial cases inherit the first hit germline. Sporadic cases are caused by inheritance of one defective RB allele and a spontaneous second hit (Option C): Sporadic cases involve two independent somatic mutations, not inheritance. Only one mutation is sufficient to cause retinoblastoma in any case (Option D): Both alleles must be inactivated.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 258

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following cancers is typically associated with a translocation involving cyclin D1? (Q879744)

A. Chronic myeloid leukemia

B. Non-Hodgkin's lymphoma

C. Acute lymphoblastic leukemia

D. Mantle cell lymphoma

Correct Answer: D. Mantle cell lymphoma

Explanation: Mantle Cell Lymphoma characteristically shows t(11;14)(q13;q32) translocation, leading to overexpression of cyclin D1, promoting cell cycle progression. Cyclin D1 is a cell cycle regulator proto-oncogene It is involved in translocation in mantle cell lymphoma and multiple myeloma It can undergo amplification in breast and esophageal cancers. Incorrect Options: Chronic myeloid leukemia (Option A): Associated with BCR-ABL translocation, not cyclin D1. Non-Hodgkin's lymphoma (Option B): A broad group; cyclin D1 translocation specifically occurs in the mantle cell subtype. Acute lymphoblastic leukemia (Option C): Associated with various chromosomal abnormalities, not cyclin D1 translocation.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page no. 253

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which type of proteins are produced as a result of MYC gene expression? (Q879741)

A. Proteins that control the cell division cycle

B. Proteins that regulate gene activity within the nucleus

C. Proteins involved in transmitting signals inside the cell

D. Proteins that act as receptors for growth-promoting signals

Correct Answer: B. Proteins that regulate gene activity within the nucleus

Explanation: MYC codes for nuclear regulatory proteins that act as transcription factors and master regulators of cell growth. Specifically, MYC influences the expression of genes involved in: Cell cycle progression - e.g., D cyclins. Ribosome biogenesis and protein synthesis - upregulates rRNA genes and rRNA processing. Metabolism - upregulates glycolytic enzymes and glutamine metabolism factors (metabolic reprogramming / Warburg effect). Telomerase expression - contributing to replicative immortality. Stemness/pluripotency - reprogramming somatic cells into pluripotent stem cells. Incorrect Options: Proteins that control the cell division cycle (Option A): MYC activates them but does not encode them. Proteins involved in transmitting signals inside the cell (Option C): MYC regulates signaling indirectly, does not encode them. Proteins that act as receptors for growth-promoting signals (Option D): MYC acts downstream of these, does not encode them.

@Neet_pg_bot

Q19: Which of the following genetic events best describes the carcinogenesis mechanism in a patient with retinoblastoma? (Q876253)

A. Balanced translocation

B. Expansion of trinucleotide repeat

C. Gene amplification

D. Loss of heterozygosity

Correct Answer: D. Loss of heterozygosity

Explanation: Correct Option D- Loss of heterozygosity: Retinoblastomas are malignant ocular tumors of young children. In hereditary retinoblastoma, an affected child inherits one defective Rb allele and one normal gene; this heterozygous state is sufficient to prevent the development of retinoblastoma. If the remaining normal Rb allele is inactivated by deletion or mutation, the loss of its suppressor function results in the appearance of a neoplasm. Loss of heterozygosity is the term for this genetic process. Incorrect Options: Option A- Balanced translocation: Sometimes a section from one chromosome of a particular pair changes places with a section from a chromosome of another pair. When the two breaks do not pass through a gene, and there is no gain or loss of material when the chromosomes are looked at under a microscope, it is called a balanced translocation. When one couple member carries a balanced chromosome translocation, the risk of miscarriage is approximately doubled. One partner has a balanced translocation in 3-5% of couples with recurrent miscarriages. Option B- Expansion of trinucleotide repeat: The mutation, referred to as “trinucleotide repeat (TNR) expansion," occurs when the number of triplets in a mutated gene exceeds the number found in a normal gene. Additionally, the number of triplets in the disease gene continues to increase as the disease gene is inherited. Slippage in DNA replication can cause trinucleotide repeats to grow. Therefore, with each cell division, the number of repeats can rise. Expanded repeats can lengthen and are also inherited. Option C- Gene amplification : Gene amplification refers to various organic and synthetic mechanisms that increase a gene's copy number "without a commensurate rise in other genes." A rise in the gene's copy number. Additionally, there can be an increase in the RNA and protein produced by that gene. An increase in the number of copies of a gene in a genome is called gene amplification. In response to signals from other cells or the environment, cancer cells, for instance, occasionally make extra copies of a gene or genes.

Q20: Which of the following mechanisms is not employed by tumour cells to evade the host immune system? (Q845522)

A. Selective outgrowth of the antigen-negative variants

B. Reduced expression of MHC molecules

C. Secretion of immunosuppressive factors

D. Enhanced antigen presentation to promote T cell activation

Correct Answer: D. Enhanced antigen presentation to promote T cell activation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Enhanced antigen presentation is not a mechanism tumour cells employ to evade the host immune system. Antigen presentation is a crucial step in activating T cells and initiating an immune response against tumour cells. Antigen-presenting cells (dendritic cells) present tumour antigens to T cells via major histocompatibility complex (MHC) molecules, leading to T cell activation and anti-tumour immune responses. While tumour cells may downregulate or alter the expression of MHC molecules to evade immune recognition, enhancing antigen presentation to promote T-cell activation is not a typical strategy employed by tumour cells for immune evasion. Mechanisms by which tumour cells evade the host immune system: Selective outgrowth of the antigen-negative variants (Option A ruled out). Reduced expression of MHC molecules (Option Bruled out). Secretion of immunosuppressive factors (Option C ruled out). Engagement of pathways that inhibit T-cell activation. Immune checkpoint inhibitors have been developed that inhibit CTLA-4, PD-1, and PD-L1. These can be used in the treatment of malignancies such as melanoma, non-small cell lung cancer, head and neck cancers, and lymphomas Immune checkpoint inhibitors CTLA-4 inhibitors PD-1 inhibitors PD-L1 (PD-1 ligand) inhibitors Ipilimumab Pembrolizumab Nivolumab Atezolizumab Avelumab Durvalumab

@Neet_pg_bot

Q21: Which of the following is true regarding the Warburg effect? (Q845521)

A. Cancer cells primarily rely on oxidative phosphorylation for ATP production.

B. It involves a shift from glycolysis to oxidative phosphorylation in cancer cells.

C. Cancer cells exhibit increased glucose uptake and preferentially metabolise glucose via glycolysis, even in the presence of oxygen.

D. It is characterised by decreased glucose uptake and utilisation by cancer cells.

Correct Answer: C. Cancer cells exhibit increased glucose uptake and preferentially metabolise glucose via glycolysis, even in the presence of oxygen.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Warburg Effect , a distinctive metabolic feature of cancer cells, involves increased glucose uptake and a preference for glycolysis over oxidative phosphorylation, even in the presence of oxygen. Otto Warburg was awarded the Nobel Prize in 1931 for this theory. Even in the presence of ample oxygen, cancer cells demonstrate a distinctive form of cellular metabolism characterised by high glucose uptake levels and increased glucose conversion to lactose (fermentation) via glycolysis (Option D ruled out) Even though ATP production is low with lactate formation compared to mitochondrial oxidative phosphorylation, it provides metabolic intermediates needed for synthesising cellular components. Application: Positive emission tomography (PET). Patients are injected with 18F-fluorodeoxyglucose (FDG) , a non-metabolizable glucose derivative preferentially taken up into tumour cells (due to glucose hunger), which can be detected by PET scan. Cancer cells primarily rely on oxidative phosphorylation for ATP production (Option A), which is not true, as cancer cells prefer glycolysis, even in the presence of oxygen. It involves a shift from glycolysis to oxidative phosphorylation in cancer cells (Option B), which is incorrect because the Warburg effect involves the opposite: a shift toward glycolysis.

@Neet_pg_bot

Q22: Which of the following statements are true regarding Lynch syndrome? (Q845519)

A. It is autosomal recessive in inheritance.

B. It is also known as hereditary breast and ovarian cancer syndrome.

C. It is caused by mutations in genes involved in nonhomologous end-joining repair.

D. Amsterdam II criteria are used for diagnosis.

Correct Answer: D. Amsterdam II criteria are used for diagnosis.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, the Amsterdam II criteria are used to diagnose Lynch syndrome (also called Hereditary Non-Polyposis Colorectal Cancer or HNPCC). An autosomal dominant disorder (Option A ruled out) Caused by mutations in DNA mismatch repair (MMR) genes, such as MLH1, MSH2, MSH6, PMS2, and EPCAM. (Option c ruled out) Amsterdam II criteria and Revised Bethesda guidelines are clinical tools used for screening and diagnosing Lynch syndrome. (Option D) Feature Description Inheritance Autosomal dominant Also known as Hereditary Non-Polyposis Colorectal Cancer (HNPCC) Caused by Mutations in MMR genes (not NHEJ genes) Diagnostic criteria Amsterdam II criteria , Bethesda criteria Associated cancers Colorectal, endometrial, ovarian, gastric, small bowel, urinary tract It is also known as hereditary breast and ovarian cancer syndrome (Option B): Incorrect – that refers to BRCA1/2 mutations, not Lynch syndrome.

@Neet_pg_bot

Q23: Which of the following diseases is associated with a defect in homologous DNA repair? (Q845517)

A. Trichothiodystrophy

B. Fanconi anemia

C. Endometrial carcinoma

D. Wermer syndrome

Correct Answer: B. Fanconi anemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Fanconi Anaemia is associated with a defect in homologous DNA repair. An autosomal recessive disorder due to failure to repair ds DNA breaks (caused by UV lights) due to defective homologous repair (due to mutation in multiple genes). Characterised by: Developmental abnormalities (short stature, skeletal abnormalities). Hypersensitivity to chemotherapeutic agents that cross-link DNA. Increased risk of bone marrow failure (aplasia) and leukaemia. Other diseases associated with a defect in homologous DNA repair: Bloom syndrome. Ataxia

telangiectasia. Familial breast cancer (mutations in BRCA 1 and BRCA 2). Werner syndrome. Rothmund-Thomson syndrome. Trichothiodystrophy (TTD) (Option A) is a rare autosomal recessive multisystem disorder characterised by defect in the TC-NER pathway (Transcription coupled-nucleotide excision repair pathway). Endometrial carcinoma (Option C): Certain subsets of endometrial cancer (most often) and colon cancer harbour mutations in DNA polymerase that result in a loss of proofreading function and the accumulation of numerous point substitutions. Wermer syndrome (Option D) : Wermer syndrome, also known as multiple endocrine neoplasia 1 (MEN 1) is characterised by tumors of the Parathyroid (adenoma), Pancreas (M/C- gastrinoma), and Pituitary adenoma (M/C- prolactinoma).

@Neet_pg_bot

Q24: A 9-year-old child presents with multiple freckle-like dark spots on sun-exposed areas such as the face and arms. The child complains of discomfort and pain upon exposure to sunlight, and there is evidence of sunburn even after brief periods outdoors. Upon further questioning, they reveal a family history of skin cancer in relatives who also experienced similar skin issues from a young age. What is the most likely diagnosis and the genetic defect in this condition? (Q845516)

A. Xeroderma pigmentosum, defective homologous repair

B. Cockyane syndrome, nucleotide excision repair

C. Xeroderma pigmentosum, nucleotide excision repair

D. Bloom syndrome, defective homologous repair

Correct Answer: C. Xeroderma pigmentosum, nucleotide excision repair

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This presentation is suggestive of Xeroderma pigmentosum (XP) , a condition caused by defective nucleotide excision repair of DNA, leading to extreme sun sensitivity, freckling, and a family history of early-onset skin cancer■■■■■■. An autosomal recessive disorder characterized by sun sensitivity, with approximately 50% of patients having acute burning on minimal sun exposure. UV radiation causes the cross-linking of pyrimidine residues , preventing normal DNA replication. Nucleotide excision repair (NER) prevents this DNA damage. Inherited loss-of-function mutations in any of these genes give rise to xeroderma pigmentosum. The onset of freckling (lentigines) on sun-exposed skin before age two years in most patients. At an

early age, there is a significantly increased risk of sunlight-induced cutaneous neoplasms (basal cell carcinoma, squamous cell carcinoma, melanoma) . Xeroderma pigmentosum, defective homologous repair (Option A): It is not caused by defective homologous repair. Cockayne syndrome, nucleotide excision repair (Option B): It is an autosomal recessive disorder caused by defective nucleotide excision repair, but unlike XP, it doesn't increase cancer risk. It is classified as a progeroid (premature aging) syndrome. Bloom syndrome, defective homologous repair (Option D): It is an autosomal recessive disorder caused by loss-of-function mutations in a helicase required for homologous recombination repair.

Q27: Identify the correctly matched pair of RAS mutation and its associated malignancy. (Q845513)

A. KRAS- Bladder cancer

B. HRAS- Lung cancer

C. KRAS- Kidney cancer

D. NRAS- Melanoma

Correct Answer: D. NRAS- Melanoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The correctly matched pair of RAS mutation and its associated malignancy is NRAS-melanoma. RAS proteins are associated with small G proteins. They flip back and forth between an excited signal-transmitting state(bound to GTP) and a silent state (bound to GDP). Stimulation of receptor tyrosine kinases by growth factors leads to an exchange of GDP for GTP. This activates RAS, which is transient because of an intrinsic GTPase activity that is accelerated by GTPase-activating proteins (GAPs) Many subtypes of RAS are associated with malignancies. Signal Transduction Protein (GTP-binding proteins) Malignancies KRAS (Option A, C ruled out) Colon, Lung, Pancreatic tumours HRAS (Option B ruled out) Bladder and kidney tumors NRAS (Option D) Melanomas, AML

@Neet_pg_bot

Q2: Which of the following best describes the mechanism by which mutations in the Ras/MAP kinase gene cause oncogenicity? (Q879232)

A. Constitutive activation of a GTP-binding protein leading to continuous MAP kinase signalling

B. Enhanced DNA repair leading to genomic instability

C. Inactivation of a tumour suppressor gene resulting in loss of cell cycle checkpoint control

D. Increased activity of tyrosine kinase receptors through gene amplification

Correct Answer: A. Constitutive activation of a GTP-binding protein leading to continuous MAP kinase signalling

Explanation: RAS is a proto-oncogene that encodes a GTP-binding protein (G-protein) involved in transmitting growth signals from the cell membrane to the nucleus. When mutated, RAS becomes constitutively active (locked in the GTP-bound form), leading to continuous downstream signalling through the MAP kinase pathway , causing uncontrolled cell proliferation - a key event in oncogenesis. Incorrect Options: Enhanced DNA repair leading to genomic instability (Option B) : RAS mutations do not enhance DNA repair; rather, they promote proliferation, not repair. Genomic instability arises from defects in DNA repair genes (e.g., BRCA1, MSH2). Inactivation of a tumour suppressor gene resulting in loss of cell cycle checkpoint control (Option C) : This describes tumour suppressor genes like RB or TP53, not RAS, which is an oncogene (gain-of-function mutation). Increased activity of tyrosine kinase receptors through gene amplification (Option D) : Seen in HER2/neu or EGFR oncogenes, not RAS. RAS acts downstream of these receptors.

Robbins & Cotran, Pathologic Basis of Diseases, 10th Edition, Pages 287.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: All of the following are correct about neuroendocrine tumours except? It has a salt and pepper appearance of chromatin Tumours arising from different organs have different microscopic features Light microscopy reveals secretory granules On microscopic examination, small, round, blue cells forming a rosette pattern are visible (Q879192)

A. 1, 2, and 3

B. Only 3

C. 2, 3, and 4

D. 1, 3, and 4

Correct Answer: B. Only 3

Explanation: The only false statement given is 'Light microscopy reveals secretory granules'. Electron microscopy reveals secretory granules. Neuroendocrine tumours (NETs) are neoplasms that arise from cells of the endocrine (hormonal) and nervous systems . They most commonly, but not only, occur in the intestine, where they are often called carcinoid tumours. Microscopic Features: Uniform, small-to-medium round cells (Statement 4) Moderate eosinophilic cytoplasm Characteristic “salt and pepper” (stippling) chromatin (Statement 1) Electron Microscopy features: Presence of electron-dense neurosecretory granules (Statement 3) Immunohistochemistry: NETs are characteristically positive for: Chromogranin A (CgA) Synaptophysin Neuron-specific enolase (NSE) CD56 High-grade NET (small-cell carcinoma) typically have a high mitotic rate and a very high Ki-67 index (>20%) Although there are many kinds of NETs, they are treated as a group of tissues because the cells of these neoplasms share common features, including a similar histological appearance, having special secretory granules , and often producing biogenic amines and polypeptide hormones (Statement 2) .

@Neet_pg_bot

Q4: Why do neoplastic cells utilise Warburg metabolism? (Q855927)

A. It decreases glucose utilization by neoplastic cells

B. It forms metabolic intermediates which are needed for cell growth and multiplication

C. It provides more energy in the form of increased ATP production

D. It prevents apoptosis and makes the cancer immortal

Correct Answer: B. It forms metabolic intermediates which are needed for cell growth and multiplication

Explanation: It forms metabolic intermediates which are needed for cell growth and multiplication The Warburg effect is a distinct metabolic feature of cancer cells, where, even in the presence of sufficient oxygen, cancer cells demonstrate a distinctive form of cellular metabolism characterised by high glucose uptake levels (Option A ruled

out) and increased glucose conversion to lactose (fermentation) via glycolysis. This shift does not increase ATP production but provides key metabolic intermediates needed for rapid cell growth and division. (Option C ruled out) Otto Warburg was awarded the Nobel Prize in 1931 for this theory. The Warburg effect is the basis of positive emission tomography (PET). Patients are injected with 18F-fluorodeoxyglucose (FDG) , a non-metabolizable glucose derivative preferentially taken up into tumour cells (due to glucose hunger), which can be detected by PET scan. It prevents apoptosis and makes the cancer immortal (Option D): While Warburg metabolism can be linked to cellular survival and resistance to certain forms of stress, its primary function is not directly about preventing apoptosis or making the cell immortal. Instead, it helps meet the increased metabolic demands of rapidly proliferating cancer cells.

↑ *Back to this question in Part A*

@Neet_pg_bot

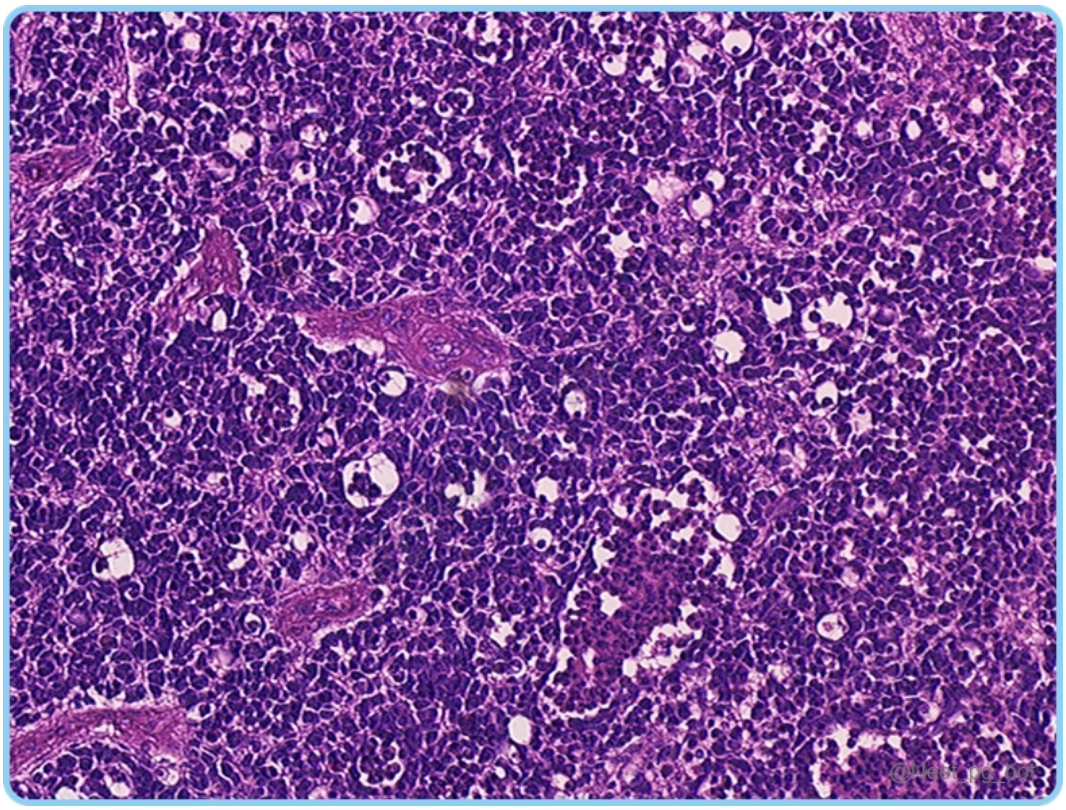
Q5: A 3-year-old boy was brought by his parents with concerns about being increasingly clumsy for the past 6 months. On examination, there is leukocoria with an absence of the red reflex in the left eye. As further workup reveals a tumour, the eye is enucleated, and the microscopic appearance is as shown in the image. Molecular analysis of the tumour indicates a loss of cell cycle control in the tumour cells. What is the most likely diagnosis? (Q859874)

A. Wilms tumor

B. Retinoblastoma

C. Ependymoma

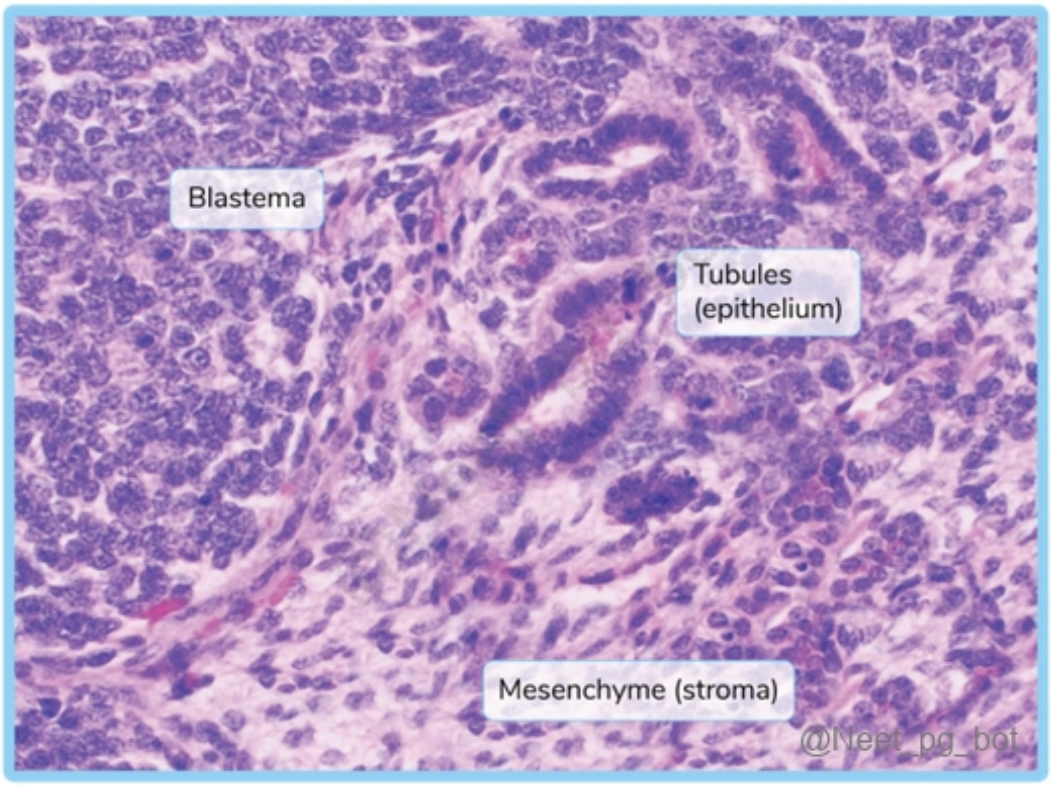
D. Neuroblastoma

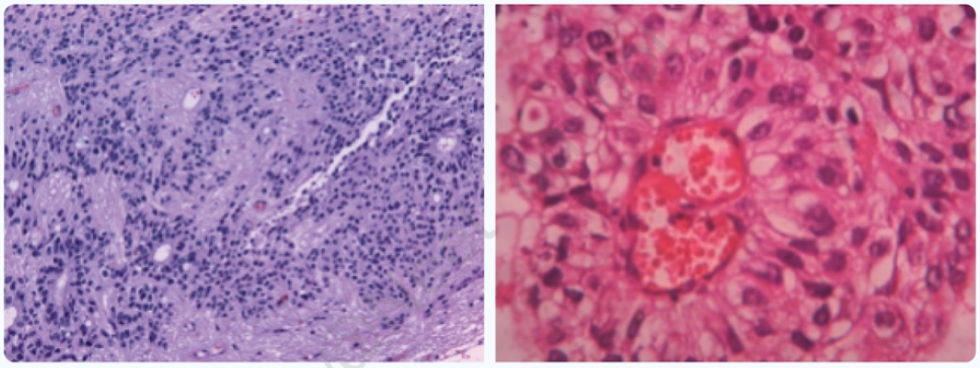


Correct Answer: B. Retinoblastoma

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The child presents with leukocoria (white pupillary reflex) and progressive clumsiness, raising suspicion for an intraocular malignancy. The absence of a red reflex suggests an opaque mass within the eye, which is highly indicative of retinoblastoma , the most common primary intraocular malignancy in children. Age of Presentation: Usually before 3 years, with non-familial cases diagnosed by 1 year. Clinical Features: Leukocoria (most common presenting sign) Strabismus (misaligned eyes) due to loss of vision Proptosis in advanced cases Orbital invasion and metastasis in late stages. Histopathology: Small round blue cells are characteristic of primitive neuroectodermal tumours. Anastomosing areas of necrosis Flexner-Wintersteiner rosettes (well-differentiated tumours) Molecular Pathogenesis: RB1 gene mutation on chromosome 13q14 , leading to loss of cell cycle control. Loss of both alleles of RB1 leads to uncontrolled retinal cell proliferation. Wilms tumour (Option A), a nephroblastoma, typically presents with an abdominal mass, hematuria, and hypertension and histologically shows a triphasic pattern with blastemal, stromal, and epithelial components. {{caption_text}} Ependymoma (Option C) arises in the fourth ventricle or spinal cord, leading to obstructive hydrocephalus, and shows perivascular pseudorosettes and true rosettes on histology. {{caption_text}} PA Neuroblastoma (Option D), a neural crest tumour usually originating in the adrenal gland or sympathetic chain, presents with an abdominal mass, periorbital ecchymoses ("raccoon eyes"), and opsoclonus-myoclonus syndrome, with histology showing Homer-Wright rosettes and immunohistochemical positivity for chromogranin, synaptophysin, and neuron-specific enolase (NSE). {{caption_text}}





HPE of Ependymoma : Perivascular pseudorosette

@Neet_pg_bot

Q6: Which of the following enzymes is responsible for the immortality of cancer cells? (Q859238)

A. Telomerase

B. Topoisomerase

C. Helicase

D. RNA polymerase

Correct Answer: A. Telomerase

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Telomerase maintains telomere length , preventing chromosome degradation. Telomere shortening occurs with each cell division, contributing to cellular ageing and death . However, telomerase extends telomeres , enabling indefinite division . In cancer cells , its overexpression promotes uncontrolled proliferation and immortality . Incorrect Options: Topoisomerase (Option B) is responsible for manipulating the structure of DNA

by inducing and resolving DNA strand breaks. Helicase (Option C) unwinds the DNA double helix, allowing other enzymes to access and replicate the DNA. RNA polymerase (Option D) synthesises RNA from a DNA template during transcription, essential for gene expression and protein synthesis. While its dysregulation can occur in cancer, it is not directly linked to cancer cell immortality.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 303 - 305

↑ *Back to this question in Part A*

@Neet_pg_bot

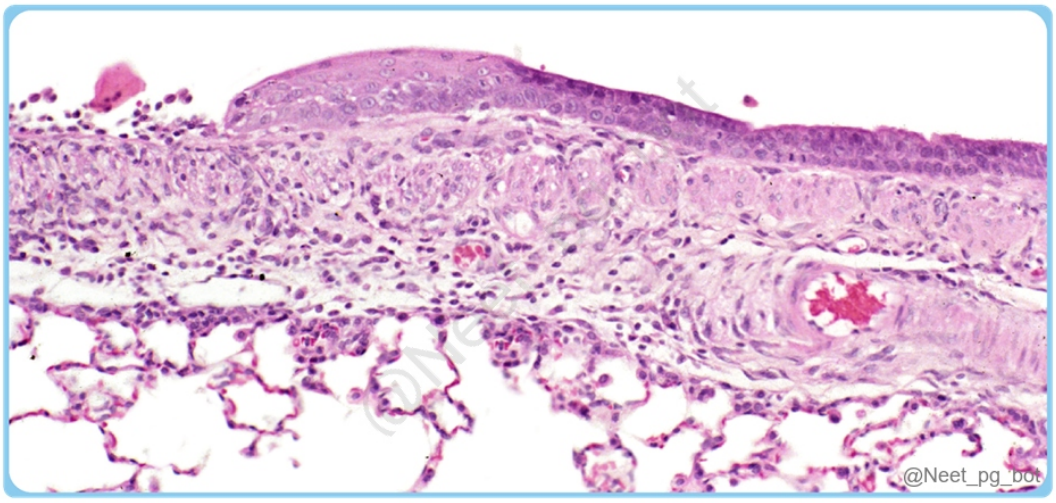
Q7: The lining epithelium of the respiratory tract of a middle-aged man who is a chronic smoker shows a change from columnar to stratified squamous epithelium, as depicted in the image below. The change is called what? {{caption_text}} (Q858510)

A. Dysplasia

B. Hypertrophy

C. Atrophy

D. Metaplasia



Correct Answer: D. Metaplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Metaplasia refers to the reversible change in which one type of adult cell is replaced by another type. In this case, the columnar epithelium of the respiratory tract is replaced by stratified squamous epithelium, often as

a result of chronic irritation, such as smoking. Metaplasia: Metaplasia is a reversible change in which another cell type replaces one differentiated cell type (epithelial or mesenchymal). Metaplasia is a change in the phenotype of differentiated cells, often in response to chronic irritation that makes cells better able to withstand stress; usually induced by altered differentiation pathway of tissue stem cells, may result in reduced functions or increased propensity for malignant transformation. Barrett's oesophagus is characterised by the replacement of the normal squamous epithelium of the lower oesophagus with columnar epithelium containing goblet cells & is considered an adaptive response to chronic exposure to gastric acid and bile reflux in the setting of GERD. The presence of Barrett's oesophagus increases the risk of developing oesophagal adenocarcinoma. {{caption_text}} Transformation of columnar epithelium to squamous epithelium: In the respiratory tract , in response to chronic irritation, such as smoking, the columnar epithelium undergoes metaplasia to squamous epithelium, leading to a condition known as squamous metaplasia. Conversion of glandular epithelium to squamous epithelium: This type of metaplasia can be seen in the cervix , where the normal glandular epithelium undergoes metaplasia to the squamous epithelium in response to chronic inflammation or irritation, leading to a condition known as cervical squamous metaplasia. Substitution of mesenchymal cells with epithelial cells: An example of this can be seen in osseous metaplasia , where mesenchymal cells differentiate into bone-forming osteoblasts, leading to the formation of ectopic bone within soft tissues. Incorrect Options: Dysplasia (Option A) refers to the abnormal development or growth of cells or tissues. It is characterised by disordered cell structures and is considered a precursor to cancer. Hypertrophy (Option B) is the increase in the size of cells, leading to the enlargement of an organ or tissue. It typically occurs in response to increased functional demand or external stimulation. Atrophy (Option C) is the reduction in the size or number of cells, leading to the shrinkage of an organ or tissue. It can result from factors such as disuse, loss of nerve supply, or inadequate blood flow.

@Neet_pg_bot

Q8: What is the fixation technique employed to examine fat in histopathology? (Q856484)

A. IHC

B. Frozen section

C. Liquid paraffin

D. Formalin-fixed

Correct Answer: B. Frozen section

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The frozen section is done for the fixation of fats. It is a technique used to examine tissue samples quickly by freezing them and then cutting them into thin slices for immediate microscopic examination. This method is often preferred for fat tissue examination because it prevents the loss of lipid content, which can be affected by formalin fixation. {{caption_text}} Advantages: It provides rapid results & ideal for intraoperative consultations (e.g., determining malignancy during surgery). It is essential for preserving certain tissue components like fat, enzymes, and lipids that might be damaged by formalin fixation. Fixatives & uses: Technique / Tissue Fixative Electron microscopy Glutaraldehyde Bone marrow (Trephine biopsy) Zenker's fluid GI biopsy Bouin's fluid Brain Formalin ammonium chloride Adrenal biopsy Orth's fluid Pap smear Ethanol IHC (Immunohistochemistry) (Option A) is used to detect specific proteins or antigens in tissue sections using targeted antibodies. Although IHC can identify markers associated with fat cells, it is not a fixation method for examining fat. Liquid paraffin (Option C) is not a fixation agent but a mounting medium applied to tissue sections on slides. It provides optical clarity and preserves the specimen but does not fix or preserve fat specifically. Formalin fixation (Option D) is a commonly used method to preserve tissue samples in histopathology. While it preserves the general structure of tissues, it is not ideal for preserving fat. Formalin can cause partial extraction of fat, leading to the loss of fat droplets and artefacts during tissue processing.

@Neet_pg_bot

Q9: A woman was diagnosed with metastatic liver adenocarcinoma with CK7-, CK20+, and CDX1+ immunohistochemistry (IHC) markers. Which of the following is the most likely primary site of origin for this metastasis? (Q856914)

A. Colon carcinoma

B. Breast carcinoma

C. Pancreatic carcinoma

D. Ovarian carcinoma

Correct Answer: A. Colon carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Colon carcinoma typically shows a CK7- and CK20+ pattern , and CDX1 is a transcription factor often expressed in the intestinal epithelium, further supporting a colon origin for the metastasis. CK7: Positive in carcinomas from the lung, breast, ovary, and pancreas. Negative in most gastrointestinal tract carcinomas, including those originating from the colon. CK20: Positive in colorectal and urothelial carcinomas. Negative in carcinomas of the lung, breast, and ovary. CDX1: Positive in adenocarcinomas of the gastrointestinal tract, particularly colorectal carcinomas. Negative in most non-gastrointestinal carcinomas, such as those from the breast, lung, ovary, and pancreas. Tumor Type CK7 CK20 CDX1 Colon carcinoma - + + Breast carcinoma + - - Pancreatic carcinoma + + - Ovarian carcinoma + - -

@Neet_pg_bot

Q10: A pap smear taken from a patient revealed hyperchromatic nuclei, irregular nuclear borders, and a low maturation index involving the whole thickness but did not breach the basement membrane. What is the diagnosis? (Q856160)

A. Dysplasia

B. Carcinoma

C. Metaplasia

D. Hyperplasia

Correct Answer: A. Dysplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The findings described in the pap smear hyperchromatic nuclei, irregular nuclear borders, and low maturation index are characteristic of dysplasia , a pre-cancerous condition. Dysplasia is abnormal cell growth and differentiation, often seen in the epithelial layer , without penetration through the basement membrane . This is reversible in the early stages (may become irreversible if the entire epithelium is involved). Carcinoma (Option B) refers to invasive cancer where the abnormal cells have breached the basement membrane and spread beyond the epithelial layer. The description clearly states that the basement membrane is intact, ruling out carcinoma. Metaplasia (Option C) is the replacement of one type of cell with another, often occurring in response to tissue damage, repair, chronic irritation, or regeneration. It does not explain the nuclear changes (hyperchromasia and irregularity) seen in the pap smear. Hyperplasia (Option D) is an increase in the number of cells in a tissue, typically in response to a stimulus. It does not usually involve abnormal nuclear features like hyperchromasia and irregular borders, which are more indicative of dysplasia .

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 65-year-old female patient is diagnosed with pure red cell aplasia and a mediastinal mass. Which of the following is a likely cause? (Q856155)

A. Thymoma

B. Non-Hodgkin lymphoma

C. Bronchogenic carcinoma

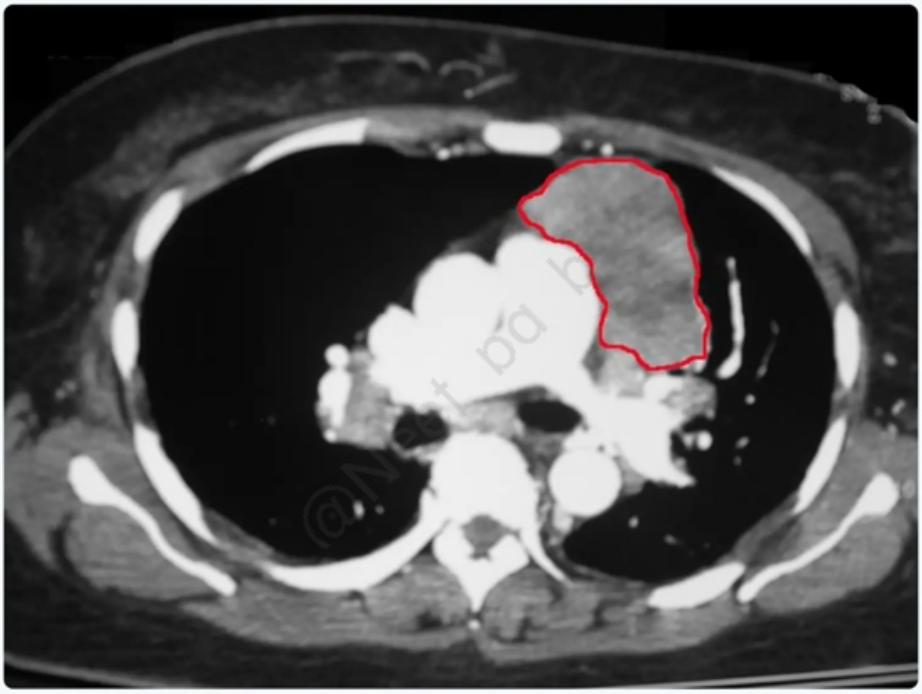
D. Germ cell tumour

Correct Answer: A. Thymoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The diagnosis of pure red cell aplasia (PRCA) in this patient, coupled with a mediastinal mass , strongly suggests a thymoma, a tumor of the thymus gland , which is located in the anterior mediastinum . It is often asymptomatic initially but can cause a range of paraneoplastic syndromes and is also associated with autoimmune diseases like myasthenia gravis. One of the paraneoplastic syndromes associated with thymoma is PRCA . In PRCA, red blood cell production in the bone marrow is selectively failed, while white blood cells and platelets are usually unaffected. This leads to severe anemia in the absence of any abnormalities in other cell lines. Thymoma Clinical features Mostly asymptomatic (small tumor), incidentally detected. It may compress the trachea (dyspnea), esophagus (dysphagia), recurrent laryngeal nerve (dysphonia or hoarseness of voice), and superior vena cava (superior vena cava syndrome). Investigations CT scan Investigation of choice It is used to determine the extent of the disease. {{caption_text}} Histology (definitive diagnosis) Noninvasive thymomas: Medullary-type epithelial cells (elongated or spindle-shaped) or a mixture of medullary- and cortical-type epithelial cells (admixture of polygonal cortical-type epithelial cells and a denser infiltrate of thymocytes). {{caption_text}} Invasive thymoma: Cytologically benign but locally invasive. The epithelial cells have abundant cytoplasm and rounded vesicular nuclei mixed with numerous thymocytes. {{caption_text}} Cytokeratin (marker to distinguish thymoma from lymphoma; thymomas are positive for cytokeratin) Non-Hodgkin lymphoma (Option B) can cause lymphadenopathy and mediastinal masses , but it is not associated with pure red cell aplasia. Bronchogenic carcinoma (Option C) may cause mediastinal masses due to lymph node involvement or direct tumour extension, but it is not commonly associated with pure red cell aplasia . Germ cell tumours (Option D) in the mediastinum can cause a mediastinal mass and are not typically linked with pure red cell aplasia .



CT scan of thymoma

@Neet_pg_bot

Q12: A patient with occupational exposure to benzene presents with repeated infections, easy fatigability, weight loss, and an evening rise in temperature. This occupational exposure will predispose him to which of the following cancers? (Q856108)

A. Leukemia

B. Lung cancer

C. Bladder cancer

D. Skin cancer

Correct Answer: A. Leukemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Occupational exposure to benzene is a well-established risk factor for the development of leukemia , particularly AML and ALL. It is a known carcinogen that can cause damage to the bone marrow, leading to disruption of normal blood cell production , which can result in leukemia . The clinical features in this case, such as repeated infections , fatigability , weight loss , and fever , also suggest a hematological malignancy like leukemia. Risk of specific carcinomas related to specific exposure Risk of carcinoma Occupation exposure Lungs (Option B ruled out) Arsenic, beryllium, cadmium, chromium, Asbestosis, Silica, radon, Nickel, and aromatic hydrocarbon. Bladder (Option C ruled out) Benzidine, Auramine, Beta-naphthylamine, Para amino-diphenyl, Magenta. Liver Vinyl chloride , Arsenic. Leukaemia Benzene , ethylene oxide. Skin (Option D ruled out) Arsenic, ionising radiation, Polycyclic aromatic hydrocarbons. Scrotum Polycyclic aromatic hydrocarbons.

@Neet_pg_bot

Q13: Which of the following is true? BRCA1 is an oncogene HER2neu is amplified only in a fraction of breast cancer EGFR+ is seen in non-small cell lung cancer N-MYC is a tumor suppressor gene (Q856708)

A. 1, 2

B. 1, 3

C. 2, 3

D. All of these

Correct Answer: C. 2, 3

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: HER2/neu is amplified only in a fraction of breast cancer: In breast cancer, amplification of the HER2 gene and overexpression of the HER2 protein can occur. HER2 amplification is not observed in all breast cancers but only in a fraction of cases. (Statement 2) Breast cancers that show HER2 amplification are referred to as HER2-positive breast cancers and can be targeted with specific therapies like trastuzumab. EGFR is seen in non-small cell lung cancer (NSCLC): In non-small cell lung cancer, mutations or overexpression of the EGFR gene can occur. (Statement 3) EGFR-targeted therapies, such as tyrosine kinase inhibitors, are used in the treatment of EGFR-positive NSCLC. BRCA1 (Breast Cancer 1) It is classified as a tumour suppressor gene. (Statement 1 ruled out) Mutations increase the risk of cancers such as breast, ovarian, prostate, and pancreatic cancers and are inherited in an autosomal dominant pattern. N-MYC It is an oncogene. (Statement 4 ruled out) It is associated with neuroblastoma (most common), small-cell lung cancer, and medulloblastoma.

@Neet_pg_bot

Q14: The human papillomavirus inactivates the Rb gene by which of the following proteins? (Q855392)

A. E6

B. E7

C. L1

D. L2

Correct Answer: B. E7

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The human papillomavirus (HPV) inactivates the retinoblastoma (RB) gene primarily through the action of the E7 protein. The E7 protein of high-risk HPV types, such as HPV-16 and HPV-18, promotes cell cycle progression by inactivating the retinoblastoma protein (p105Rb). E7 binds to p105Rb, disrupting its interaction with the E2F transcription factor, which releases E2F to activate genes essential for cell cycle progression and DNA replication. Consequently, the cell cycle becomes dysregulated, and uncontrolled cell proliferation can occur, a hallmark of HPV-associated cancers. High-risk HPV types (HPV 16, 18): High-grade cervical dysplasia and invasive cancer. Low-risk HPV types (HPV 6, 11): Genital warts (condyloma acuminatum and low-grade changes in cervical cells). Oncogenic Activities of E6 Protein (Option A ruled out) Oncogenic Activities of E7 Protein (Option B) Binds to and promotes degradation of p53 → Impairs cell growth and apoptosis regulation. Stimulates expression of TERT (telomerase reverse transcriptase) → Facilitates cellular immortalisation by maintaining telomere length. Disrupts interaction between RB protein and E2F transcription factors Inactivates CDK inhibitors (e.g., p21 and p27). Activates cyclins A and E L1 (Option C) protein is the major capsid protein of HPV and plays a role in the virus particle assembly. L2 (Option D) protein is a capsid protein of HPV, which assists in entering the viral DNA into the host cell during infection.

@Neet_pg_bot

Q15: Which of the following is true about anaplasia? (Q857175)

A. Loss of cohesion between cells

B. Loss of differentiation

C. Change of epithelium type

D. Benign and fully reversible

Correct Answer: B. Loss of differentiation

Explanation: Anaplasia refers to the loss of differentiation of cells. It is a characteristic feature of malignant tumours and is associated with the loss of normal tissue organisation and cellular features. Anaplastic cells often exhibit pleomorphism, hyperchromatic nuclei, an increased nuclear-to-cytoplasmic ratio, and increased mitotic activity. Loss of cohesion between cells (Option A) is a characteristic feature of malignancy. Change of epithelium type (Option C) : Metaplasia refers to the reversible change of one mature cell type to another mature cell type in response to certain stimuli or chronic irritation. Benign and fully reversible (Option D) : Anaplasia is typically seen in malignant tumours and is not fully reversible.

Robbins and Cotrans Pathologic Basis of Disease, 10th Edition, Pages 270-272

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following statements is true about proto-oncogenes? KIT has decreased expression via the tyrosine kinase signalling pathway in GIST. KRAS mutation is more commonly associated with small-cell lung cancer. ERBB2 is overexpressed in association with breast carcinomas. PDGFR-β has suppressed expression in colorectal cancer. (Q855121)

A. 2 only

B. 3 only

C. 1 and 4

D. 2 and 3

Correct Answer: B. 3 only

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ERBB2 (HER2/neu) is a proto-oncogene encoding a receptor tyrosine kinase. In many breast cancers, ERBB2 undergoes gene amplification, increasing HER2 protein levels. (Statement 3) This leads to excessive receptor activation and uncontrolled signaling. It stimulates key cancer pathways like RAS–MAPK and

PI3K–AKT. About 15–20% of breast carcinomas show HER2 overexpression. These tumors are biologically aggressive if left untreated. HER2 status is determined using IHC and FISH in clinical practice. Trastuzumab and other HER2-targeted drugs significantly improve outcomes, confirming its oncogenic role. KIT has decreased expression in GIST (Statement 1) - Incorrect.GIST most often shows activating mutations and increased activity of the KIT tyrosine kinase receptor (CD117+), not decreased expression. KRAS mutation is more common in small-cell lung cancer (Statement 2) - Incorrect. KRAS mutations are common in non–small cell lung cancer (especially adenocarcinoma), not in small-cell lung cancer. PDGFR-β has suppressed expression in colorectal cancer (Statement 4) - Incorrect. There is no characteristic suppression of PDGFR-β in colorectal cancer; proto-oncogene involvement typically means activation, not decreased expression.

@Neet_pg_bot

Q17: A 25-year-old woman presents with lower abdominal discomfort. The surgical image is given below. What is the most likely diagnosis? (Q866741)

A. Serous cystadenoma

B. Immature teratoma

C. Mature cystic teratoma

D. Endometrioma

Correct Answer: C. Mature cystic teratoma

Explanation: Teratomas are tumours that originate from all three germ layers (ectoderm, mesoderm, and endoderm) and are commonly found in the ovaries. They are often seen in young women and can contain a variety of tissue types, such as hair, teeth, and muscle, which reflects their origin from all three germ layers. Mature teratoma Mature teratomas, or dermoid cysts , are common benign ovarian tumours found in young women. They are bilateral in 10-15% of cases. They contain tissues from all three germ layers, including skin, hair, and teeth, and can rarely undergo malignant transformation to squamous cell carcinoma. Grossly, they are unilocular cysts with a thin wall and hair; microscopically, they have stratified squamous epithelium and sebaceous glands. Immature teratoma: (Option B) Bulky, solid ovarian tumours that contain immature neuroepithelium, cartilage, bone, and muscle, with areas of necrosis and haemorrhage. They grow rapidly, often spreading beyond the ovary. They are seen in young females and have a high risk of malignancy. They have small, round blue cells (Immature neural components). Monodermal teratoma: Monodermal teratomas consist predominantly of a single type of tissue, such as thyroid tissue in struma ovarii or neuroendocrine cells in carcinoid tumours. They lack immature or embryonic-like tissues and typically do not have a high risk of malignancy. Serous cystadenoma (Option A): It is the most common ovarian epithelial tumor, usually seen in older women. It is unilocular, bilateral in >50% and is mostly malignant. The characteristic histologic feature is the presence of psamomma bodies (seen in 40-45%) which is composed of concentric rings of lamellar calcifications. Endometrioma (Option D): “chocolate cyst” of endometriosis, filled with old blood, not sebaceous material or calcified teeth.

@Neet_pg_bot

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Neurosecretory bodies are seen in all of the following, except: (Q855069)

A. Medullary thyroid carcinoma

B. Pituitary adenoma

C. Paraganglioma

D. Adrenal cortical tumour

Correct Answer: D. Adrenal cortical tumour

Explanation: Neurosecretory bodies are collections of secretory granules, typically seen in tumours that arise from neuroendocrine cells, such as medullary thyroid carcinoma, pituitary adenoma, and paraganglioma. However, adrenal cortical tumours originate from the adrenal cortex and do not typically contain neurosecretory bodies. Adrenocortical Neoplasms: It causes various forms of hyperadrenalism, including both adenomas and carcinomas. These tumours are common in adults, with carcinomas being more prevalent in children. Li-Fraumeni syndrome (due to TP53 mutations) and Beckwith-Wiedemann syndrome (linked to IGF-2 overexpression) increase the risk for adrenocortical carcinoma. Types of Adrenocortical Neoplasms: Functional adenomas : It often causes hyperaldosteronism or Cushing syndrome, with virilizing neoplasms usually being carcinomas. Some neoplasms do not secrete hormones; their functionality is assessed via clinical evaluation and hormone testing. Nonfunctional Adenomas : Usually asymptomatic, often detected incidentally. Small, well-circumscribed lesions (up to 2.5 cm) have a normal surrounding adrenal cortex and are yellow-brown due to lipid content. Microscopically, they resemble normal adrenal cortex cells with minimal mitotic activity and a Ki-67 index < 5%. Adrenocortical Carcinomas : Rare and typically more functional than adenomas, often associated with virilism and other hyperadrenalism symptoms. These large, invasive tumours (>20 cm) can invade the adrenal vein, vena cava, and lymphatics, with frequent metastases to regional nodes and distant organs. Survival rates are low, with a median of 2 years. Neuroendocrine tumors: Carcinoid tumor Pituitary adenoma (Option B) Pancreatic Neuroendocrine Tumor (PanNET) Medullary Thyroid Carcinoma (MTC) (Option A) Pheochromocytoma Paraganglioma (Option C) Small Cell Lung Cancer (SCLC) Large Cell Neuroendocrine Carcinoma (LCNEC) Neuroblastoma

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Match the following microscopic appearance and the respective tumour in which they are seen Microscopic appearance Tumor 1. Schiller Duval bodies a. Krukenberg tumor 2. Presence of teeth, hair, etc B. Granulosa cell tumor 3. Signet ring cells C.

Yolk sac tumour 4. Call-Exner bodies d. Teratoma (Q855924)

A. 1-c, 2-a, 3-d, 4-b

B. 1-b, 2-c, 3-a, 4-d

C. 1-d, 2-b, 3-c, 4-a

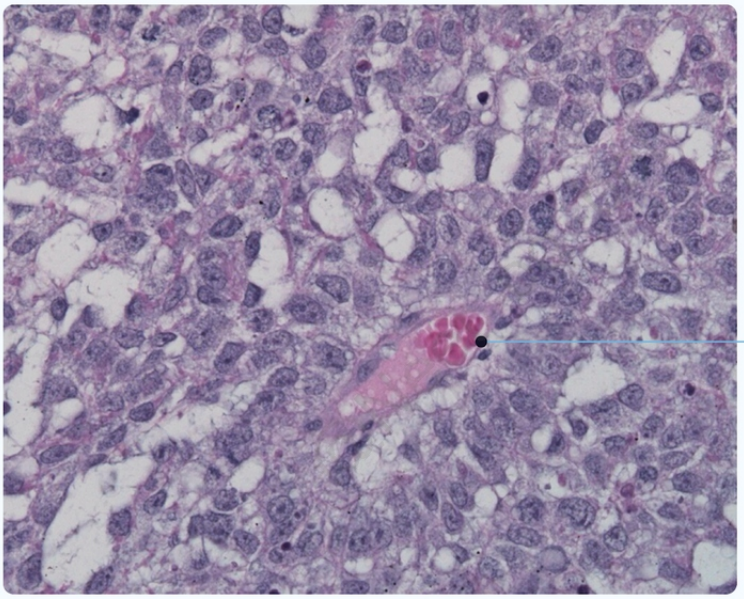
D. 1-c, 2-d, 3-a, 4-b

Correct Answer: D. 1-c, 2-d, 3-a, 4-b

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Microscopic Appearance Tumor Schiller Duval bodies Yolk sac tumour Presence of teeth, hair, etc. Teratoma Signet ring cells Kruckenberg tumor Call-Exner bodies Granulosa cell tumor Yolk Sac tumour or endodermal sinus tumour: Common in infants and children up to 3 years old. Morphology: Gross : Solid grey-white with a gelatinous or mucoid appearance. Microscopy: 50% of the tumours show a lace-like network of medium-sized cuboidal, flattened, or spindled cells with endodermal sinuses (Schiller-Duval or glomerular bodies). {{caption_text}} Eosinophilic, hyaline-like globules containing α-fetoprotein (AFP) and α1-antitrypsin are present. Granulosa cell tumour: Originates from granulosa cells of the ovarian follicle. Occurs in postmenopausal women (adult type) or at any age (juvenile type) Juvenile cases may present with precocious sexual development, while adults may experience abnormal uterine bleeding and endometrial hyperplasia (which can lead to carcinoma) Microscopically, Call-Exner bodies and coffee bean nuclei are observed Elevated inhibin levels, CD99 positivity, and FOXL2 mutations are seen. {{caption_text}} Signet ring cells: They are typically associated with Krukenberg tumours, which are metastases of diffuse gastric carcinoma to the ovaries. Grossly, Krukenberg tumours often present with bilateral, symmetric ovarian enlargement with an intact capsule. Signet ring cells contain mucin that pushes the nucleus to the periphery, creating a "signet ring" appearance. {{caption_text}} Teratoma: Teratomas in adult males are typically large , ranging from 5 to 10 cm in diameter , with a heterogeneous appearance consisting of various organoid structures , such as neural tissue, muscle, epidermis, cartilage, thyroid gland, or intestinal wall. These elements may be mature or immature , sharing histologic features with fetal or embryonic tissue. Microscopically, these structures are embedded in a fibrous or myxoid stroma. {{caption_text}}



@Neet_pg_bot

Q20: The type of cancer that rarely spreads through the lymphatic system is: (Q855915)

A. Squamous cell carcinoma

B. Merkel cell carcinoma

C. Basal cell carcinoma

D. Malignant melanoma

Correct Answer: C. Basal cell carcinoma

Explanation: BCC (basal cell carcinoma) is typically localized, grows slowly, and has a low metastasis potential. It rarely spreads to lymph nodes or distant organs, making it less likely to disseminate than SCC (Squamous Cell Carcinoma), MCC (Merkel Cell Carcinoma), or malignant melanoma. Metastasis (distant spread) All cancers are going to show metastasis except: BCC (Basal cell carcinoma / Rodent's ulcer) Brain Tumor/Glioma Types of metastatic spread: Hematogenous spread Lymphatic spread Transcoelomic spread Direct seeding of body cavities or surfaces Hematogenous spread Lymphatic spread Transcoelomic spread Veins are more prone to invasion than arteries due to their thinner walls. Tumours use existing lymphatic vessels at their margins. Follows natural routes of lymphatic drainage. Tumour invades the serosal wall of the coelomic cavity, releasing tumour fragments into coelomic fluid, which is implanted elsewhere in the body cavity. Seen in most of the sarcomas. Seen in most carcinomas. Seen in Krukenberg tumour in the ovary due to metastasis from gastric carcinoma to the ovary. Exceptions: Synovial sarcoma Rhabdomyosarcoma *These tumours are spread by the lymphatic route. Exceptions: HCC RCC Follicular carcinoma of the thyroid Choriocarcinoma *These tumours are spread by a hematogenous route. Direct Seeding of Body Cavities or Surfaces: It occurs when malignant neoplasms spread to anatomical spaces that lack physical barriers, such as the peritoneal cavity (more commonly), but they can also affect other body cavities, such as the pleural, pericardial, subarachnoid, and joint spaces. Examples include: Pseudomyxoma peritonei is characterized by the presence of a gelatinous neoplastic mass filling the peritoneal cavity arising from the rupture of mucus-secreting appendiceal (most common cause) or ovarian carcinomas. Gastric carcinoma can spread to the distal end of the peritoneal cavity (Pouch of Douglas) and is known as the ‘Blummer shelf.’ Medulloblastoma from the cerebellum spreads to the spinal cord by ‘Drop metastasis.’ Squamous cell carcinoma (SCC) (Option A) arises from squamous cells in the outermost skin layer and can occur in the skin, lips, mouth, throat, esophagus, lungs, and other organs. It has a higher metastatic potential than basal cell carcinoma, often spreading via the lymphatic route. Merkel cell carcinoma (MCC) (Option B) is a rare, aggressive skin cancer arising from touch-sensitive Merkel cells. It typically occurs on sun-exposed areas like the head, neck, and arms and has a high tendency to spread via the lymphatic system. Malignant melanoma (Option D) is an aggressive skin cancer arising from melanocytes, with a high potential for lymphatic and hematogenous metastasis to organs like the liver, lungs, brain, and bones. Early detection and treatment are crucial for better outcomes.

@Neet_pg_bot

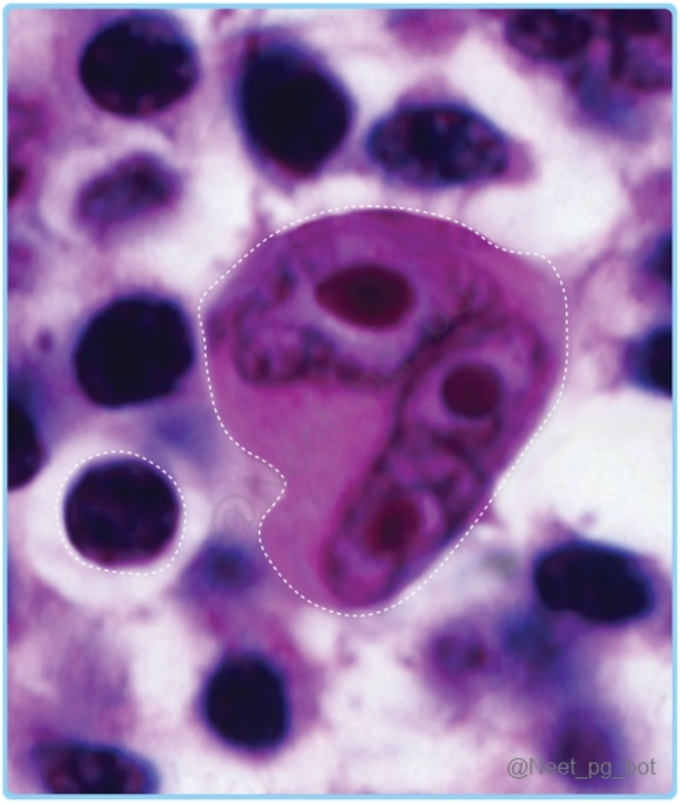
Q21: The following picture shows a lymph node biopsy of a 30-year-old male with cervical lymphadenopathy. The diagnosis is: (Q858133)

A. Acute myeloid leukemia (AML)

B. Hodgkin disease

C. Human papillomavirus (HPV)

D. Chronic lymphocytic leukemia (CLL)



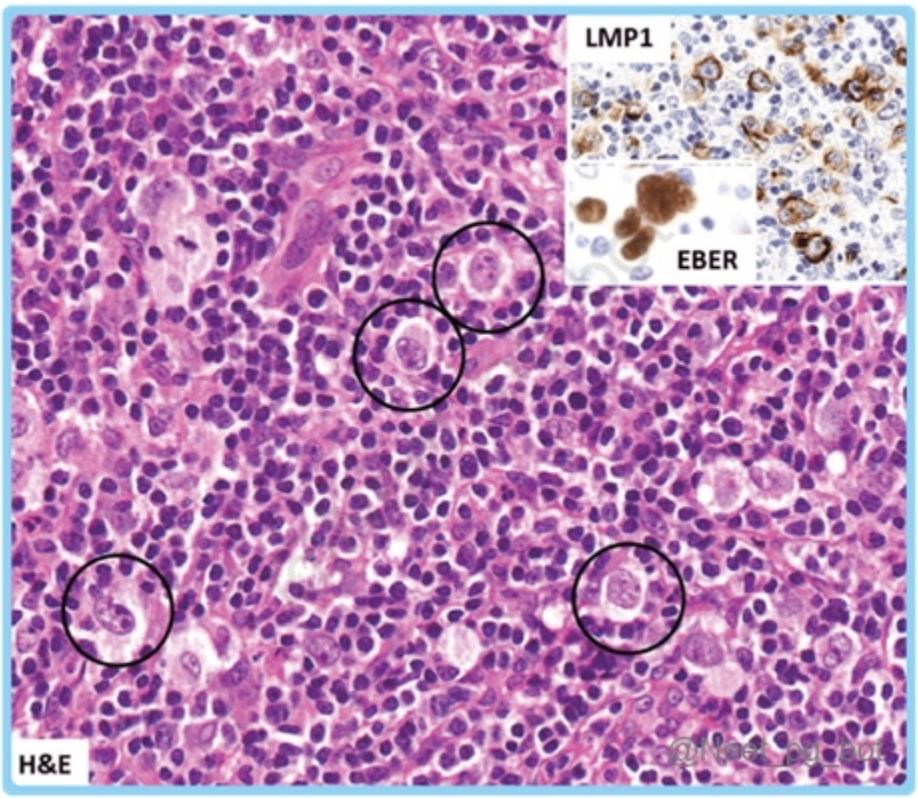
Correct Answer: B. Hodgkin disease

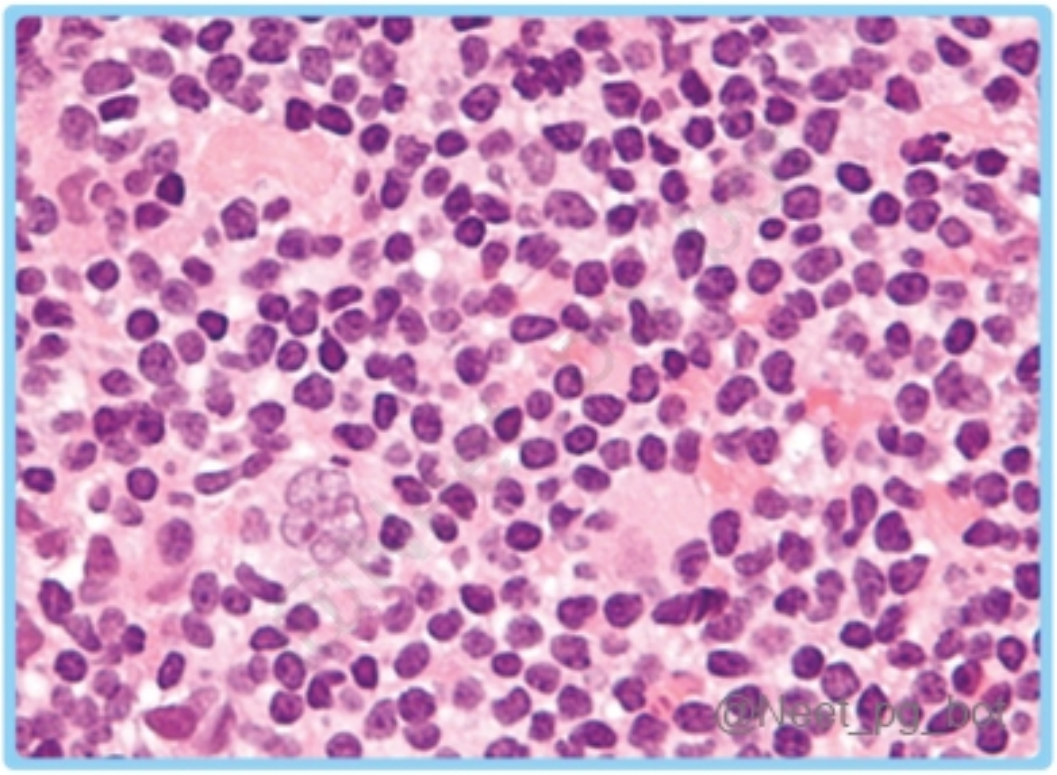
■ *Listen (English)*

■ *Listen (Hindi)*

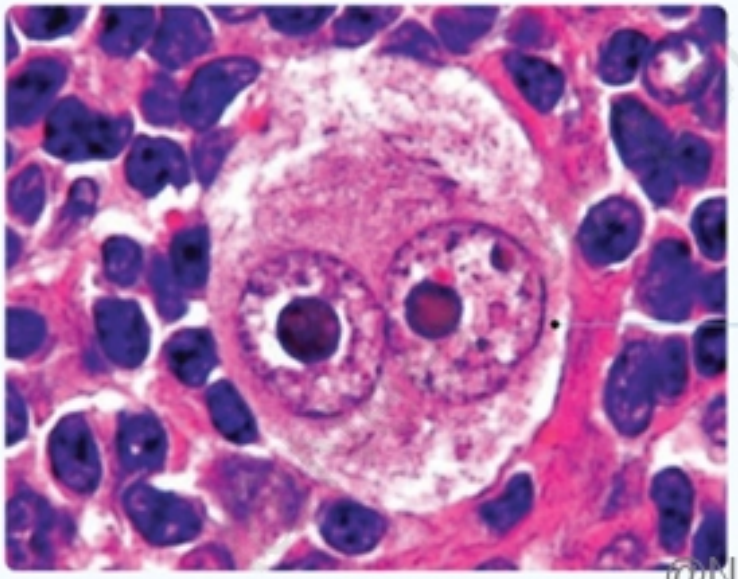
Explanation: The given clinical scenario and histopathological findings suggest a diagnosis of Hodgkin lymphom a, and the HPE reveals the presence of characteristic Reed-Sternberg cells. Hodgkin lymphoma typically spreads in an orderly, contiguous manner from one lymph node group to the next adjacent group without skipping areas. Histopathological variants of Hodgkin's Lymphoma 1. Mononuclear cells {{caption_text}} Single nucleus with a large, inclusion-like nucleolus with abundant cytoplasm. Seen in Mixed Cellularity Hodgkin Lymphoma 2. Popcorn cells {{caption_text}} Cells with multiple infolded nuclear membranes, small nucleoli, fine chromatin, and abundant pale cytoplasm. Seen in Nodular lymphocyte - Predominant Hodgkin lymphoma. 3. Reed-sternberg

cell {{caption_text}} It is characterised by two nuclear lobes, large inclusion-like nucleoli , and abundant cytoplasm and is typically surrounded by lymphocytes, macrophages, and an eosinophil. 4. Lacunar cells {{caption_text}} Typically found in the nodular sclerosis subtype. Nuclei are more delicate, folded, or multilobate. Abundant pale cytoplasm often gets disrupted during sectioning, creating an appearance where the nucleus sits in an empty space (lacuna). Incorrect Options: Acute myeloid leukaemia (AML) (Option A) is a type of cancer characterized by the rapid proliferation of abnormal myeloid blasts in the bone marrow and peripheral blood and is characterised by the presence of blasts ≥ 20% and myeloblasts with Auer rods. {{caption_text}} Human papillomavirus (HPV) (Option C) is a sexually transmitted virus, including low-risk strains 6 & 11, causing benign genital warts, and high-risk strains 16 & 18 , linked to cervical carcinoma, vulvar intraepithelial neoplasia (VIN), and vulvar carcinoma. It is characterised by the presence of enlarged, hyperchromatic nuclei with perinuclear halos (koilocytes) in the superficial layers of the epithelium. {{caption_text}} Chronic lymphocytic leukaemia (CLL) (Option D) is a malignancy of mature B-cells not associated with lytic bone lesions or elevated calcium. It shows Smudge cells (or parachute/basket cells) due to the fragility of lymphocytes during slide preparation and convent girl appearance (a lot of homogenous, small, mature-like, round lymphocytes with scant cytoplasm). {{caption_text}}

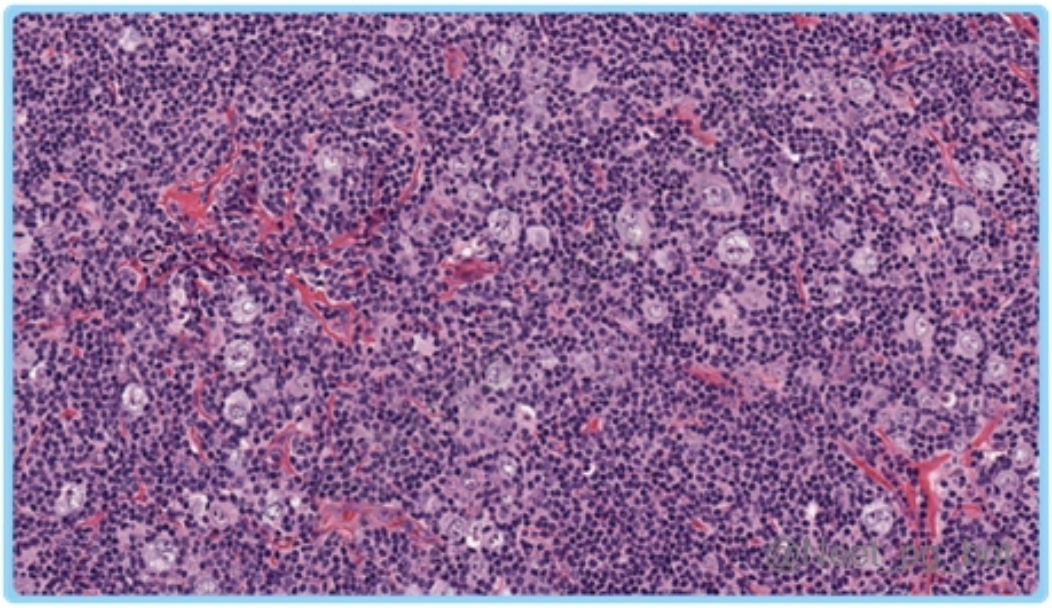


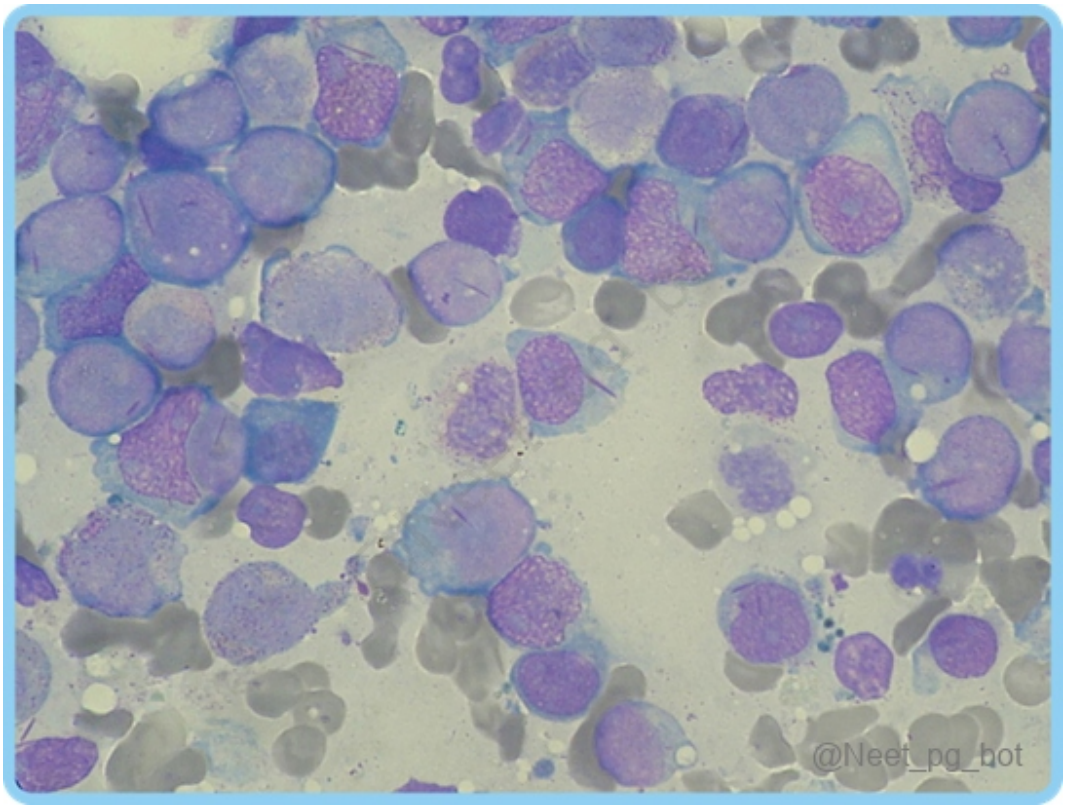


@Neet_pg_bot

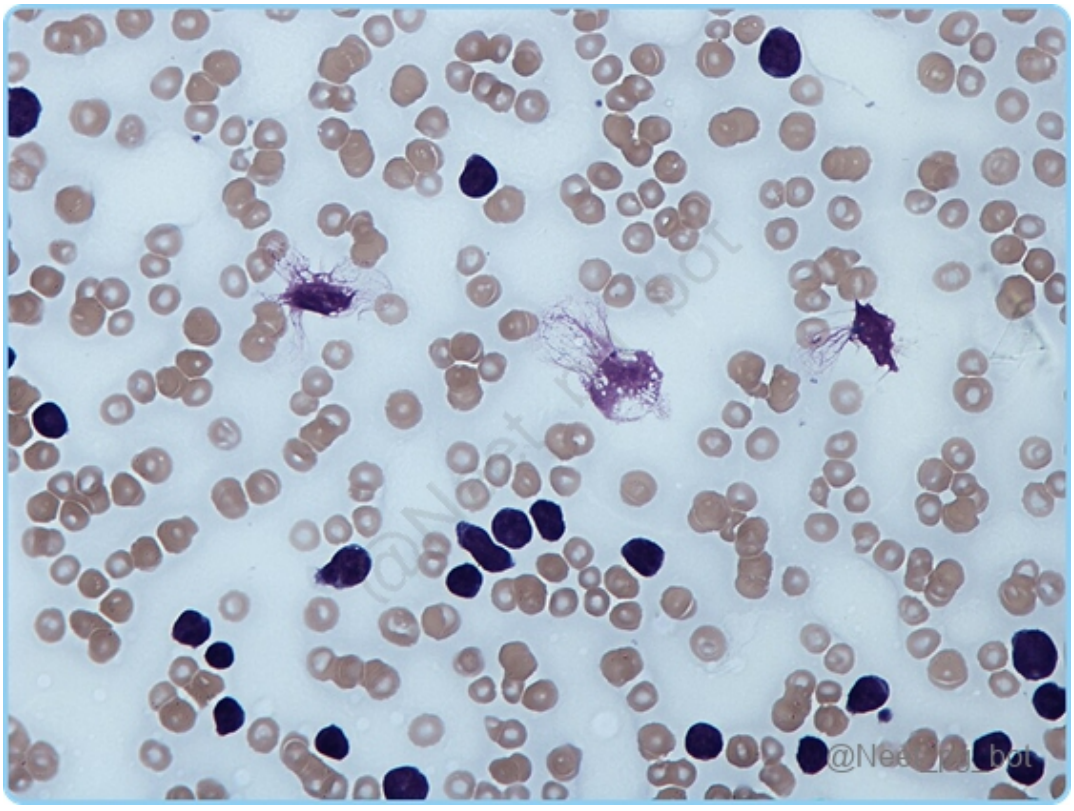


@Neet_pg_bot





@Neet_pg_bot



References:

Robbins & Cotran, Pathologic Basis of Disease, 10th Edition, Page 612

↑ *Back to this question in Part A*

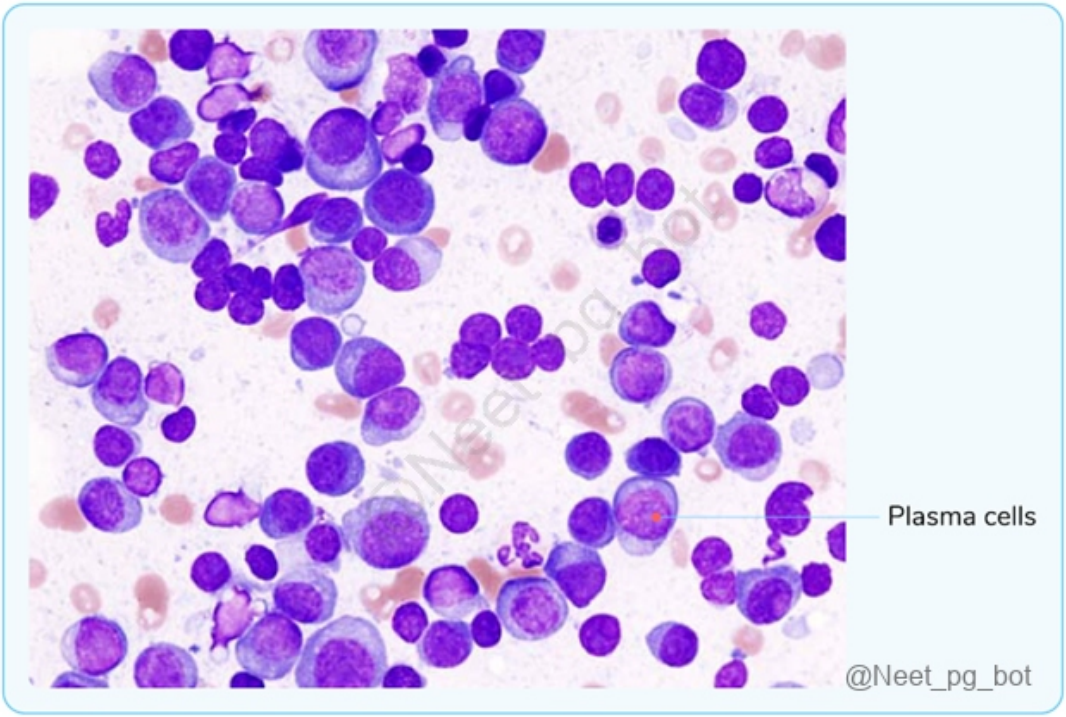
Q22: A 70-year-old male comes with complaints of hip pain. An X-ray of the hip shows lytic lesions and elevated serum calcium levels. Bone marrow plasma cells are 42%, and the cells seen are given in the image below. What is the most likely diagnosis? (Q858126)

A. Multiple myeloma

B. CLL

C. ALL

D. CML



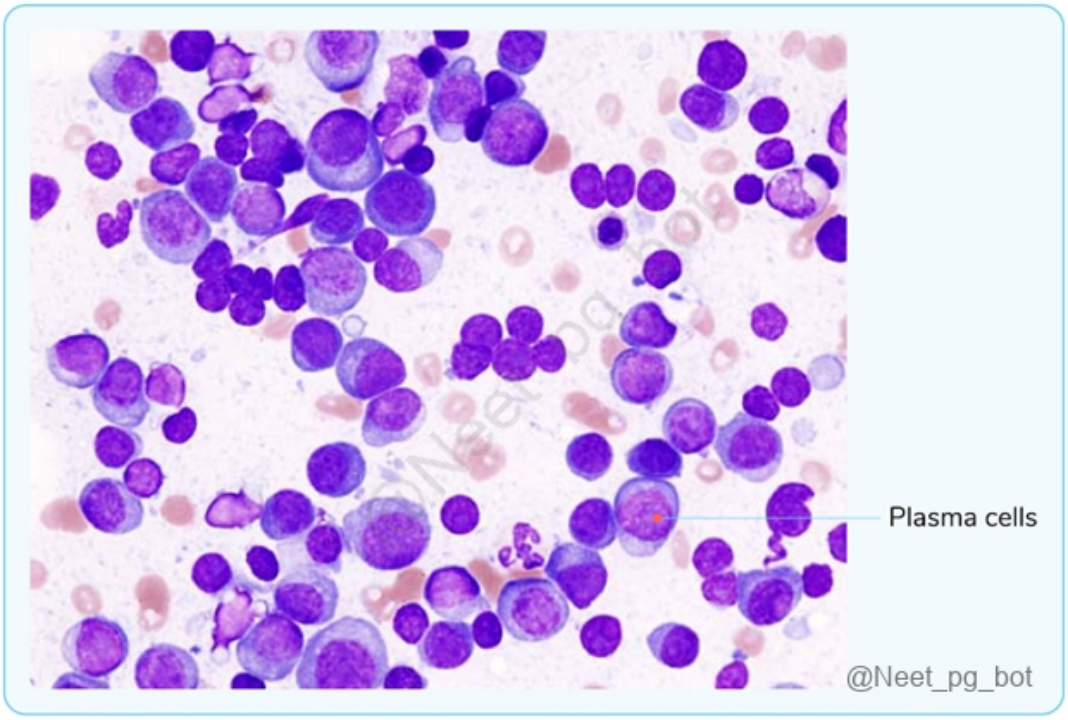
Correct Answer: A. Multiple myeloma

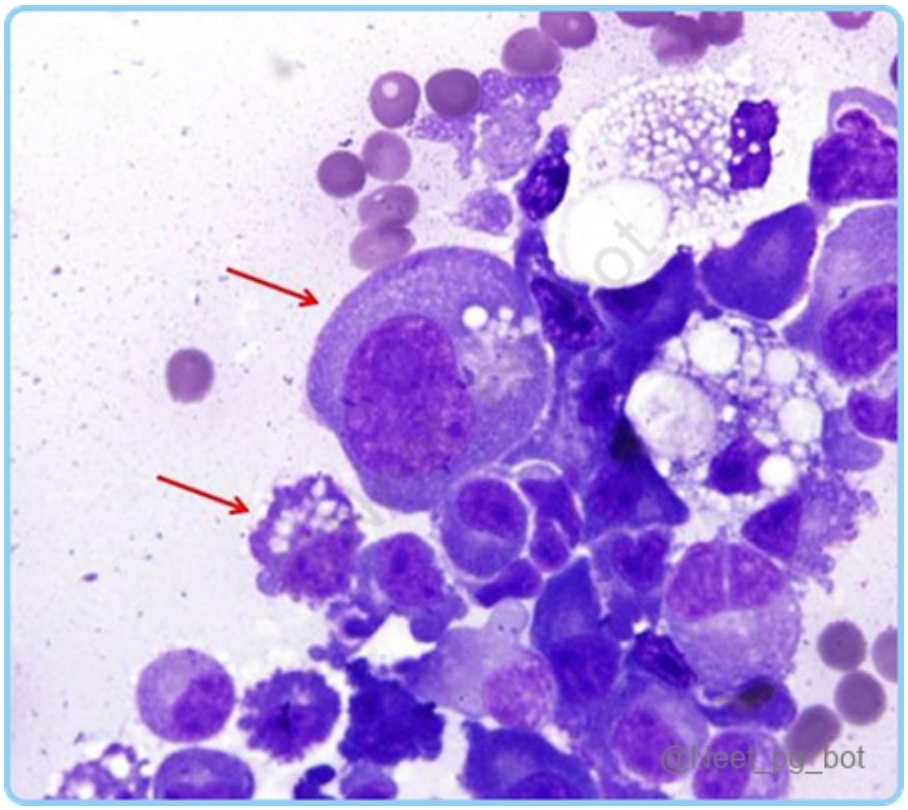
Listen (English)

Listen (Hindi)

Explanation: Multiple myeloma is characterised by malignant plasma cell proliferation in the bone marrow, leading to lytic bone lesions and elevated serum calcium levels (due to bone resorption). The presence of plasma cells further supports the diagnosis. Bone Marrow Biopsy Findings of Multiple Myeloma: Increased number of plasma cells in the marrow, often >30% of cellularity. Plasma cells may infiltrate the interstitium subtly or completely replace normal elements. HPE: Eccentric nucleus with perinuclear clearing (prominent Golgi) and

abundant basophilic cytoplasm. {{caption_text}} Normal-appearing plasma cells, plasmablasts with vesicular nuclear chromatin and prominent single nucleolus, or bizarre, multinucleated cells may predominate. Other Cytologic Variants (due to dysregulated Ig synthesis and secretion): Flame cells: Fiery red cytoplasm. Mott cells: Contain multiple grapelike cytoplasmic droplets. {{caption_text}} Inclusions: Russell bodies: Globular cytoplasmic inclusions. Dutcher bodies: Globular nuclear inclusions. Incorrect Options: CLL (Option B) is a malignancy of mature B-cells, not associated with lytic bone lesions or elevated calcium. It shows Smudge cells (or parachute/basket cells) due to the fragility of lymphocytes during slide preparation and convent girl appearance (a lot of homogenous, small, mature-like, round lymphocytes with scant cytoplasm). {{caption_text}} ALL (Option C) affects immature lymphocytes and typically presents with other hematologic symptoms, not lytic bone lesions and elevated calcium. It shows Lymphoblasts in bone marrow >=20%, Cytoplasmic vacuolations, fat (Oil Red O Positive) and hand mirror-shaped cells. {{caption_text}} CML (Option D) is a myeloproliferative disorder that primarily affects granulocytes and is not associated with plasma cells or lytic bone lesions. It presents with Leukocytosis with cell types including Neutrophils (multilobed nucleus), metamyelocytes (indented nucleus), myelocytes (D-shaped nucleus), and eosinophils (orange cells) College girl/garden party appearance: Due to the variety of cell appearances Shift to the Left: Presence of immature cell types, mainly immature neutrophils, in the blood.





@Neet_pg_bot

Q23: Asbestos exposure may be associated with which of the following malignancies? (Q858108)

A. Mesothelioma

B. Acute myeloid leukemia

C. Hepatic angiosarcoma

D. Skin carcinoma

Correct Answer: A. Mesothelioma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Asbestos exposure is most strongly associated with mesothelioma Mesothelioma A rare cancer arising from mesothelial cells that most commonly affects the pleura. It can also affect the peritoneum, pericardium and tunica vaginalis. Aetiology Asbestos: Mesothelioma is the most specific asbestos-associated cancer It is not associated with smoking Pathology Advanced pleural mesothelioma can cause extensive pleural fibrosis and thickening, making the affected side rigid and immobile. Later stages fix the mediastinum in place due to pleural thickening and fibrosis. The mediastinal shift is not a characteristic feature of mesothelioma. M/C cytogenetic abnormality in mesothelioma: Homozygous deletion of chromosome 9p , leading to loss of tumour suppressor gene - CDKN2A. Clinical features Progressive dyspnea, chest pain, weight loss, chronic cough, hemoptysis. Decreased breath sounds and dullness to percussion (due to pleural effusion or thickening). Diagnosis CT scan: Pleural thickening, effusion, or frozen hemithorax (not causing a mediastinal shift in the presence of effusion) Confirmed by biopsy: Epithelioid mesothelioma shows tubules, nests, or papillary structures with uniform round to oval nuclei and eosinophilic cytoplasm. Sarcomatoid mesothelioma consists of spindle-shaped cells resembling fibrosarcoma. Biphasic mesothelioma displays a mixture of both patterns. Specific markers for mesothelioma: Calretinin Epithelial membrane antigen Cytokeratin Mesothelin Prognosis Poor (median survival of 9-21 months). {{caption_text}} Mesothelioma- Gross {{caption_text}} Mesothelioma- H & E stain {{caption_text}} Mesothelioma- Calretinin stain Incorrect Options: Acute myeloid leukaemia (Option B) : While there are some associations between certain environmental toxins and leukaemia, asbestos is not a significant cause of AML. Other agents like benzene are more strongly linked with leukaemia. Hepatic angiosarcoma (Option C) is primarily associated with exposure to vinyl chloride and arsenic , not asbestos. Skin carcinoma (Option D) , particularly basal cell carcinoma and squamous cell carcinoma, is largely linked to UV radiation . Asbestos exposure is not a major risk factor for skin carcinoma.

@Neet_pg_bot

Q25: Which of the following features does not distinguish between necrosis and apoptosis? (Q840014)

A. Enzymatic degradation

B. Association with underlying pathology

C. Lipid change

D. Intact membrane

Correct Answer: B. Association with underlying pathology

Explanation: Correct Option B - Association with underlying pathology : Underlying pathological condition is not an important feature of differentiation between necrosis and apoptosis as necrosis and apoptosis both can be triggered by an underlying disease/ pathological condition. Incorrect Options: Option A - Enzymatic degradation: In necrosis, cellular contents leak out and undergo enzymatic digestion, while in apoptosis, they're enclosed until released as apoptotic bodies, with the membrane intact until engulfed by phagocytic cells. Option C - Lipid change: In apoptosis, inflammation is rare, while in necrosis, it's common due to released cellular contents triggering inflammation. Option D - Intact membrane: In apoptosis, the cell membrane remains intact, whereas in necrosis, it is disrupted.

@Neet_pg_bot

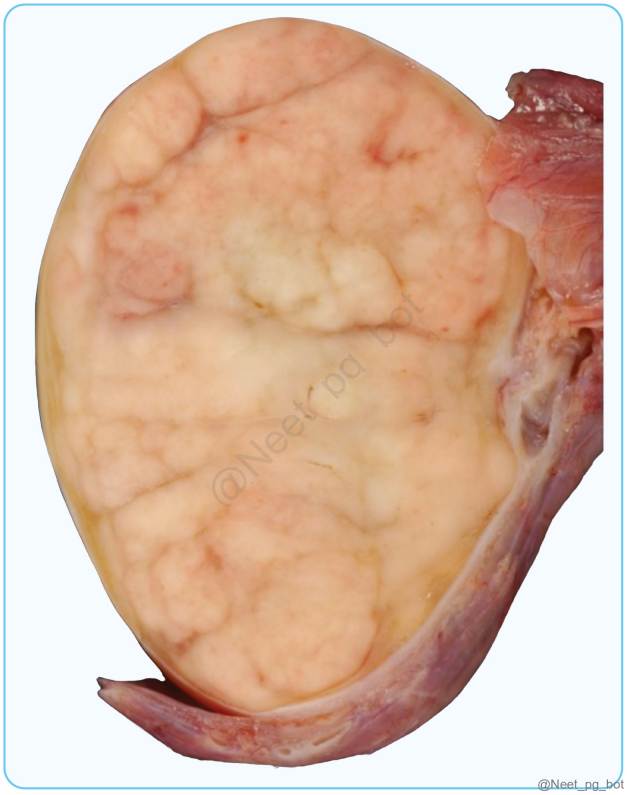
Q26: A 35-year-old male presents with a testicular mass, and a gross image of the mass is provided. What is the most likely diagnosis? (Q860552)

A. Teratoma

B. Seminoma

C. Yolk sac tumour

D. Choriocarcinoma



Correct Answer: B. Seminoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The testicular mass described, with a homogeneous, grey-white, lobulated cut surface and no signs of haemorrhage or necrosis, is most consistent with a diagnosis of Seminoma . It is the most common germ cell tumour of the testis. A similar presentation in the ovary is called dysgerminoma , and germinoma is present in the pineal gland . Incidence: Peak incidence in the fourth decade. Genetics: Seminomas contain isochromosome 12p and express OCT3/4 & NANOG. Gross: Seminoma has a homogeneous, grey-white, lobulated cut surface, usually devoid of haemorrhage or necrosis. Generally, the tunica albuginea is not penetrated, but extension to the epididymis, spermatic cord, or scrotal sac occasionally occurs. {{caption_text}} Histology of seminoma : It consists of sheets of monomorphic cells arranged in poorly defined lobules, separated by fibrous septa with lymphocytic (T cell) infiltration. Classic seminoma cells are large, round to polyhedral, with distinct membranes, central nuclei, and prominent nucleoli. The cytoplasm is clear or watery containing glycogen. {{caption_text}} Teratoma (Option A) are germ cell tumours containing tissues from all three germ layers (ectoderm, mesoderm, and endoderm). They can be benign (mature) or malignant (immature) and are commonly found in the testes, ovaries, or midline. Histologically, they present as heterogeneous masses with various tissue types (e.g., neural, muscle, epidermis, cartilage, thyroid, or intestinal tissue), often showing necrosis, calcification, or hair/teeth/bone. {{caption_text}} Yolk sac tumor (Option C) is a malignant germ cell tumour, commonly found in the testes or ovaries, especially in children and young adults. It produces alpha-fetoprotein (AFP) and appears as a solid mass with haemorrhage and necrosis, presenting in younger patients, particularly in the first two years of life. Microscopically, show a lace-like network of cuboidal or spindled cells with Schiller-Duval bodies and eosinophilic globules containing α-fetoprotein (AFP). {{caption_text}} Choriocarcinoma (Option D) is a rare, highly malignant germ cell tumour, typically in the testes, ovaries, or placenta, that secretes hCG. It presents with

pain, swelling, and elevated hCG levels, often with haemorrhage, necrosis, and mixed trophoblastic cells. Microscopically, it contains syncytiotrophoblasts (multinucleated, hCG-containing) and cytotrophoblasts (polygonal, clear cytoplasm). {{caption_text}} {{caption_text}}

Q27: What is the tumour marker for a carcinoid tumour? (Q860551)

A. Beta-HCG

B. Calcitonin

C. 5-HIAA

D. Alpha-fetoprotein

Correct Answer: C. 5-HIAA

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The tumour marker for a Carcinoid Tumor is 5-HIAA (5-hydroxy indole acetic acid). Carcinoids are derived from Argentaffin cells that secrete serotonin. It is commonly caused by neuroendocrine tumours of the midgut that metastasise to the liver. It is also seen with ovarian tumours or bronchial carcinoids. They secrete mediators like serotonin (5-hydroxytryptamine), kallikrein, bradykinin, histamine, and prostaglandins. Clinical features: Diarrhea and abdominal cramping Flushing and pruritus due to histamine Wheezing and dyspnea due to bronchospasm Pellagra (diarrhoea, dermatitis, dementia) Carcinoid heart disease: Tricuspid regurgitation leading to right heart failure Diagnosis: Elevated twenty-four-hour urine for 5-HIAA. Elevated serum serotonin. Elevated serum chromogranin A. Octreoscan for localising the source. Tumor marker Associated conditions Alpha-fetoprotein (AFP) (Option D ruled out) Hepatocellular carcinoma (HCC) Hepatoblastoma Yolk sac tumour (endodermal sinus tumour) Nonseminomatous germ cell tumour of testis ↑ AFP: abdominal wall defects, neural tube defects ↓ AFP: associated with trisomy 21, 18, and 13 β-HCG (Option A ruled out) Nonseminomatous testicular germ cell tumours (choriocarcinoma, embryonal cell carcinoma, mixed germ cell tumour, seminoma) Ovarian cancer: choriocarcinoma (gestational trophoblastic disease) Carcinoembryonic antigen (CEA) Colorectal cancer Pancreatic cancer Breast cancer Lung cancer (especially in non-small cell cancers) Gastric cancer Prostate-specific antigen (PSA) Prostate cancer Benign prostatic hyperplasia Prostatitis Calcitonin (Option B ruled out) Medullary thyroid cancer (both sporadic and associated with MEN 1 and MEN 2) Alkaline phosphatase Metastases to bone or liver Paget disease of the bone Placental alkaline phosphatase Seminoma Lactate dehydrogenase Ovarian cancer (dysgerminoma) Testicular germ cell tumours (both seminoma and nonseminoma) Lymphomas Ewing's sarcoma Neuron specific enolase (NSE) Neuroendocrine tumors Small cell lung cancer Carcinoid tumour Neuroblastoma CA 19–9 Pancreatic adenocarcinoma Colon cancer Cholangiocarcinoma CA 15–3 and CA 27–29 Breast cancer CA 125 Ovarian carcinoma Other gynecologic malignancies S-100 protein (S100A) and (S100B) Malignant melanoma SMRP Mesothelioma

Q28: Epithelial-mesenchymal transition induced by which pair of transcription factors? (Q853375)

A. TF IIA & TF IIB

B. Cathepsin & MMP 8

C. SNAIL & TWIST

D. STAT-5 & HIF-1 alpha

Correct Answer: C. SNAIL & TWIST

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Epithelial-mesenchymal transition (EMT) is induced by the transcription factors SNAIL and TWIST. It is a process where epithelial cells lose their polarity and cell-cell adhesion, gaining migratory and invasive properties to transform into mesenchymal stem cells, multipotent stromal cells. t is hypothesized that E-cadherin (transmembrane glycoproteins that mediate the homotypic adhesion of epithelial cells) expression is transiently silenced through this process. It is controlled by the transcription factors SNAIL and TWIST. There is downregulation of epithelial markers (e.g., E-cadherin) and also upregulation of mesenchymal markers (e.g., vimentin and smooth muscle actin). TF IIA & TF IIB (Option A) are essential general transcription factors that are key to the initiation of transcription by RNA polymerase II. TFIIA contributes to transcriptional regulation by modulating the initiation process and ensuring correct gene expression. TFIIB is responsible for forming the transcription initiation complex and facilitating the transition from initiation to elongation. Cathepsin & MMP 8 (Matrix Metalloproteinase-8) (Option B) are enzymes that degrade proteins in the extracellular matrix, playing key roles in tissue remodelling and inflammation. Cathepsins aid in wound healing and immune responses but can contribute to cancer metastasis and inflammation. Elevated MMP-8 is linked to diseases like periodontal disease, arthritis, and cancer, where it contributes to tissue damage and remodelling. STAT-5 & HIF-1 alpha (Option D) are transcription factors. STAT-5, activated by cytokine receptors, regulates cell survival, differentiation, and immune responses and is key in hematopoiesis and cancers like leukaemia. HIF-1 alpha responds to low oxygen levels, activating genes for angiogenesis, metabolism, and erythropoiesis, and plays a critical role in tumour growth in hypoxic environments.

Q30: Which of the following is not correct? (Q853368)

A. C- MYC - Burkitts lymphoma

B. Least radiosensitive phase is S phase of cell cycle

C. Least radiosensitive cell is platelet

D. Cyclin E triggers cells to move from G0 to G1 and G1 to S phase

Correct Answer: D. Cyclin E triggers cells to move from G0 to G1 and G1 to S phase

Explanation: Cyclin D triggers cells to move from G0 to G1 and G1 to S phase Cyclin E prepares the cell for DNA replication in S phase Cyclin A activates DNA replication inside nucleus in S phase Cyclin B promotes the assembly of mitotic spindle and other tasks in the cytoplasm to prepare for mitosis Option A, B, C are correct.

• [05_Immunity] 019 Types Of Immunity

« Back to Folder Directory

[05_Immunity] 019 Types Of Immunity — Quick Jump

Q1 (p. 1446) *Q2 (p. 1447)* *Q3 (p. 1449)* *Q4 (p. 1450)* *Q5 (p. 1451)* *Q6 (p. 1452)*
Q7 (p. 1453) *Q8 (p. 1456)* *Q9 (p. 1457)* *Q10 (p. 1459)* *Q11 (p. 1460)* *Q12 (p. 1461)*

Q1: Which of the following is not a feature of innate immunity? (Q845264)

A. Present since birth

B. Made of epithelial barriers, phagocytes, innate lymphoid cells (ILCs) and NK cells

C. Quick, non-specific response

D. Has a lag phase between exposure and response

Correct Answer: D. Has a lag phase between exposure and response

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The lag phase between exposure and response is not a feature of innate immunity as it acts rapidly against pathogens. The lag phase is a feature of adaptive immunity. It specifically targets the pathogen causing infection, so it first needs to recognize the pathogen. This means that it’s slower to respond than the innate immune system, but it’s more accurate when it does respond. Because of immunological memory, the next time it faces the same pathogen, there is a quick and robust response. Innate immunity is the body's first line of defense against pathogens, present since birth. It responds similarly to all germs and foreign substances, hence the term non-specific immune system. Adaptive Immunity : Requires time to recognize specific pathogens, resulting in a slower initial response, but it develops immunological memory for a quicker, more robust response upon re-exposure. Difference between innate and acquired immunity: Innate/native immunity Acquired/adaptive immunity Present since birth (Option A) Occurs after exposure to the pathogen Quick, non-specific response (Option C) Slower, specific response to a pathogen No immunological memory Has immunological memory Examples include : Epithelial barriers like skin, GIT. (Option B) Plasma proteins like C-reactive protein. Phagocytes: Neutrophils, macrophages, dendritic cells. Natural Killer (NK) cells : Specialized lymphocytes that destroy virally infected or tumor cells. Complement System : Specifically the Alternative and Lectin pathways. Cells are of 2 types : B lymphocytes: Provides humoral immunity and produces antibodies T lymphocytes: Involved in cell-mediated immunity and help with immunity against intracellular microbes Complement System : Specifically the Classical pathway (activated by antibody-antigen complexes).

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 45-year-old male presents with a fever, sore throat, and swollen lymph nodes. He is diagnosed with a viral infection. Which of the following cells is most likely involved in the early defense against the offending agent in this patient? (Q845266)

A. NK cells

B. T cells

C. Macrophages

D. Histocytes

Correct Answer: A. NK cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this scenario, the patient has a viral infection, and the body's initial defense mechanism against the virus is Natural Killer (NK) cells. Natural Killer cell (NK) : First line of defence against Tumor cells and Virus NK cell: < 10 % Produced by a large granular lymphocyte. Constitutes 5 to 10% of circulating blood lymphocytes. Function: It can be part of both innate and adaptive immunity. Innate immunity: Directly kill the virus-infected cells or tumour cells. Adaptive immunity: Antibody-dependent cell-mediated cytotoxicity. Structure of NK cell: Has 2 arms Activating receptor → NKG2D Inhibitory receptor → CD94 CD Markers: CD16 → Receptor for Fc IgG CD56 CD 94 NK cells towards self cells & foreign cells: NK cells and Self cells NK cells and Foreign cells Do not kill their own cells All self-cells express MHC-I When MHC-I is detected, NK cells use their inhibitory arm to prevent killing self-cells Viruses & cancer cells suppress MHC-I expression When MHC-I is downregulated, the activating arm of NK cells becomes dominant and kills the cell T cells (Option B) are important in the adaptive immune response against viruses, they are not typically involved in the body's immediate defense mechanism during the early stages of infection. Macrophages and Histiocytes (Option C & D) are part of the innate immune system and play a role in the immune response to viral infections. However, NK cells are more directly involved in the early defence against viruses due to their ability to recognize and kill virus-infected cells without prior sensitization.

@Neet_pg_bot

Q3: A 20-year-old medical student went for a screening health test and was injected with PPD intradermally. Identify the immune cell in the skin that picks up the PPD to present it to T cells. (Q845274)

A. Langhans cells

B. Follicular dendritic cells

C. Langerhans cells

D. Natural killer cells

Correct Answer: C. Langerhans cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario describes the Mantoux test. Langerhans cells are specialized dendritic cells found in the skin and mucosa. They are responsible for antigen presentation in the immune system. They are part of the body's first line of defense and belong to the innate immune system. Dendritic cells(DC) are the most potent antigen-presenting cells(APC) for initiating T-cell responses against protein antigens. Dendritic cell properties: They have many cytoplasmic processes resembling dendrites and receptors that sense microbes and cell damage that stimulate the secretion of cytokines. This has a critical role in inflammation and antiviral defense. They express receptors for capturing antigens, including TLRs and lectins. They are located under the epithelia and interstitia of all tissues, which are common sites for capturing antigens. They have a higher concentration of MHCs and are present in greater numbers in the epidermis than other APCs. Immature DCs within the epidermis are called Langerhans cells. Antigen Presenting Cells: This antigen will be presented on the MHC, and then given to T cells. Langhans cells/Langhans giant cells (Option A) are multinucleated giant cells found in granulomas. They consist of huge cytoplasm and multiple nuclei that are derived from the fusion of multiple activated macrophages. Follicular dendritic cells (Option B) are specialized cells found in lymphoid follicles within lymph nodes and the spleen. They play a crucial role in presenting antigens to B cells and are involved in the formation and maintenance of the germinal center reaction. NK cells (Option D) are not APCs. They destroy abnormal cells, such as virus-infected or malignant cells.

@Neet_pg_bot

Q5: Toll-like receptors are predominantly expressed in which of the following cell types? (Q845386)

A. Macrophages

B. Endothelial cells

C. Natural killer cells

D. All of the above

Correct Answer: D. All of the above

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Toll-like receptors (TLRs) are a family of pattern-recognition receptors expressed on immune cells like macrophages, dendritic cells, and natural killer cells, as well as on non-immune cells like endothelial cells.

Pattern recognition receptors Receptor Type Cellular Compartment Function Toll-like Receptors (TLRs) Plasma membrane, endosomal vesicles Detect microbial components (e.g., bacterial lipopolysaccharides, viral RNA) The final effect of antigen binding to TLR is the activation of transcription factors: 1. NF-κB : Stimulates the synthesis and secretion of cytokines and expression of adhesion molecules. 2. Interferon regulatory factors (IRFs): stimulate the production of antiviral cytokines and interferons.

@Neet_pg_bot

Q6: An 8-year-old child is brought with complaints of fever and burning micturition. She was diagnosed to have UTI with toxin-producing strains of E.coli. Where are blood-borne antigens trapped in the immune response to these toxins? (Q845387)

A. Lymph nodes

B. Thymus

C. Bone marrow

D. Spleen

Correct Answer: D. Spleen

Explanation: In the immune response to toxin-producing strains of E. coli causing UTI, blood-borne antigens are primarily trapped and processed in the spleen. The spleen is an important secondary lymphoid organ where circulating antigens, including those derived from bacteria and their toxins, are captured by specialized cells such as macrophages. These antigens are then presented to immune cells, initiating an immune response to neutralize the toxins and clear the infection. Secondary Lymphoid Organs: This group includes the spleen, lymph nodes, and mucosal/cutaneous lymphoid tissues (MALT/SALT), all of which are sites where adaptive immune responses are initiated. Lymph Nodes (Option A): While also secondary lymphoid organs, lymph nodes are responsible for trapping and filtering tissue-borne antigens that arrive via the lymphatic vessels, rather than those circulating in the blood. Primary Lymphoid Organs (Options B & C): The thymus and bone marrow are where immune cells (T and B lymphocytes) develop and mature; they are not the primary sites for trapping foreign antigens during an active infection.

@Neet_pg_bot

Q7: Which of the following HLA gene regions encodes Class II MHC molecules? (Q845389)

A. HLA-A

B. HLA-B

C. HLA-C

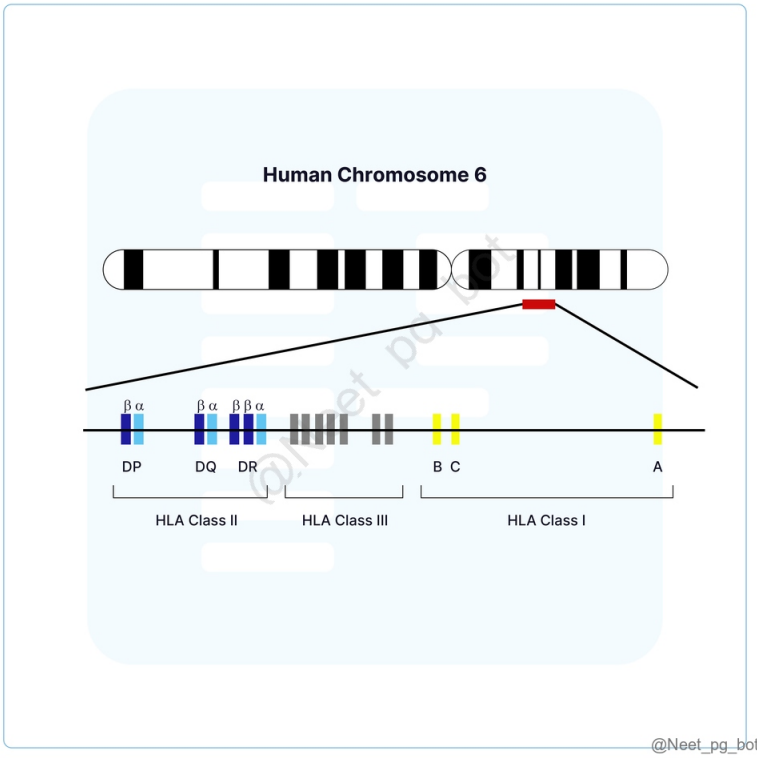
D. HLA-D

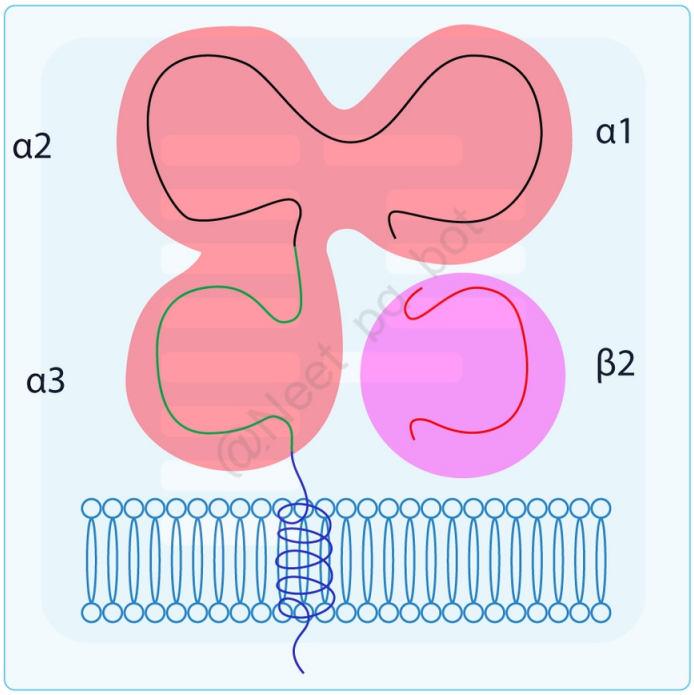
Correct Answer: D. HLA-D

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Class II MHC molecules are encoded in a region called HLA-D. Major Histocompatibility Complex (MHC): Made by HLA gene Located on the short arm of chromosome 6p The structure of HLA gene: HLA consists of three regions, which have been designated as class I, class II, and class III based on the structure and function of gene products. Gene region Encoded products Class I HLA-A, HLA-B, HLA-C, HLA-E, and HLA-G MHC-I Class II HLA-DP, HLA-DQ, and HLA-DR. MHC-II Class III C2, C4, Properdin, Tumor necrosis factor (TNF), complement and heat shock proteins HLA E → Help in the processing of Natural Killer cells HLA G (Gestationalis): Feto-maternal tolerance Fetal cells are coated with HLA G and hence mother does not treat those as foreign cells Difference between MHC-I and MHC-II: Characteristics MHC-I MHC-II Structure It has α1 chain, α2 chain, α3 chain, and β-2 microglobulin It has α1 chain, α2 chain, β1 Chain, β2 Chain Antigen Binding Cleft At the junction of α1 and α2 At the junction of α1 and β1 Present on cells All nucleated cells in the body Platelets Present in all the antigenpresenting cells Not present RBC (Adsorb MHC-1 from surrounding cells), Sperms - Present to cells MHC I → CD8 cells MHC II → CD4 cells Testing Alloantisera testing Mixed lymphocyte reaction testing





@Neet_pg_bot

Q8: A patient presented with a fever and loose stool for one week. He was diagnosed with typhoid infection. Which of the following MHC class is responsible for antigen presentation in this patient? (Q845390)

A. Class I

B. Class II

C. Class III

D. Non-MHC-dependent antigen presentation

Correct Answer: B. Class II

Explanation: In a patient with typhoid infection (caused by Salmonella typhi), antigen presentation primarily involves MHC class II molecules, which present antigens derived from extracellular pathogens to activate an immune response. Class I MHC class I molecules present endogenous antigens derived from intracellular pathogens, such as viruses and some bacteria. Class II MHC class II molecules present exogenous antigens derived from extracellular pathogens, such as Salmonella typhi, the bacterium responsible for typhoid fever. Class III MHC class III molecules are not involved in antigen presentation. They encode components of the complement system and other immune-related molecules. Non-MHC-dependent antigen presentation While non-MHC-dependent antigen presentation can occur through mechanisms like CD1 molecules presenting lipid antigens. Class II MHC molecules are expressed on the surface of antigen-presenting cells (APCs), such as dendritic cells, macrophages, and B cells. These cells process exogenous antigens derived from extracellular microbes and proteins after internalization into endosomes or lysosomes. The internalized proteins are broken down into peptides and associated with class II MHC in the vesicles and transported to the cell surface as stable peptide-MHC complexes. The class II-peptide complex is recognized by CD4+/helper T cells. Class II MHC molecules present antigens derived from extracellular pathogens to CD4+ helper T cells, initiating an immune response.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which component functions as the antigen binding site in MHC complexes 1 and 2, respectively? (Q845404)

A. MHC 1 - beta microglobulin; MCH 2 - alpha 3 domain

B. MHC 1 - alpha 1 and 2; MHC 2 - alpha 1 and beta 1

C. MHC 1 - alpha 1 and beta 1; MHC 2 - alpha 1 and 2

D. MHC 1 - invariant chain; MHC 2 - beta microglobulin

Correct Answer: B. MHC 1 - alpha 1 and 2; MHC 2 - alpha 1 and beta 1

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In MHC class I molecules, the alpha 1 and beta 1 domains together form the antigen-binding site, which binds to peptides derived from intracellular proteins. MHC-1 molecules are expressed on all nucleated cells, antigen-presenting cells, and platelets Mature RBCs that lack a nucleus don't express MHC-1 They are heterodimers with a polymorphic α or heavy chain linked non-covalently to a smaller β2-microglobulin. The antigen is bound within a groove between the α1 and α2 domains of the alpha chain. This, along with the β2-microglobulin, forms a stable complex to be displayed on the cell surface. B cells, dendritic cells, and mononuclear phagocytes expresses MHC class II molecules, as they are professional antigen-presenting cells involved in initiating immune responses. In MHC class II molecules, similar to MHC class I, the antigen-binding site is also formed by the alpha 1 and beta 1 domains, binding peptides derived from extracellular proteins presented by antigen-presenting cells. They consist of 2 alpha and 2 beta chains of equal length. The invariant chain is a protein structure associated with MHC-2. It is associated with MHC-2 within endosomes to prevent the binding of endogenous antigens. The invariant chain is later broken down, while MHC-2 is moved to the cell surface.

@Neet_pg_bot

Q10: A newborn delivered by a mother who received no prenatal care is being evaluated. On examination, the baby has severe oedema, icterus, and organomegaly and is in respiratory distress. What immunoglobulin class was responsible for this child's presentation? (Q845407)

A. IgG

B. IgM

C. IgA

D. IgE

Correct Answer: A. IgG

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario describes Hemolytic disease of the newborn (HDN) , also known as erythroblastosis fetalis. This occurs when maternal antibodies cross the placenta and attack fetal red blood cells (RBCs). Pathophysiology: This condition is often caused by Rh (Rhesus) blood group incompatibility, where the mother is Rh-negative and the fetus is Rh-positive. During pregnancy, maternal antibodies of the IgG class against the Rh antigen can cross the placenta and attack the fetal red blood cells (RBCs), leading to hemolysis (destruction of RBCs) in the fetus. This results in various degrees of anaemia and potentially severe complications for the newborn. Mechanism: This crossing is facilitated by active transplacental transfer mechanisms, primarily mediated by syncytiotrophoblast cells expressing neonatal Fc receptors (FcRn) . These receptors interact with the Fc domain of IgG, permitting their transfer. Result: This leads to hemolysis, severe anemia, edema (hydrops fetalis), and icterus (jaundice). This phenomenon is also responsible for newborns' passive immunity, with IgG being the most abundant antibody in their circulation. IgM (Option A) are multinucleated giant cells found in granulomas. They consist of huge cytoplasm and multiple nuclei that are derived from the fusion of multiple activated macrophages. It cannot cross the placenta due to its large size (pentameric structure). IgD and IgE (Option C and D) are also incapable of crossing the placenta. Key Features of Immunoglobulins (The "GAMED" Table): Class Key Characteristics & Functions IgG Most abundant in serum. The only antibody that crosses the placenta (provides passive immunity to the newborn). Fixes complement and opsonizes bacteria. IgA Found in secretions (tears, saliva, mucus, colostrum). Prevents attachment of bacteria and viruses to mucous membranes. Exists as a dimer with a J-chain. IgM First antibody produced in an initial immune response. Large pentameric structure (highest avidity). Excellent at fixing complement. Cannot cross placenta. IgE Mediates Type I Hypersensitivity (allergic) reactions. Binds to mast cells and basophils. Provides defense against parasitic infections (helminths). IgD Found primarily on the surface of B cells as an antigen receptor. Its precise physiological function in serum is unclear.

Name	Properties	Structure
IgA	Found in mucous, saliva,tears, and breast milk. Protects against pathogens.	
IgD	Part of the B cell receptor. Activates basophils and mast cells.	
IgE	Protects against parasitic worms. Responsible for allergic reactions.	
IgG	Secreted by plasma cells in the blood. Able to cross the placenta into the fetus.	
IgM	May be attached to the surface of a B cell or secreted into the blood. Responsible for early stages of immunity.

@Neet_pg_bot

Q11: A 65-year-old male presents to the emergency department with a fever, productive cough, and shortness of breath. He is diagnosed with pneumonia. Which of the following cytokines is most likely to be elevated in this patient due to the activation of classical macrophages in response to the infection? (Q845411)

A. Interleukin- 1

B. Interleukin- 2

C. Interleukin- 4

D. Interleukin- 10

Correct Answer: A. Interleukin- 1

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Interleukin-1 will be elevated in this patient due to the activation of classical macrophages in response to the infection. Macrophages act as antigen-presenting cells and play vital roles in innate, humoral and cell-mediated immune responses. The two main pathways of macrophage function are classical (M1) and

alternative (M2) pathways, each driven by different stimuli and resulting in different macrophage functions. Stimuli Functions and Secretions Role Classical (M1) Activation Microbial products (e.g., LPS), IFN-γ Pro-inflammatory and microbicidal functions: NO, lysosomal enzymes, TNF-α, IL-1, IL-12, IL-23 Host defense Microbial destruction Inflammation Alternative (M2) Activation IL-4, IL-13 (Option C) Tissue repair, resolution of inflammation, secretion of TGF-β, growth factors, IL-10 Tissue remodeling Angiogenesis, Immunoregulation Wound healing Tissue repair and homeostasis Interleukin-2 (IL-2) (Option B) aka T-cell growth factor is a cytokine with pleiotropic effects on the immune system and is not associated with classical macrophage activation. Interleukin-10 (IL-10) (Option D) is an anti-inflammatory cytokine released from alternatively activated macrophages.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 98.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 10-year-old boy is brought with a history of eating sand. His stool examination showed Ascaris eggs. What type of T-cell is responsible for dealing with this infection? (Q845415)

A. TH1 cells

B. TH2 cells

C. TH17 cells

D. Treg cells

Correct Answer: B. TH2 cells

- *Listen (English)*
- *Listen (Hindi)*

Explanation: TH2 cells (CD4+) are responsible for dealing with helminthic (parasitic) infections. IL-4 is the main cytokine that induces naive CD4+ T cells to differentiate into T-helper type 2 (Th2) cells. Five major CD4 T helper cell (TH) subsets have been identified: TH1, TH2, TH17, Treg (T regulatory), and Tfh (follicular T helper) cells. Subtype Function and Characteristics Key Cytokines TH1 (Option A) Involved in chronic inflammatory diseases. Activated by IL-12 from APCs. Secrete IFN-gamma, activating macrophages. Stimulates macrophages to form epithelioid cells and giant cells. IFN-gamma TH2 Responsible for the alternative pathway of macrophage activation. Release cytokines IL-4, IL-5, and IL-13. To expel parasites from the body, stimulate eosinophil activation, antibody production (especially IgE), and mucus production. IL-4, IL-5, IL-13 TH17 (Option C) Defend against extracellular bacteria and fungi. Secrete IL-17 and IL-22, attracting neutrophils and monocytes. IL-17, IL-22 Treg (T regulatory) (Option D) Suppresses immune response, maintains homeostasis and self-tolerance. Inhibit T cell proliferation and cytokine production, preventing autoimmune reaction. IL-10, TGF-beta Tfh (Follicular T helper) Assist B cells in rapid proliferation and antibody production. Help produce antibodies with greater affinity. IL-21

[05_Immunity] 020 Types Of Hypersensitivity Reactions — Quick Jump

Q1 (p. 1464) *Q2 (p. 1465)* *Q3 (p. 1467)* *Q4 (p. 1469)* *Q5 (p. 1469)* *Q6 (p. 1470)*
Q7 (p. 1471) *Q8 (p. 1472)* *Q9 (p. 1473)* *Q10 (p. 1474)* *Q11 (p. 1475)* *Q12 (p. 1476)*

Q1: A 35-year-old woman presents to the clinic with sudden hives, facial swelling, and difficulty breathing shortly after eating shrimp at a restaurant. She reports similar reactions in the past. She appears anxious, with pronounced facial swelling and wheezing. Which sequence correctly describes the immunological events in this type of reaction? (Q845417)

A. Allergen exposure → Mast cell activation → IgE production → Th2 cell activation → Release of inflammatory mediators

B. Th2 cell activation → Allergen exposure → IgE production → Mast cell activation → Release of inflammatory mediators

C. Allergen exposure → Th2 cell activation → IgE production → Mast cell activation → Release of inflammatory mediators

D. Allergen exposure → Th2 cell activation → Mast cell activation → IgE production → Release of inflammatory mediators

Correct Answer: C. Allergen exposure → Th2 cell activation → IgE production → Mast cell activation → Release of inflammatory mediators

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given scenario is an example of anaphylaxis following shrimp intake, which is an example of a type 1 hypersensitivity reaction. Rapid anaphylactic reactions triggered by allergens like food or insect stings are IgE-mediated Type I hypersensitivity responses. Step 1: First Exposure (Sensitization phase) Allergen enters the body. Naive CD4+ T-cells → differentiate into TH2 cells . TH2 cells release cytokines : IL-4 → stimulates B-cells to class switch and produce IgE . IL-5 → activates eosinophils . IL-13 → enhances IgE production and mucus secretion. IgE antibodies bind to FCERI receptors on mast cells (mast cells now become sensitized). Step 2: Second Exposure (Effector phase) Allergen re-enters the body. It binds to IgE already attached on mast cells . This causes cross-linking (polymerization) of IgE molecules. Cross-linking triggers mast cell degranulation . Mast cells release mediators : Histamine → vasodilation, increased vascular permeability, itching, bronchospasm. Leukotrienes & Prostaglandins → prolonged inflammation. Cytokines → recruit more immune cells Note: Anaphylactoid reactions: Anaphylactoid reactions involve direct degranulation of mast cells and basophils, causing symptoms similar to anaphylaxis but without IgE mediation (non-immunologically mediated. These

reactions can occur even on first exposure since prior sensitization is not required. They are commonly triggered by drugs such as NSAIDs.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 205-208

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following cytokines acts on B cells to stimulate class switching to IgE and promotes the development of additional Th2 cells in type I hypersensitivity reactions? (Q845419)

A. IL-4

B. IL-5

C. IL-13

D. IL-10

Correct Answer: A. IL-4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Interleukins Role IL-4 Key cytokine in driving the allergic response Enhances Ig E-mediated reaction Stimulates B cells to undergo class switching to IgE and promotes the expansion of Th2 cells IL-5 (Option B) Development and activation of eosinophils→ Recruited to the site of allergen exposure→ Release inflammatory mediators and enzymes→ Tissue damage and inflammation IL-13 (Option C) Amplifies IgE production Acts on epithelial cells to stimulate mucus secretion IL-10 (Option D) Anti-inflammatory cytokine Inhibits cytokine production by Th1 cells and macrophages. Th-Cell Differentiation Pathway: When a naive $CD 4+ T cell encounters an antigen, the local cytokine environment determines its specialization: Th Cell Type Inducing Cytokines Key Cytokines Produced Primary Immune Function Th1 IL-12, IFN- γ IFN-γ , IL-2 Cell-mediated immunity ; activates macrophages to kill intracellular pathogens (e.g., TB). Th2 IL-4 IL-4, IL-5, IL-13 Humoral immunity ; defense against helminths and mediates Type I Hypersensitivity . Th17 TGF-β, IL-6 IL-17, IL-22 Recruitment of neutrophils ; defense against extracellular bacteria and fungi. Treg TGF-β, IL-2 TGF-β, IL-10 Immune tolerance ; suppresses autoimmunity and limits the inflammatory response.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 207

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 45-year-old patient with a history of allergic asthma presents with worsening respiratory symptoms. The sputum sample shows the presence of Charcot-Leyden crystals. Which of the following is NOT typically associated with this phase of hypersensitivity reaction? (Q845420)

A. Recruitment of eosinophils to the site of inflammation by chemokines like eotaxin

B. Production of IL-5 by Th2 cells to activate eosinophils

C. Release of histamine and tryptase by eosinophils

D. Liberation of major basic protein and eosinophil cationic protein by activated eosinophils

Correct Answer: C. Release of histamine and tryptase by eosinophils

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given scenario suggests that the patient's presentation involves eosinophils, particularly the identification of Charcot-Leyden crystals (composed of galectin-10 protein) in the extracellular space, which is derived from eosinophils. (suggestive of delayed phase of type 1 HSR). Histamine and tryptase are preformed mediators released by mast cells during the early phase of Type I hypersensitivity (Option B) , not by eosinophils in the late phase. Early phase reaction Late phase reaction Onset Immediate (within minutes of allergen exposure). Delayed (several hours after exposure) and can last for days. Cells involved Mast cells, basophils. Eosinophils, T lymphocytes. Cellular events Activation of mast cells and basophils. Recruitment and activation of leukocytes, especially eosinophils. Mediators Histamine, leukotrienes (LTB4, LTC4, LTD4), prostaglandins (PGD2) and Platelet-activating factor (PAF). Cytokines (e.g., IL-4, IL-5, TNF), chemokines (e.g., eotaxin) Initiating event Exposure to allergen triggers cross-linking of IgE on mast cells/basophils. Recurrent inflammation, sustained by recruited leukocytes. Effect on tissues Vasodilation, increased vascular permeability, smooth muscle contraction. Sustained inflammation and tissue damage due to leukocyte infiltration. Clinical manifestations Allergic rhinitis (hay fever), urticaria (hives), Angioedema bronchoconstriction. Allergic asthma exacerbation, persistent inflammation, and tissue damage. Therapeutic Approach Antihistamines for symptomatic relief. Adrenaline in anaphylactic shock Broad-spectrum anti-inflammatory drugs (e.g., steroids) to suppress inflammation and prevent tissue damage.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following is not an example of a Type I hypersensitivity reaction? (Q845421)

A. Graft rejection

B. Vernal Keratoconjunctivitis

C. Casoni test

D. P-K reactions

Correct Answer: A. Graft rejection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Graft rejection is not an example of a type I hypersensitivity reaction. Acute graft rejection involves Type II and Type IV hypersensitivity reactions. Hyperacute graft rejection involves Type II hypersensitivity reactions. Chronic graft rejection involves Type IV hypersensitivity reactions. Examples of Type I hypersensitivity reactions: Allergic conditions include Allergic rhinitis, Allergic dermatitis, Allergic conjunctivitis, or Vernal Keratoconjunctivitis (Option B). Bronchial asthma Casoni test: Done for detection of Echinococcus granulosus (Hydatid cyst) (Option C) . Drug reactions P-K reactions (Option D) The PK reaction is a laboratory technique used to demonstrate type I hypersensitivity, which involves IgE antibodies and mast cell degranulation, often leading to immediate allergic reactions. Theobald Smith phenomenon.(Theobald Smith phenomenon is the term for the development of hypersensitivity to bacteria in animals after repeated injections)

References:

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 208

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following diseases is not an example of a Type II hypersensitivity reaction? (Q845426)

A. Rheumatic fever

B. Multiple sclerosis

C. Immune thrombocytopenic purpura

D. Pernicious anaemia

Correct Answer: B. Multiple sclerosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Multiple sclerosis is an example of a type IV hypersensitivity reaction, not type II. Examples of Type II hypersensitivity reactions are: Mnemonic: My Blood Group Is Rh Positive My Myasthenia Gravis Blood Blood transfusion reaction Group Good pasture syndrome, Graves disease Is Immune hemolytic anaemia, Immune thrombocytopenic purpura R Rh incompatibility, Rheumatic fever H Hyperacute transplant rejection Positive Pemphigus (Bullous), Pernicious Anemia

Type B hypersensitivity (Antibody-mediated)	
Opsonization and complement → Phagocytosis	Transfusion reaction, erythroblastosis fetalis, AIHA, ITP.
Complement, F_c receptor-mediated → Inflammation	Goodpasture syndrome, Acute Rheumatic fever, vascular rejections, vasculitis.
Antibody-mediated cellular dysfunctions	Myasthenia gravis, Pemphigus Vulgaris, Graves disease, Pernicious Anemia, Insulin-resistant diabetes, Hemolytic disease of the newborn.

@Neet_pg_bot

References:

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 204-215

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following statements regarding pernicious anaemia is incorrect? (Q845428)

A. Natural Killer (NK) cells participate in Antibody-dependent cellular cytotoxicity.

B. Opsonisation involves IgG antibodies coating cells, enhancing phagocytosis via Fc receptors.

C. When antibodies deposit in intracellular tissues, the injury is due to inflammation and not phagocytosis or cell lysis.

D. Myasthenia gravis is an example of antibody-mediated cell surface receptor dysfunction.

Correct Answer: C. When antibodies deposit in intracellular tissues, the injury is due to inflammation and not phagocytosis or cell lysis.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In pernicious anemia, the type of hypersensitivity involved is Type II hypersensitivity, also known as antibody-mediated hypersensitivity. Antibodies cannot reach intracellular antigens in living cells, they target cell surface/extracellular matrix antigens. Immune complex mediated injury occurs in extracellular tissue spaces, not inside cells. Mechanisms of Hypersensitivity Reactions: Type Name Primary Mediator Detailed Mechanism Clinical Examples I Immediate IgE Antigens cross-link IgE on mast cells/basophils, triggering release of histamine and vasoactive mediators. Anaphylaxis, Asthma, Hay fever. II Antibody-Mediated IgG & IgM Antibodies bind to antigens on cell surfaces or extracellular matrix. Damage occurs via opsonization , phagocytosis , complement-mediated lysis , or ADCC (via NK cells). Pernicious Anemia , Myasthenia Gravis , Autoimmune Hemolytic Anemia. III Immune Complex Antigen-Antibody Complexes Complexes form in circulation and deposit in blood vessel walls or tissues, triggering complement activation and neutrophil-mediated inflammation. SLE (Lupus), Serum sickness, Glomerulonephritis. IV Cell-Mediated T-Lymphocytes Delayed response (lag phase) driven by CD4+ T cells (cytokine-mediated inflammation) or CD8+ T cells (direct cell killing). No antibodies involved. Tuberculin (Mantoux) test, Contact dermatitis, Type 1 Diabetes.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 209, 210

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: An 11-year-old boy presents to the emergency department with swelling in his face and legs, decreased urine output, and dark-colored urine. His parents reported that he had a sore throat about three weeks ago, which resolved without treatment. Urinalysis shows proteinuria and hematuria. Which type of hypersensitivity reaction is associated with this condition? (Q845438)

A. Type I hypersensitivity

B. Type II hypersensitivity

C. Type III hypersensitivity

D. Type IV hypersensitivity

Correct Answer: C. Type III hypersensitivity

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario suggests Post-streptococcal glomerulonephritis (PSGN), a classic example of a Type III hypersensitivity reaction . PSGN is an immune complex-mediated disease caused by the deposition of circulating immune complexes (composed of streptococcal antigens and antibodies) in the kidney glomeruli, leading to inflammation and damage. Examples of type III hypersensitivity: (mnemonic- SHARP) Serum sickness, Schick test, SLE (Hematological lesion) Henoch Schonlein purpura Arthus reaction Reactive arthritis Post-streptococcal Glomerulonephritis (PSGN), Polyarteritis Nodosa (PAN) PSGN vs HSP: Feature Post-Streptococcal Glomerulonephritis (PSGN) Henoch-Schönlein Purpura (HSP) / IgA Vasculitis Hypersensitivity Type III (Immune complex-mediated) Type III (Systemic small-vessel vasculitis) Primary Trigger Preceding Group A Strep infection (Pharyngitis or Skin/Impetigo) Often follows an Upper Respiratory Infection (URI) Major Antibody IgG and IgM complexes IgA -dominant immune complexes Kidney Biopsy (IF) "Starry Sky" or Lumpy-bumpy appearance (C3 and IgG deposits) Mesangial IgA deposits (identical to IgA Nephropathy) Complement Levels Low C3 levels (classic finding) Normal complement levels Systemic Features Limited primarily to the kidney (Nephritic syndrome) Tetrad: Palpable purpura (legs/buttocks), Arthralgia, Abdominal pain, Renal disease Latent Period 1–3 weeks after Strep infection Days after URI (much shorter or concurrent)

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 210-212

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following is typically associated with localized immune-complex mediated hypersensitivity? (Q845440)

A. Serum sickness

B. Arthus reaction

C. Membranous glomerulonephritis

D. Reactive arthritis

Correct Answer: B. Arthus reaction

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The “Arthus reaction” is localized immune-complex mediated or Type III hypersensitivity reaction, characterized by localized tissue necrosis caused by acute immune complex vasculitis, often occurring in the skin. Systemic type III hypersensitivity Localised type III hypersensitivity Involves the widespread formation of immune complexes in circulation and can deposit in various tissues and organs throughout the body, including the kidneys (leading to glomerulonephritis), joints, skin, blood vessels, and other sites. (e.g., in chronic infections or autoimmune diseases). Immune complexes are deposited at specific sites of antigen exposure, such as the skin (as in the Arthus reaction) or joint spaces, leading to local inflammation (localized swelling, redness, pain) and tissue

damage. Clinical Examples : Systemic Lupus Erythematosus (SLE) : Complex deposition in multiple organs. Serum Sickness : Reaction to foreign serum proteins (e.g., antivenom or certain medications). Post-Streptococcal Glomerulonephritis (PSGN) : Occurs after certain streptococcal infections. Reactive Arthritis : Joint inflammation triggered by an infection elsewhere in the body. Clinical Examples : Arthus Reaction : Localized skin necrosis following subcutaneous injection of an antigen in a sensitized individual. Hypersensitivity Pneumonitis : Localized lung inflammation (e.g., Farmer's lung) due to inhaled environmental antigens. Local Swelling/Pain : Redness and pain at the site of antigen exposure.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 210- 212

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 40-year-old man presents with jaundice and fatigue, recently diagnosed with hepatitis B infection. Further investigation reveals abnormal liver function tests, indicating hepatic injury. Which of the following statements regarding the mechanisms of hypersensitivity involved in this case is true? (Q845442)

A. CD8+ T cells differentiate into Th1 and Th17 cells upon antigen exposure

B. CD4+ T cells differentiate into Th2 cells upon exposure to antigen

C. Cytotoxic T-lymphocytes (CTLs) directly kill virus-infected cells via the Fas-Fas ligand pathway

D. Perforin-granzyme-dependent killing is a mechanism employed by CD4+ T cells

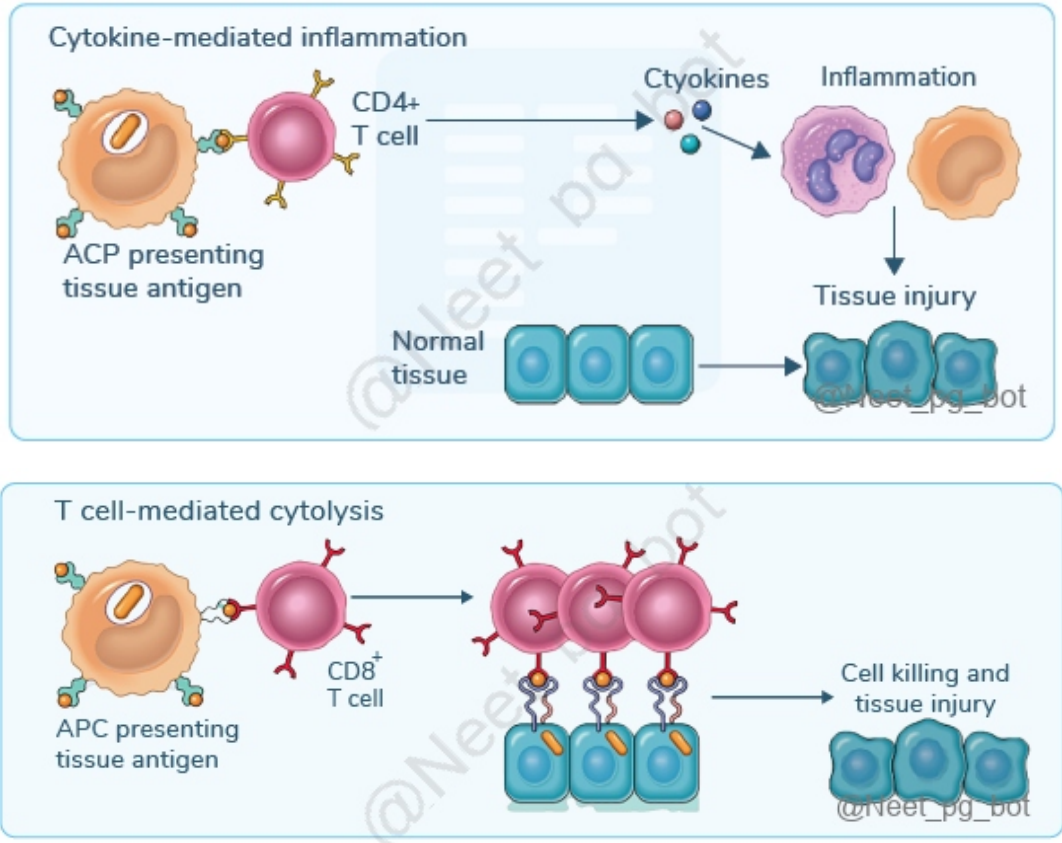
Correct Answer: C. Cytotoxic T-lymphocytes (CTLs) directly kill virus-infected cells via the Fas-Fas ligand pathway

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The type of hypersensitivity involved in hepatitis B virus (HBV) infection is Type IV. Mechanisms of Type IV hypersensitivity Description Examples Cytokine-mediated inflammation (mediated by CD4+ T cells) CD4+ T cells recognise protein antigens presented by APCs and differentiate into Th1 and Th17 cells (Options A and B ruled out) . Th1 cells secrete cytokines like IFN-γ, activating macrophages to cause tissue damage and fibrosis. Th17 cells produce IL-17 to recruit neutrophils, promoting inflammation. Tuberculin test (a classic example of delayed-type hypersensitivity) Granulomas Contact dermatitis Rheumatoid arthritis Multiple sclerosis IBD Psoriasis T cell-mediated cytotoxicity (mediated by CD8+ T cells) Cytotoxic T lymphocytes (CTLs) directly kill antigen-bearing target cells, including tumour cells, virus-infected cells, and allogeneic tissue, during graft rejection. CTLs use perforin-granzyme-dependent killing (Option D ruled out) and Fas-Fas ligand-dependent killing mechanisms to induce apoptosis in target cells. (Option C) Type 1 DM Hepatic injury in HBV infection

Graft vs host disease



References:

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 212-215

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 35-year-old woman presents with a history of persistent cough and unintentional weight loss. The physician suspects a TB infection and performs a tuberculin skin test. Which of the following is not an example of the type of hypersensitivity reaction associated with this test? (Q845444)

A. Contact dermatitis from poison ivy exposure.

B. Rheumatoid arthritis.

C. Crohn's disease.

D. Reactive arthritis.

Correct Answer: D. Reactive arthritis.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Reactive arthritis shows Type III hypersensitivity. The tuberculin skin test (TST) mentioned in the scenario represents a cell-mediated hypersensitivity reaction (Type IV or delayed-type hypersensitivity reaction). The tuberculin skin test (TST), or Mantoux test, detects latent tuberculosis infection (LTBI) by injecting a small amount of purified protein derivative (PPD) intradermally over the forearm. Examples of Type IV hypersensitivity reactions: Contact dermatitis from exposure to Urushiol from poison ivy or poison oak Detergent Artificial jewellery (Ni and Cd) Granuloma Mantoux test Lepromin test Inflammatory Bowel Disease (Crohn's disease) Rheumatoid arthritis (Type IV > Type III hypersensitivity) Multiple sclerosis Sarcoidosis Psoriasis

@Neet_pg_bot

Q11: Which of the following statements accurately describes Type V hypersensitivity? (Q845446)

A. Antibodies bind to cell surface receptors, leading to altered cellular function

B. Immune complexes form and deposit in tissues, triggering localized inflammation and damage.

C. Antibodies target cell surface antigens, resulting in complement activation and cell destruction.

D. IgE antibodies mediate the release of histamine from mast cells, causing immediate allergic reactions.

Correct Answer: A. Antibodies bind to cell surface receptors, leading to altered cellular function

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Type V hypersensitivity: Involves IgG antibodies binding to cell surface receptors, altering the normal function of those cells. The antibodies may mimic hormones or block receptor function Leads to altered cellular activity without direct destruction of the cells. It can cause overstimulation or inhibition of normal cellular functions. Graves' disease: Antibodies stimulate the thyroid hormone receptor, causing hyperthyroidism. Myasthenia gravis : Antibodies block acetylcholine receptors at the neuromuscular junction, leading to muscle weakness. IgE antibodies mediate the release of histamine from mast cells, causing immediate allergic reactions (Option B) is a hallmark of Type I hypersensitivity, involving immediate reactions and allergic responses mediated by IgE. Immune complexes form and deposit in tissues, triggering localized inflammation and damage (Option C) describes Type III hypersensitivity, which involves immune complex deposition leading to inflammation. Antibodies target cell surface antigens, resulting in complement activation and cell destruction (Option D) is characteristic of Type II hypersensitivity, where antibody binding leads to direct cell damage through complement activation.

https://www.medicalnewstoday.com/articles/hypersensitivity-reactions#type-3

https://dermnetnz.org/topics/allergies-explained

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Which of the following sequences correctly describes the phases of pathogenesis in Type III hypersensitivity? (Q845447)

A. Formation of immune complexes → Inflammation and tissue injury → Deposition in blood vessels.

B. Deposition of immune complexes → Formation of antibodies → Tissue injury and inflammation.

C. Formation of immune complexes → Deposition in tissues → Inflammation and tissue injury.

D. Antibody production → Immune complex formation → Activation of cytotoxic T cells.

Correct Answer: C. Formation of immune complexes → Deposition in tissues → Inflammation and tissue injury.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Phases of Type 3 hypersensitivity: 1. Formation of Immune Complexes : After introducing a protein antigen, antibodies are formed (typically within one week) and react with the antigen in circulation, creating antigen-antibody complexes. 2. Deposition of Immune Complexes : These complexes circulate and are deposited in blood vessels, particularly in organs like the kidneys and joints. Medium-sized complexes formed in slight antigen excess are most pathogenic. 3. Inflammation and Tissue Injury: Deposited immune complexes trigger acute inflammation about 10 days post-antigen exposure, leading to symptoms like fever, joint pain, and proteinuria. Complement activation contributes to tissue injury, with serum C3 levels potentially serving as a marker for disease activity.

Q31 (p. 1516)	*Q32 (p. 1517)*				

Q1: In healthy individuals, what is the typical ratio of CD4+ to CD8+ T lymphocytes? (Q890517)

A. 1:2

B. 2:1

C. 1:4

D. 4:1

Correct Answer: B. 2:1

Explanation: In the peripheral blood of healthy adults, T lymphocytes constitute about 60–70% of circulating lymphocytes , of which approximately 60% are CD4+ (helper T cells) and about 30% are CD8+ (cytotoxic T cells) , resulting in a CD4+:CD8+ ratio of approximately 2:1 . CD4+ T cells primarily function as helper cells that activate macrophages and B cells, whereas CD8+ T cells function as cytotoxic T lymphocytes that destroy infected cells. A decreased CD4+:CD8+ ratio is classically seen in HIV infection due to progressive depletion of CD4+ T cells.

@Neet_pg_bot

Q2: Which of the following conditions belongs to the spectrum of IgG4-related disorders? Mikulicz syndrome Riedel thyroiditis Idiopathic retroperitoneal fibrosis Autoimmune pancreatitis Sclerosing cholangitis (Q890556)

A. 1,2

B. 1,2,4

C. 1,4,5

D. All of the above

Correct Answer: D. All of the above

Explanation: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory disorder characterized by dense lymphoplasmacytic infiltrates rich in IgG4-positive plasma cells, storiform fibrosis, and obliterative phlebitis , often with increased serum IgG4 levels . It can involve multiple organ systems, and several conditions previously thought to be isolated diseases are now recognized as part of this spectrum, including: Mikulicz syndrome (salivary and lacrimal gland involvement) Riedel thyroiditis Idiopathic retroperitoneal fibrosis Autoimmune pancreatitis (prototype lesion) Sclerosing cholangitis These conditions represent different manifestations of a single multisystem disease process .

@Neet_pg_bot

Q3: Which of the following best describes the cell type that forms the characteristic lupus erythematosus (LE) cell? (Q890555)

A. Monocyte

B. Neutrophil

C. Basophil

D. Lymphocyte

Correct Answer: B. Neutrophil

Explanation: The classic lupus erythematosus (LE) cell is a phagocytic leukocyte, most commonly a neutrophil that has engulfed the denatured nuclear material of another injured cell. This nuclear material is coated with antinuclear antibodies (ANA) , forming a homogeneous, round inclusion called an LE body , which

characteristically displaces the neutrophil nucleus to the periphery . This phenomenon reflects immune complex formation against nuclear antigens in systemic lupus erythematosus (SLE) and was historically used as a diagnostic test. Monocyte (Option A): Occasionally, monocytes can form LE cells by engulfing denatured nuclear material, but this is less common. Basophil (Option C): Basophils do not form LE cells; their role is mainly in allergic reactions. Lymphocyte (Option D): Lymphocytes are the source of autoantibodies but do not form LE cells.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 200

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following autoantibodies is least likely to cause a homogeneous nuclear staining pattern on immunofluorescence? (Q890554)

A. Anti-histone antibodies

B. Anti-chromatin antibodies

C. Anti-double-stranded DNA antibodies

D. Anti-RNA antibodies

Correct Answer: D. Anti-RNA antibodies

Explanation: Anti-RNA-associated antibodies (such as anti-Sm and anti-U1 RNP) target ribonucleoproteins and characteristically produce a speckled nuclear staining pattern on immunofluorescence rather than a homogeneous pattern. In contrast, a homogeneous (diffuse) nuclear staining pattern is typically produced by antibodies directed against double-stranded DNA, chromatin (nucleosomes), and histones , which are components of tightly packed nuclear material. Anti-histone antibodies (Option A) are associated with homogeneous staining , commonly seen in drug-induced lupus. Anti-chromatin antibodies (Option B) target nucleosomes and produce a homogeneous pattern . Anti-double stranded DNA antibodies (Option C) are classically associated with a homogeneous nuclear staining pattern and are strongly linked to systemic lupus erythematosus.

@Neet_pg_bot

Q5: Which mechanism primarily contributes to the development of autoimmunity in Epstein-Barr virus infection? (Q890553)

A. Molecular mimicry

B. Polyclonal B-cell activation

C. Upregulation of co-stimulatory molecules

D. Cross-reactive antigen recognition

Correct Answer: B. Polyclonal B-cell activation

Explanation: Epstein-Barr virus (EBV) infects B lymphocytes via the CD21 receptor and induces their proliferation and survival by activating signaling pathways such as NF-κB and JAK/STAT . EBV acts as a polyclonal B-cell mitogen , leading to expansion of multiple B-cell clones. This nonspecific activation of B cells can result in the production of a wide range of antibodies, including potentially autoreactive antibodies , thereby contributing to breakdown of self-tolerance and development of autoimmunity. Molecular mimicry (Option A) is a general mechanism of autoimmunity but is not the primary mechanism associated with EBV in this context. Upregulation of co-stimulatory molecules (Option C) represents a general mechanism of immune activation and is not specific to EBV-induced autoimmunity. Cross-reactive antigen recognition (Option D) overlaps with molecular mimicry and is not the dominant mechanism in EBV infection.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 291

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following genes is a frequently implicated non-HLA susceptibility gene associated with multiple autoimmune diseases? (Q890552)

A. FOXP3

B. PTPN22

C. NOD2

D. AIRE

Correct Answer: B. PTPN22

Explanation: Polymorphisms in the PTPN22 gene are frequently associated with multiple autoimmune diseases , including type 1 diabetes, rheumatoid arthritis, systemic lupus erythematosus, Graves' disease, and Hashimoto thyroiditis. PTPN22 encodes a protein tyrosine phosphatase that negatively regulates T-cell receptor signaling , and disease-associated variants may impair this regulatory function, leading to excessive activation of self-reactive lymphocytes and loss of immune tolerance. FOXP3 (Option A) mutations cause immune dysregulation syndromes such as IPEX due to defective regulatory T cells, but these are rare monogenic disorders and not broadly

associated with common autoimmune diseases. NOD2 (Option C) is primarily associated with Crohn's disease , involving innate immune dysfunction and abnormal responses to gut microbes rather than generalized autoimmunity. AIRE (Option D) mutations cause autoimmune polyendocrine syndrome type 1 (APS-1) , a rare monogenic disorder due to defective central tolerance.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 194

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following autoimmune diseases is predominantly driven by T cell-mediated inflammation, although autoantibodies and immune complexes also contribute to its pathogenesis? (Q890551)

A. Pemphigus vulgaris

B. Pernicious anemia

C. Rheumatoid arthritis

D. Goodpasture syndrome

Correct Answer: C. Rheumatoid arthritis

Explanation: Rheumatoid arthritis is a chronic systemic autoimmune disease predominantly driven by CD4■ T cells (Th1 and Th17) , which initiate and sustain synovial inflammation through cytokines such as TNF-α, IL-17, IL-6, and IFN-γ . These cytokines activate macrophages and synovial fibroblasts, leading to chronic inflammation, angiogenesis, and formation of pannus , an invasive granulation tissue that progressively destroys articular cartilage and subchondral bone . In addition, autoantibodies , notably rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) form immune complexes that further amplify inflammation via complement activation. Thus, rheumatoid arthritis is a T-cell-dominant autoimmune disease with significant contribution from humoral immunity , representing a mixed (Type IV + Type III) mechanism of tissue injury . Pemphigus vulgaris (Option A) is an antibody-mediated (Type II hypersensitivity) disorder caused by IgG antibodies against desmogleins, leading to loss of cell adhesion (acantholysis) and blister formation. Pernicious anemia (Option B) is primarily antibody-mediated , involving antibodies against intrinsic factor and parietal cells, causing vitamin B12 deficiency; associated T-cell-mediated gastric mucosal damage may also contribute. Goodpasture syndrome (Option D) is a classic Type II hypersensitivity disease in which antibodies against basement membrane (type IV collagen) trigger complement activation and inflammation, leading to glomerulonephritis and pulmonary hemorrhage.

@Neet_pg_bot

Q8: Which of the following proteins are encoded by genes in the MHC class III region? Complement component C4 Tumour necrosis factor (TNF) Heat shock proteins β2-microglobulin (Q890532)

A. 2,3

B. 1,3,4

C. 1,2,3

D. 4 only

Correct Answer: C. 1,2,3

Explanation: The MHC class III region (located on chromosome 6p21.3) encodes a variety of proteins involved in inflammation and innate immunity , rather than antigen presentation. These include: Complement components such as C2, C4, and factor B Cytokines , including TNF-α and lymphotoxins (LTA, LTB) Heat shock proteins Unlike MHC class I and II molecules, MHC class III does not encode antigen-presenting molecules , but instead produces proteins that participate in immune and inflammatory responses. β2-microglobulin (4): It is a component of MHC class I molecules but is encoded outside the MHC locus (chromosome 15).

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 175

https://en.wikipedia.org/wiki/MHC_class_III

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following cytokines is a potent activator of basophils? (Q890529)

A. IL-3

B. IL-2

C. IFN-γ

D. TNF-α

Correct Answer: A. IL-3

Explanation: IL-3 is a key cytokine that promotes basophil growth, survival, and activation , and enhances their effector functions such as histamine release and leukotriene production . It also increases basophil responsiveness to various stimuli , making it a potent activator in allergic and inflammatory responses. IL-2 (Option B): Primarily stimulates T-cell proliferation and activation , with no major role in basophil activation. IFN-γ (Option C): Activates macrophages and promotes Th1 immune responses , not basophil activation. TNF-α (Option D): A pro-inflammatory cytokine involved in systemic inflammation, but not a primary activator of basophils.

@Neet_pg_bot

Q10: Which of the following statements about γδ T-cells are correct? They kill extracellular bacteria using granulysin and perforin. They require antigen processing and presentation for recognition. They can directly kill infected macrophages. They protect against mycobacterial infections. (Q890528)

A. 2 only

B. 1,2

C. 2,3,4

D. 1,3,4

Correct Answer: D. 1,3,4

Explanation: γδ T cells are a subset of T lymphocytes that recognise peptides, lipids, and small molecules without requiring MHC-mediated antigen presentation , and are commonly found at epithelial surfaces , where they contribute to early immune defence. They possess cytotoxic functions and can release molecules such as perforin and granulysin , contributing to antimicrobial activity. (Statement 1) γδ T cells have cytotoxic potential and can target infected macrophages. (Statement 3) They also contribute to host defence against intracellular pathogens , including mycobacteria, through cytotoxic activity and cytokine production. (Statement 4) γδ T cells do not require classical MHC-restricted antigen presentation. (Statement 2)

@Neet_pg_bot

Q11: Which of the following cell types shows recirculation? (Q890526)

A. Plasma cells

B. T lymphocytes

C. Plasma cells and T lymphocytes

D. B lymphocytes and plasma cells

Correct Answer: B. T lymphocytes

Explanation: Lymphocytes continuously recirculate between the blood and secondary lymphoid organs. This process is most important for T lymphocytes , which migrate through lymphoid tissues to encounter antigen and to sites of infection to perform effector functions. Although B lymphocytes also recirculate , plasma cells are terminally differentiated cells that reside in the bone marrow and lymphoid tissues and do not recirculate, as they secrete antibodies that act at distant sites. Plasma cells (Option A): Do not recirculate; they are tissue-resident antibody-secreting cells.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 174

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Papain digestion of an immunoglobulin molecule produces which of the following end products? (Q890525)

A. 2 Fc and 1 Fab fragments

B. 1 variable chain and 1 constant chain

C. 1 Fc and 2 Fab fragments

D. 2 Fc and 2 Fab fragments

Correct Answer: C. 1 Fc and 2 Fab fragments

Explanation: Papain cleaves the immunoglobulin molecule at the hinge region above the interchain disulfide bonds , separating the antigen-binding arms from the constant region. This produces two Fab fragments , each with a single antigen-binding site (monovalent), and one intact Fc fragment , which mediates effector functions such as

complement activation and Fc receptor binding. In contrast, pepsin cleaves below the hinge region , resulting in a single F(ab')■ fragment , in which the two Fab portions remain linked (bivalent), while the Fc region is degraded into smaller fragments. Thus, papain generates separate Fab fragments and an intact Fc , whereas pepsin preserves the linkage between Fab regions but destroys the Fc portion.

https://pmc.ncbi.nlm.nih.gov/articles/PMC9137653/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which class of antibodies is primarily produced in response to polysaccharide and lipid antigens? (Q890524)

A. IgG

B. IgM

C. IgD

D. IgA

Correct Answer: B. IgM

Explanation: Polysaccharide and lipid antigens are T-cell-independent antigens that activate B cells without T-cell help. Because these responses lack CD40L and cytokine-mediated signals from helper T cells , there is minimal or no class switching , and the predominant antibody produced is IgM . In contrast, protein antigens induce T cell-dependent responses , which involve helper T cells and lead to isotype switching with production of IgG, IgA,

or IgE , as well as affinity maturation. IgG (Option A): Produced after class switching in T cell-dependent responses. IgD (Option C): Primarily expressed on the surface of naive B cells and not secreted in significant amounts. IgA (Option D): Produced after class switching, especially in mucosal immune responses.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 179

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Which cytokine primarily stimulates B cells to induce and produce IgE antibodies? (Q890523)

A. IL-1

B. IL-2

C. IL-4

D. IL-6

Correct Answer: C. IL-4

Explanation: IL-4 is the principal cytokine that induces class switch recombination to IgE in B cells. It is produced by Th2 helper T cells and plays a central role in type 2 immune responses and allergic diseases . IL-4–mediated IgE production leads to sensitisation of mast cells and is a key mechanism in type I hypersensitivity reactions . IL-13 may also promote IgE production , but IL-4 is the primary cytokine responsible for class switching. IL-1 (Option A): A pro-inflammatory cytokine involved in innate immune responses; it does not induce IgE class switching. IL-2 (Option B): Primarily promotes T-cell proliferation and survival, without a direct role in IgE production. IL-6 (Option D): Promotes B-cell differentiation into plasma cells , but is not specifically involved in IgE class switching.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 624

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: On antigen-presenting cells, which of the following molecules provide the necessary costimulatory signals to activate T cells? (Q890521)

A. CD28 and CD86

B. CD80 only

C. CD28 and CD80

D. CD80 and CD86

Correct Answer: D. CD80 and CD86

Explanation: The principal costimulators for T-cell activation are the B7 proteins—CD80 (B7-1) and CD86 (B7-2) , which are expressed on antigen-presenting cells (APCs) and bind to CD28 on naive T cells . Activation of T cells requires two signals: Signal 1: Recognition of antigen presented by MHC molecules via the T-cell receptor (TCR) Signal 2 (costimulation): Interaction of CD80/CD86 on APCs with CD28 on T cells Costimulatory molecules are induced on APCs during innate immune responses to microbes , ensuring that adaptive immune responses are generated appropriately. In the absence of costimulation, T cells become anergic (functionally unresponsive) . CD28 and CD86 (Option A): CD28 is expressed on T cells, not on APCs. CD80 only (Option B): Both CD80 and CD86 function as costimulators; CD80 alone is not sufficient as the best answer. CD28 and CD80 (Option C): CD28 is present on T cells, whereas CD80 is on APCs; both are not expressed on APCs.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 177

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which feature is shared by both natural killer (NK) cells and cytotoxic T lymphocytes (CTLs)? (Q890519)

A. They are restricted by MHC class I molecules

B. They need antibodies to mediate their effect

C. They can target virus-infected cells

D. Their activity is antigen-specific

Correct Answer: C. They can target virus-infected cells

Explanation: Both natural killer (NK) cells (innate immunity) and cytotoxic T lymphocytes (CTLs) (adaptive immunity) are capable of killing virus-infected cells . NK cells recognise target cells with reduced MHC class I expression and do not require antigen-specific recognition. CTLs (CD8+ T cells) recognise viral peptides presented on MHC class I molecules and require antigen-specific activation. Thus, while their mechanisms differ, both cell types share the ability to eliminate virus-infected cells. They are restricted by MHC class I molecules (Option A): Only CTLs are MHC class I–restricted; NK cells are not restricted and instead detect decreased MHC

class I expression. They need antibodies to mediate their effect (Option B): NK cells can mediate antibody-dependent cellular cytotoxicity (ADCC), but CTLs do not use antibodies and kill target cells directly. Their activity is antigen-specific (Option D): CTLs are antigen-specific, whereas NK cells are not and act through innate immune recognition.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 5-year-old boy presents with severe, chronic diarrhoea, failure to thrive, and a rash. His medical history includes a diagnosis of type 1 diabetes mellitus and thyroiditis. Laboratory tests show elevated levels of anti-enterocyte antibodies. Based on these findings, which mechanism is most likely impaired in this patient's condition? (Q845501)

A. Central tolerance

B. Peripheral tolerance

C. Anergy

D. Hidden antigen

Correct Answer: B. Peripheral tolerance

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario likely describes IPEX (immune dysregulation, polyendocrinopathy, enteropathy, X-linked) due to defective peripheral tolerance. IPEX is an X-linked immune dysregulation disorder that presents in childhood. It occurs due to defects in the FOXP3 gene, which plays a crucial role in peripheral tolerance mediated by CD4+ T regulatory cells. Defects in FOXP3 lead to dysfunctional CD4+ T regulatory cells, impairing their ability to maintain immune tolerance and resulting in autoimmune reactions against various tissues, particularly within the gastrointestinal tract. Tolerance: Two types of tolerance: Central tolerance Peripheral tolerance Central tolerance: Peripheral tolerance: If central tolerance fails, peripheral tolerance works T Regulatory cells: They are type of CD4 T cells, that started expressing CD25+/IL2 Receptor on them T regulatory cell is made by FOXP3 gene They have an immunosuppressive action Immunosuppression is achieved by ↑-CTLA4 gene and ↑PD1 gene Mutation in FOXP3 gene → IPEX Immune Dysregulation Polyendocrinopathy X linked disorder Mutation of IL2 Receptor is seen in: Inflammatory Bowel disease Multiple sclerosis Killing of Self-reactive cells: Killing occurs by Apoptosis Apoptosis is mediated by CD95/Fas CD95/Fas mutation →

Autoimmune lymphoproliferative syndrome (ALPS) Anergy: T cells: When an antigen enters a cell, the APC presents it via MHC to T cell receptor (made up of α and β chains) Signal 1: Antigen has been presented between the MHC and the T cell receptor Signal 2: Binding of CD28 with CD80 and Cd86 T cell activation requires two signals T cells contain CD28 molecule When CD28 binds to B7.1 (CD80) and B7.2 (CD86), present on APC → signal 2 gets generated When both signals are generated → T cell Activation For Foreign Ag: Signal 1 and 2 will be generated and T cell gets activated In case of Self Ag: Signal 2 will not be generated If only one signal is present, the T cell go into anergy B cells: Signal 1 B cells have IgM and IgD B cell present the antigen to the T cell Signal 2: CD40 receptor on the B cell, binds to CD40 ligand on the T® cell, creating a co-stimulatory signal For Foreign Ag: Signal 1 and 2 will be generated → B cell Activation For Self Ag: Only Signal 1 gets generated → B cell go into anergy Cryptic/Hidden Antigen: Sites where antigens are not exposed to B and T cells B - Brain antigens All brain antigens are hidden by Blood brain barrier, except area Prostema E – Eyes All Eye antigens are hidden by Blood Ocular Barrier, except optic nerve T – Testes All antigens of testes are hidden by Blood Testicular Barrier, except epididymis Example Trauma of eye → Damage to Blood Ocular Barrier → All Ag of the Eye are exposed to B and T cells → Ag considered foreign → Killing (B/L Traumatic Uveitis)

@Neet_pg_bot

Q18: Activation of NOD-like receptors by gain-of-function mutations is most likely to result in which of the following conditions? (Q890516)

A. Malignancy

B. Granulomatous disease

C. Autoinflammatory syndrome

D. Autoimmune disorders

Correct Answer: C. Autoinflammatory syndrome

Explanation: Gain-of-function mutations in NOD-like receptors (NLRs) lead to inappropriate activation of the inflammasome , resulting in increased production of interleukin-1 (IL-1) and inflammation. These mutations cause autoinflammatory syndromes , which are characterised by innate immune dysregulation and occur without involvement of adaptive immunity . Although certain mutations (e.g., NOD2) may be associated with granulomatous inflammation , the primary classification of these conditions is autoinflammatory rather than granulomatous or autoimmune. Malignancy (Option A): NOD-like receptor (NLR) gain-of-function mutations are not primarily associated with neoplastic transformation; they mainly cause dysregulated innate immune activation and inflammation. Granulomatous disease (Option B): Granulomatous inflammation can occur (e.g., NOD2 in Blau syndrome), but these conditions are primarily classified as autoinflammatory syndromes rather than granulomatous diseases. Autoimmune disorders (Option D): Autoimmune diseases involve adaptive immunity (T and B cells), whereas autoinflammatory syndromes result from innate immune dysregulation, particularly involving inflammasome activation and IL-1 production.

@Neet_pg_bot

Q19: Which of the following immune cells are capable of mediating antibody-dependent cellular cytotoxicity (ADCC)? (Q890515)

A. Only macrophages

B. Only natural killer (NK) cells

C. Neutrophils and eosinophils

D. NK cells, neutrophils, and eosinophils

Correct Answer: D. NK cells, neutrophils, and eosinophils

Explanation: Antibody-dependent cellular cytotoxicity (ADCC) is a mechanism in which target cells coated with IgG antibodies are recognised by immune effector cells via Fc receptors (FcγR) and are lysed without phagocytosis. Natural killer (NK) cells are the primary and most important mediators of ADCC. Macrophages also play a significant role. In addition, neutrophils and eosinophils can participate in ADCC through Fc receptor–mediated mechanisms. Thus, ADCC is mediated by multiple immune cells, with NK cells being the principal effectors.

Q20: Which of the following is not a feature of dermatomyositis? (Q845621)

Correct Answer: Unknown

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Image B represents panniculitis (raised reddish lesions on skin) which is commonly seen in diseases like erythema nodosum. Dermatomyositis: An inflammatory myopathy that affects skin as well as skeletal muscles. Proximal muscles will be involved. Characteristic rashes include: Gottron papules (Option A) - Raised erythematous rash over metacarphalangeal and interphalangeal joints. Heliotrope rash (Option C) - Erythematous discoloration of eyelids with periorbital edema. Mechanic's hands (Option D) - Presence of fissures/cracks on hands and palms. V-sign (Necklace sign) - Rash on the sun-exposed anterior neck and chest. Shawl sign over the back of the neck and shoulders. Nail bed changes with dilated capillaries. The histological hallmark of dermatomyositis: Perifascicular atrophy (Atrophy of the muscle fibers which are located at the periphery).

@Neet_pg_bot

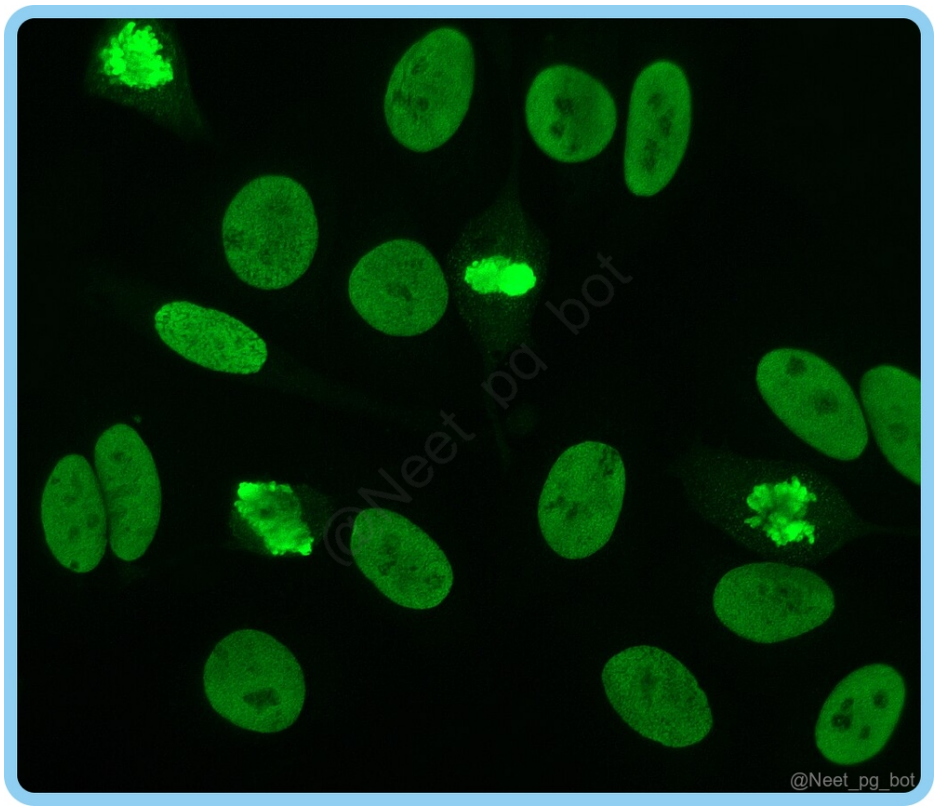
Q21: A 28-year-old female presents with fatigue, joint pain, and a rash. A blood test reveals positive anti-nuclear antibodies. Which of the following fluorescence patterns is most commonly associated with systemic lupus erythematosus (SLE)? (Q845616)

Correct Answer: Unknown

Explanation: The homogeneous fluorescence pattern of ANA is often associated with SLE, reflecting uniform nucleus staining. The most common test for ANAs is indirect immunofluorescence, which detects antibodies to nuclear antigens, with fluorescence patterns indicating the specific antibody type. Four basic patterns are recognized Homogeneous or diffuse staining of nuclei (Option A) Antibodies reactive with dsDNA, nucleosomes, and histones, and is common in systemic lupus erythematosus Speckled pattern (Option B) Antibodies against various nuclear antigens, including Sm and RNPs Nucleolar pattern (Option C) Antibodies against nucleolar proteins Anti-centromere antibodies (Option D) Systemic sclerosis, Sjögren syndrome, and other diseases



@Neet_pg_bot

Q22: A 30-year-old woman is being evaluated for proximal muscle weakness. Which of the following is consistent with a diagnosis of polymyositis? (Q845529)

A. CD4+ T cell infiltration in affected tissue

B. Endomysial inflammation

C. Associated with underlying malignancies

D. Vascular injury involved in pathogenesis

Correct Answer: B. Endomysial inflammation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Endomysial inflammation is a consistent feature of polymyositis. Polymyositis is an inflammatory myopathy that typically presents with proximal muscle weakness. It is mediated by CD8+ T lymphocytes . Histologically, it is characterized by an endomysial inflammatory infiltrate with patchy necrosis. Dermatomyositis Histologic findings include ■■■■■■peripheral or peri fascicular infiltrates and atrophy in a segmental pattern. Perifascicular infiltrates: Perifascicular atrophy:

@Neet_pg_bot

Q23: A 32-year-old woman presents with fatigue, muscle weakness, and joint pain. On examination, she has a rash over her cheeks, along with Raynaud's phenomenon and swollen fingers. Laboratory tests reveal positive anti-U1 RNP antibodies. Which of the following conditions is this patient most likely suffering from? (Q845527)

A. Systemic lupus erythematosus

B. Scleroderma

C. Mixed connective tissue disease

D. Sjögren's syndrome

Correct Answer: C. Mixed connective tissue disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mixed connective tissue disease (MCTD) is characterised by a combination of features, including muscle weakness, joint pain, a rash over the cheeks (often referred to as a butterfly or malar rash), Raynaud's phenomenon, and anti-U1 RNP antibodies. MCTD features overlap between systemic lupus erythematosus, scleroderma (systemic sclerosis), and polymyositis . It is characterised by synovitis in the fingers, Raynaud's phenomenon, myositis, and mild renal involvement. Over time, MCTD may progress to classic systemic lupus erythematosus (SLE) or systemic sclerosis. Antibody: Anti-U1 RNP (ribonucleoprotein) antibody . Treatment: Corticosteroids .

@Neet_pg_bot

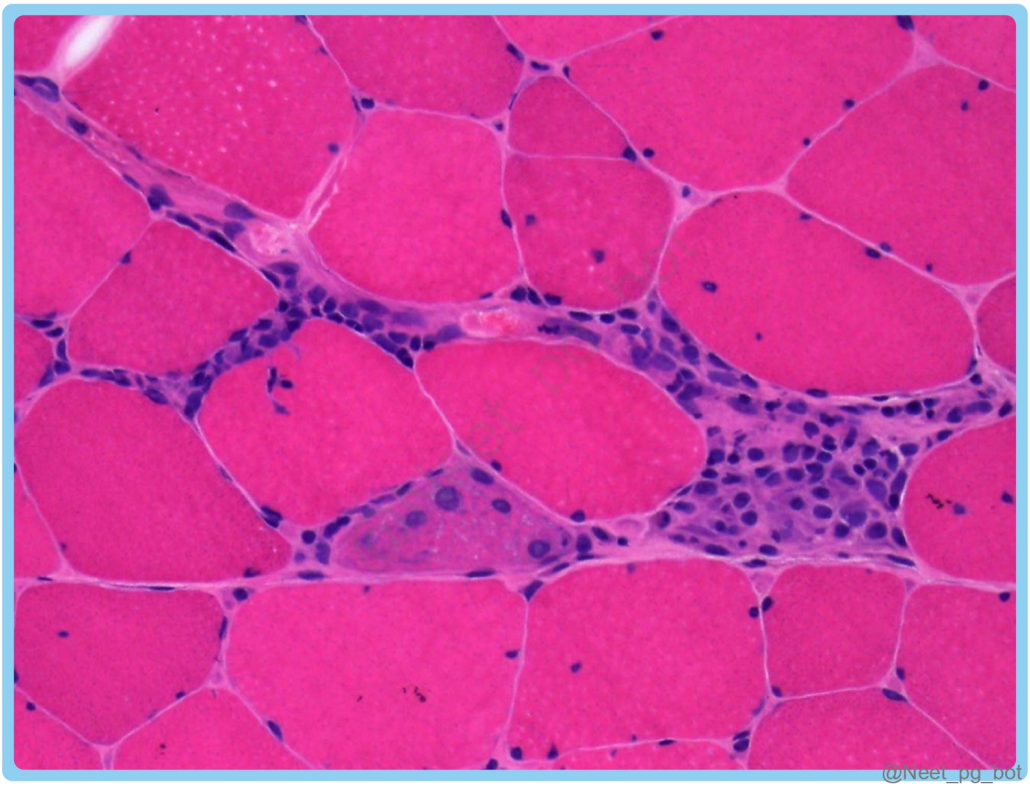
Q24: A 45-year-old woman presents with progressive proximal muscle weakness over the past 6 months. On examination, the hip and shoulder girdle muscles have symmetrical weakness. Laboratory investigations show elevated serum creatine kinase (CK) levels. A muscle biopsy reveals endomysial inflammation with CD8+ T lymphocytes and muscle fiber necrosis. Which of the following is the most likely diagnosis? (Q845525)

A. Dermatomyositis

B. Myasthenia gravis

C. Inclusion body myositis

D. Polymyositis



Correct Answer: D. Polymyositis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The features of progressive proximal muscle weakness along with the findings of endomysial inflammation on biopsy and no dermatological findings, suggest the diagnosis of polymyositis. In Polymyositis, endomysial inflammation is seen with no skin findings and no atrophy.It presents with proximal muscle weakness. Dermatomyositis (Option A) also presents with proximal muscle weakness and elevated CK levels, but it typically includes skin manifestations (e.g., heliotrope rash, Gottron's papules on hands, mechanic's hands), which are not mentioned here. Muscle biopsy in dermatomyositis typically shows perifascicular atrophy and inflammation. Inclusion Body Myositis (IBM) (Option C): Involves the distal muscles. Muscle biopsy shows inclusion bodies (amyloid-like material which forms inclusions in muscle fibres), which are positive for Congo-red staining.

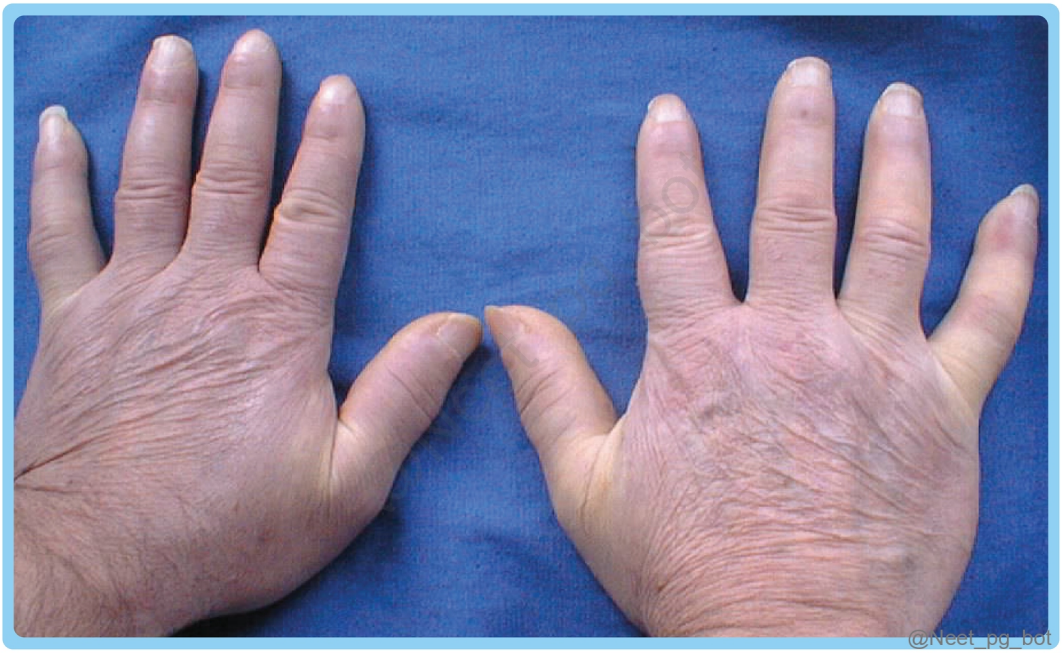
Q25: A 60-year-old woman complains of bilateral hand pain and stiffness, especially in the morning. On examination, you notice diffuse thickening and tightening of the skin all over her body. Echo showed pulmonary hypertension. Laboratory tests show positive Anti-SCL-70 antibodies What is the most likely diagnosis? (Q845523)

A. Rheumatoid arthritis

B. Osteoarthritis

C. CREST syndrome

D. Systemic sclerosis



Correct Answer: D. Systemic sclerosis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The patient's presentation of diffuse sclerosis and echo showing pulmonary hypertension is highly suggestive of systemic sclerosis, also known as scleroderma. Scleroderma, also known as systemic sclerosis, is a rare autoimmune disease characterized by excessive collagen production, which leads to thickening and hardening of the skin and other organs. Subtypes In systemic sclerosis: Limited systemic sclerosis (CREST syndrome) features calcinosis, Raynaud phenomenon, oesophagal dysmotility, sclerodactyly, and telangiectasia. It is characterized by a positive anti-centromere antibody (option C) Diffuse systemic sclerosis (scleroderma) features widespread skin thickening starting from fingers, positive Anti-SCL-70/Anti-topoisomerase antibody , and extensive organ involvement: GIT dysfunction, musculoskeletal inflammation, scleroderma renal crisis, interstitial lung fibrosis, pulmonary hypertension, and cardiac manifestations.\ Feature Limited Sclerosis (CREST) Diffuse Systemic Sclerosis Skin Involvement Restricted to distal extremities (fingers/hands/feet) and the face. Widespread ; involves trunk, proximal limbs, and face. Onset Gradual/Indolent. Rapidly progressive. Classic Mnemonic CREST Syndrome (Calcinosis, Raynaud’s, Esophageal dysmotility, Sclerodactyly, Telangiectasia). N/A (More aggressive systemic disease). Antibody Marker Anti-Centromere (Highly specific). Anti-Scl-70 (Anti-DNA topoisomerase I) and Anti-RNA polymerase III . Vascular Disease Late-onset Pulmonary Arterial Hypertension (PAH) . Early-onset Raynaud’s phenomenon (precedes skin changes). Organ Involvement Late or limited organ involvement (except PAH). Early and severe Interstitial Lung Disease , Renal Crisis, and Cardiac involvement. Prognosis Generally better long-term survival. Higher mortality due to early organ failure. Rheumatoid arthritis (Option A) : This condition is characterized by symmetrical joint pain and swelling and is distinguished by the presence of rheumatoid factor and anti-cyclic citrullinated peptide. Osteoarthritis (Option B) is a degenerative joint disease affecting weight-bearing joints without skin involvement or autoimmune features.

@Neet_pg_bot

Q26: A 20-year-old female complains of recurrent episodes of her fingers turning symmetrically white, which are associated with pain and a tingling sensation. This is worse when exposed to cold water and is relieved when she dips her fingers in warm water. The autoimmune panel is negative. What is the likely diagnosis? (Q845520)

A. Primary Raynaud phenomenon

B. Dermatomyositis

C. Secondary Raynaud phenomenon

D. Calcinosis cutis

Correct Answer: A. Primary Raynaud phenomenon

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario describes the Raynaud phenomenon (an exaggerated vasoconstriction of arteries and arterioles in response to cold or emotional stress. The fingers classically show these colour changes in this order: Red: Proximal vasodilation White: Central vasoconstriction Blue: Distal cyanosis. Primary Raynaud's phenomenon is characterized by symmetric episodes of finger whitening induced by cold, resulting from hyper reactive smooth muscle cells in the blood vessel walls. It occurs without an underlying disorder and typically does not lead to ulcers. Tests for autoimmune conditions yield negative results in such cases. Secondary Raynaud's phenomenon results from underlying arterial disease seen in autoimmune disorders like mixed connective tissue disease, CREST syndrome, and SLE. It shows asymmetric finger involvement and progressive worsening of symptoms over time. (Option C) Dermatomyositis (Option B) may involve the hands, with classical lesions being Gottron papules (multiple hyperkeratotic, flat, red papules over the dorsum of the metacarpophalangeal joints) and mechanic hands (fissuring with hyperkeratotic papules, scaling, and fissures along the sides of the fingers and palms). Autoimmune panel is positive. Calcinosis cutis (Option D) is a characteristic lesion of CREST syndrome, referring to the deposition of calcific nodules in the skin of the hands. It is an autoimmune disorder because of anti-centromeric antibody.

References:

Robbins and Cotran's Pathologic Basis of Disease, 10th Edition, Page 516, 1129 Primary vs Secondary Raynauds

@Neet_pg_bot

Q27: A 55-year-old woman has had persistent dry eyes and mouth for the past several months. She also reports difficulty in swallowing solid foods and occasional blurred vision. On examination, she has bilateral parotid gland enlargement. She has a history of rheumatoid arthritis. Which antibodies are specific for this disease? (Q845518)

A. Anti-Sm

B. Anti La

C. Anti-Scl 70

D. Anti-U1 RNP

Correct Answer: B. Anti La

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Based on the above clinical scenario, the patient can be diagnosed with Sjogren's syndrome. Clinical presentation: Xerophthalmia (Dry Eyes): Leads to a "gritty" sensation and can cause keratoconjunctivitis sicca. Xerostomia (Dry Mouth): Causes difficulty swallowing dry food, dental caries, and parotid gland enlargement. Extraglandular Manifestations: Can include Raynaud phenomenon, cutaneous vasculitis, interstitial lung disease, and peripheral neuropathy. Patient presents with: Dry eyes due to antibodies attacking the lacrimal gland. Dry mouth due to antibodies attacking the salivary gland. Pathogenesis: Salivary gland involvement → Dry mouth (Xerostomia) → Halitosis (Bad breath) Lacrimal gland involvement → Dry eyes (Keratoconjunctivitis sicca) → Gritty sensation in eyes Antibodies are of 2 types: Anti-SS-A (Anti-Ro) antibodies: Most sensitive Anti-SS-B (Anti-La) antibodies: Most specific Diagnosis: Rheumatoid Factor (RF): Often positive even in the absence of Rheumatoid Arthritis. ANA: Typically positive in a speckled pattern. Lip Biopsy: The "gold standard" for diagnosis, showing focal lymphocytic sialadenitis (clusters of lymphocytes around minor salivary glands). Schirmer Test: Used to quantify decreased tear production. Histology: Intense lymphocytic infiltrate (primarily CD4 + T cells) with germinal center formation. Ductal Changes: Hyperplasia of lining cells leading to the formation of epimyoepithelial islands . Management: Sicca Symptoms: Artificial tears, frequent water intake, and pilocarpine or cevimeline (muscarinic agonists to stimulate secretions). Systemic Disease: Hydroxychloroquine or immunosuppressants (methotrexate) for joint or skin involvement. Regular Screening: Critical monitoring for the development of lymphoma, especially if there is persistent parotid swelling or lymphadenopathy. Autoantibody Associated Autoimmune Condition Anti-Sm (Smith) (Option A) Systemic lupus erythematosus (SLE) Anti-Scl-70 (anti-topoisomerase I) (Option C) Diffuse systemic sclerosis (scleroderma) Anti-U1 RNP (Ribonucleoprotein) (Option D) Mixed connective tissue disease (MCTD)

Robbins and Cotran's Pathologic Basis of Disease, 10th Edition, Page 230

↑ *Back to this question in Part A*

@Neet_pg_bot

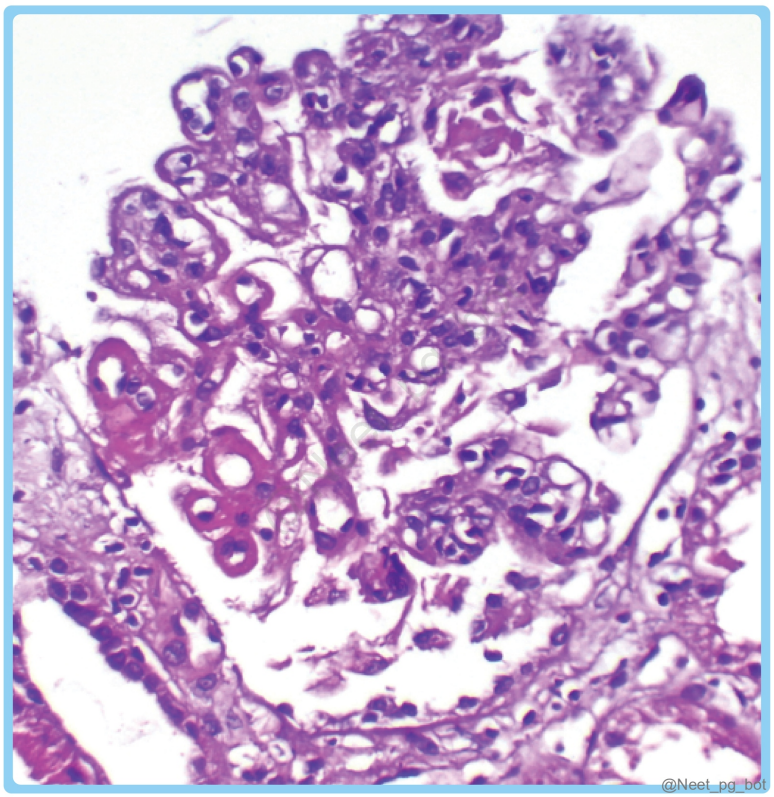
Q28: A 45-year-old woman with SLE complains of red, frothy urine for the past two months despite being on treatment. Urine analysis shows RBCs and proteins. An image of renal biopsy is given below. Which of the following accurately describes the histopathological findings? (Q845510)

A. Diffuse capillary wall thickening.

B. Wire loop lesions

C. Glomerular crescents

D. Kimmelstiel-Wilson lesion



Correct Answer: B. Wire loop lesions

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Wire loop lesions are a characteristic histopathological finding in lupus nephritis. Wire loop means that capillary loop has become thicker due to subendothelial deposits. Seen more commonly in classes 3,4, and 5 of lupus nephritis (There are a total of 6 classes). Lupus Nephritis (LN): Lupus Nephritis (LN) is a frequent and serious complication of Systemic Lupus Erythematosus (SLE), representing a Type III Hypersensitivity reaction where immune complexes deposit within the glomeruli. 6 Classes of Lupus Nephritis: Class Type Key Pathological Features Class I Minimal Mesangial LN Normal appearance on light microscopy; immune complexes seen only on immunofluorescence or electron microscopy. Class II Mesangial Proliferative LN Purely mesangial hypercellularity or mesangial matrix expansion. Usually presents with mild hematuria/proteinuria. Class III Focal LN Active or inactive focal, segmental, or global endo- or extracapillary glomerulonephritis involving < 50% of all glomeruli. Class IV Diffuse LN Same as Class III but involving ≥ 50% of all glomeruli. This is the most common and severe form . Class V Membranous LN Global or segmental subepithelial immune deposits. Often presents with high-grade nephrotic syndrome . Class VI Advanced Sclerotic LN ≥90% of glomeruli are globally sclerosed without residual activity. Represents end-stage renal disease. Management of Lupus Nephritis: Generally divided into two phases: Induction (to achieve remission) and Maintenance (to prevent flares). General Measures (For all patients): Hydroxychloroquine: Recommended for all SLE patients to reduce flares and protect the kidneys. ACE Inhibitors/ARBs: Used to control blood pressure and reduce proteinuria. Statins: To manage hyperlipidemia associated with nephrotic syndrome. Classes I & II: Usually require no specific immunosuppressive therapy for the kidneys; treatment is directed at extra-renal SLE symptoms. Classes III & IV (Proliferative): Aggressive therapy is required. Induction: High-dose Corticosteroids plus either Mycophenolate Mofetil (MMF) or Cyclophosphamide . Maintenance: Low-dose steroids with MMF or Azathioprine . Class V

(Membranous): If nephrotic-range proteinuria is present, treat similarly to proliferative LN (MMF + Steroids). Class VI (Sclerotic): Immunosuppression is usually not effective; management focuses on preparation for dialysis or renal transplantation. Glomerular crescents (Option C) are seen in crescentic/Rapidly Progressive Glomerulonephritis(RPGN), Kimmelstiel-Wilson lesion (Option D) is a feature of diabetic nephropathy.

Robbins and Cotran's Pathologic Basis of Disease, 10th Edition, Page no 226, 909, 1111

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: A 19-year-old woman presents with malaise, joint pain, and fever for the past 3 months. Physical examination shows a malar rash and mouth ulcers. She has significant proteinuria and decreased GFR. Which of the following antibodies are most specific and most sensitive, respectively? (Q845509)

A. ANA, Anti ds DNA

B. Anti-Sm, ANA

C. Anti- Ro, Anti- La

D. Anti-beta-2-glycoprotein, Anticardiolipin

Correct Answer: B. Anti-Sm, ANA

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Based on the above clinical scenario mentioning malar rash and multi-organ involvement, the most likely diagnosis is systemic lupus erythematosus (SLE). Anti-Smith antibodies (ASA) are most specific for SLE. Anti-double-stranded DNA (dsDNA) antibodies are most sensitive for SLE. Marker/Antibody Clinical Significance Anti-Smith (anti-Sm) antibodies Highly specific for SLE (<30% of patients) Anti-dsDNA antibodies Highly specific for SLE (60-70% of patients); correlates with the disease Antinuclear antibodies (ANA) Highly sensitive but not specific for SLE Anti-Ro (SSA) and Anti-La (SSB) antibodies Found in SLE and Sjögren syndrome; associated with neonatal lupus Anti-ribosomal-P antibodies Specific for neuropsychiatric manifestations in SLE Anti-histone antibodies Seen in drug-induced lupus; less specific for SLE Complements C3 and C4 Low levels indicate complement consumption and disease activity

@Neet_pg_bot

Q30: A 30-year-old woman presents with a history of fatigue, fever, and weight loss. She also reports joint pain, swelling and a rash, as shown below. What is the most likely diagnosis? (Q845508)

A. Dermatomyositis

B. Systemic Lupus Erythematosus

C. Psoriatic Arthritis

D. Ankylosing Spondylitis

Correct Answer: B. Systemic Lupus Erythematosus

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's clinical presentation suggests systemic lupus erythematosus (SLE). Systemic Lupus Erythematosus (SLE): It is a combination of type 2 and type 3 hypersensitivity reactions (Type3>2) Genetic Associations: HLA DQ Polymorphism Early complement deficiency (C1, C2, C4) Klinefelter syndrome (47XXY) Immunological Association: Associated with NETS (Neutrophil extracellular traps) Environmental Associations: Associated with UV Exposure Gender Bias (More common in females) SLE - Criteria: Total of 11 criteria; 4 are needed for the diagnosis Mnemonic: MD SOAP BRAIN M - Malar Rash: Butterfly-shaped rash on face (sparing nasolabial fold) D - Discoid Rash S – Serositis: ■■■■■■■ Pleuritis Pericarditis O - Oral Ulcer: Aphthous (painless) ulcers A - Arthritis: ■■■■■■■ Non-erosive arthritis ≥2 Peripheral joints P - Photosensitivity B - Blood: ■■■■■■■ Pancytopenia Microscopically → formation of LE cells + R - Renal: Lupus Nephritis Has a total of 6 classes (Class I to Class VI) Most characteristic lesion → Wire loop lesion (Seen in Class III, IV, & V) Maximum wire loop lesions seen in Class IV Sub-endothelial deposits of Ag-Ab complex result in Wire loop lesions A - ANA (Anti-nuclear antibody) I - Immunological (antibody) N - Neurological (Psychosis) LE cell: Neutrophil or a monocyte that has engulfed damaged nuclear material (Hematoxylin body)-Damaged by ANA Antibodies in SLE: Most sensitive: ANA (Anti-nuclear antibody) Most specific: Anti-Smith (Anti-Sm) antibody Antibody that is both sensitive & specific: Anti-dsDNA antibody Anti-Ro antibody: Associated with Neonatal Lupus, Shrinking lung, Photosensitivity, and Congenital Heart Block Anti-Ribosomal P Ab: Associated with Psychosis Anti U1 RNP Ab: Associated with Raynaud's Phenomenon Anti-phospholipid antibody (APLA) syndrome → Recurrent abortions Immunofluorescence patterns of ANA: Mnemonic: HPNSC H - Homogeneous pattern (Entire nucleus is green): Antibodies against: Chromatin, Histone, and Anti-dsDNA P - Peripheral or Rim pattern ■■■■■■■ Enhancement at periphery Antibodies against Anti- dsDNA Bright green dots-r RNA

nucleous N - Nucleolar pattern : Antibody against RNA S - Speckled pattern: Mpst common and least specific pattern Antibodies against Anti-Sm, AntiRo & Anti-La (Sjogren's Syndrome) C - Centromeric pattern: Anti-centromere antibody Associated with CREST syndrome Other organs affected by SLE: Heart: Libman-Sach Endocarditis Lungs: Shrinking Lung Spleen: Onion-skinning around blood vessels

Robbins and Cotran Pathologic basis of disease, 10th Edition, Page 230-236.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q31: Which of the following is an immune-privileged site? (Q845507)

A. Heart

B. Lung

C. Kidney

D. Testis

Correct Answer: D. Testis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Among the given options, the testis is an immune-privileged site. The testis, eye, and brain are called immune-privileged sites because antigens are sequestered/isolated from the immune system without communicating with blood and lymph. Brain Blood-brain barrier Eyes Blood-ocular barrier Testes Blood-testicular barrier These tissues fail to elicit immune responses and are ignored by the immune system. If the antigens of these tissues are released as a consequence of trauma or infection, an immune response will result, leading to prolonged inflammation and injury. This is the postulated mechanism for post-traumatic orchitis and uveitis.

Robbins and Cotrans Pathologic Basis of Disease, 10th Edition, Page 217-218

↑ *Back to this question in Part A*

@Neet_pg_bot

Q32: Match the following processes in immune tolerance with their associated regulators. Process Regulators 1. Negative selection a. CD-28 2. Anergy b. FOXP3 3. Deletion by apoptosis c. AIRE 4. Suppression by regulatory T cells d. CD95 (Q845505)

A. 1-c, 2-a, 3-d, 4-b.

B. 1-a, 2-c, 3-d, 4-b.

C. 1-c, 2-b, 3-d, 4-a.

D. 1-a, 2-d, 3-c, 4-b.

Correct Answer: A. 1-c, 2-a, 3-d, 4-b.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Negative selection or clonal deletion : Process in which T cells expressing receptors for self-antigens encounter these antigens in the thymus and are then killed by apoptosis. AIRE (autoimmune regulator) is a regulator protein critical for deleting these T cells. A defect in AIRE leads to autoimmune polyendocrine syndrome (AIPS). Tolerance: Two types of tolerance: Central tolerance Peripheral tolerance Central tolerance: Peripheral tolerance: If central tolerance fails, peripheral tolerance works T Regulatory cells: They are type of CD4 T cells, that started expressing CD25+/IL2 Receptor on them T regulatory cell is made by FOXP3 gene They have an immunosuppressive action Immunosuppression is achieved by ↑CTLA4 gene and ↑PD1 gene Mutation in FOXP3 gene → IPEX Immune Dysregulation Polyendocrinopathy X linked disorder Mutation of IL2 Receptor is seen in: Inflammatory Bowel disease Multiple sclerosis Killing of Self-reactive cells: Killing occurs by Apoptosis Apoptosis is mediated by CD95/Fas CD95/Fas mutation → Autoimmune lymphoproliferative syndrome (ALPS) Anergy: T cells: When an antigen enters a cell, the APC presents it via MHC to T cell receptor (made up of α and β chains) Signal 1: Antigen has been presented between the MHC and the T cell receptor Signal 2: Binding of CD28 with CD80 and Cd86 T cell activation requires two signals T cells contain CD28 molecule When CD28 binds to B7.1 (CD80) and B7.2 (CD86), present on APC → signal 2 gets generated When both signals are generated → T cell Activation For Foreign Ag: Signal 1 and 2 will be generated and T cell gets activated In case of Self Ag: Signal 2 will not be generated If only one signal is present, the T cell go into anergy B cells: Signal 1 B cells have IgM and IgD B cell present the antigen to the T cell Signal 2: CD40 receptor on the B cell, binds to CD40 ligand on the T® cell, creating a co-stimulatory signal For Foreign Ag: Signal 1 and 2 will be generated → B cell Activation For Self Ag: Only Signal 1 gets generated → B cell go into anergy Cryptic/Hidden Antigen: Sites where antigens are not exposed to B and T cells B - Brain antigens All brain antigens are hidden by Blood brain barrier, except area Prostema E – Eyes All Eye antigens are hidden by Blood Ocular Barrier, except optic nerve T – Testes All antigens of testes are hidden by Blood Testicular Barrier, except epididymis Example Trauma of eye → Damage to Blood Ocular Barrier → All Ag of the Eye are exposed to B and T cells → Ag considered foreign → Killing (B/L Traumatic Uveitis)

@Neet_pg_bot

Q2: A 52-year-old HIV-positive male presents with multiple raised, violaceous plaques and nodules over both legs. The lesions have gradually increased in number over the past few months. Skin biopsy shows a dermal lesion composed of irregular, slit-like vascular spaces lined and surrounded by plump, spindle-shaped cells. The stroma contains extravasated red blood cells, hemosiderin deposits, areas of haemorrhage, and a mixed mononuclear inflammatory infiltrate. Occasional mitotic figures are seen. Which of the following infectious agents is associated with this tumour? (Q890583)

A. Human herpesvirus type 8

B. Epstein-Barr virus

C. Cytomegalovirus

D. Human papillomavirus

Correct Answer: A. Human herpesvirus type 8

Explanation: The described lesion is classic for Kaposi sarcoma (KS) , the most common neoplasm in patients with AIDS . Clinically, it presents as violaceous plaques and nodules , and histologically shows: Proliferation of spindle-shaped cells Irregular, slit-like vascular spaces Extravasated red blood cells and hemosiderin deposition

Chronic inflammatory infiltrate Kaposi sarcoma is strongly associated with human herpesvirus 8 (HHV-8) , which is necessary but not sufficient for tumour development. In AIDS patients, HIV-induced immunosuppression acts as a cofactor , allowing widespread HHV-8 infection and tumour progression. HHV-8 establishes latent infection and produces viral proteins that: Promote cell proliferation (e.g., viral cyclin D homologues) Inhibit tumour suppressors such as p53 Stimulate angiogenesis and inflammation , contributing to lesion formation KS lesions are unique in that many are polyclonal or oligoclonal , especially in early stages, reflecting a proliferation driven by cytokines and angiogenic factors rather than purely malignant transformation. Epstein-Barr virus (Option B) is associated with B-cell lymphomas (e.g., Burkitt lymphoma, primary CNS lymphoma), not Kaposi sarcoma. Cytomegalovirus (Option C) causes opportunistic infections such as retinitis, pneumonitis, and gastrointestinal ulcers , not vascular tumours. Human papillomavirus (Option D) is associated with epithelial neoplasms , including cervical and anogenital cancers, not vascular tumours like Kaposi sarcoma.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Pages 227-228

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 30-year-old HIV-positive patient presents with persistent, painless swelling of multiple lymph nodes. A lymph node biopsy is performed. Which of the following histopathological findings is least likely to be observed in this patient? (Q890582)

A. Florid follicular hyperplasia

B. Destruction of germinal centres

C. Hematoxylin bodies

D. Expansion of monocytoid B cells in the sinuses

Correct Answer: C. Hematoxylin bodies

Explanation: Hematoxylin bodies are not seen in HIV lymphadenopathy. They represent denatured nuclear material bound by autoantibodies and are characteristic of systemic lupus erythematosus (SLE) . HIV-associated lymphadenopathy demonstrates dynamic, stage-dependent morphologic changes reflecting progressive immune dysfunction. In early HIV infection , there is marked follicular hyperplasia (Option A) characterised by: Enlarged, irregular (“serpiginous”) germinal centres Attenuation of mantle zones Germinal centres encroaching into interfollicular T-cell areas Underlying mechanism: polyclonal B-cell activation As the disease progresses, this hyperplastic phase evolves into lymphoid involution , with: Destruction and eventual hyalinization of germinal centres (Option B) Disruption of the follicular dendritic cell (FDC) network Marked lymphocyte depletion “Burnt-out” lymph nodes that may contain opportunistic pathogens with minimal inflammatory response Expansion of monocytoid B cells in the sinuses (Option D) may occur as a reactive change in lymph nodes and can be seen in chronic immune stimulation.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 200, 229

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: In patients with HIV/AIDS, which of the following is the most frequently observed brain tumour? (Q890581)

A. Oligodendroglioma

B. Primary CNS lymphoma

C. Ependymoma

D. Pilocytic astrocytoma

Correct Answer: B. Primary CNS lymphoma

Explanation: In patients with HIV/AIDS and other forms of immunosuppression, the most common primary brain tumour is primary CNS lymphoma , which is typically a diffuse large B-cell lymphoma . These tumours are often multifocal , involve deep periventricular regions , and show a characteristic tendency for perivascular infiltration .

In immunosuppressed individuals, the malignant B cells are commonly latently infected with Epstein-Barr virus (EBV) , which plays a key role in tumour pathogenesis. These lymphomas are aggressive and have a worse prognosis compared to similar tumours in immunocompetent individuals. A critical clinical point is that opportunistic infections (especially toxoplasmosis) are more common than tumours in AIDS patients and may present as ring-enhancing lesions , often mimicking CNS lymphoma. Other listed tumors such as oligodendroglioma, ependymoma, and pilocytic astrocytoma, are not associated with HIV-related immunosuppression .

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 1182

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following immune cells is least likely to be directly infected by HIV during the course of the disease? (Q890580)

A. Helper T cells (CD4+ cells)

B. Neutrophils

C. Dendritic cells

D. Macrophages

Correct Answer: B. Neutrophils

Explanation: HIV infects cells by binding to the CD4 receptor and chemokine co-receptors CCR5 or CXCR4 , which determine viral tropism: R5 (CCR5-using) strains → infect monocytes/macrophages and dendritic cells (M-tropic) X4 (CXCR4-using) strains → infect CD4+ T cells (T-tropic) The major target cells include: CD4+ helper T cells (Option A) → primary targets; progressive depletion leads to immunodeficiency Macrophages (Option D) → infected due to low-level CD4 expression; serve as long-lived viral reservoirs Dendritic cells (Option C) → capture HIV at mucosal sites and transfer it to T cells, facilitating infection In contrast, neutrophils (Option B) lack CD4 receptors and the required chemokine co-receptors , and therefore are not directly infected by HIV , making them the least likely target.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 220

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 6-year-old boy presents with recurrent eczema, recurrent pneumonia and otitis media since infancy, and easy bruising. Laboratory investigations show thrombocytopenia with small platelets and abnormal immunoglobulin levels. Which of the following statements regarding his condition is correct? Serum IgE is elevated Serum IgA is elevated Serum IgM is normal Serum IgG is normal (Q890569)

A. 2, 3 and 4

B. 1, 2 and 4

C. 2 and 4 only

D. 1, 2 and 3

Correct Answer: B. 1, 2 and 4

Explanation: Wiskott-Aldrich syndrome (WAS) is an X-linked immunodeficiency caused by mutations in the WAS gene , which encodes a protein involved in linking cell surface receptors to the actin cytoskeleton , thereby affecting lymphocyte activation, migration, and immune synapse formation. It is characterised by the triad of: Eczema Recurrent infections Thrombocytopenia with small platelets (microthrombocytopenia) The characteristic immunoglobulin profile is: IgE ↑ (Statement 1: correct) IgA ↑ (Statement 2: correct) IgM ↓ (Statement 3: incorrect) IgG usually normal (Statement 4: correct) Patients also have defective antibody responses, particularly to polysaccharide antigens , and progressive defects in T-cell function.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 218

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: In patients diagnosed with common variable immunodeficiency (CVID), which of the following best describes the typical finding in peripheral B-cell numbers? (Q890567)

A. B-cell count is consistently reduced

B. B-cell count is markedly increased

C. B-cells are completely absent

D. B-cell count is usually within the normal range

Correct Answer: D. B-cell count is usually within the normal range

Explanation: Common variable immunodeficiency (CVID) is characterised by hypogammaglobulinemia due to impaired differentiation of B cells into plasma cells , resulting in defective antibody production. Despite this functional defect, most patients have normal or near-normal numbers of circulating B cells in peripheral blood and lymphoid tissues. The primary abnormality lies in the failure of B cells to mature into antibody-secreting plasma cells , rather than a deficiency in B-cell numbers. This leads to recurrent sinopulmonary infections , along with increased susceptibility to certain viral and gastrointestinal infections, and a higher risk of autoimmune diseases and lymphoid malignancies.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 217

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Mutation in which of the following is responsible for the development of X-linked lymphoproliferative disorder, characterised by an abnormal immune response to Epstein-Barr virus (EBV)? (Q890564)

A. SLAM-associated protein

B. WAS gene

C. LYST gene

D. FOXP3 gene

Correct Answer: A. SLAM-associated protein

Explanation: X-linked lymphoproliferative disease (XLP) is characterised by an inability to eliminate Epstein-Barr virus (EBV) , leading to severe or fatal infectious mononucleosis and an increased risk of B-cell lymphomas . The disorder is most commonly caused by mutations in the SH2D1A gene , which encodes the SLAM-associated protein (SAP) . SAP is required for effective T-cell and natural killer (NK) cell activation , particularly in response to EBV-infected B cells. Its deficiency results in impaired cytotoxic function and uncontrolled lymphoproliferation. SAP is also essential for the development of T follicular helper (Tfh) cells , and its absence leads to defective germinal centre formation and impaired production of high-affinity antibodies . WAS gene (Option B) mutations cause Wiskott-Aldrich syndrome . LYST gene (Option C) mutations cause Chediak-Higashi syndrome . FOXP3 gene (Option D) mutations cause IPEX syndrome , characterised by regulatory T-cell dysfunction and autoimmunity.

Q9: Individuals with selective IgA deficiency most commonly show reduced levels of which IgG subclass? (Q890563)

A. IgG1

B. IgG2

C. IgG3

D. IgG4

Correct Answer: B. IgG2

Explanation: Selective IgA deficiency is the most common primary immunodeficiency and is characterised by markedly reduced or absent serum and secretory IgA , leading to impaired mucosal immunity. It is frequently associated with deficiencies in IgG subclasses, most consistently IgG2 . IgG2 plays a critical role in immune responses against polysaccharide antigens of encapsulated bacteria such as Streptococcus pneumoniae and Haemophilus influenzae . Deficiency of IgG2 results in impaired opsonisation and clearance of these organisms, contributing to recurrent sinopulmonary infections , a hallmark clinical feature in symptomatic patients. Although deficiencies of other IgG subclasses (such as IgG3 or IgG4) may occasionally be seen, these associations are variable and less consistent , making IgG2 deficiency the most reliable and clinically significant finding .

Q10: Which of the following genes is not typically associated with the development of severe combined immunodeficiency (SCID)? (Q890562)

A. IL-7Rα

B. RAG1 and RAG2

C. JAK3

D. BTK

Correct Answer: D. BTK

Explanation: Severe combined immunodeficiency (SCID) results from genetic defects that impair T-cell development , leading to combined defects in both cell-mediated and humoral immunity . Several genes are commonly involved: IL-7Rα (Option A) mutations impair T-cell development, causing an autosomal recessive form of SCID (T■ B■ NK■). RAG1 and RAG2 (Option B) are required for V(D)J recombination; mutations prevent normal T- and B-cell maturation, resulting in SCID (T■ B■). JAK3 (Option C) is involved in signalling through the common γ-chain cytokine receptor; mutations lead to SCID (T■ B■ NK■). In contrast, BTK (Option D) mutations cause X-linked agammaglobulinemia (XLA) , characterised by defective B-cell maturation with normal T-cell function . Therefore, BTK is not associated with SCID.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Pages 215-216

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 7-month-old infant presents with persistent oral thrush and extensive diaper rash. History reveals multiple serious infections since birth, requiring repeated hospital admissions. Oral examination shows easily scrapable white patches. Thymic biopsy demonstrates underdeveloped Hassall's corpuscles. Which of the following statements about this condition is correct? The most common form of SCID is X-linked Adenosine deaminase (ADA) enzyme deficiency is the most common cause Hematopoietic stem cell transplantation is the preferred treatment It is due to defects in both humoral and cell-mediated immune responses (Q890561)

A. 1,2

B. 2,3,4

C. 1,3,4

D. All of the above

Correct Answer: C. 1,3,4

Explanation: Severe combined immunodeficiency (SCID) is a group of disorders characterised by profound defects in both cell-mediated (T-cell) and humoral (B-cell) immunity , leading to severe, recurrent infections early in life, including opportunistic infections such as candidiasis. The most common form is X-linked SCID , caused by mutations in the common γ-chain (IL2RG) of cytokine receptors, resulting in defective T-cell development

(Statement 1). Adenosine deaminase (ADA) deficiency is the most common autosomal recessive cause of SCID but is not the most common overall cause (Statement 2). Hematopoietic stem cell transplantation (HSCT) is the mainstay of treatment and can restore immune function (Statement 3). Because T cells are essential for B-cell activation, SCID results in combined defects in both humoral and cell-mediated immunity (Statement 4).

↑ *Back to this question in Part A*

@Neet_pg_bot

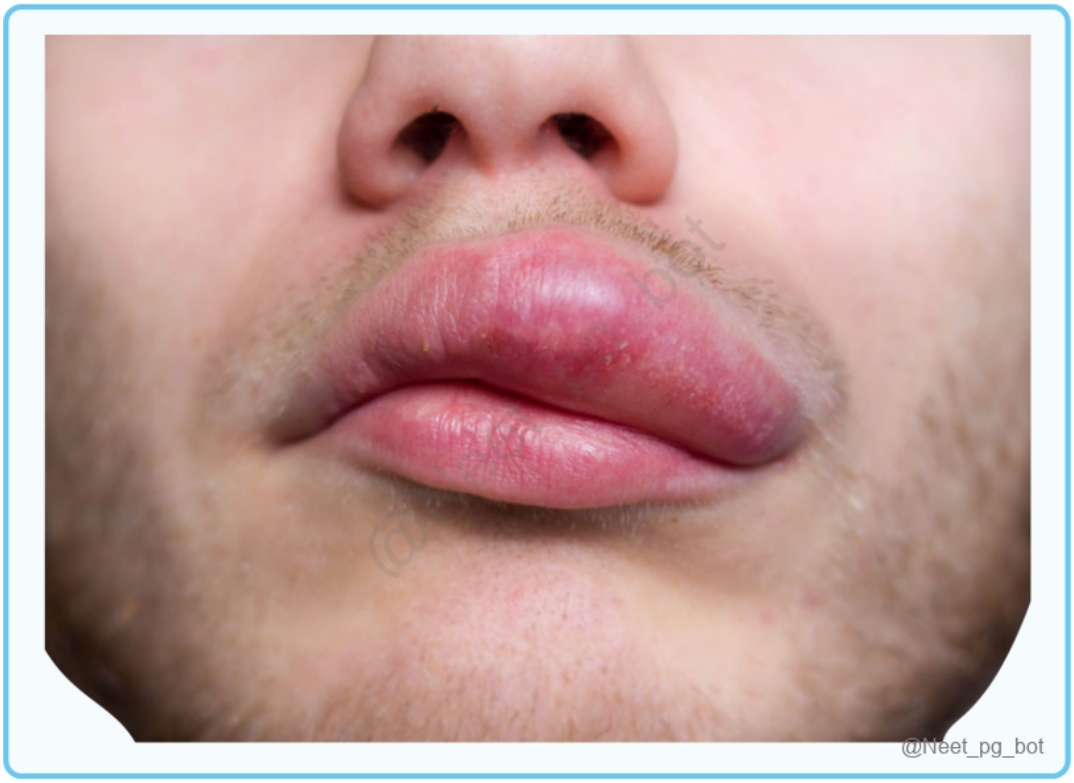
Q12: A young adult develops recurrent episodes of facial and lip swelling accompanied by abdominal pain and vomiting following minor stress or trauma. There is no associated urticaria. Which of the following complement deficiencies is most likely responsible? (Q890560)

A. C1 inhibitor

B. C2

C. C3

D. C5,C6, C7, C8, C9



Correct Answer: A. C1 inhibitor

Explanation: Hereditary angioedema is caused by a deficiency of C1 esterase inhibitor (C1-INH) , an autosomal dominant disorder. This leads to unregulated activation of the kallikrein-kinin system and increased production of bradykinin , resulting in increased vascular permeability and recurrent, non-urticarial edema of the skin and mucosal surfaces, including the gastrointestinal tract. Episodes are often triggered by minor trauma or emotional stress . C2 (Option B) deficiency is associated with increased susceptibility to infections and SLE-like autoimmune disease , not angioedema. C3 (Option C) deficiency leads to severe recurrent pyogenic infections due to impaired opsonisation. Deficiencies of terminal complement components C5-C9 (Option D) impair formation of the membrane attack complex and predispose to recurrent Neisseria infections .

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Pages 214-215

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following complement deficiencies is correctly matched with its associated disorder? (Q890559)

A. C1 esterase inhibitor - Hereditary angioedema

B. C3 - Recurrent Neisseria infections

C. Factor H - Glomerulonephritis

D. C6-C9 - Hemolytic uremic syndrome

Correct Answer: A. C1 esterase inhibitor - Hereditary angioedema

Explanation: Deficiency of C1 esterase inhibitor (C1-INH) causes hereditary angioedema , an autosomal dominant disorder characterised by recurrent episodes of oedema involving the skin, mucous membranes, and airways. This results from unregulated activation of the kallikrein system and increased bradykinin production , leading to increased vascular permeability. Complement deficient Disorder C1 esterase inhibitor Hereditary angioedema C3 (Option B) Recurrent pyogenic infections with encapsulated bacteria (like pneumococci) Factor H (Option C) Atypical hemolytic uremic syndrome (aHUS) and thrombotic microangiopathy C6-C9 (Option D) Recurrent Neisseria (gonococcal and meningococcal) infections C2, C4, or C1q SLE

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page 214

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 6-month-old infant presents with persistent fever and rapid breathing for 1 week. History reveals multiple previous infections. Blood culture grows Serratia marcescens. Nitroblue tetrazolium (NBT) test is negative. Which of the following statements about this condition is true? (Q890558)

A. It is inherited in an autosomal dominant manner

B. Due to lymphocytic inflammatory reaction

C. Primarily affects the adaptive immune system

D. It is due to defects in leukocytic superoxide production

Correct Answer: D. It is due to defects in leukocytic superoxide production

Explanation: Chronic granulomatous disease (CGD) is caused by inherited defects in components of the phagocyte NADPH oxidase complex , leading to impaired generation of superoxide (O■•) and reactive oxygen species . This defect results in impaired intracellular killing of microbes , particularly catalase-positive organisms such as Serratia marcescens . The nitroblue tetrazolium (NBT) test is negative due to failure of the oxidative burst. Most cases are X-linked (gp91phox deficiency) , while others are autosomal recessive (e.g., p47phox, p67phox) ; it is not inherited in an autosomal dominant manner (Option A). The disease is a defect of innate immunity affecting phagocytes , not a lymphocyte-mediated process (Option B) and does not primarily involve the adaptive immune

system (Option C) . The impaired neutrophil response leads to chronic inflammation with macrophage-rich granuloma formation .

@Neet_pg_bot

Q15: In a pediatric clinic, a six-year-old male presents with a history of frequent respiratory and skin infections, eczema flare-ups, and microthrombocytopenia. Given these symptoms, which genetic evaluation method would be the most effective for confirming the suspected diagnosis? (Q845948)

A. WASP gene mutation analysis

B. ANA titer

C. FISH

D. B cell tyrosine kinase activity detection

Correct Answer: A. WASP gene mutation analysis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: WASP gene mutation analysis, specific to Wiskott-Aldrich syndrome. Wiskott-Aldrich syndrome is an X-linked recessive disease characterized by the triad of: Thrombocytopenia Eczema Recurrent infections Wiskott-Aldrich syndrome is caused by mutations in the gene located at Xp11.23, which encodes the Wiskott-Aldrich syndrome protein (WASP). ANA titre (Option B): These are typically associated with SLE (systemic lupus erythematosus) FISH (Option C): FISH (Fluorescence In Situ Hybridization) is a molecular cytogenetic technique used to detect and localize specific DNA sequences within the chromosomes. It is used for identifying microdeletion, amplification or translocation. B cell tyrosine kinase activity detection (Option D): Detection of B-cell tyrosine kinase activity is relevant for X-linked agammaglobulinemia (XLA), characterized by the absence of mature B cells and low levels of immunoglobulins.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 169

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: In a pediatric clinic, a six-year-old male presents with a history of frequent respiratory and skin infections, eczema flare-ups, and thrombocytopenia. Given these symptoms, which genetic evaluation method would be the most effective for confirming the suspected diagnosis? (Q845648)

A. WASP gene mutation analysis

B. ANA titer

C. FISH

D. B cell tyrosine kinase activity detection

Correct Answer: A. WASP gene mutation analysis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: WASP gene mutation analysis, specific to Wiskott-Aldrich syndrome. Wiskott-Aldrich syndrome is an X-linked recessive disease characterised by the triad of: Thrombocytopenia Eczema Recurrent infections Wiskott-Aldrich syndrome is caused by mutations in the gene located at Xp11.23, which encodes the Wiskott-Aldrich syndrome protein (WASP). Pathophysiology: WASP is a key regulator of the actin cytoskeleton in hematopoietic cells. Its absence leads to defective T-cell interaction and abnormal platelet formation. Confirmation: Genetic analysis to identify mutations in the WAS gene is the definitive method for confirming this diagnosis.\ ANA Titer (Option B): Anti-Nuclear Antibody (ANA) titers are used as a screening tool for systemic autoimmune diseases , such as Systemic Lupus Erythematosus (SLE). While patients with immunodeficiencies can have associated autoimmunity, an ANA titer is not specific for any primary immunodeficiency and would not identify the underlying genetic cause of this child's symptoms. FISH (Fluorescence In Situ Hybridization) (Option C): FISH is used to detect and locate specific DNA sequences on chromosomes. It is the classic test for diagnosing DiGeorge Syndrome (detecting the 22q11.2 deletion). While FISH is a powerful genetic tool, it is not the primary method for detecting the point mutations or small deletions typically found in the WAS gene. B-cell tyrosine kinase activity detection (Option D): This test evaluates the function of Bruton Tyrosine Kinase (BTK) . Reduced BTK activity or expression is diagnostic for X-linked Agammaglobulinemia (Bruton's) . While Bruton's presents with recurrent infections, it does not feature the thrombocytopenia or eczema seen in this patient.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 169

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 35-year-old male with a known history of selective IgA deficiency receives a blood transfusion during surgery. Shortly after the transfusion, he develops acute allergic reactions, including hives and difficulty breathing. Given his IgA deficiency, which blood products should have been considered to minimize the risk of such complications? (Q845676)

A. Standard red blood cells with no modification

B. Plasma products that are rich in IgA

C. Washed red blood cells

D. Fresh frozen plasma

Correct Answer: C. Washed red blood cells

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Patients with selective IgA deficiency risk developing anaphylactic reactions if they receive IgA blood products. To minimize this risk, it is essential to transfuse blood products that have been processed to reduce IgA levels, such as washed red blood cells with normal saline multiple times to remove plasma components such as antibodies. In contrast, standard red blood cells or IgA-rich products could trigger severe allergic reactions, as seen in this patient. Selective IgA deficiency: Selective IgA deficiency is the most common primary immunodeficiency . It is characterized by a significant decrease or total absence of serum and secretory IgA, while other immunoglobulin levels (IgG, IgM) and T-cell counts remain normal. Clinical Presentation: ■■■■■■■ Recurrent Sinopulmonary Infections: Such as sinusitis, otitis media, and pneumonia. Gastrointestinal Infections: Frequent giardiasis due to lack of mucosal protection. Autoimmune Disorders: Strong association with Celiac disease, SLE, and Rheumatoid Arthritis. Atopy: Increased incidence of asthma, eczema, and food allergies. Some patients develop anti-IgA antibodies (IgE class). Diagnosis: Measure serum IgA (quantitative nephelometry); confirm with normal IgG/IgM and vaccine responses (e.g., pneumococcal). Screen for anti-IgA antibodies if transfusion reactions occur. Comparison with other B-cell Deficiencies: Feature Selective IgA Deficiency X-linked Agammaglobulinemia (Bruton) Common Variable Immunodeficiency (CVID) Ig Levels Only IgA low All Ig classes low Multiple classes low (IgG/IgA/IgM) B-cell Count Normal Decreased/Absent Normal Age of Onset Any age; often asymptomatic After 6 months (loss of maternal IgG) 2nd–4th decade (20s–30s) Special Risk Anaphylaxis to blood Enteroviral infections High risk of gastric cancer/Lymphoma

@Neet_pg_bot

Q18: A 7-year-old child presents with recurrent skin abscesses and pneumonia. He also has a history of skeletal abnormalities, including scoliosis and delayed shedding of primary teeth. His lab work shows elevated serum IgE levels. What is the most likely diagnosis? (Q845675)

A. Job syndrome

B. Bruton's Agammaglobulinemia

C. Wiskott-Aldrich syndrome

D. Ataxia-Telangiectasia

Correct Answer: A. Job syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of recurrent infections with delayed shedding of primary teeth, along with the findings of elevated serum IgE levels, indicates the diagnosis of Job syndrome or hyper IgE syndrome . Hyper IgE syndrome (Job syndrome): Deficiency of Th17 cells due to STAT3 mutation → impaired recruitment of neutrophils to sites of infections. The clinical presentation is classically remembered by the mnemonic FATED : F – Facies: Coarse facial features. A – Abscesses: Recurrent "cold" (non-inflamed) staphylococcal abscesses. T – Teeth: Retained (delayed shedding) of primary teeth. E – IgE: Massive elevation of serum IgE . D – Dermatological: Eczema/Dermatitis. Skeletal: Bone abnormalities such as scoliosis and frequent fractures from minor trauma. Bruton's Agammaglobulinemia (X-linked Agammaglobulinemia) (Option B): Defect: Mutation in Bruton Tyrosine Kinase (BTK) , which is essential for B-cell maturation. Key Lab Findings: Absence of B cells (CD19+, CD20+) in peripheral blood and low levels of all immunoglobulin classes (IgG, IgA, IgM, IgE). Clinical Presentation: Recurrent bacterial and enteroviral infections starting after 6 months of age (once maternal IgG wanes). Why it's wrong: This patient has elevated IgE, whereas Bruton patients have near-zero IgE. Wiskott-Aldrich Syndrome (Option C): Defect: Mutation in the WASP gene ; T cells cannot reorganize their actin cytoskeleton. Clinical Triad (WATER): W iskott- A ldrich, T hrombocytopenia (small platelets/purpura), E czema, and R ecurrent pyogenic infections. Key Lab Findings: Low IgM , high IgA, and high IgE. Why it's wrong: While IgE is high, Wiskott-Aldrich is dominated by bleeding/purpura due to microthrombocytopenia, not skeletal or dental issues. Ataxia-Telangiectasia (Option D): Defect: Mutation in the ATM gene , leading to failure of DNA double-strand break repair. Clinical Triad: Ataxia (cerebellar atrophy), Telangiectasias (spider angiomas, often in the eyes), and IgA deficiency . Key Lab Findings: Low IgA, IgG, and IgE ; characteristically elevated Alpha-fetoprotein (AFP) . Why it's wrong: It presents with neurological decline and vascular markings, not skeletal abnormalities or high IgE. Feature Job Syndrome Bruton's (XLA) Wiskott-Aldrich Ataxia-Telangiectasia Main Defect Th17/STAT3 B-cell maturation (BTK) Actin cytoskeleton DNA Repair (ATM) Signature Lab ↑ ■■■■ ■■■↑ IgE ↓ All Ig classes ↑ IgE/IgA, ↓ IgM ↑ AFP , ↓ IgA Unique Sign Retained teeth Absent tonsils Small platelets Ataxia/Spider veins Infections "Cold" Abscesses Encapsulated bacteria Encapsulated bacteria Sinopulmonary

Harrison's Principles of Internal Medicine, 21st Edition, Page 449

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 4-year-old boy presents with recurrent bacterial infections, including pneumonia and otitis media. He also has a history of chronic diarrhoea. Laboratory tests reveal elevated IgM levels with markedly reduced IgG, IgA, and IgE levels. Flow cytometry shows normal numbers of CD19+ B cells and CD3+ T cells. Genetic testing reveals a mutation in the CD40L gene. Which of the following pathogens is the patient most at risk for developing severe infections with? (Q845674)

A. Streptococcus pneumoniae

B. Haemophilus influenzae

C. Staphylococcus aureus

D. Pneumocystis jirovecii

Correct Answer: D. Pneumocystis jirovecii

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of recurrent infections along with the findings of mutation in CD40L gene suggests the diagnosis of Hyper IgM syndrome . Hyper IgM syndrome: It follows X-linked mode of inheritance. Normally, the antigen binds to the antibody on B cells and is then presented to the T cells and the B-cell and T-cell numbers remains normal. CD40L (also known as CD154) on antigen-activated CD4+ helper T cells binds to CD40 on B cells, macrophages, and dendritic cells (DCs). This interaction is crucial for triggering Ig class switching (from IgM to IgG, IgA, and IgE) and affinity maturation in B cells. In hyper IgM syndrome, there is a defect in the CD40 receptor or CD40 ligand (most common). As a result, patients have high IgM levels but low levels of IgG, IgA, and IgE, and are prone to recurrent infections. In addition, these patients are also susceptible to pneumonia caused by Pneumocystis jirovecii . Autoimmune disorders are a common complication of Hyper IgM syndrome, and autoimmune hemolytic anemia is one of the more frequent autoimmune manifestations. Clinical Features of Hyper IgM syndrome: Recurrent sinopulmonary infections (pneumocystis pneumonia, bacterial otitis/sinusitis). Opportunistic: cryptosporidium (causes sclerosing cholangitis), chronic diarrhea Neutropenia (especially X-HIGM), hepatobiliary disease, autoimmunity (anemia, thrombocytopenia), and malignancy risk (liver cancer, lymphoma). Diagnosis of Hyper IgM syndrome : Labs: Hypogammaglobulinemia (low IgG/A/E, high/normal IgM); poor vaccine responses Flow cytometry: absent CD40L on activated T cells; genetic testing Management of Hyper IgM syndrome: IVIG/SCIG replacement, PCP prophylaxis (TMP-SMX), antibiotics for neutropenia (G-CSF if severe) HSCT as curative option (best early for X-HIGM) Gene therapy under investigation

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 244, 245

↑ *Back to this question in Part A*

@Neet_pg_bot

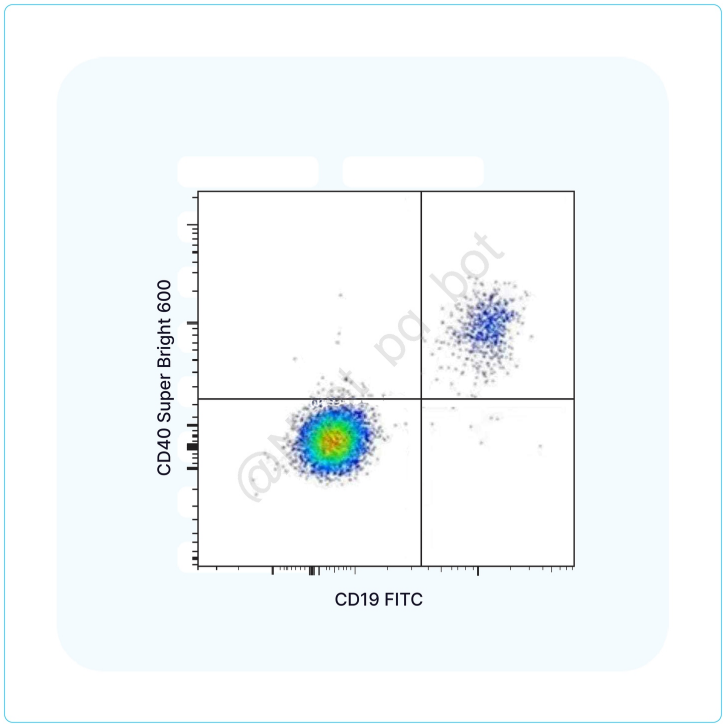
Q20: A patient presents with autoimmune hemolytic anemia, thrombocytopenia and neutropenia. Based on the flow cytometry findings, what is the most likely diagnosis? (Q845673)

A. Paroxysmal Nocturnal Hemoglobinuria

B. Hyper IgE syndrome

C. Hyper IgM syndrome

D. Glanzmann Thrombasthenia



@Neet_pg_bot

Correct Answer: C. Hyper IgM syndrome

Explanation: The clinical presentation of autoimmune hemolytic anaemia, thrombocytopenia and neutropenia with the flow cytometry findings showing CD40 negative and CD19 negative, is most likely suggestive of Hyper IgM syndrome. Hyper IgM syndrome: In hyper IgM syndrome, mature B cells are present, but they are incapable of Ig class switching and affinity maturation because of a defect in the CD40 receptor or CD40 ligand . The patient's serum will have elevated levels of IgM but no IgA or IgE and extremely low levels of IgG. Occasionally, the IgM antibodies react with blood cells, giving rise to autoimmune hemolytic anemia, thrombocytopenia, and neutropenia. Flow cytometry: Flow cytometry results are typically represented as histograms or dot plots: Histograms : Represent the frequency distribution of a single parameter. Dot plots : Display two parameters on the x- and y-axes. The given image is a dot plot and it has 4 quadrants as follows: Quadrant 1 (green) Negative for antigen A, positive for antigen B Quadrant 2 (purple) Negative for both antigens Quadrant 3 (yellow) Positive for both antigens Quadrant 4 (red) Positive for antigen A, negative for antigen B The dot plot in the question has CD19 (pan B-cell marker) on the X-axis and CD40 on the Y-axis . The majority of the cells are in the double negative quadrant, indicating that both CD40 and CD19 are almost negative in this patient, suggesting the diagnosis of hyper IgM syndrome. Hyper IgM syndrome (Option C) is characterized by CD40L deficiency (X-linked) or CD40 deficiency (autosomal recessive), which affects both B and T cells. Paroxysmal Nocturnal Hemoglobinuria (Option A): A flow cytogram of blood from a patient with PNH shows a population of red cells that is deficient in both CD55 and CD59. Glanzmann Thrombasthenia (Option D): It is a platelet disorder characterized by glycoprotein IIb/IIIa defect, also known as CD41 (GpIIb) and CD61 (GpIIIa). Hence CD41 and CD61 are both negative on flow cytometry.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 7-year-old boy is brought to the pediatric clinic due to recurrent infections, including pneumonia and abscesses. He has a history of photophobia and exhibits partial oculocutaneous albinism. On examination, he has notable nystagmus and ataxia. Genetic testing confirms a defect in the LYST gene. Which of the following laboratory findings would be most characteristic of this patient's condition? (Q845672)

A. Decreased immunoglobulin levels

B. Elevated eosinophil count

C. Presence of giant granules in leukocytes

D. Elevated platelet count

Correct Answer: C. Presence of giant granules in leukocytes

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient is presenting with the classical signs of Chédiak-Higashi Syndrome (CHS) , a rare autosomal recessive disorder caused by a mutation in the LYST gene (Lysosomal Trafficking gene defect). Chédiak-Higashi Syndrome (CHS): C: C NS/neurological abnormalities HE: He morrhage DI: D ecreased I mmunity → ↑ Inflammation A: A lbinism (silvery gray hair), hypopigmentation K: Coarse cytoplasmic granules Decreased immunoglobulin levels (Option A): While patients are immunodeficient, the primary defect is in phagocytic function and Natural Killer (NK) cell activity, not necessarily a lack of antibodies (though advanced stages can see various shifts). Elevated eosinophil count (Option B): This is characteristic of Hyper-IgE syndrome (Job Syndrome), which also presents with "cold" abscesses and skin issues, but lacks albinism and giant granules. Elevated platelet count (Option D): Patients with CHS actually often have thrombocytopenia (low platelet count) and defective dense granules in platelets, leading to easy bruising and bleeding tendencies.

@Neet_pg_bot

Q22: Match the following. i) X-linked Agammaglobulinemia a) WAS ii) Job syndrome b) LYST iii) Wiskott-Aldrich syndrome c) STAT3 iv) Ataxia Telangiectasia d) BTK v) Chediak-Higashi syndrome e) ATM (Q845671)

A. i-d, ii-c, iii-b, iv-e, v-a

B. i-c, ii-d, iii-a, iv-e, v-b

C. i-d, ii-b, iii-a, iv-e, v-c

D. i-d, ii-c, iii-a, iv-e, v-b

Correct Answer: D. i-d, ii-c, iii-a, iv-e, v-b

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: X-linked (Bruton) Agammaglobulinemia BTK Job syndrome (Hyper IgE syndrome) STAT3 Wiskott-Aldrich syndrome WAS Ataxia Telangiectasia ATM Chediak-Higashi syndrome LYST 1. Job Syndrome (Hyper-IgE Syndrome): Gene: Autosomal dominant mutation in STAT3 . Mechanism: Defective STAT3 leads to a failure of Th17 cell differentiation. Without Th17 cells, there is a lack of IL-17, which is essential for recruiting neutrophils to sites of fungal and bacterial infections. Clinical Points: Massive elevation of IgE . "Cold" abscesses: Staphylococcal skin infections that lack the typical warmth and redness because neutrophils aren't recruited properly. Skeletal/Dental: Retention of primary teeth (delayed shedding), coarse facial features, and scoliosis. 2. X-linked (Bruton) Agammaglobulinemia: Gene: Mutation in BTK (Bruton Tyrosine Kinase). Mechanism: The BTK gene is located on the X chromosome and is vital for B-cell signaling. A defect prevents pre-B cells from maturing into mature B cells. Clinical Points: Absent B cells: Extremely low levels of CD19+, CD20+, and CD21+ cells in peripheral blood. Hypogammaglobulinemia: Very low levels of all immunoglobulin classes (IgG, IgA, IgM, IgD, IgE). Infections: Recurrent sinopulmonary and GI infections (e.g., Giardia) starting after 6 months of age once maternal IgG disappears. 3. Wiskott-Aldrich Syndrome: Gene: X-linked recessive mutation in the WAS gene. Mechanism: The WASP protein is responsible for organizing the actin cytoskeleton in hematopoietic cells. Without it, T cells cannot properly interact with other cells, and platelets are formed incorrectly. Clinical Points: Thrombocytopenia: Characterized by small platelets and a low platelet count, leading to bleeding and purpura. Immunology: Low to normal IgG and IgM; elevated IgA and IgE . Triad: Recurrent infections, eczema, and thrombocytopenia. 4. Ataxia-Telangiectasia: Gene: Autosomal recessive mutation in the ATM gene. Mechanism: The ATM protein detects DNA double-strand breaks and coordinates repair. A defect leads to accumulated DNA damage, cell cycle instability, and hypersensitivity to ionizing radiation. Clinical Points: Neurological: Progressive cerebellar ataxia (difficulty walking). Vascular: Telangiectasias (spider-like dilated capillaries) usually seen on the conjunctiva or skin. Lab Markers: Low IgA and IgG; characteristically elevated Alpha-fetoprotein (AFP) . 5. Chédiak-Higashi Syndrome: Gene: Autosomal recessive mutation in the LYST (Lysosomal Trafficking Regulator) gene. Mechanism: Defective vesicle fusion and lysosomal trafficking . This results in the formation of giant granules in neutrophils and prevents cytotoxic T cells from secreting their granules. Clinical Points: Microscopy: Pathognomonic giant granules in neutrophils and platelets. Albinism: Partial oculocutaneous albinism (melanocytes cannot distribute pigment granules). Neurological: Peripheral neuropathy and progressive neurodegeneration.

@Neet_pg_bot

Q23: An 8-month-old male infant presents with a history of severe, recurrent bacterial infections. On physical examination, the tonsils were found to be absent. Peripheral blood examination reveals an absence of B cells, while the T cell count is normal. Additionally, serum analysis reveals undetectable levels of immunoglobulins (IgG, IgA, and IgM). Which of the following most accurately explains the molecular mechanism responsible for this patient's immunodeficiency? (Q845670)

A. BTK gene mutation

B. RAG1/2 gene mutation

C. CD40L deficiency

D. BAFF receptor abnormality

Correct Answer: A. BTK gene mutation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical vignette suggests that the infant is suffering from Bruton's agammaglobulinemia (X-linked agammaglobulinemia) , which is due to a defect in the BTK gene. It is a X-linked recessive disorder, most commonly seen in boys and symptoms usually start after 6 months, when maternal antibodies decline. A BTK gene defect prevents B-cell precursors from maturing into functional B cells, blocking plasma cell formation and causing low immunoglobulin levels. Lymphoid germinal centers remain underdeveloped. RAG1/2 gene mutation (Option B) leads to severe combined immunodeficiency (SCID) , where both B and T cell functions are impaired due to defective V(D)J recombination. CD40 ligand deficiency (Option C) leads to Hyper IgM syndrome , where T-B cell interactions are defective, but B cells are still present. BAFF (B-cell activating factor) receptor abnormality (Option D) can contribute to common variable immunodeficiency (CVID) . However, CVID typically presents later in childhood or adulthood and is characterized by low serum immunoglobulin levels and impaired antibody responses with the presence of B cells.

@Neet_pg_bot

Q24: A 30-year-old female patient presents with a history of recurrent respiratory infections, chronic diarrhoea, and autoimmune manifestations. Laboratory investigations reveal low levels of serum immunoglobulins (IgG, IgA, and IgM). BAFF gene defect noted. Which of the following immunodeficiency disorders is most likely associated with these clinical findings? (Q845669)

A. X-linked agammaglobulinemia (XLA)

B. Common variable immunodeficiency (CVID)

C. Hyper IgM syndrome

D. Severe Combined Immunodeficiency (SCID)

Correct Answer: B. Common variable immunodeficiency (CVID)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above mentioned case scenario of a middle aged women with recurrent infections and autoimmune manifestations along with low sreum levels of IgG, IgA and IgM with BAFF gene defect points towards the diagnosis of Common variable immunodeficiency (CVID). Incorrect options: X-linked agammaglobulinemia (XLA) (Option A): Usually presents in male infants Caused by BTK gene defect → absence of mature B cells Females are usually carriers, not affected Hyper IgM Syndrome(Option C): It is caused due to impaired class switching and affinity maturation of antibodies, resulting in elevated IgM levels and reduced IgG and IgA. It also presents with recurrent bacterial infections. Severe Combined Immunodeficiency (SCID) (Option D): Severe infections in infancy Defect in T-cell development , often affecting B cells secondarily Not compatible with adult onset

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 245

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 6-year-old child presents with recurrent bacterial infections, delayed wound healing, and poor pus formation. Genetic testing reveals a mutation in the SLC35C1 gene, leading to a deficiency in Sialyl Lewis X (SLex) synthesis. Which of the following is the most likely consequence of this deficiency? (Q845668)

A. Leukocyte adhesion deficiency II

B. Defective opsonisation

C. Reduced chemokine production

D. Increased neutrophil apoptosis

Correct Answer: A. Leukocyte adhesion deficiency II

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of recurrent bacterial infections, delayed wound healing, and poor pus formation suggests a failure of white blood cells to migrate from the blood into the tissues. The specific mutation in the SLC35C1 gene leads to Leukocyte Adhesion Deficiency Type II (LAD II) . Mechanism: This gene encodes a fucose transporter. Its deficiency prevents the synthesis of Sialyl Lewis X (SLex) , which is the ligand on neutrophils that binds to E-selectin and P-selectin on the endothelium. Without this binding, neutrophils cannot "roll" along the vessel wall, which is the essential first step of extravasation. Unlike LAD I, LAD II is also associated with severe growth retardation and the Bombay blood phenotype because fucose is required for the H-antigen in the ABO system. Feature LAD I LAD II LAD III Defect CD18 (common β 2 subunit of Integrins) SLC35C1 (Fucose transporter / Sialyl Lewis X) FERMT3 (Kindlin-3 / Integrin activation) Process Affected Firm Adhesion and Transmigration Rolling (Initial tethering) Integrin activation Unique Clinical Signs Delayed separation of the umbilical cord Growth retardation, Bombay blood group, Intellectual disability Bleeding tendency (Glanzmann-like platelet defect) Pus Formation Poor/Absent Poor/Absent Poor/Absent Defective Opsonization (Option B): Mechanism: Opsonization involves coating a pathogen with antibodies (IgG) or complement proteins (C3b) to make it more "appetizing" to phagocytes. While this would lead to recurrent infections, it does not explain the failure of leukocytes to enter the tissue (lack of pus) or the specific SLex deficiency mentioned in the prompt. Reduced Chemokine Production (Option C): Mechanism: Chemokines (like IL-8) are signaling proteins that create a chemical gradient to guide neutrophils to the site of injury. In LAD, the signals (chemokines) are usually present, but the "machinery" on the leukocyte (integrins or selectin ligands) is broken, so they cannot respond to those signals. Increased Neutrophil Apoptosis (Option D): Mechanism: This would lead to Neutropenia (low absolute neutrophil count). In LAD II, the blood work typically shows Leukocytosis (elevated white cell count) because the neutrophils are "trapped" in the bloodstream and cannot exit into the tissues.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 241.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: A 2-year-old child presents with recurrent bacterial infections, delayed wound healing, and poor pus formation despite having a normal leukocyte count. Upon further investigation, a defect is identified in the integrin-mediated adhesion of leukocytes. Which of the following conditions is most likely responsible for this clinical presentation? (Q845667)

A. Chronic granulomatous disease (CGD)

B. Leukocyte Adhesion Deficiency Type 1 (LAD-1)

C. Hyper IgM syndrome

D. Severe Combined Immunodeficiency (SCID)

Correct Answer: B. Leukocyte Adhesion Deficiency Type 1 (LAD-1)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A young child with repeated infections and delayed wound healing, but with a normal WBC count, suggests that its a qualitative issue as opposed to a quantitative WBC issue. The defect identified in integerin-mediated adhesion of leukocytes also suggests a functional issue, suggesting the diagnosis of LAD 1. Leukocyte adhesion deficiency 1 (I=Integrin) Defective leukocyte adhesion because of mutations in the β2 chain of CD11/CD18 Integrins, with history of delayed umbilical cord shedding. Chronic Granulomatous Disease (CGD) (Option A): Defect in PHOX gene, resulting in deficiency of NADPH oxidase. Hyper IgM Syndrome (Option C): Loss of function of CD40 or CD40 ligand results in impaired class switching and affinity maturation of antibodies. SCID (Option D): SCID is caused by multiple genetic defects with both X-linked and AR inheritance.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 241.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: Which of the following disorders is characterised by absent tonsils and lymph nodes, markedly decreased levels of serum immunoglobulins (particularly IgG, IgA, and IgM), and a lack of mature B cells in peripheral blood? (Q845666)

A. Common Variable Immunodeficiency (CVID)

B. Severe Combined Immunodeficiency (SCID)

C. X-linked Agammaglobulinemia (XLA)

D. Hyper-IgM Syndrome

Correct Answer: C. X-linked Agammaglobulinemia (XLA)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above-mentioned clinical scenario points towards the diagnosis of X-linked agammaglobulinemia (Bruton Agammaglobulinemia). More commonly seen in B oys. Defect in B -cells - mature B-cells are not formed, due to a defective B TK gene Since mature B-cells are not formed, there is a deficiency in plasma cells, which leads to decreased levels of immunoglobulin, out of which IgG is most severely decreased. Since IgG is required for opsonization, there will be increased susceptibility to infections by capsulated organisms. Common Variable Immunodeficiency (CVID) (Option A): B- and T-cell deficiency. Options B, D: Absent tonsils and lymph nodes are not specific to SCID and Hyper-IgM Syndrome.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 243,244

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: A 5-year-old male presents with progressive difficulty in coordinating movements, slurred speech, and frequent infections. Physical examination reveals the findings shown in the image below and dysarthria. Laboratory investigations show decreased levels of serum IgA, IgG, and IgE. Which of the following is the most likely diagnosis? (Q845665)

A. Hereditary spastic paraplegia

B. Friedreich ataxia

C. Ataxia Telangiectasia

D. Spinocerebellar ataxia type 1

Correct Answer: C. Ataxia Telangiectasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario (dysarthria, slurred speech, recurrent infections, telangiectasia shown in the image above, decreased serum IgA, IgG, and IgE) suggests ataxia telangiectasia. Ataxia Telangiectasia (AT) is an autosomal-recessive disorder, characterized by abnormal gait(ataxia), vascular malformations (telangiectases), neurological deficits, increased tumors, and immunodeficiency. It affects both B and T cells, mainly causing defective production of IgA, IgE and IgG antibodies. Patients frequently experience respiratory tract infections, autoimmune issues, and There is increased risk of malignancy. It is caused by a mutation in the gene on chromosome 11q22 encoding the ATM protein kinase. Hereditary spastic paraplegia (Option A) presents with spasticity in the lower limbs but does not typically present with immunodeficiencies or telangiectasias. Friedreich ataxia (Option B) is a trinucleotide repeat disorder that presents with progressive gait and limb ataxia, with GAA repeats in the genome.It does not typically present with telangiectasias or immunodeficiency. Spinocerebellar ataxia (Option D) type 1 is characterised by progressive cerebellar ataxia but does not typically present with telangiectasias or immunodeficiency.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 255

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: An 8-month-old infant is brought to the clinic with a history of persistent, severe respiratory infections since birth. Physical examination reveals failure to thrive and absent tonsils and lymph nodes. The child is diagnosed with adenosine deaminase deficiency; what is the most appropriate diagnosis? (Q845650)

A. DiGeorge Syndrome

B. X-linked Agammaglobulinemia (XLA)

C. Hyper-IgM Syndrome

D. Severe Combined Immunodeficiency (SCID)

Correct Answer: D. Severe Combined Immunodeficiency (SCID)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above clinical scenario with adenosine deaminase (ADA) deficiency points towards the diagnosis of Severe Combined Immunodeficiency (SCID) . Severe Combined Immunodeficiency (SCID): B cells, T cells, and NK cells are affected Types: XLR (X-linked recessive variety) AR (Autosomal Recessive Variety) X-linked Recessive (XLR) Variety Autosomal Recessive (AR) Variety Most common type . Defect in g amma subunit of cytokine receptor → IL-2, IL-4, IL-7, IL-15 will not form IL-2 and IL-15: Defective NK cells . IL-7: Defective T-cell development . IL-4: No isotype switching → failure to produce IgG, IgA, and IgE . In XLR type of SCID → Primarily T cells and NK cells are defective; B cell maturity alone is affected. Types: ADA (Adenosine deaminase) deficiency: Most common in AR SCID. ADA deficiency → ↑ toxic metabolites → damage to B, T, and NK cells . JAK-3 defect: Affects cytokine development. Defective T and NK cells . RAG-1 and 2 gene (Recombinant Activation Gene) defect: Responsible for development of B and T cell receptors . Options A, B, and C do not typically lead to a virtual absence of peripheral lymphoid organs, as seen in adenosine deaminase deficiency.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 242, 243

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: A 4-year-old child presents with recurrent infections, congenital heart defects, and facial dysmorphisms, including a long face with a prominent nasal bridge. Genetic testing reveals a microdeletion on chromosome 22q11. What is the most likely diagnosis? (Q845649)

A. Down syndrome

B. Turner syndrome

C. DiGeorge syndrome

D. Cri-du-chat syndrome

Correct Answer: C. DiGeorge syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: DiGeorge syndrome , or 22q11.2 deletion syndrome , is characterised by a microdeletion on chromosome 22q11. Clinical features represented by CATCH22 C : Cardiac defects, especially conotruncal anomalies A : Abnormal facial features, such as low set ears, hypertelorism, and short philtrum T : Thymic hypoplasia C : Cleft palate or cellular immune deficiency H : Hypoparathyroidism with hypocalcemia In DiGeorge syndrome, there is failure or hypoplasia of the 3rd and 4th pharyngeal pouches , which leads to: Thymic hypoplasia or aplasia , causing T-cell immunodeficiency. Parathyroid hypoplasia or aplasia , causing hypocalcemia. Down syndrome (Option A): Down syndrome is characterized by trisomy 21. Turner syndrome (Option B): Turner syndrome results from complete or partial monosomy of the X chromosome. Cri-du-chat syndrome (Option D): Cri-du-chat syndrome is caused by a deletion on the short arm of chromosome 5. It presents with a high-pitched cat-like cry, intellectual disability, microcephaly, and facial dysmorphisms but lacks the cardiac anomalies and thymic aplasia seen in DiGeorge syndrome.

[05_Immunity] 023 Amyloidosis — Quick Jump

Q1 (p. 1550) *Q2 (p. 1550)* *Q3 (p. 1551)* *Q4 (p. 1552)* *Q5 (p. 1552)* *Q6 (p. 1553)*
Q7 (p. 1553) *Q8 (p. 1554)* *Q9 (p. 1555)* *Q10 (p. 1555)* *Q11 (p. 1556)* *Q12 (p. 1557)*
Q13 (p. 1558)

Q1: Which of the following sites is most commonly affected in secondary (AA) amyloidosis? (Q879914)

A. Heart and brain

B. Kidneys and liver

C. Lungs and spleen

D. Skin and skeletal muscle

Correct Answer: B. Kidneys and liver

Explanation: Secondary (AA) amyloidosis is systemic and typically associated with chronic inflammatory conditions (e.g., rheumatoid arthritis, ankylosing spondylitis, IBD). Caused by the deposition of serum amyloid A (SAA) protein secondary to chronic inflammatory conditions. Kidneys are the most commonly affected organ, often leading to proteinuria and renal dysfunction. Liver and spleen may also be involved, but deposition in the heart and brain is rare in AA amyloidosis.

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 232

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 58-year-old man with end-stage renal disease has been receiving hemodialysis for 6 years. He now presents with joint pain, carpal tunnel syndrome, and shoulder stiffness. Laboratory tests show normal inflammatory markers and no evidence of plasma cell disorder. Which type of amyloid is most likely responsible for his symptoms? (Q879916)

A. AA amyloid

B. AL amyloid

C. Aβ2-m

D. ATTR

Correct Answer: C. Aβ2-m

Explanation: β2-microglobulin amyloidosis occurs in patients on long-term hemodialysis due to the accumulation of β2-microglobulin, which is poorly cleared by older dialysis membranes. Clinical manifestations are usually musculoskeletal, including joint, tendon, ligament, and muscle involvement, with carpal tunnel syndrome being relatively common. The incidence of this complication has decreased with modern dialysis filters that better remove β2-microglobulin. Incorrect Options: AA amyloid (Option A): Derived from serum amyloid A during chronic inflammation; associated with chronic infections or autoimmune diseases, not dialysis. AL amyloid (Option B): Composed of immunoglobulin light chains; seen in plasma cell dyscrasias like multiple myeloma, not in long-term dialysis patients. ATTR (Option D): Transthyretin-derived amyloid; associated with hereditary amyloidosis and senile cardiac amyloidosis, not dialysis-related disease.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 233

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which type of amyloid is commonly deposited in the pancreas of patients with type 2 diabetes mellitus? (Q879919)

A. AL amyloid

B. AA amyloid

C. Islet amyloid polypeptide (IAPP)

D. β2-microglobulin

Correct Answer: C. Islet amyloid polypeptide (IAPP)

Explanation: In type 2 diabetes, amyloid deposits are localized to the islets of Langerhans. The protein responsible is IAPP (amylin), co-secreted with insulin by β-cells. These deposits contribute to β-cell dysfunction, worsening hyperglycemia. AL amyloid (Option A) is from plasma cell disorders, AA amyloid (Option B) is secondary to chronic inflammation, and β2-microglobulin (Option D) occurs in long-term hemodialysis.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 233

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: In medullary thyroid carcinoma, amyloid deposits are primarily derived from which of the following? (Q879920)

A. Thyroglobulin

B. Calcitonin

C. Parathyroid hormone

D. Islet amyloid polypeptide

Correct Answer: B. Calcitonin

Explanation: Medullary thyroid carcinoma (MTC) arises from C-cells of the thyroid. These cells secrete calcitonin, which can form amyloid deposits (sometimes called ACal deposits) within the tumor. These deposits are localized and serve as a helpful diagnostic feature. Thyroglobulin (Option A) is secreted by follicular cells, parathyroid hormone (Option C) by parathyroid glands, and IAPP (Option D) is related to pancreatic islets.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 233

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following organs is most commonly affected in AL (primary) amyloidosis? (Q879921)

A. Kidneys

B. Liver

C. Heart

D. Pancreas

Correct Answer: A. Kidneys

Explanation: AL amyloidosis is caused by deposition of immunoglobulin light chains produced by clonal plasma cells. The kidneys are most frequently involved, often presenting with proteinuria and nephrotic syndrome. Other commonly affected organs include the heart (restrictive cardiomyopathy), liver , and peripheral nerves, but the kidneys are the primary target. Pancreatic involvement is rare in AL amyloidosis; localized islet amyloid in diabetes involves IAPP, not AL protein.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 231-232

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: In primary (AL) amyloidosis, the typical bone marrow finding is? (Q879936)

A. Extensive osteolytic lesions with >30% plasma cells

B. Modest increase in plasma cells producing monoclonal light chains

C. Normal plasma cell count with no monoclonal proteins

D. Hypercellular marrow with granulocytic predominance

Correct Answer: B. Modest increase in plasma cells producing monoclonal light chains

Explanation: In AL amyloidosis, most patients do not have overt multiple myeloma. Bone marrow typically shows a modest increase in plasma cells that secrete monoclonal immunoglobulins or free light chains (kappa or lambda). These light chains deposit in tissues as amyloid, causing systemic manifestations.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 231-232

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following is the preferred initial investigation for suspected systemic amyloidosis? (Q879937)

A. Kidney biopsy

B. Abdominal fat pad aspiration stained with Congo red

C. Bone marrow aspirate

D. Radiolabeled serum amyloid P scintigraphy

Correct Answer: B. Abdominal fat pad aspiration stained with Congo red

Explanation: Abdominal fat pad aspiration is minimally invasive and can detect systemic amyloid deposits with Congo red staining. Amyloidosis Investigation: Tissue Biopsy (gold standard) Kidney (if renal manifestations present) Rectal or gingival tissue Abdominal fat aspirate stained with Congo red (specific but less sensitive) Serum and Urine Studies (especially in AL amyloidosis) Protein electrophoresis Immunoelectrophoresis to detect monoclonal proteins or free light chains Bone Marrow Aspirate Shows monoclonal plasmacytosis, even if overt multiple myeloma is absent Imaging / Scintigraphy Radiolabeled serum amyloid P component scintigraphy Rapid, specific, shows extent of amyloid deposition and can monitor treatment response

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 234

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following stains is most commonly used to detect amyloid deposits in kidney biopsies? (Q879938)

A. Hematoxylin and eosin

B. Congo red

C. Masson’s trichrome

D. Periodic acid–Schiff

Correct Answer: B. Congo red

Explanation: Congo red is the standard stain for detecting amyloid in kidney tissue, including glomeruli, vessels, and interstitium. When viewed under polarized light, amyloid shows apple-green birefringence, confirming the diagnosis. Other stains may show structural changes but cannot specifically identify amyloid. Incorrect Options: Hematoxylin and eosin (Option A): Shows eosinophilic deposits but is nonspecific for amyloid. Masson’s trichrome (Option C): Highlights collagen and fibrosis, not amyloid. Periodic acid–Schiff (Option D): Stains basement membranes and carbohydrates, not specific for amyloid.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 234

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: When stained with Congo red and viewed under polarized light, amyloid deposits in tissue typically show? (Q879939)

A. Bright red fluorescence

B. Apple-green birefringence

C. Blue-black metachromasia

D. Orange-red color under light microscope only

Correct Answer: B. Apple-green birefringence

Explanation: Congo red stain is the standard for detecting amyloid in tissues such as kidney, rectal mucosa, fat pad, or gingiva. Under polarized light, amyloid deposits exhibit apple-green birefringence , which is considered diagnostic. The test is specific but less sensitive, so negative results do not completely exclude amyloidosis.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 234

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Identify the false statements regarding the amyloid. 1) It is a proteoglycan. 2) It is a misfolded protein seen intracellularly. 3) They show cross-β-pleated sheet conformation in light microscopy. 4) 95% of amyloid consists of fibril proteins. 5) It appears as an amorphous, basophilic, hyaline, extracellular substance. (Q845450)

A. 1,2,3

B. 2,5

C. 3,4

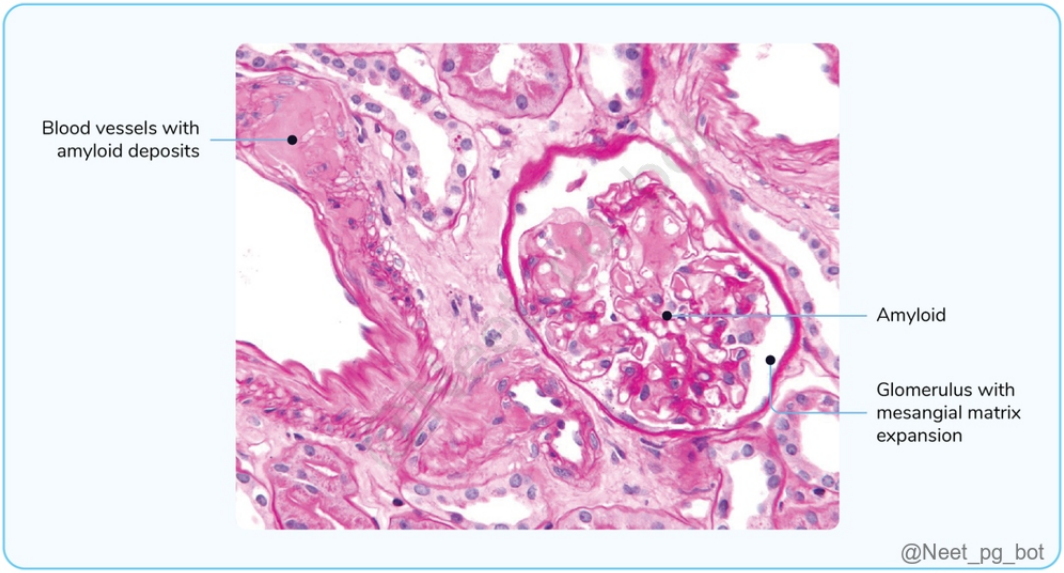
D. 2,3,5

Correct Answer: D. 2,3,5

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Amyloid is defined as a proteoglycan and a misfolded protein , seen extracellularly . (Statements 1 and 2) The presence of abundant charged sugar groups in these adsorbed proteins gives the deposits staining characteristics that were thought to resemble starch (amylose). Therefore, the deposits were called amyloid 95% of amyloid consists of fibril proteins, with the remaining 5% being glycosaminoglycans (dermatan sulfate and heparan sulfate) and plasma proteins, notably serum amyloid P . (Statement 4) Physical nature of amyloid: Light microscopy with H & E stains: Amyloid is an amorphous , eosinophilic , hyaline , and extracellular substance. (Statement 5) Electron microscopy: All types of amyloid, regardless of clinical setting or chemical composition, consist of continuous, nonbranching fibrils with a diameter of approximately 7.5 to 10 nm. X-ray crystallography and infrared spectroscopy: Characteristic cross-β-pleated sheet conformation is responsible for the distinctive Congo-red staining and apple-green birefringence of the amyloid. (Statement 3)



References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 259, 260

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Match the following. Condition Amyloid protein 1 Chronic inflammation i ATTR 2 Alzheimer’s disease ii AA 3 Familial amyloid polyneuropathy iii AIAPP 4 Diabetes mellitus iv Aβ (Q845453)

A. 1-i, 2-ii, 3-iii, 4-iv

B. 1-ii, 2-iv, 3-iii, 4-i

C. 1-ii, 2-iv, 3-i, 4-iii

D. 1-iii, 2-ii, 3-i, 4-iv

Correct Answer: C. 1-ii, 2-iv, 3-i, 4-iii

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Amyloidosis is a condition characterised by extracellular deposits of fibrillar proteins. These abnormal fibrils are produced by the aggregation of misfolded proteins. Important amyloid-disease associations: Disease Amyloid Multiple myeloma and other monoclonal plasma cell disorders AL Chronic inflammation AA Alzheimer's disease Aβ Familial amyloid polyneuropathy ATTR (mutated form of transthyretin) Diabetes mellitus AIAPP Hemodialysis associated amyloidosis Aβ 2 m Familial Meditterean Fever AA Senile systemic amyloidosis ATTR (Increased quantity of TTR, no mutation is seen) Medullary carcinoma of the thyroid Acal Isolated atrial amyloidosis AANF Types: Primary amyloidosis. Seen in multiple myeloma and other monoclonal plasma cell proliferations . AL type of amyloidosis is seen. Amyloid light chain (AL) protein is made up of complete immunoglobulin light chains, the amino-terminal fragments of light chains, or both. Most of the AL proteins analyzed are composed of λ light chains or their fragments, but κ chains are present in some cases. The AL type of amyloid fibril protein is produced from free Ig light chains secreted by monoclonal plasma cells. Secondary amyloidosis (Reactive systemic amyloidosis). Occurs secondary to chronic inflammatory conditions such as: Rheumatoid arthritis Chronic infections (e.g. tuberculosis, osteomyelitis) Inflammatory bowel disease In this condition, serum amyloid A (SAA) , an acute-phase reactant protein, is produced in high quantities by the liver in response to inflammation. When SAA is persistently elevated, it misfolds and deposits as AA amyloid fibrils in tissues.

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 259-262

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 65-year-old male with a history of multiple myeloma in remission presents with fatigue, weight loss, and abdominal discomfort. He reports early satiety and a palpable firm mass in the left upper quadrant. Which finding is not associated with this condition? (Q845454)

A. Sago's spleen

B. Lardaceous spleen

C. Carpal tunnel syndrome

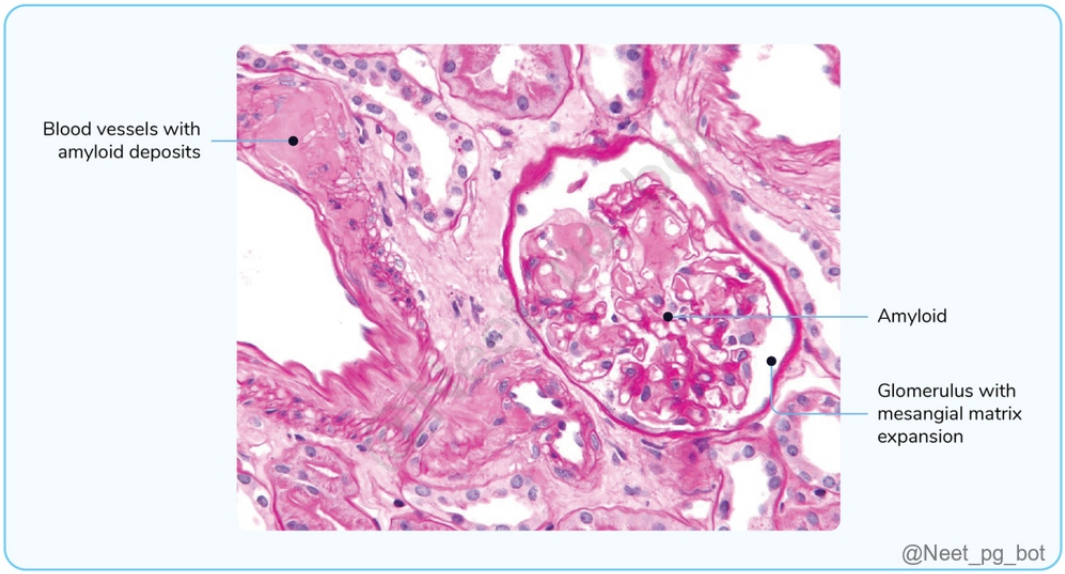
D. Nephritic syndrome

Correct Answer: D. Nephritic syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario of a male with fatigue , weight loss , abdominal discomfort , swelling in the left upper quadrant (splenomegaly), and a history of multiple myeloma is suggestive of AL amyloidosis . Nephritic syndrome is not associated with this condition, rather, nephrotic syndrome can be seen. Sago spleen (Option A): It refers to amyloid deposits largely limited to the splenic follicles (white pulp), producing tapioca-like granules on gross inspection. Lardaceous spleen (Option B): This involves amyloid deposition in the walls of the splenic sinuses and connective tissue framework in the red pulp. Carpal tunnel syndrome (Option C): Can be associated with amyloidosis, especially in patients on long-term hemodialysis due to amyloid deposition in the carpal ligament. Nephrotic syndrome: Amyloidosis more commonly causes nephrotic syndrome (not nephritic) due to glomerular amyloid deposition. Nephritic syndrome is characterised by inflammation, while amyloidosis involves protein deposition without significant inflammation. The image below shows a histopathological biopsy of renal amyloidosis.



References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page no. 263,264

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 60-year-old man with poorly controlled hypertension and diabetes presents with fatigue, shortness of breath, ankle swelling, hepatomegaly, and bilateral lower extremity oedema. Labs show proteinuria and elevated serum creatinine. Which staining technique is most appropriate to confirm the diagnosis? (Q845458)

A. Periodic acid Schiff (PAS) stain

B. Masson trichome stain

C. Congo red stain

D. Oil red O

Correct Answer: C. Congo red stain

Explanation: The clinical presentation of a patient with poorly controlled diabetes and hypertension, hepatomegaly, bilateral lower extremity oedema, proteinuria, and elevated serum creatinine highly point towards a diagnosis of AA amyloidosis , where chronic inflammation leads to the production of SAA , resulting in amyloid deposition in various organs. Congo red stain is the most appropriate technique to confirm the diagnosis of amyloidosis. Detection Feature Gross stain Lugol's iodine Mahogany brown colour Microscopic stain 1. Congo red (Best stain) Light microscopy: Salmon pink Polarizing microscopy: Apple Green birefringence 2. Thioflavin T Require UV light to visualize it under microscope 3. Methyl Violet 4. Crystal Violet 5. PAS The given images below show Congo red staining in amyloidosis. Periodic acid Schiff (PAS) stain(Option A): While positive for amyloid, it's not specific and less commonly used for diagnosis. Masson trichrome stain(Option B): Primarily used for connective tissue (collagen appears blue, smooth muscles appear red, the nucleus appears black), not specific for amyloid. Oil red O(Option D): Used for lipids, not applicable for amyloid detection.

Q1: Which immune cells primarily mediate acute cellular rejection of a kidney allograft? (Q879941)

A. B cells producing preformed antibodies

B. CD8■ cytotoxic T lymphocytes and CD4■ helper T cells

C. Natural killer (NK) cells only

D. Macrophages without T cell involvement

Correct Answer: B. CD8■ cytotoxic T lymphocytes and CD4■ helper T cells

Explanation: Acute cellular rejection is mediated mainly by T cells: CD8■ cytotoxic T lymphocytes (CTLs) directly kill graft cells expressing alloantigens. CD4■ helper T cells secrete cytokines that recruit and activate other inflammatory cells, causing tissue damage. Acute antibody-mediated (humoral) rejection involves antibodies binding to graft endothelium, activating complement. Hyperacute rejection is mediated by preformed antibodies (often IgM) causing immediate endothelial injury. Chronic rejection involves T cells and alloantibodies promoting fibrosis and graft arteriosclerosis over months to years. Incorrect Options: B cells producing preformed antibodies (Option A) : These are primarily involved in hyperacute rejection , not acute cellular rejection. Natural killer (NK) cells only (Option C) : NK cells may play a minor role but are not the primary mediators of acute cellular rejection. Macrophages without T cell involvement (Option D) : Macrophages are involved in inflammation, but they require activation by T cells ; they don’t mediate acute rejection independently.

References:

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 209-210

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A kidney transplant patient develops sudden anuria immediately after reperfusion. The graft is cyanotic and mottled. Biopsy shows fibrinoid necrosis of

arteries and thrombi in arterioles, with neutrophilic infiltration. What type of rejection is most likely? (Q879955)

A. Hyperacute rejection

B. Acute cellular (T cell–mediated) rejection

C. Acute antibody-mediated rejection

D. Chronic rejection

Correct Answer: A. Hyperacute rejection

Explanation: Hyperacute rejection occurs immediately after transplantation due to preformed antibodies against donor antigens. Pathologic features: Fibrinoid necrosis of arteries and arterioles Thrombosis of small vessels Neutrophilic infiltration Clinically, the graft is nonfunctional and must be removed. Incorrect Options: Acute cellular rejection (Option B) occurs days to weeks later, mediated by CD8■ and CD4■ T cells, with tubulitis and endotheliitis. Acute antibody-mediated rejection (Option C) involves antibody and complement deposition (C4d) in glomeruli and peritubular capillaries. Chronic rejection (Option D) develops over months to years, with interstitial fibrosis, vascular occlusion, and glomerulopathy

@Neet_pg_bot

Q3: Which of the following organs are primarily affected in acute graft-versus-host disease (GVHD)? (Q879962)

A. Skin, liver (bile ducts), and intestines

B. Heart, lungs, and kidneys

C. Brain, pancreas, and spleen

D. Lymph nodes and bone marrow only

Correct Answer: A. Skin, liver (bile ducts), and intestines

Explanation: Acute GVHD occurs days to weeks after allogeneic HSC transplant. Major target organs: Skin : lymphocyte infiltration and keratinocyte apoptosis → rash (neck, ears, palms, soles, then generalized) Liver : destruction of small bile ducts → cholestatic jaundice Gut : mucosal ulceration → bloody diarrhea Chronic GVHD can involve additional systemic features (skin fibrosis, thymic involution, autoimmunity).

Robbins, Cotran & Kumar Pathologic Basis of Disease, 11th Edition, Page. 211-212

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 20-year-old girl was diagnosed with acute lymphoblastic leukaemia (ALL). Her medical team has determined that a bone marrow transplant is necessary to achieve remission and prevent disease recurrence. She has an identical twin sister, who is an eligible donor. What type of grafting was done on this patient? (Q845524)

A. Allograft

B. Autograft

C. Isograft

D. Xenograft

Correct Answer: C. Isograft

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A graft from an identical twin donor is called an isograft. An isograft is an organ or tissue taken from a donor and transplanted to a recipient with the same genetic constitution as the donor. Type of Graft Description Autograft (Option B) An organ or tissue is taken from an individual and grafted on him/ herself Isograft Grafts between genetically identical individuals, such as identical twins Allograft (Option A) Graft between two genetically non-identical members of the same species (e.g. organ transplants between two non-identical and compatible individuals. Xenograft (Option D) Graft from one species to another (e.g., pig skin is a temporary substitute for burn treatment). Synthetic Graft Artificial materials or bioengineered constructs replace or support damaged tissue (e.g., artificial skin substitutes, bone graft substitutes).

Ananthanarayan and Paniker's Textbook of Microbiology, 10th Edition, Pages 185-186

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: What is the minimum HLA matching that should be achieved to proceed with the transplant in the pediatric population? (Q845526)

A. 4/6

B. 6/6

C. 6/8

D. 8/10

Correct Answer: A. 4/6

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Three alleles from each parent (hence, 6) are required in a pediatric group for allogeneic transplants, including HLA-A, HLA-B, and HLA-DR . In children, a match of at least 4/6 genes involving HLA-A, B, and DR is required to proceed for grafting.. Identical twins will always have complete 6/6 matching genes.

www.uptodate.com/contents/kidney-transplantation-in-adults-hla-matching-and-outcomes

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 35-year-old woman with end-stage renal disease recently received a compatible donor organ from her brother. The kidney transplant surgery proceeds as planned, but within minutes of reperfusion, the kidney becomes mottled, cyanotic and anuric. What is the cause for this presentation? (Q845528)

A. Preformed antibodies in the donor

B. Preformed antibodies in the recipient

C. Cytotoxic T-lymphocyte-mediated injury

D. CD4+ cells mediated inflammation

Correct Answer: B. Preformed antibodies in the recipient

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario suggests hyperacute graft rejection due to preformed antibodies in the recipient. Hyperacute Graft Rejection Hyperacute Graft Rejection is the most rapid and catastrophic form of graft rejection, occurring immediately on the operating table or within the first 48 hours of transplantation. Pathogenesis: Hyperacute rejection is caused by preformed circulating IgG antibodies against donor antigens (mainly HLA or ABO), which may arise from prior pregnancies, multiple blood transfusions, or previous organ transplants. Mechanism: Preformed antibodies bind to donor endothelial antigens, activating complement and causing widespread thrombosis, vascular occlusion, ischemia, and graft necrosis, leading to a kidney that rapidly becomes cyanotic, flaccid, and anuric (sometimes with a few drops of blood). Clinical features: Hyperacute rejection presents with a mottled blue ischemic kidney, loss of graft tone, and absent urine output (anuria) or occasionally hematuria (few drops of blood). Immunologically, hyperacute rejection represents a Type II hypersensitivity reaction mediated by antibodies .

Robbins and Cotran Pathologic Basis of Disease, 10th edition, page no. 235-236

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 45-year-old man, two weeks post-kidney transplant, presents with sudden oliguria, fever, and graft site swelling. Biopsy shows glomerular and peritubular capillary inflammation with complement deposition. What is the most likely diagnosis? (Q845530)

A. Acute humoral rejection

B. Acute calcineurin inhibitor nephrotoxicity

C. Acute cellular rejection

D. BK virus infection

Correct Answer: A. Acute humoral rejection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Acute humoral rejection, also known as acute antibody-mediated rejection (ABMR), is the most likely diagnosis. Acute rejection occurs days to weeks after transplant. It is of 2 types: Acute humoral rejection → mediated by antibodies. Acute cellular rejection (option 3) → cell-mediated by T-lymphocytes. Acute humoral rejection: Newly formed antibodies cause damage to kidneys leading to inflammation. This damage to kidneys activates the complement system and the C4d complement gets deposited around the peritubular capillaries. C4d complement is the marker of acute humoral rejection. Incorrect options: Acute Calcineurin Inhibitor (CNI) Nephrotoxicity (option 2) Presents with sudden rise in creatinine, hypertension, and vasoconstriction Biopsy

shows arteriolar hyalinosis, isometric tubular vacuolization. BK Virus Infection (option 4) Occurs 2–12 months post-transplant Biopsy shows viral inclusions in tubular epithelial cells (“decoy cells”), tubulointerstitial nephritis, not glomerular or peritubular capillary inflammation. No C4d complement deposition.

Robbins and Cotran Pathologic Basis of Disease 10th edition, Page236 Cyclosporine and tacrolimus nephrotoxicity - UpToDate BK Virus Nephropathy in Kidney Transplantation: A State-of-the-Art Review - PMC (nih.gov)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 45-year-old male patient presents with a widespread rash, severe diarrhoea, and jaundice. He underwent bonemarrow transplantation for acute myeloid leukaemia and received cells from a matched, unrelated donor. Which is the most likely diagnosis? (Q845531)

A. Acute transplant rejection

B. Chronic transplant rejection

C. Graft-versus-host disease

D. Immune reconstitution inflammatory syndrome

Correct Answer: C. Graft-versus-host disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical presentation and history of hematopoietic stem cell (HSC) transplant suggests that the patient most likely has graft-versus-host disease (GVHD) Graft-versus-Host Disease (GVHD) : The three key organs involved in GVHD are Skin (rash), Intestine (diarrhoea) and Liver (jaundice). GVHD is like a war between the graft and the host . Mechanism: Graft (donor marrow) → rich in immunocompetent T-cells Host (recipient) → immunocompromised (due to cancer + immunosuppressive drugs) The immunocompetent graft cells will attack the weaker host tissues, most commonly affecting the skin, intestine, and liver. Tupes of GVHD: Acute GVHD : Occurs within the first 100 days of transplant. Chronic GVHD : Occurs ≥100 days post-transplant.

References:

Robbins and Cotran Pathologic Basis of Disease 10th edition, Page 239 Immune Reconstitution Inflammatory Syndrome - StatPearls - NCBI Bookshelf (nih.gov)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 55-year-old male patient who has undergone kidney transplantation is now presenting with signs of renal dysfunction. Which complement activation product is a known histological marker for the diagnosis of antibody-mediated rejection in transplant biopsies? (Q845532)

A. C3d

B. C5a

C. C3b

D. C4d

Correct Answer: D. C4d

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Antibody-mediated rejection means humoral rejection. Types of acute graft rejection: Acute humoral rejection (antibody-mediated). Acute cellular rejection (cell-mediated). Mechanism: In a cute humoral rejection, the recipient forms new antibodies against donor tissue. These antibodies activate the complement system, which produces C4d. C4d deposition around tubules and capillaries serves as a key marker of acute humoral (antibody-mediated) rejection. Image: Immunoperoxidase stain shows C4d deposition in peritubular capillaries and a glomerulus.

Robbins and Cotran Pathologic Basis of Disease 10th ed page 580, 238.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A patient presented with oliguria for the last three days. She is a known case of diabetic nephropathy and underwent an allogeneic renal transplant four years ago. The physician suspects a possibility of graft rejection. Which of the following is not true regarding the suspected condition in this patient? (Q845533)

A. Predominantly antibody-mediated reaction

B. Manifests as interstitial fibrosis and narrowing of graft blood vessels

C. HPE shows duplication of the basement membrane

D. Its morphologic correlate in the lung is bronchiolitis obliterans

Correct Answer: A. Predominantly antibody-mediated reaction

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: An allogenic transplant refers to a transplant between members of the same species, and the development of symptoms 4 years post-transplant indicates chronic graft rejection. Morphological hallmark features of chronic renal graft rejection (GOTI): G → Glomerular Basement Membrane Duplication (Option C) . O → Obliteration of blood vessels. T → Tubular atrophy. I → Interstitial fibrosis (Option B) . In lung transplant , chronic graft rejection morphologically correlates with bronchiolitis obliterans (Option D) . Chronic rejection is a Type IV hypersensitivity reaction, driven mainly by T-cell–mediated immune responses rather than antibodies (Option A) . Graft arteriosclerosis is caused by T-cell cytokines and antibody deposition in chronic graft rejection.

Q37 (p. 1609)					

Q1: A 78-year-old male presents with fatigue, breathlessness, and palpitations. On examination, he has pedal oedema, with a pulse rate of 55 bpm, BP of 100/70 mmHg, and oxygen saturation of 94%. ECG is normal, and echocardiography reveals restrictive cardiomyopathy. A cardiac biopsy stained with Congo red shows apple-green birefringence under polarised light. What is the most likely diagnosis? (Q857590)

A. Heart failure

B. Cardiac amyloidosis

C. Hemosiderosis

D. Dystrophic calcification

Correct Answer: B. Cardiac amyloidosis

Explanation: The hallmark feature is apple-green birefringence under polarised light after Congo red staining, characteristic of amyloid deposits. Cardiac amyloidosis causes restrictive cardiomyopathy, presenting with symptoms like fatigue, breathlessness, and oedema. Congo red stain identifies amyloid fibrils in tissue. {{caption_text}} Amyloidosis is abnormal extracellular deposits of fibrillar proteins that cause tissue damage and functional compromise. These proteins are misfolded and aggregate, forming amyloid deposits. Amyloid deposits appear as eosinophilic, hyaline, and extracellular substances on hematoxylin and eosin stains. They are confirmed by Congo red staining, which shows red under ordinary light and apple-green birefringence under polarised light. Morphology: Amyloid deposition is often widespread, but organ involvement can vary: Kidney: Most commonly and severely affected, with amyloid deposits in the glomeruli, arteries, and arterioles. Spleen: Enlarged, showing two patterns of amyloid deposits: "sago spleen" (follicular) and "lardaceous spleen" (sinusoidal). Liver: Amyloid deposits in the space of Disse; liver function is generally preserved despite enlargement. Heart: Commonly

involved in senile systemic amyloidosis, with deposits starting subendocardially and in the myocardium. Other organs: May include the tongue (macroglossia), lungs (respiratory tract involvement), and brain (Alzheimer's plaques). Types: Type of Amyloidosis Amyloid Protein Associated Conditions Primary Amyloidosis (AL) Amyloid Light Chain (AL) Plasma cell disorders (e.g., multiple myeloma) Secondary Amyloidosis (AA) Amyloid-Associated (AA) Chronic inflammation (e.g., rheumatoid arthritis, IBD) Hereditary Amyloidosis Transthyretin (TTR) Familial amyloid polyneuropathies (e.g., familial Mediterranean fever) Hemodialysis-Associated β2-Microglobulin Long-term hemodialysis Senile Systemic Amyloidosis Transthyretin (TTR) Ageing, mutations in TTR Localised Amyloidosis Varies (often AL type) Specific organs (e.g., tongue, lung, skin, bladder) Endocrine Amyloidosis Medullary thyroid carcinoma (Acal) Endocrine tumours (e.g., medullary thyroid carcinoma, pancreatic islet tumours)

@Neet_pg_bot

Q2: In a patient with Bare Lymphocyte Syndrome, graft-versus-host disease (GVHD) does not occur. Which of the following causes it? (Q855987)

A. Complement deficiency

B. Deficiency of CD4 T lymphocytes

C. MHC Class II deficiency in lymphocytes

D. MHC Class I deficiency in lymphocytes

Correct Answer: C. MHC Class II deficiency in lymphocytes

Explanation: Bare Lymphocyte Syndrome (BLS) caused by MHC Class II deficiency (most common form) prevents the development of CD4+ T cells , which are essential for initiating graft-versus-host disease (GVHD). Bare Lymphocyte Syndrome: Typically caused by mutations in transcription factors essential for the expression of Class II MHC genes . The absence of Class II MHC molecules leads to the underdevelopment of CD4+ T cells , which play a crucial role in cellular immunity and assist B cells. As a result, Class II MHC deficiency results in a combined immunodeficiency. Additionally, other forms of the syndrome can be caused by mutations in antigen receptor chains or signalling molecules critical for the maturation of T or B cells. Complement deficiency (Option A) does not affect T cell function or MHC expression, making it unrelated to GVHD, which requires donor T cell recognition of host MHC. Deficiency of CD4 T lymphocytes (Option B) is a secondary effect, not the cause of bare lymphocyte syndrome or prevention of GVHD. MHC Class I deficiency in lymphocytes (Option D) affects CD8■ T cell function but does not significantly impair CD4■ T cell-mediated GVHD, which relies on MHC Class II recognition.

@Neet_pg_bot

Q3: Which of the following is not a part of innate immunity? (Q855074)

A. Alpha defensins

B. B lymphocytes

C. Gamma delta T lymphocytes

D. Alternate pathway

Correct Answer: B. B lymphocytes

Explanation: B cells are antigen-specific immune cells. They require antigen recognition and T-cell help for activation. They undergo clonal expansion and antibody production. These features belong to adaptive immunity, not innate immunity. Incorrect Options: Option A) Alpha-defensins : Antimicrobial peptides from neutrophils & Paneth cells. Directly kill microbes without prior exposure. Part of innate immunity. Option C) Gamma-delta T lymphocytes : Act quickly and do not require classical antigen presentation. Recognize stress antigens and provide

early defense. Considered innate-like immunity. Option D) Alternate complement pathway: Triggered directly by microbial surfaces. Does not require antibodies for activation. A major component of innate immunity.

@Neet_pg_bot

Q4: Which of the following cytokines is not involved in the Th1 response? (Q855089)

A. IFN gamma

B. IL-2

C. IL-12

D. IL-4

Correct Answer: D. IL-4

Explanation: IL-4 is primarily associated with the Th2 response , not the Th1 response. It promotes the differentiation of T cells into Th2 cells and is involved in humoral immunity and allergic responses. Subtype Function and Characteristics Key Cytokines TH1 Involved in chronic inflammatory diseases. Activated by IL-12 (Option C) from APCs. Secrete IFN-gamma, activating macrophages. Stimulates macrophages to form epithelioid cells and giant cells. IFN-gamma (Option A) IL-2 (Option B) TH2 Responsible for the alternative pathway of macrophage activation. Release cytokines IL-4 , IL-5, and IL-13. To expel parasites from the body, stimulate eosinophil activation, antibody production (especially IgE), and mucus production. IL-4 , IL-5, IL-13 TH17 Defend against extracellular bacteria and fungi. Secrete IL-17 and IL-22, attracting neutrophils and monocytes. IL-17, IL-22 Treg (T regulatory) It suppresses immune response and maintains homeostasis and self-tolerance. Inhibit T cell proliferation and cytokine production, preventing autoimmune reaction. IL-10, TGF-beta Tfh (Follicular T helper) Assist B cells in rapid proliferation and antibody production. Help produce antibodies with greater affinity. IL-21 {{caption_text}}

@Neet_pg_bot

Q5: A person was brought to the emergency department with facial swelling, itching, and hypotension following a bee sting. The mentioned clinical features are due to the increase in which of the following immunoglobulins? (Q857097)

A. IgA

B. IgE

C. IgM

D. IgG

Correct Answer: B. IgE

Explanation: The clinical features of facial swelling, itching, and hypotension suggest anaphylaxis, an allergic reaction mediated by IgE antibodies that trigger the release of histamine and other inflammatory mediators from mast cells and basophils upon exposure to an allergen, such as a bee sting. Type I hypersensitivity reactions involve an immediate (early) and a late-phase reaction. Early phase reaction Late phase reaction Onset Immediate (within minutes of allergen exposure). Delayed (several hours after exposure) and can last for days. Cells involved Mast cells, basophils. Eosinophils, T lymphocytes. Cellular events Activation of mast cells and basophils. Recruitment and activation of leukocytes, especially eosinophils. Mediators Histamine , leukotrienes (LTB4, LTC4, LTD4), prostaglandins (PGD2) and Platelet-activating factor (PAF). Cytokines (e.g., IL-4, IL-5, TNF), chemokines (e.g., eotaxin). Initiating event Exposure to allergen triggers cross-linking of IgE on mast cells/basophils. Recurrent inflammation, sustained by recruited leukocytes. Effect on tissues Vasodilation, increased vascular permeability, smooth muscle contraction. Sustained inflammation and tissue damage due to leukocyte infiltration. Clinical manifestations Allergic rhinitis (hay fever), urticaria (hives), Angioedema bronchoconstriction. Allergic asthma exacerbation, persistent inflammation, and tissue damage. Therapeutic Approach Antihistamines for symptomatic relief. Adrenaline in anaphylactic shock. Broad-spectrum anti-inflammatory drugs (e.g., steroids) to suppress inflammation and prevent tissue damage. IgA (Option A) primarily involves mucosal immunity and protects against pathogens at mucosal surfaces (e.g., in the respiratory and gastrointestinal tracts), not in allergic reactions. IgM (Option C) is the first antibody produced in response to infection but is not involved in allergic reactions like those caused by bee stings. IgG (Option D) plays a crucial role in immunity and neutralising toxins, but it is not the primary immunoglobulin involved in allergic reactions, which are driven by IgE.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 205-208

↑ *Back to this question in Part A*

Q6: A Rh-negative mother delivered an Rh-positive baby, and Coomb's test was positive for the baby. What is the mechanism of hypersensitivity seen in this scenario? (Q857100)

A. Antigen-dependent cellular cytotoxicity

B. Antibody-dependent cellular cytotoxicity

C. Antigen-antibody immune complex deposition

D. CD4 T-cell-mediated cytokine release

Correct Answer: B. Antibody-dependent cellular cytotoxicity

Explanation: This scenario involves Type II hypersensitivity, where the Rh-negative mother's immune system produces IgG antibodies against her fetus's Rh-positive red blood cells. These antibodies cross the placenta and bind to the fetal red blood cells, initiating their destruction by activating immune cells through antibody-dependent cellular cytotoxicity (ADCC). This leads to hemolytic disease in the newborn and results in a positive Coomb's test, which detects antibodies bound to the fetal red blood cells. Mechanisms of Type II hypersensitivity Description Examples Opsonisation and Phagocytosis IgG antibodies coat cells, helping phagocytes recognise circulating antigen-opsonin complexes through Fc receptors or complement activation, leading to phagocytosis. Autoimmune hemolytic anemia Immune thrombocytopenic purpura Rh hemolytic disease of the newborn . Complement activation and inflammation Antibody deposition in extracellular tissues triggers inflammation rather than phagocytosis or cell lysis. The deposited antibodies activate the complement system, attracting neutrophils and monocytes via their Fc receptors. Activated leukocytes release enzymes, causing tissue damage. Goodpasture syndrome. Acute rheumatic fever. Antibody-dependent cellular cytotoxicity (ADCC) Natural killer cells bind to antibody-antigen complexes, inducing apoptotic cell death. Pernicious anemia Insulin resistant diabetes Antibody-mediated cellular dysfunction (non-cytotoxic) Antibodies physically impair or dysregulate cellular function by binding to cell surface receptors. This includes both activation (e.g., thyroid hormone receptor in Graves disease) and inhibition (e.g., acetylcholine receptor in Myasthenia gravis). Graves disease Myasthenia gravis Note: Myasthenia gravis and Graves disease are now classified as Type V hypersensitivity (Type V > Type II) Type V hypersensitivity reaction: Antibodies against cellular receptors. Mnemonic: My Blood Group Is Rh Positive My Myasthenia Gravis Blood Blood transfusion reaction Group Good pasture syndrome, Graves disease Is Immune hemolytic anaemia, Immune thrombocytopenic purpura R Rh incompatibility , Rheumatic fever H Hyperacute transplant rejection Positive Pemphigus (Bullous), Pernicious Anemia Type II hypersensitivity (Antibody-mediated) Opsonisation and complement activation→Phagocytosis Transfusion reaction, erythroblastosis fetalis , AIHA, ITP. Complement, F c receptor-mediated →Inflammation. Goodpasture syndrome, Acute Rheumatic fever, vascular rejections, vasculitis. Antibody-mediated cellular dysfunctions. Myasthenia gravis, Pemphigus Vulgaris, Graves disease, Pernicious Anemia, Insulin-resistant diabetes, Hemolytic disease of the newborn.

@Neet_pg_bot

Q7: Which of the following conditions is associated with hypocalcemia, thymic hypoplasia, cardiac abnormalities, and deletion of chromosome 22q11.2? (Q857124)

A. Williams syndrome

B. Pitt syndrome

C. DiGeorge syndrome

D. Cri-du-chat syndrome

Correct Answer: C. DiGeorge syndrome

Explanation: DiGeorge syndrome (22q11.2 deletion syndrome) is caused by a deletion on the long arm of chromosome 22. It is characterised by hypocalcemia, thymic hypoplasia, and cardiac abnormalities and occurs in 1 in 4000 births. The condition is often overlooked due to its variable clinical features. These features include: Congenital heart defects Abnormalities of the palate Facial dysmorphism Developmental delay T-cell immunodeficiency Hypocalcemia Key features: Thymic hypoplasia leading to T-cell immunodeficiency Parathyroid hypoplasia causing hypocalcemia Cardiac malformations affecting the outflow tract Facial anomalies (e.g., mild facial dysmorphology) Diagnosis: The condition is suspected clinically but confirmed by FISH (Fluorescence in situ hybridisation) testing. Around 90% of DiGeorge syndrome and 80% of velocardiofacial syndrome cases show the 22q11.2 deletion. This test can also identify deletions in individuals with conotruncal cardiac defects but no other features of the syndrome. Williams Syndrome (Option A) is a genetic disorder caused by a deletion on chromosome 7 , not 22q11.2. It is characterised by cardiovascular problems, developmental delays, and distinctive facial features, but it does not involve thymic hypoplasia, cardiac abnormalities like those seen in DiGeorge syndrome, or hypocalcemia. Pitt Syndrome (Option B) is a rare genetic condition linked to mutations in the FLNA gene, leading to developmental and cardiac abnormalities. It doesn’t involve the same chromosome 22q11.2 deletion or the associated features of thymic hypoplasia, immunodeficiency, or hypocalcemia seen in DiGeorge syndrome. Cri-du-chat Syndrome (Option D) is caused by a deletion on the short arm of chromosome 5. The main features include a distinctive high-pitched cry, intellectual disability, and certain facial features, but it does not include the hallmark features of DiGeorge syndrome, such as thymic hypoplasia, cardiac defects, and hypocalcemia.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 169

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 24-year-old female patient presented with a malar rash, recurrent oral ulcers, and multiple joint pains. She has a relevant past history and does not take any medication. Upon further investigations, thrombocytopenia was seen, and the anti-Smith (anti-Sm) antibody was positive. What is the most likely diagnosis? (Q857140)

A. Scleroderma

B. Sjögren syndrome

C. Systemic lupus erythematosus (SLE)

D. Rheumatoid arthritis

Correct Answer: C. Systemic lupus erythematosus (SLE)

Explanation: The most likely diagnosis is Systemic Lupus Erythematosus (SLE) , an autoimmune disorder that commonly affects young women and presents with features such as: Malar rash (butterfly-shaped rash over the cheeks and nose), Recurrent oral ulcers , Joint pain (often non-erosive arthritis), Thrombocytopenia , Positive anti-Smith (anti-Sm) antibodies , which are highly specific for SLE. While scleroderma , Sjögren syndrome , and rheumatoid arthritis share overlapping symptoms, the positive anti-Sm antibody is most specific to SLE, confirming the diagnosis. SLE is a chronic autoimmune disease with the production of many antibodies like antinuclear antibodies (ANAs), anti-double-stranded DNA (dsDNA), and anti-Smith (Sm). These autoantibodies form immune complexes that deposit in tissues, causing inflammation and damage. It is more common in women. Clinical Manifestations of SLE: Skin: Malar rash (butterfly rash), photosensitivity, discoid lesions, and mucosal ulcers. Joints: Non-erosive arthritis commonly affects the hands, wrists, and knees. Renal: Lupus nephritis ranging from asymptomatic proteinuria to severe kidney failure. The major cause of morbidity and mortality in SLE. Cardiovascular: Pericarditis, myocarditis, increased risk of atherosclerosis and coronary artery disease. Pulmonary: Pleurisy and pleural effusion, pulmonary hypertension and interstitial lung. Neurologic: Neuropsychiatric symptoms ranging from headaches and cognitive dysfunction to seizures and psychosis. Hematologic: Anemia, leukopenia, and thrombocytopenia. The risk of thrombotic events is increased. Marker/Antibody Clinical Significance Anti-Smith (anti-Sm) antibodies Highly specific for SLE (<30% of patients) Anti-dsDNA antibodies Highly specific for SLE (60-70% of patients); correlates with the disease Antinuclear antibodies (ANA) Highly sensitive but not specific for SLE Anti-Ro (SSA) and Anti-La (SSB) antibodies Found in SLE and Sjögren syndrome; associated with neonatal lupus Anti-ribosomal-P antibodies Specific for neuropsychiatric manifestations in SLE Anti-histone antibodies Seen in drug-induced lupus; less specific for SLE Complements C3 and C4 Low levels indicate complement consumption and disease activity

Q9: Xenograft is: (Q857173)

A. Graft across species

B. Grafts from the same species

C. Graft from the same individual

D. Graft between genetically identical individuals

Correct Answer: A. Graft across species

Explanation: Type of Graft Description Autograft An organ or tissue is taken from an individual and grafted on him/ herself (Option C ruled out) Isograft Grafts between genetically identical individuals, such as identical twins (Option D ruled out) Allograft Graft between two genetically non-identical members of the same species (e.g.

organ transplants between two non-identical and compatible individuals. (Option B ruled out) Xenograft Graft from one species to another (e.g., pig skin is a temporary substitute for burn treatment). (Option A) Synthetic Graft Artificial materials or bioengineered constructs replace or support damaged tissue (e.g., artificial skin substitutes, bone graft substitutes).

@Neet_pg_bot

Q10: A child, upon disturbing a bee hive, had several stings. After a few minutes, the child developed symptoms of shock, respiratory failure, and vascular collapse. Which of the following is the principal mediator of this reaction? (Q857559)

A. Adrenaline

B. Histamine

C. Dopamine

D. Substance P

Correct Answer: B. Histamine

Explanation: The reaction indicates anaphylaxis , a severe allergic response to bee stings. Histamine, released by mast cells and basophils, is the principal mediator, causing vasodilation, increased vascular permeability, bronchoconstriction, and smooth muscle contraction, leading to shock, respiratory failure, and vascular collapse. Type I hypersensitivity reactions involve an immediate (early) and a late-phase reaction. Early phase reaction Late phase reaction Onset Immediate (within minutes of allergen exposure). Delayed (several hours after exposure) and can last for days. Cells involved Mast cells, basophils. Eosinophils, T lymphocytes. Cellular events Activation of mast cells and basophils. Recruitment and activation of leukocytes, especially eosinophils. Mediators Histamine , leukotrienes (LTB4, LTC4, LTD4), prostaglandins (PGD2) and Platelet-activating factor (PAF). Cytokines (e.g., IL-4, IL-5, TNF), chemokines (e.g., eotaxin). Initiating event Exposure to allergen triggers cross-linking of IgE on mast cells/basophils. Recurrent inflammation, sustained by recruited leukocytes. Effect on tissues Vasodilation, increased vascular permeability, smooth muscle contraction. Sustained inflammation and tissue damage due to leukocyte infiltration. Clinical manifestations Allergic rhinitis (hay fever), urticaria (hives), Angioedema bronchoconstriction. Allergic asthma exacerbation, persistent inflammation, and tissue damage. Therapeutic Approach Antihistamines for symptomatic relief. Adrenaline in anaphylactic shock. Broad-spectrum anti-inflammatory drugs (e.g., steroids) to suppress inflammation and prevent tissue damage. {{caption_text}}

@Neet_pg_bot

Q11: A boy presents with recurrent episodes of melena. On examination, there is eczema of the skin with multiple petechiae. His platelet count is low, with normal RBC and WBC counts. Which of the following is the diagnostic investigation for this patient? (Q855956)

A. WASP gene mutation

B. Anti-platelet antibodies

C. Bone marrow biopsy

D. Electron microscopy

Correct Answer: A. WASP gene mutation

Explanation: The patient's presentation of recurrent melena (indicative of gastrointestinal bleeding), eczema, petechiae (small skin haemorrhages), and low platelet count with normal RBC and WBC counts suggests Wiskott-Aldrich Syndrome (WAS) , an X-linked recessive disease characterized by the triad of: Thrombocytopenia Eczema Recurrent infections It is caused by mutations in the gene located at Xp11.23, which encodes the Wiskott-Aldrich syndrome protein (WASP). WASP belongs to a family of proteins that are believed to link membrane receptors, such as antigen receptors, to cytoskeletal elements. IgM levels in the serum are low , but levels of IgG are usually normal. Paradoxically, the levels of IgA and IgE are often elevated . Patients are also prone to developing B-cell lymphomas. WASP may be involved in cytoskeleton-dependent responses, including cell migration and signal transduction. It may lead to early death. The only treatment is hematopoietic stem cell (HSC) transplantation . Anti-platelet antibodies (Option B) are typically found in conditions like immune thrombocytopenic purpura (ITP), but the patient's history and presentation point more toward WAS. Bone marrow biopsy (Option C) is generally used to assess hematologic disorders like leukaemia or myelodysplastic syndromes, which do not match this case. Electron microscopy (Option D) is helpful for diagnosing certain intracellular abnormalities, but it's not the first diagnostic test for WAS.

@Neet_pg_bot

Q12: Which of the following mediators is involved in the early phase of type 1 hypersensitivity? Mast cell Histamine Neutrophils Prostaglandins Leukotrienes (Q855445)

A. 1, 5

B. 1, 2, 3, 4

C. 1, 2, 4, 5

D. 2, 3, 4

Correct Answer: C. 1, 2, 4, 5

Explanation: The mediators involved in the early phase of Type 1 Hypersensitivity include mast cells, histamine, prostaglandins, and leukotrienes. Mast cells Histamine Prostaglandins Leukotrienes Primary effector cells. Activated by allergens cross-linking with IgE antibodies. Released by mast cells. Causes vasodilation, increased vascular permeability, smooth muscle contraction, and mucus production. They are lipid mediators released by mast cells. Contribute to vasodilation, vascular permeability, and bronchoconstriction. A group of lipid mediators released by mast cells. Promote bronchoconstriction, increased vascular permeability, and the recruitment of other inflammatory cells. It involves an immediate (early) and a late-phase reaction. Early phase reaction Late phase reaction Onset Immediate (within minutes of allergen exposure). Delayed (several hours after exposure) and can last for days. Cells involved Mast cells, basophils. Eosinophils, T lymphocytes. Cellular events Activation of mast

cells and basophils. Recruitment and activation of leukocytes, especially eosinophils. Mediators Histamine, leukotrienes (LTB4, LTC4, LTD4), prostaglandins (PGD2) and Platelet-activating factor (PAF). Cytokines (e.g., IL-4, IL-5, TNF), chemokines (e.g., eotaxin) Initiating event Exposure to allergen triggers cross-linking of IgE on mast cells/basophils. Recurrent inflammation, sustained by recruited leukocytes. Effect on tissues Vasodilation, increased vascular permeability, smooth muscle contraction. Sustained inflammation and tissue damage due to leukocyte infiltration. Clinical manifestations Allergic rhinitis (hay fever), urticaria (hives), Angioedema bronchoconstriction. Allergic asthma exacerbation, persistent inflammation, and tissue damage. Therapeutic Approach Antihistamines for symptomatic relief. Adrenaline in anaphylactic shock Broad-spectrum anti-inflammatory drugs (e.g., steroids) to suppress inflammation and prevent tissue damage. {{caption_text}}

@Neet_pg_bot

Q13: A person was brought to the emergency department with facial swelling, itching, and hypotension following a bee sting. The mentioned clinical features are due to an increase in which immunoglobulin? (Q856690)

A. IgA

B. IgE

C. IgM

D. IgG

Correct Answer: B. IgE

Explanation: The clinical features of facial swelling, itching, and hypotension following a bee sting are due to an Allergic Reaction (Type 1 Hypersensitivity Reaction) mediated by the immune system, particularly through IgE (Immunoglobulin E) antibodies. IgE plays a key role in allergic responses by binding to receptors on mast cells and basophils after exposure to an allergen, like bee venom. Upon re-exposure to the allergen, it binds to IgE on mast cells and basophils, triggering the release of histamine, leukotrienes, and prostaglandins, which cause the symptoms. Symptoms: Characteristic symptoms of an allergic reaction are: Facial swelling (angioedema) Itching, and Hypotension. Histamine causes blood vessel dilation and increased permeability, leading to facial swelling and itching. In severe cases, it can induce hypotension and trigger anaphylaxis. IgA (Option A) is primarily involved in mucosal immunity, protecting the mucous membranes of the respiratory, digestive, and genitourinary tracts. It is not typically associated with immediate hypersensitivity reactions like those seen in response to bee stings. IgM (Option C) is the first antibody produced during an immune response. It is involved in the primary immune response and is not specifically associated with allergic reactions or the symptoms described in the scenario. IgG (Option D) is the most abundant antibody in the bloodstream and is involved in long-term immunity. While IgG can play a role in some types of allergic reactions, it is not the primary immunoglobulin responsible for the immediate hypersensitivity reactions seen in response to a bee sting.

@Neet_pg_bot

Q14: Isotype switching is seen in: (Q856894)

A. Helper T cells

B. Activated B cells

C. Cytotoxic T cells

D. B cells

Correct Answer: B. Activated B cells

Explanation: Isotype switching , also known as class switching, occurs in activated B cells . This process allows B cells to produce different classes of antibodies (e.g., IgM, IgG, IgA, IgE) in response to specific signals, such as cytokines from helper T cells, during an immune response. Isotype switching , also referred to as class switching or immunoglobulin class switch recombination (CSR), is a process that takes place in activated B cells. During this process, B cells change the class of antibodies they produce, transitioning from IgM to other isotypes such as IgG, IgA, or IgE. Isotype switching enables B cells to generate antibodies with diverse effector functions while preserving the antigen-binding specificity of the original antibody. IL-4 Key cytokine in driving the allergic response Enhances Ig E-mediated reaction Stimulates B cells to undergo class switching to IgE and promotes the expansion of Th2 cells Defect in class switching - Hyper IgM Syndrome, caused by defects in CD40L (X-linked) or CD40/AID/UNG (autosomal recessive), leads to high IgM with low IgG, IgA, and IgE, causing recurrent infections. Diagnosis involves immunoglobulin levels and genetic testing, with treatment including IVIG and prophylactic antibiotics.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 202.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: B-cells are induced to produce IgE by which of the following? (Q854863)

A. IL-2

B. IL-4

C. IL-1

D. IL-6

Correct Answer: B. IL-4

Explanation: IL-4 plays a crucial role in the activation of B-cells to produce immunoglobulin E (IgE). It is a cytokine primarily produced by Th2 helper cells, mast cells, and basophils. IL-4 stimulates B-cells to undergo class switching to IgE, which is an important mediator in allergic reactions and responses to parasitic infections. Interleukins in Type-1 hypersensitivity reaction: Interleukins Role IL-4 Key cytokine in driving the allergic response Enhances Ig E-mediated reaction Stimulates B cells to undergo class switching to IgE and promotes the expansion of Th2 cells IL-5 Development and activation of eosinophils→ Recruited to the site of allergen exposure→ Release inflammatory mediators and enzymes→ Tissue damage and inflammation IL-13 Amplifies IgE production Acts on epithelial cells to stimulate mucus secretion IL-10 Anti-inflammatory cytokine Inhibits cytokine production by Th1 cells and macrophages. IL-2 (Option A) is primarily involved in the growth and proliferation of T-cells, especially CD4+ and CD8+ T-cells, and does not induce IgE production. IL-1 (Option C) is a pro-inflammatory cytokine that promotes fever and immune responses, but it does not directly induce IgE production. IL-6 (Option D) is involved in the acute-phase response and the differentiation of B-cells into plasma cells, but it is not specifically involved in inducing IgE production.

@Neet_pg_bot

Q16: A graft from an identical twin is called: (Q854871)

A. Allograft

B. Autograft

C. Isograft

D. Xenograft

Correct Answer: C. Isograft

Explanation: Isograft is a graft transplanted between two genetically identical individuals, such as identical twins. Since there is no genetic difference between the individuals, the recipient's immune system typically does not recognise the graft as foreign, resulting in no rejection. Type of Graft Description Autograft (Option B) An organ or tissue is taken from an individual and grafted on him/ herself. Isograft Grafts between genetically identical individuals, such as identical twins Allograft (Option A) Graft between two genetically non-identical members of the same species (e.g. organ transplants between two non-identical and compatible individuals. Xenograft (Option D) Graft from one species to another (e.g., pig skin is a temporary substitute for burn treatment). Synthetic Graft Artificial materials or bioengineered constructs replace or support damaged tissue (e.g., artificial skin substitutes, bone graft substitutes).

References:

Ananthanarayan and Paniker's Textbook of Microbiology, 10th Edition, Pages 185,186

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Graft from an identical twin is called: (Q859849)

A. Allograft

B. Autograft

C. Isograft

D. Xenograft

Correct Answer: C. Isograft

Explanation: Type of Graft Description Autograft An organ or tissue is taken from an individual and grafted on him/ herself (Option B ruled out) Isograft Grafts between genetically identical individuals, such as identical twins (Option C) Allograft Graft between two genetically non-identical members of the same species (e.g. organ transplants between two non-identical and compatible individuals. (Option A ruled out) Xenograft Graft from one species to another (e.g., pig skin is a temporary substitute for burn treatment). (Option D ruled out) Synthetic Graft Artificial materials or bioengineered constructs replace or support damaged tissue (e.g., artificial skin substitutes, bone graft substitutes).

Ananthanarayan and Paniker's Textbook of Microbiology, 10th Edition, Pages 185 and 186

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A teenager developed swelling of the face, lips, and tongue and also found it difficult to breathe within a few minutes of consuming prawns. What type of hypersensitivity is seen here? (Q859855)

A. Type 1

B. Type 2

C. Type 3

D. Type 4

Correct Answer: A. Type 1

Explanation: The above clinical case is suggestive of an anaphylactic reaction to prawns, which is a type-1 hypersensitivity reaction. Type I hypersensitivity is also known as an immediate reaction and involves the IgE-mediated release of antibodies against the soluble antigen. This results in mast cell degranulation and the release of histamine and other inflammatory mediators. Type Mechanism Immune Components Features Examples Type I: Immediate (Option A) IgE-mediated degranulation of mast cells and basophils after allergen binding. IgE antibodies Mast cells Histamine Rapid onset (minutes) Localised or systemic reactions Mediated by histamine. Anaphylaxis Allergic rhinitis Asthma Urticaria (hives) Food allergies Type II: Cytotoxic (Option B ruled out) Antibody-mediated destruction or dysfunction of target cells. IgG , IgM antibodies Complement Phagocytes Targets specific cells or tissues. Cell lysis or dysfunction. Involves complement activation. Autoimmune hemolytic anemia Goodpasture syndrome Myasthenia gravis Graves' disease Type III: Immune Complex (Option C ruled out) Deposition of immune complexes in tissues, leading to inflammation and damage. IgG , IgM Antibodies Complement Neutrophils Immune complex deposition in vessels. Tissue inflammation and damage (vasculitis). Systemic lupus erythematosus (SLE) Post-streptococcal glomerulonephritis Serum sickness Type IV: Delayed (Option D ruled out) T-cell-mediated immune response, leading to inflammation and tissue damage. T cells (CD4+, CD8+) Macrophages Delayed onset (48–72 hours). Involves cytokine release and macrophage recruitment. Contact dermatitis Tuberculin skin test (PPD) Granulomatous inflammation (e.g., tuberculosis)

References:

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 204 - 214

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Which type of cells are implicated in the development of contact dermatitis in a 12-year-old boy who presented to the emergency department? (Q859906)

A. Helper T cells

B. Neutrophils

C. NK cells

D. Cytotoxic T cells

Correct Answer: A. Helper T cells

Explanation: Contact dermatitis is an inflammatory skin condition that occurs when the skin comes into contact with an allergen or irritant. The pathogenesis involves a complex interplay between various immune cells, including antigen-presenting cells (such as dendritic cells), T cells (including helper T cells), and other immune mediators. Helper T cells are activated upon recognition of the allergen, and they release cytokines that recruit and activate other immune cells, leading to the characteristic inflammation and skin reactions seen in contact dermatitis. The type of hypersensitivity involved in contact dermatitis is Type IV . Mechanisms of Type IV hypersensitivity Description Examples Cytokine-mediated inflammation (mediated by CD4+ T cells) CD4+ T cells recognise protein antigens presented by APCs and differentiate into Th1 and Th17 cells . Th1 cells secrete cytokines like IFN-γ, activating macrophages to cause tissue damage and fibrosis. Th17 cells produce IL-17 to recruit neutrophils, promoting inflammation. Tuberculin test (a classic example of delayed-type hypersensitivity) Granulomas Contact dermatitis Rheumatoid arthritis Multiple sclerosis IBD Psoriasis T cell-mediated cytotoxicity (mediated by CD8+ T cells) Cytotoxic T lymphocytes (CTLs) directly kill antigen-bearing target cells, including tumour cells, virus-infected cells, and allogeneic tissue, during graft rejection. CTLs use perforin-granzyme-dependent killing and Fas-Fas ligand-dependent killing mechanisms to induce apoptosis in target cells. Type 1 DM Hepatic injury in HBV infection Graft vs host disease Helper T cells play a crucial role in the immune response by coordinating and regulating other immune cells. They release cytokines that activate and recruit other cells to the site of inflammation, including in the case of contact dermatitis. Neutrophils (Option B) are typically involved in acute inflammation and play a major role in fighting bacterial infections. While neutrophils may be recruited to the site of inflammation in some cases of contact dermatitis, they are not the primary cells involved in the pathogenesis of the condition. NK cells (Option C) are a type of cytotoxic lymphocyte that plays a role in the innate immune response. They are primarily involved in recognising and eliminating virally infected and tumour cells. NK cells are not typically the primary cells involved in contact dermatitis. Cytotoxic T cells (Option B) are a type of T lymphocyte that directly kills infected or abnormal cells. They play a critical role in the immune response against viruses and tumour cells. While they may be involved in certain immune responses, they are not the primary cells in contact dermatitis.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Pages 212-215

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A patient with a deficiency of CD40 is most likely to exhibit which of the following immunological abnormalities? (Q857448)

A. Absence of B cells

B. Absence of T cells

C. Elevated IgM levels

D. Elevated IgG levels

Correct Answer: C. Elevated IgM levels

Explanation: CD40 deficiency is a primary immunodeficiency disorder that results in a form of Hyper IgM Syndrome . The CD40 molecule on B cells normally interacts with CD40 ligand (CD40L) on activated T helper cells, which is essential for immunoglobulin class switching from IgM to IgG, IgA, and IgE. In CD40 deficiency, this interaction is defective, so B cells cannot switch antibody classes properly. Consequently, the patient has normal or increased IgM levels with decreased levels of IgG, IgA, and IgE. This leads to increased susceptibility to infections, especially sinopulmonary and gastrointestinal infections. Other immune abnormalities like neutropenia and opportunistic infections may also occur. Absence of B cells (Option A): B cells are present but functionally impaired. Absence of T cells (Option B): T cells are present. Elevated IgG levels (Option D): IgG is decreased due to defective class switching.

Apurba S Shastry, Sandhya Bhat, Essentials of Medical Microbiology, 3rd Edition, Page 184 -191

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A patient underwent a bone marrow transplant without HLA matching. In which of the following disorders transplant rejection does not occur: (Q865422)

A. Bare lymphocyte syndrome

B. Chediak Higashi syndrome

C. Wishkott Aldrich syndrome

D. Job’s syndrome

Correct Answer: A. Bare lymphocyte syndrome

Explanation: Bone marrow transplant (BMT) rejection is mediated by recipient T lymphocytes recognizing donor HLA antigens as foreign. Therefore, the integrity and function of recipient T cells (especially CD8■ cytotoxic T cells) are crucial for mounting a rejection response. Bare Lymphocyte Syndrome (BLS): It is a type of MHC class II deficiency , and in some forms, MHC class I expression is also defective. Because of absent or defective HLA expression , CD4■ (helper) and sometimes CD8■ (cytotoxic) T cells are profoundly dysfunctional or absent. Result: These patients are immunologically unable to recognize or reject transplanted tissue , even in the absence of HLA matching. Hence, rejection does not occur in BLS due to lack of HLA molecule expression and impaired T cell function . Chediak-Higashi Syndrome (Option B) is an autosomal recessive condition with defect in lysosomal trafficking regulator gene (LYST), leading to defective neutrophil function. T and B cell immunity is relatively intact — rejection is possible. Wiskott-Aldrich Syndrome (Option C) X-linked disorder with combined immunodeficiency, characterized by thrombocytopenia, eczema, and recurrent infection. It is caused by mutations in the gene located at Xp11.23 that encodes Wiskott-Aldrich syndrome protein (WASP). Although T-cell dysfunction is present, it is not severe enough to completely prevent rejection . Job’s Syndrome (Hyper-IgE syndrome) (Option C) Impaired Th17 pathway with eosinophilia and recurrent infections. T cell immunity is abnormal but not absent , so rejection can occur . Syndrome T Cell Function Graft Rejection Expected? Bare

Lymphocyte Syndrome Severely impaired/absent ■ No rejection Chediak-Higashi Syndrome Mostly intact ■ Yes Wiskott-Aldrich Syndrome Impaired, not absent ■ Possible Job's Syndrome Impaired Th17 cells ■ Possible

Robbins and Cotran's Pathologic Basis of Disease, 10th Edition, Page 241, 246.

↑ *Back to this question in Part A*

@Neet_pg_bot

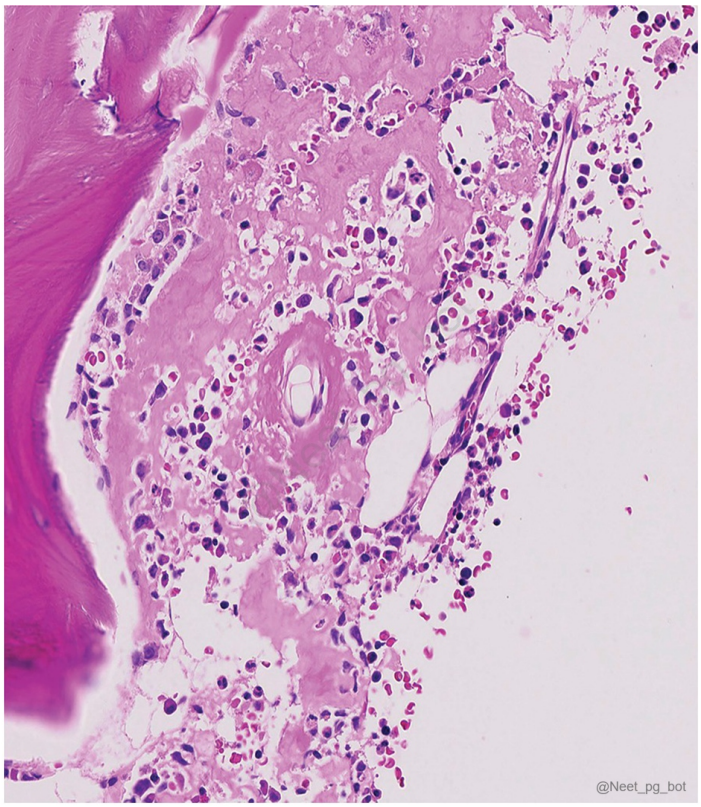
Q22: A patient presented to the OPD with hepatosplenomegaly, and his bone marrow showed 22% of plasma cells. Biopsy reveals pinkish acellular material deposition. What is the most likely diagnosis? (Q844184)

A. Myxoid degeneration of the bone marrow

B. Amyloidosis

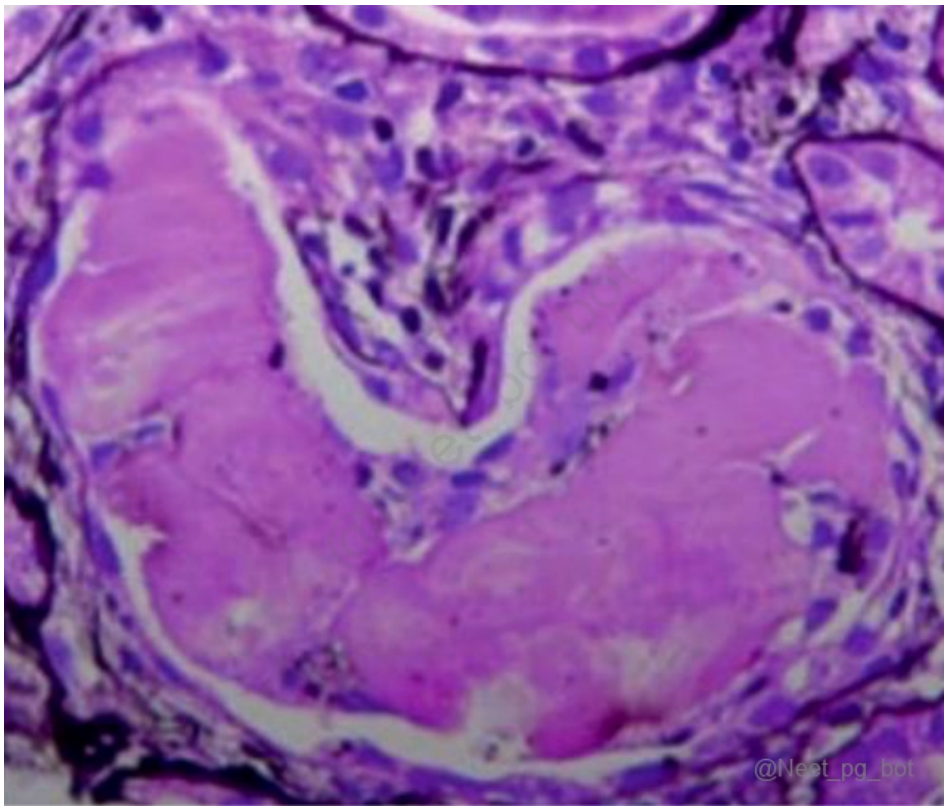
C. Plasma cell leukemia

D. Hemolytic anemia



Correct Answer: B. Amyloidosis

Explanation: The given clinical features, along with increased plasma cells and microscopic findings of pinkish acellular material deposition, are suggestive of primary amyloidosis. Primary amyloidosis results from a plasma cell dyscrasia , most commonly multiple myeloma , where abnormal plasma cells produce excess light chains (κ or λ) . These light chains misfold and deposit as amyloid fibrils in tissues. Biopsy shows Amorphous pink material on H&E , Apple-green birefringence with Congo red stain, λ light chain more commonly involved than κ. Increased plasma cells produce IgG antibodies with excess light chains that deposit as AL protein, deposition in the kidney, resulting in myeloma kidney. The excess proteins are excreted in the urine, called Bence Jones proteinuria Light chain cast Light chain cast in the kidney is referred to as a fractured cast because it will have pink areas with gaps (white). Incorrect Options: Option A) Myxoid degeneration of the bone marrow : Myxoid change shows basophilic, gelatinous, mucopolysaccharide-rich material, not pink acellular eosinophilic deposits. Does not correlate with elevated plasma cells. Option C) Plasma cell leukemia : Requires >20% circulating plasma cells in peripheral blood , not just bone marrow involvement. Histology would show sheets of plasma cells, not acellular eosinophilic material. Option D) Hemolytic anemia : Bone marrow in hemolysis shows erythroid hyperplasia , not pink acellular deposits. Does not cause this histological picture.



References:

.

@Neet_pg_bot

Q23: A child is brought to the OPD by his parents with complaints of recurrent infections. On mediastinal imaging, the thymus gland was found to be absent. Based on further investigation, ADA levels are low. What is the most likely diagnosis? (Q844212)

A. Bruton's hypogammaglobulinemia

B. Bare lymphocyte syndrome

C. DiGeorge syndrome

D. Severe combined immunodeficiency (autosomal recessive)

Correct Answer: D. Severe combined immunodeficiency (autosomal recessive)

Explanation: Correct Option D - Severe combined immunodeficiency (autosomal recessive): Severe combined immunodeficiency (SCID) is characterized by a lack of both T and B cells, leading to severe immune deficiency. Adenosine deaminase (ADA) deficiency is seen in autosomal recessive SCID. Incorrect Options: Options A, B, and C do not have ADA deficiency.

Prepladder notes

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 7-year-old boy presents with a history of recurrent bacterial and fungal infections, particularly involving the skin and respiratory tract. The patient's parents report that he has had multiple abscesses and lymphadenitis. Dihydrorhodamine test results show an abnormal pattern. What is the primary suspicion based on these findings? (Q860539)

A. CGD

B. SCID

C. Sialyl Lewis X

D. LAD

Correct Answer: A. CGD

Explanation: The history of recurrent bacterial and fungal infections, especially affecting the skin and respiratory tract, along with multiple abscesses, lymphadenitis, and an abnormal Dihydrorhodamine (DHR) test result, strongly suggests Chronic Granulomatous Disease (CGD). It is characterised by increased susceptibility to recurrent infections caused by catalase-positive organisms. Cause : Defect in NADPH oxidase, an enzyme complex in phagocytes. Mechanism : A defect in NADPH oxidase leads to the inability to produce the reactive oxygen species (ROS) required to kill certain bacteria and fungi. Clinical Presentation : Recurrent infections, particularly with catalase-positive organisms (e.g., Staphylococcus aureus, Aspergillus), granuloma formation. This defect is identified by the abnormal DHR test, which measures the production of ROS in neutrophils. SCID (Severe Combined Immunodeficiency) (Option B) is a genetic disorder affecting both humoral and cell-mediated immunity, presenting with thrush, diaper rash, and failure to thrive in infants. It involves defects in T and B cells, leading to severe, broad immune deficiencies, unlike the phagocyte-specific defect seen in CGD. Sialyl Lewis X (Option C) is a carbohydrate on leukocytes that helps with adhesion and migration during immune responses. Its deficiency impairs neutrophil trafficking, leading to immune deficiency and recurrent infections, but does not typically cause abnormalities in the DHR test. LAD (Leukocyte Adhesion Deficiency) (Option D) is a genetic disorder causing defective neutrophil adhesion, impairing migration to infection sites, leading to recurrent infections, poor wound healing, and delayed umbilical cord separation. The DHR test is normal in LAD, as it assesses phagocyte function, not adhesion.

@Neet_pg_bot

Q25: Which of the following organs is a primary lymphoid organ? (Q860208)

A. Lymph node

B. Spleen

C. Thymus

D. MALT

Correct Answer: C. Thymus

Explanation: The thymus is a primary lymphoid organ. Lymphoid Organs are structures involved in the production, maturation, and storage of immune cells, essential for the immune system to detect and respond to pathogens. They are classified as: Primary lymphoid organ (Development and maturation of T and B lymphocytes) Secondary lymphoid organ (Site of adaptive immune responses to antigens) Primary Lymphoid Organs Secondary Lymphoid Organs Bone Marrow: Origin of all blood cells from pluripotent hematopoietic stem cells (a process called hematopoiesis). Hematopoiesis shifts to bone marrow from the liver after fetal life, eventually confined to axial bones after puberty. Progenitor T and B cells develop in bone marrow; B cells mature here, while T cell progenitors migrate to the thymus. Lymph Nodes: (Option A ruled out) Filter antigens and activate T and B cells.

Structured into cortex (B cell area), paracortex (T cell area), and medulla (rich in plasma cells). Spleen: (Option B ruled out) Largest secondary lymphoid organ, involved in filtering blood-borne antigens. Contains white pulp (T and B cells) and red pulp (site of RBC destruction). Thymus: (Option C) Site of T cell proliferation and maturation. Developed from the third/fourth pharyngeal pouch in embryonic life. Active during childhood, decreases in size after puberty. Thymic hormones (e.g., thymulin, thymopoietin) help attract and mature T cells. Central tolerance occurs here, removing self-reactive T cells to prevent autoimmunity. Mucosa-associated Lymphoid Tissue (MALT): (Option D ruled out) Located in mucosal sites (intestine, respiratory, urogenital tracts) to protect against pathogens. Includes loose clusters of lymphoid cells and organised structures (e.g., tonsils, Peyer's patches in intestines). {{caption_text}}

@Neet_pg_bot

Q26: Which of the following antibodies is specific for scleroderma? (Q857434)

A. Anti-topoisomerase/Anti-scl 70 antibody

B. Anti-La antibody

C. Anti-Jo-1 antibody

D. Anti-U1 RNP antibodies

Correct Answer: A. Anti-topoisomerase/Anti-scl 70 antibody

Explanation: Anti-topoisomerase/Anti-scl 70 antibody are highly specific for scleroderma, especially diffuse scleroderma Anti centromere antibody is involved in limited scleroderma (also known as CREST syndrome). Scleroderma (systemic sclerosis) is an autoimmune disease characterized by fibrosis of the skin and internal organs. Diffuse & Limited Systemic Sclerosis Features Diffuse Limited Skin involvement Proximal & Distal extremities, face, trunk Distal to elbows, face Raynaud's Phenomenon Onset <1 year/at the time of skin changes Precede skin diseases by years Organ Involvement Pulmonary (Interstitial fibrosis), Renal (Renovascular hypertensive crisis), GI & Cardiac GI, Biliary cirrhosis, Pulmonary artery hypertension Nail fold capillaries Dilatation and dropout Dilatation without significant dropout Antinuclear antibodies Anti-topoisomerase 1 Anticentromere Antibodies Conditions Anti-La antibody (Option B) Sjogren's syndrome Anti-Jo-1 antibody (Option C) Dermatomyositis Anti-U1 RNP antibodies (Option D) Mixed connective tissue disease (MCTD)

@Neet_pg_bot

Q27: Which of the following genes is responsible for the regulation of T lymphocytes by the thymus? (Q857440)

A. AIRE

B. Notch 1

C. E2A

D. Rag1/2

Correct Answer: A. AIRE

Explanation: AIRE (autoimmune regulator) is a gene responsible for regulating T cell selection in the thymus. During negative selection, T cells that recognize self-antigens are eliminated through apoptosis. AIRE plays a crucial role in this process by promoting the deletion of self-reactive T cells. A defect in AIRE results in autoimmune polyendocrine syndrome (APS). Notch 1 (Option B) is involved in the initial development of T cells , including determining whether a progenitor cell will become a T cell, but it does not regulate the elimination of self-reactive T cells , which is the role of AIRE . E2A (Option C) is a transcription factor more relevant to B cell development and not directly related to T cell selection in the thymus. Rag1/2 (Option D) are enzymes responsible for the rearrangement of T cell receptor (TCR) genes during T cell development, but they do not directly regulate negative selection.

@Neet_pg_bot

Q28: Blood transfusion reactions are mediated by which type of hypersensitivity reaction? (Q866752)

A. Type I

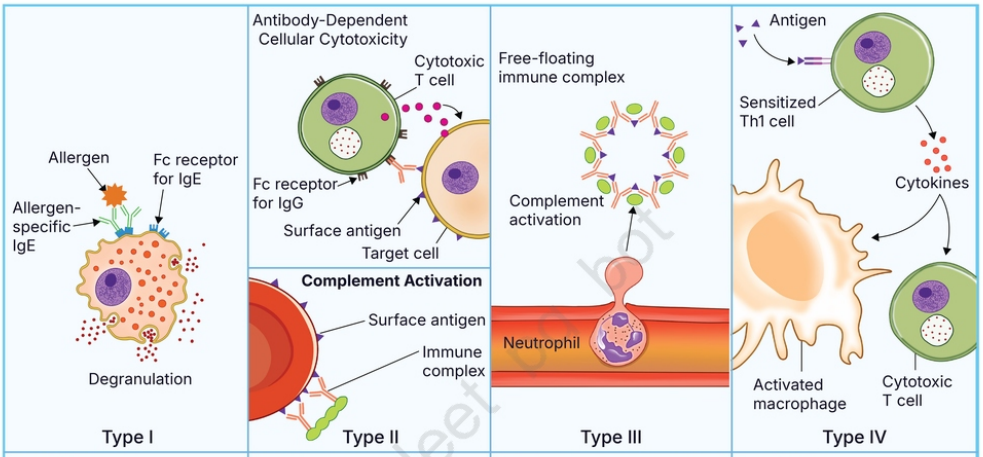
B. Type II

C. Type III

D. Type IV

Correct Answer: B. Type II

Explanation: Blood transfusion reactions (specifically acute hemolytic transfusion reactions) occur when the recipient’s immune system attacks donor red blood cells due to ABO incompatibility. Mechanism: Type of hypersensitivity: Type II (antibody-mediated cytotoxic). Pathophysiology: Pre-existing IgM antibodies in the recipient bind to antigens (A or B) on donor RBCs. This activates the complement cascade, leading to: RBC lysis (intravascular hemolysis) Release of haemoglobin Inflammatory cytokine release Clinical presentation: fever, chills, hypotension, flank pain, hemoglobinuria, possible DIC. Type I (Option A): IgE-mediated (allergies, anaphylaxis). Type III (Option C): Immune complex–mediated (e.g., serum sickness, post-strep GN). Type IV (Option D): T-cell–mediated (delayed, e.g., TB skin test, contact dermatitis).



IgE-Mediated Hypersensitivity	IgG-Mediated Cytotoxic Hypersensitivity	Immune Complex-Mediated Hypersensitivity	Cell-Mediated Hypersensitivity
IgE is bound to mast cells via its Fc portion. When an allergen binds to these antibodies, crosslinking of IgE induces degranulation.	Cells are destroyed by bound antibody, either by activation of complement or by a cytotoxic T cell with and Fc receptor for the antibody (ADCC)	Antigen-antibody complexes are deposited in tissues, causing activation of complement, which attracts neutrophils to the site	Th1 cells secrete cytokines, which activate macrophages and cytotoxic T cells and can cause macrophage accumulation at the site
Causes localized and systemic anaphylaxis, seasonal allergies including hay fever, food allergies such as those to shellfish and peanuts, hives and eczema	Red blood cells destroyed by complement and antibody during a transfusion of mismatched blood type or during erythroblastosis fetalis	Most common forms of immune complex disease are seen in glomerulonephritis, rheumatoid arthritis, and systemic lupus erythematosus	Most common forms are contact dermatitis, tuberculin reaction, autoimmune diseases such as diabetes mellitus type I, multiple sclerosis , and rheumatoid arthritis

Q29: Which type of hypersensitivity reaction is a type 2 lepra reaction? (Q820565)

A. Type I hypersensitivity

B. Type II hypersensitivity

C. Type III hypersensitivity

D. Type IV hypersensitivity

Correct Answer: C. Type III hypersensitivity

Explanation: Correct Option C - Type III hypersensitivity: Type 2 lepra reaction, also known as erythema nodosum leprosum, is a type III hypersensitivity reaction. The type 2 lepra reaction occurs in patients with: Lepromatous leprosy Borderline lepromatous leprosy Incorrect Options: Options A, B, and D are incorrect.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: After class switching, a particular class of antibody is produced, but IgM and IgD are expressed concomitantly on the surface of a B cell due to which of the following phenomena? (Q854696)

A. Allelic exclusion

B. Alternate RNA splicing

C. Somatic hypermutation

D. Affinity maturation

Correct Answer: B. Alternate RNA splicing

Explanation: B cells express both IgM and IgD antibodies simultaneously due to alternative RNA splicing . This mechanism allows the same heavy chain gene to be spliced in different ways, resulting in the production of both IgM and IgD isotypes. Although IgM and IgD are derived from the same heavy chain gene, the splicing process generates distinct versions of the RNA transcript, one for IgM and one for IgD. Both antibodies share the same antigen-binding specificity but differ in their constant regions , which determine their respective isotypes. Allelic exclusion (Option A) ensures that only one allele of the immunoglobulin gene is expressed in a B cell at a time, maintaining clonal specificity, but it does not account for the co-expression of IgM and IgD. Somatic hypermutation (Option C) takes place after antigen exposure and enhances the affinity of antibodies, but it does not play a role in the simultaneous expression of IgM and IgD. Affinity maturation (Option D) is a process that improves antibody affinity during the immune response, but it does not generate multiple antibody classes concurrently.

@Neet_pg_bot

Q31: What method is employed for the detection of autoantibodies? (Q854704)

A. Direct Immunofluorescence

B. ELISA

C. Indirect Immunofluorescence

D. FISH

Correct Answer: C. Indirect Immunofluorescence

Explanation: Indirect immunofluorescence is used to detect autoantibodies, particularly antinuclear antibodies (ANA), a hallmark of autoimmune diseases. The test employs a single anti-human globulin fluorescent conjugate, making it versatile and reducing the need for multiple conjugates. Type Description Limitation Direct Immunofluorescence Detects antigen directly using a fluorescent-labelled antibody. (Option A ruled out) Requires separate fluorescent conjugates for each antigen. Indirect Immunofluorescence It uses antiglobulin fluorescent conjugate to detect human antibodies, enhancing versatility. Allows the use of a single anti-human conjugate. ELISA (Option B) is widely used for quantifying specific autoantibodies , but it is not the first-line method for detecting autoantibodies broadly. FISH (Option D) is a molecular cytogenetic technique used to detect and localize specific DNA sequences within the chromosomes. It is not for detecting autoantibodies.

@Neet_pg_bot

Q32: A young person with recurrent seasonal conjunctivitis presents with itchiness and eye-watering. What is the most likely cell involved in the immediate phase of this condition? (Q858100)

A. Eosinophils

B. Mast cells

C. Neutrophils

D. Lymphocytes

Correct Answer: B. Mast cells

Explanation: The condition described is allergic conjunctivitis , where the immediate phase involves an IgE-mediated hypersensitivity reaction , with mast cells playing a central role in the response. Type I Hypersensitivity (early) is an immediate IgE-mediated reaction where mast cells release histamine and other mediators upon allergen exposure, causing itching, eye-watering, redness, and swelling. There are two phases in Type I hypersensitivity: the immediate and late-phase responses. Type I hypersensitivity reaction phases and its features Phase Timing Mechanism Immediate Phase Seconds to minutes Mast cell/basophil degranulation : IgE cross-linking leads to the release of histamine and other mediators. Late Phase 4-12 hours, peaks at 24-48 hours, lasting up to days Inflammatory cell recruitment : Cytokines/chemokines attract eosinophils, neutrophils, and macrophages, causing sustained inflammation. (Options A & C ruled out) Lymphocytes (Option D) , especially T-helper cells , play a role in delayed hypersensitivity (Type IV hypersensitivity), but they are not the primary cells involved in the immediate response.

Robbins and Cotran Pathologic Basis of Disease,10th Edition, Pages 204 - 208

↑ *Back to this question in Part A*

@Neet_pg_bot

Q33: Which of the following is implicated in the pathogenesis of rheumatoid arthritis? (Q858104)

A. IgE-mediated

B. Defective cellular and humoral immunity

C. Autoimmunity

D. Chronic microbial infections

Correct Answer: C. Autoimmunity

Explanation: Rheumatoid arthritis (RA) is a chronic autoimmune disorder where the immune system mistakenly attacks healthy tissues. The pathogenesis of rheumatoid arthritis (RA) begins with antigenic exposure in genetically predisposed individuals, leading to the activation of CD4+ T-cells . These T-cells release inflammatory

cytokines such as TNF-α , IL-1 , IL-6 , and interferon-γ , which activate endothelial cells , B lymphocytes , and macrophages . This cascade of immune activation leads to chronic inflammation , joint damage , and deformities that characterise RA. Rheumatoid arthritis Epidemiology Male to female ratio - 1:3. Peaks between 25 and 55 years. Remains constant between 55 and 75. Genetics Strongly associated with the HLA-DRβ1 gene. Higher concordance in monozygotic twins. Triggers and suppressors Cigarette smoking and infections can trigger RA in genetically predisposed individuals by citrullination of proteins. RA may remit during pregnancy and can first appear postpartum due to immune suppression and hormonal changes. Pathogenesis Incorrect Options: IgE-mediated (Option A) immune response is primarily seen in allergic reactions, not in rheumatoid arthritis. Defective cellular and humoral immunity (Option B) : While immune dysfunction plays a role in RA, the specific issue is not a general defect in immunity but rather an autoimmune response where the immune system attacks its own tissues. Chronic microbial infections (Option D) can trigger or exacerbate autoimmune diseases , but they are not the direct cause of RA. However, certain infections may contribute to disease flares or trigger the initial immune response.

@Neet_pg_bot

Q34: Which of the following is a marker of natural killer cells? (Q855942)

A. CD68

B. CD3

C. CD25

D. CD94

Correct Answer: D. CD94

Explanation: CD94 is a marker associated with natural killer (NK) cells and plays a role in regulating their activity and interactions with other immune cells. Natural Killer cell (NK) : Produced by a large granular lymphocyte. Constitutes 5 to 10% of circulating blood lymphocytes. Function: It can be part of both innate and adaptive immunity. Innate immunity: Directly kill the virus-infected cells or tumour cells. Adaptive immunity: Antibody-dependent cell-mediated cytotoxicity. Markers for NK cells : CD 16, CD 56, CD 94 . CD 56: The role is still not fully understood. CD 16: Detect and bind to Fc fragment of IgG on target cells and kill the cell by perforins and by releasing toxins and granzymes. Nk cells have 2 different kinds of receptors. Activating receptors: NKG2D. Inhibitory receptors: CD94 , CD 96 (these prevent self-cells from being attacked by NK cells). Cytokines produced by Nk cells : IFN-Y: (Cytokine majorly responsible for granuloma formation). This cytokine leads to the activation of macrophages in epithelioid cells. Cytokines responsible for the proliferation of NK cells: IL-2 and IL-15. CD68 (Option A) : A marker of macrophages and other monocytes, not NK cells. CD3 (Option B) : Found on T cells, particularly T cell receptors. CD25 (Option C) : The alpha chain of the IL-2 receptor, primarily expressed on activated T cells.

@Neet_pg_bot

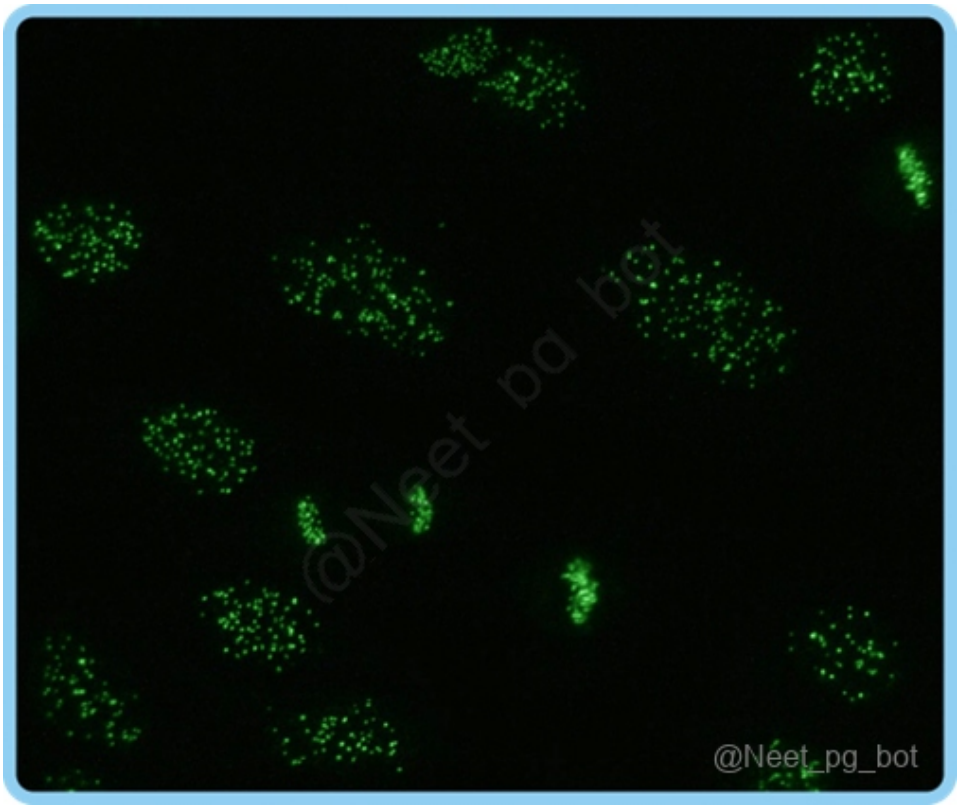
Q35: The below-given ANA pattern on immunofluorescence (IF) is seen; identify the pattern. (Q857429)

A. Nucleolar

B. Speckled

C. Centromeric

D. Diffuse



Correct Answer: C. Centromeric

Explanation: The image shows a centromeric ANA pattern, which refers to the staining of the centromere region of chromosomes, producing a pattern of discrete speckles or dots concentrated in the centre of the nucleus. This pattern is seen in conditions such as Limited Scleroderma or CREST syndrome . Homogeneous or diffuse staining of nuclei (Option D ruled out) Antibodies reactive with dsDNA, nucleosomes, and histones, This is seen in SLE,

Drug-induced lupus Mixed connective tissue disorder {{caption_text}} Speckled pattern (Option B ruled out) Antibodies against various nuclear antigens, including Sm and RNPs It is seen in SLE Scleroderma Sjogren's syndrome {{caption_text}} Nucleolar pattern (Option A ruled out) Antibodies against nucleolar proteins. It is seen in Scleroderma and Polymyositis. {{caption_text}} Anti-centromere antibodies (Option C) Systemic sclerosis, Sjögren syndrome, and other diseases {{caption_text}} {{caption_text}}

Q36: Which of the following cells is responsible for graft rejection? (Q793603)

A. Macrophages

B. T cells

C. B cells

D. Plasma cells

Correct Answer: B. T cells

Explanation: Correct Option B - T cells: When a graft is transplanted into a recipient, the immune system recognizes the graft as foreign and triggers an immune response. This response is primarily mediated by T cells, which can recognize and respond to specific foreign antigens. The T cells recognize and bind to the foreign antigens expressed by the graft. This triggers the activation of other immune cells, such as macrophages, which can help to engulf and destroy the foreign tissue. Incorrect Options: Options A, C, and D are incorrect.

• [06_CVS_ Blood Vessels and Vasculitis] 026 Sclerosis And Vascular Tumors

« Back to Folder Directory

[06_CVS_ Blood Vessels and Vasculitis] 026 Sclerosis And Vascular Tumors — Quick Jump

Q1 (p. 1611) *Q2 (p. 1612)* *Q3 (p. 1614)* *Q4 (p. 1616)* *Q5 (p. 1616)* *Q6 (p. 1619)*
Q7 (p. 1620) *Q8 (p. 1621)* *Q9 (p. 1622)* *Q10 (p. 1624)* *Q11 (p. 1625)*

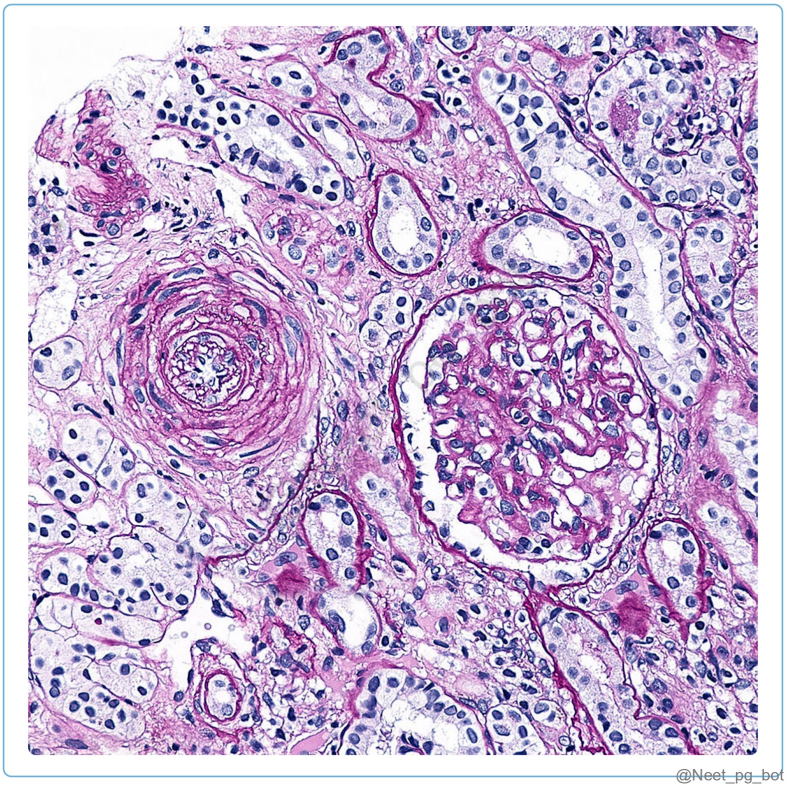
Q1: A 60-year-old male with a chronic history of diabetes, hypertension and hypercholesterolemia came to the clinic for follow-up. His BP has not been under control for many years. He has a vascular lesion similar to the image shown below. What does this image indicate? {{caption_text}} (Q845201)

A. Atheromatous plaques

B. Thick arterial wall due to deposition of pink, hyaline material

C. Onion-skin appearance

D. Lipid deposition within the vessel wall



Correct Answer: C. Onion-skin appearance

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Onion-skin appearance refers to hyperplastic arteriolosclerosis, where the arteriole shows concentric, laminated (onion-layered) smooth muscle proliferation and basement membrane duplication. It is characteristically seen in malignant hypertension, where severe, long-standing elevation of BP causes narrowing of arterioles. The laminated layers give the vessel wall a “onion-skin” morphology on histology. This is a hallmark change in accelerated or malignant hypertension. Incorrect Options: Option A) Atheromatous plaques : Seen in large arteries, not arterioles. Option B) Thick arterial wall due to deposition of pink, hyaline material : Describes hyaline arteriolosclerosis of benign hypertension/diabetes, not the laminated “onion-skin” pattern. Option D) Lipid deposition within the vessel wall : Refers to fatty streaks/atherosclerosis, not arteriolar hyperplasia.

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 492, 493.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 65-year-old male presents with high pulse pressure. Histopathological examination is shown below. The arteries appear thickened, but there is no significant

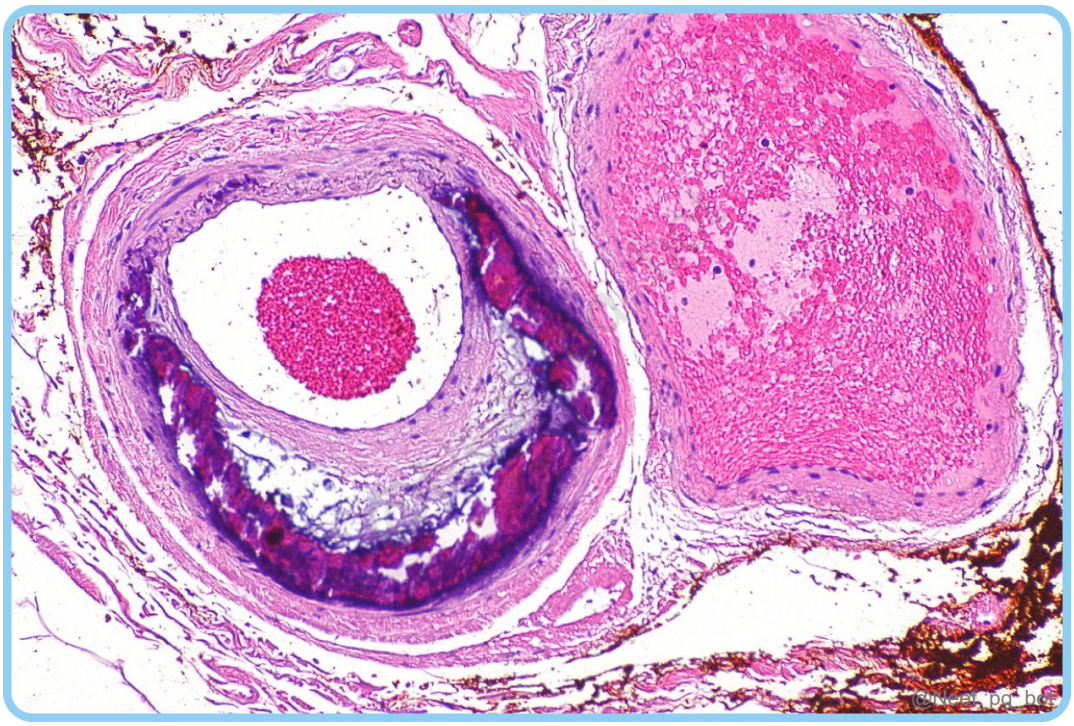
luminal narrowing. Which of the following conditions is the likely cause? {{caption_text}} (Q845207)

A. Atherosclerosis

B. Monckeberg medial calcific sclerosis

C. Hyperplastic arteriosclerosis

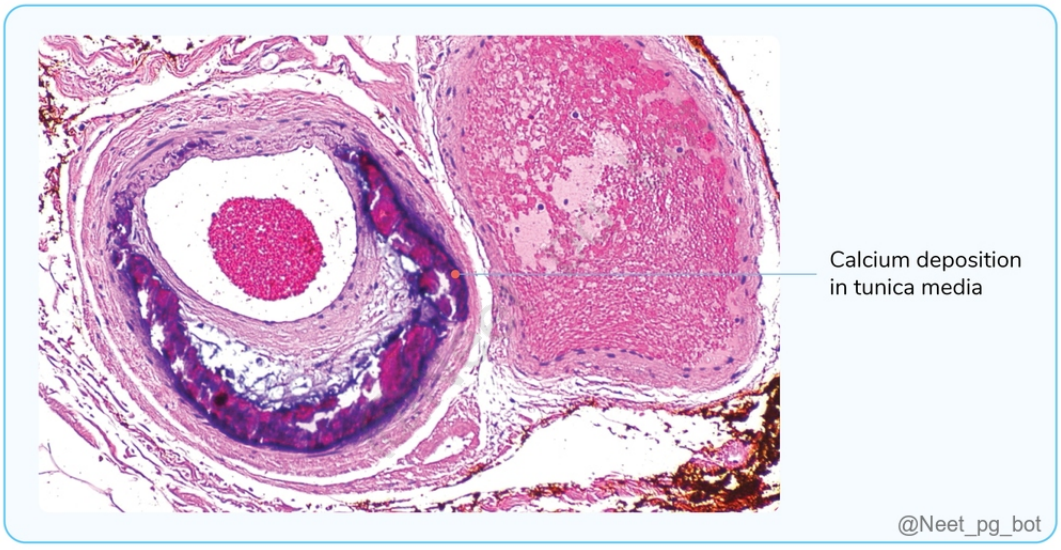
D. Hyaline arteriosclerosis



Correct Answer: B. Monckeberg medial calcific sclerosis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Monckeberg medial calcific sclerosis, also known as calcific medial degeneration: Calcific: Blue coloured dystrophic calcification due to old age. Medial: Calcium is getting deposited into the tunica media of the blood vessel. Degeneration: Degeneration occurring due to old age and not due to any pathology. It is often asymptomatic and discovered incidentally in imaging studies such as X-rays or histopathological examinations. {{caption_text}} {{caption_text}} Atherosclerosis (Option A): Due to hypercholesterolemia, and on HPE foam cells are seen in blood vessels. Hyperplastic arteriosclerosis (Option C): Seen in malignant hypertension. Hyaline arteriosclerosis (Option D): Seen in benign hypertension and diabetes.



References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 492, 493.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Arrange the following steps of atherosclerosis formation in the correct order. Endothelial injury and dysfunction Accumulation of lipoproteins Platelet adhesion and factor release Smooth muscle and collagen formation (Q845209)

A. 1>2>3>4

B. 1>2>4>3

C. 2>3>4>1

D. 1>3>2>4

Correct Answer: A. 1>2>3>4

Explanation: Atherosclerosis is the thickening and hardening of arteries due to plaque buildup in the inner lining of an artery, representing a chronic inflammatory and healing response of arterial wall's to endothelial injury. The pathogenesis of atherosclerosis is as follows: Endothelial injury and dysfunction cause increased vascular permeability, leukocyte adhesion, and thrombosis. (Statement 1) Accumulation of lipoproteins (LDL) (Statement 2) Monocyte adhesion to the endothelium, migration into intima and transformation into macrophages and foam cells. Platelet adhesion .(Statement 3) Factor release from activated platelets, macrophages inducing SMC(smooth muscle cell) recruitment SMC proliferation, extracellular matrix production(ECM) Lipid accumulation is both extracellular and within macrophages and SMC. Calcification of ECM and necrotic debris.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 493-498

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 65-year-old male presents with sudden-onset severe abdominal pain radiating to his back. On physical examination, a pulsatile mass is palpated in his abdomen. He has a history of hypertension, hyperlipidemia, and smoking. Based on the clinical presentation and risk factors, which of the following is the most likely diagnosis? (Q845213)

A. Takayasu's arteritis

B. Diverticulitis

C. Abdominal aortic aneurysm

D. Pancreatitis

Correct Answer: C. Abdominal aortic aneurysm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of sudden-onset severe abdominal pain radiating to the back, along with a pulsatile abdominal mass, is highly suggestive of an abdominal aortic aneurysm (AAA). Aneurysms are mainly due to atherosclerosis, but may also arise from genetic disorders, trauma, or infections. AAA results from medial degeneration weakening the aortic wall. It may be silent or present with sudden abdominal/back pain, pulsatile mass, and shock on rupture. Management : Depending on the aneurysm size, symptoms, and patient’s condition. <5.5 cm & asymptomatic: Monitor >5.5 cm, symptomatic, or rapidly enlarging: Elective repair Medical: Control risk factors to slow progression

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 504-507.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Match the following types of aortic dissections. a. {{caption_text}} 1. Stanford Type A b. {{caption_text}} 2. Debakey type I c. {{caption_text}} 3. Debakey II 4.

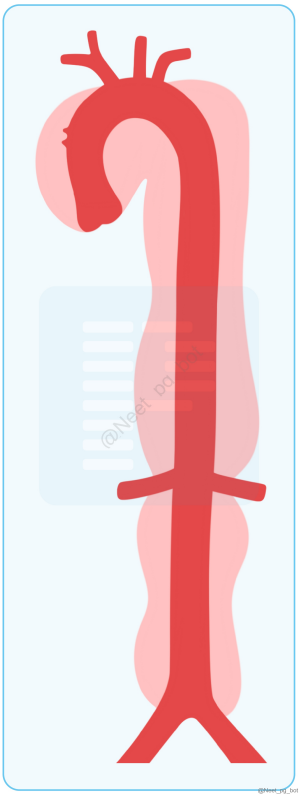
Debakey III (Q845216)

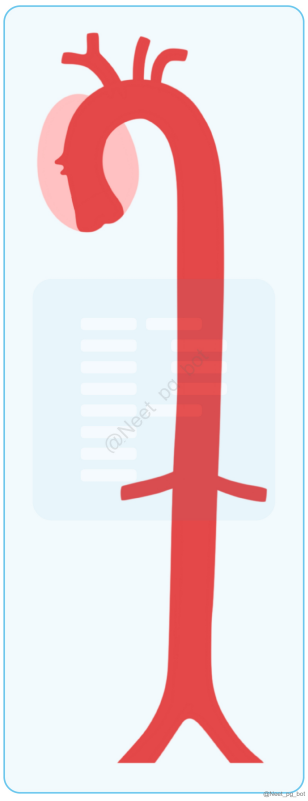
A. A-2, B-4, C-1

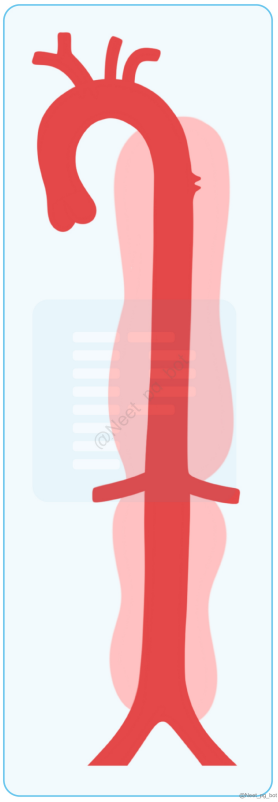
B. A-3, B-1, C-4

C. A-2, B-1, C-4

D. A-4, B-3, C-1







Correct Answer: C. A-2, B-1, C-4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Aortic aneurysms are divided into various types with respect to Stanford and DeBakey classification as follows: DeBakey Classification Stanford Classification DeBakey Classification: Type Origin Extent Type I (Option A) Ascending aorta Extends into arch and descending aorta Type II Ascending aorta Confined to ascending aorta Type III (Option C) Descending aorta Starts distal to left subclavian artery IIIa Limited to thoracic aorta IIIb Extends below diaphragm {{caption_text}} Stanford Classification: Type Description Management Implication Type A (Option B) Involves the ascending aorta (± arch, descending aorta) Surgical emergency Type B Involves only the descending aorta , distal to the left subclavian artery Medical management unless complications arise Relation Between Stanford and DeBakey: Stanford Type A = DeBakey Type I and II Stanford Type B = DeBakey Type III

@Neet_pg_bot

Q6: Which of the following is an intermediate-grade vascular tumour? (Q845224)

A. Kaposi sarcoma

B. Angiosarcoma

C. Hemangiopericytoma

D. Pyogenic granuloma

Correct Answer: A. Kaposi sarcoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Classification of vascular tumours: Benign vascular tumour: Hemangioma, pyogenic granuloma, etc. Intermediate vascular tumour: Kaposi sarcoma Malignant vascular tumour: Angiosarcoma, hemangiopericytoma Kaposi sarcoma is an intermediate-grade vascular tumour. It is caused by Human Herpes Virus 8. (HHV8) It is associated with HIV/Immunodeficiency. M/c location is skin of lower limbs > lymph nodes

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 518.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 6-month-old infant is brought to the clinic with a rapidly expanding, clearly defined, bright red lesion on the face. Upon examination, the lesion feels soft, yields to pressure, and temporarily loses color when pressure is applied. Which of the following is the most likely diagnosis? (Q845227)

A. Pyogenic granuloma

B. Infantile hemangioma

C. Nevus flammeus

D. Venous malformation

Correct Answer: B. Infantile hemangioma

Explanation: The given clinical scenario suggests infantile/capillary hemangioma. Capillary hemangiomas are common benign vascular tumors in infants. They may be isolated or part of PHACE syndrome (posterior fossa malformations, hemangiomas, arterial anomalies, cardiac defects, eye abnormalities, and sternal clefting). and typically undergo rapid growth followed by spontaneous regression. They typically present as swiftly enlarging, vivid red lesions. A key distinguishing trait is their soft, yielding texture, which momentarily loses colour under pressure due to their abundant blood supply. {{caption_text}}

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 519, 520.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 30-year-old patient presents with a history of multiple tumours in various organs, including the brain, retina, and kidneys. On examination, retinal angiomas and cerebellar hemangioblastomas are noted. The patient's family history reveals similar manifestations in relatives. Which of the following lesions is commonly associated with this syndrome? (Q845327)

A. Glioblastoma multiforme

B. Adenomatous polyps

C. Capillary hemangioma

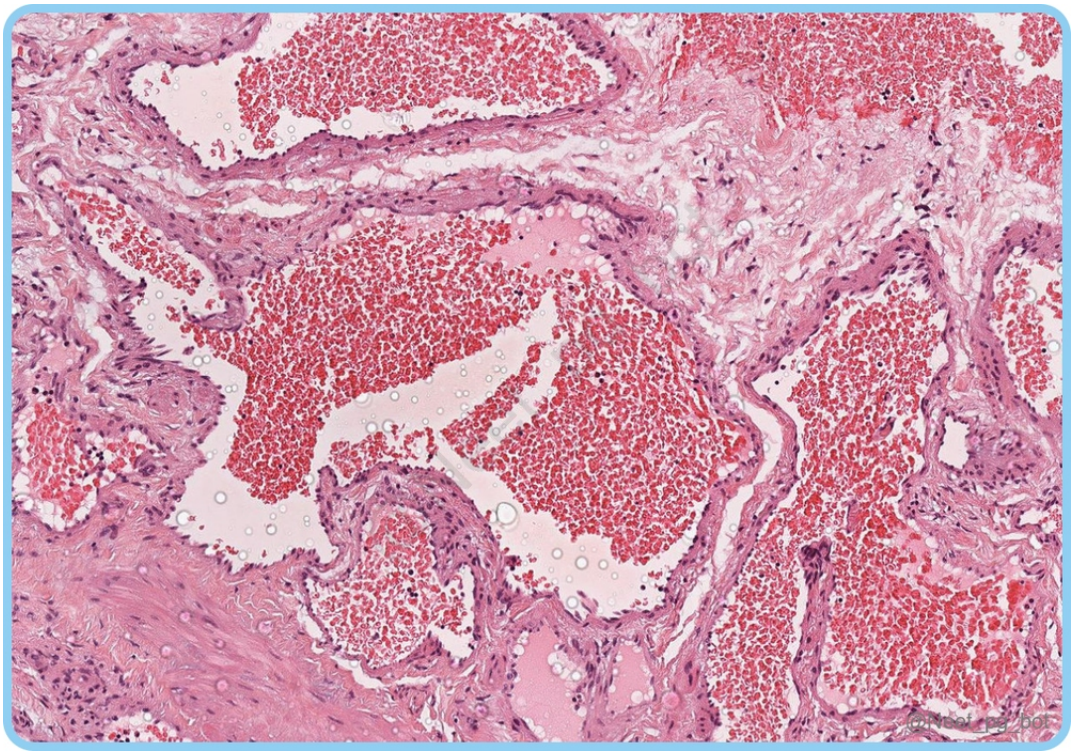
D. Cavernous hemangioma

Correct Answer: D. Cavernous hemangioma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario represents von Hippel-Lindau syndrome , commonly associated with cavernous hemangiomas. VHL Syndrome is associated with the deletion of chromosome 3p. Inheritance: Autosomal dominant It is associated with Cavernous hemangiomas. {{caption_text}}



References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 520.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 45-year-old individual complains of a throbbing mass on the tip of their index finger. Upon examination, the lesion is bluish and extremely tender to the touch. Which of the following is the most probable diagnosis? (Q845331)

A. Ganglion cyst

B. Bacillary angiomatosis

C. Glomus tumour

D. Cavernous lymphangioma

Correct Answer: C. Glomus tumour

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Glomus tumours are benign tumours originating from the glomus bodies of blood vessels. -modified smooth muscle cells specialised in temperature regulation. Glomus bodies: These are the arterio-venous (A-V) anastomoses responsible for thermoregulation of the body. Usually present at the tip of fingers, They typically manifest as excruciatingly painful, pulsating masses , often found under the nails of the fingers (subungual swelling). {{caption_text}} Ganglion cyst (Option A): A Ganglion cyst is a benign cystic swelling arising from tendon sheaths or joint capsules, commonly seen on the dorsum of the wrist. It is typically smooth, soft, and fluctuant and may cause mild discomfort, but not severe tenderness. Bacillary angiomatosis (Option B): Bacillary angiomatosis is a vascular proliferative infection caused by Bartonella species (usually Bartonella henselae or Bartonella quintana). It occurs mainly in immunocompromised individuals, especially AIDS patients and produces multiple red or purple vascular skin lesions that may resemble pyogenic granulomas. However, these lesions are not typically localized to the fingertip, and intense localized tenderness with throbbing pain is not characteristic. Cavernous lymphangioma (Option D): A Cavernous lymphangioma is a benign congenital malformation of lymphatic vessels. It usually appears in infancy or childhood, and is commonly found in the neck, axilla, or oral cavity. The lesions are soft, compressible, and painless

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th Rdition, Page 520

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 60-year-old HIV-positive patient presents with multiple reddish-purple nodules on the lower extremities. On examination, the lesions are non-tender, non-pruritic, and do not blanch with pressure. There is also evidence of mucosal involvement in the oral cavity. Which of the following is the most likely diagnosis? (Q845338)

A. Hemangiopericytoma

B. Hemangioendothelioma

C. Kaposi sarcoma

D. Angiosarcoma

Correct Answer: C. Kaposi sarcoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Kaposi sarcoma is an intermediate-grade vascular tumour. Most commonly associated with immunocompromised individuals, particularly those with HIV/AIDS. It arises from blood vessels and typically presents with multiple reddish-purple nodules on the skin. It is caused by Human Herpes Virus 8 (HHV8) M/c location is skin of lower limbs > lymph nodes The Latency Associated Nuclear Antigen (LANA) is positive, it is an antigen for HHV8. {{caption_text}}

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 520-523.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 28-year-old woman, 20 weeks pregnant, presents with a painful, growing, reddish lump on her gums (as shown below) that bleeds when brushing or eating. The lesion is tender, and she denies any history of trauma or irritation. What is the most likely diagnosis? {{caption_text}} (Q846620)

A. Hemangiopericytoma

B. Kasabach-Merritt Syndrome

C. Angiosarcoma

D. Lobular Capillary Hemangioma

Correct Answer: D. Lobular Capillary Hemangioma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The scenario and image are consistent with a diagnosis of Lobular Capillary Hemangioma (also known as Pyogenic Granuloma or Granuloma Gravidarum or Pregnancy Tumor). It regresses after pregnancy, so in most cases, surgical ressection or any treatment is not needed. Microscopically: Lobular capillary hemangioma (LCH) {{caption_text}} {{caption_text}}

Q13 (p. 1639)	*Q14 (p. 1640)*	*Q15 (p. 1641)*	*Q16 (p. 1642)*	*Q17 (p. 1645)*	*Q18 (p. 1646)*
Q19 (p. 1647)	*Q20 (p. 1647)*	*Q21 (p. 1649)*			

Q1: Which of the following best describes using Triphenyl tetrazolium chloride (TTC) in myocardial infarction? (Q845321)

A. It is used to measure blood flow in coronary arteries

B. It helps visualize viable myocardial tissue after an infarction.

C. It acts as an anticoagulant to prevent clot formation.

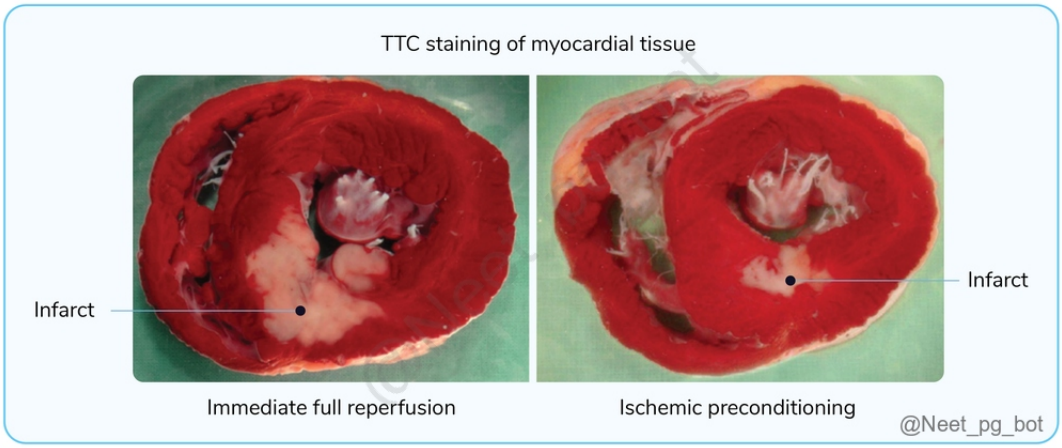
D. It assists in the diagnosis of arrhythmias following a heart attack.

Correct Answer: B. It helps visualize viable myocardial tissue after an infarction.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: TPTC, or Triphenyl Tetrazolium Chloride, is a stain or dye applied to heart tissue, which is used as a gross stain rather than a microscopic stain. Procedure: The heart specimen is cut into slices, and drops of TPTC are applied to each slice. Principle: TPTC stains LDH1 (lactate dehydrogenase isoenzyme 1). Normal, viable heart tissue contains LDH1 and stains brick-red, whereas infarcted, dead heart tissue has lost LDH1 and therefore appears pale. A brick-red color indicates viable myocardium, while pale color indicates infarcted myocardium. Thus, TPTC is used to visualize myocardial tissue viability after myocardial infarction. {{caption_text}}



References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 548

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A pathology report of a heart specimen describes "brisk interstitial infiltrate of neutrophils" and "coagulative necrosis with loss of nuclei. What is the most likely age of this infarct? (Q884942)

A. 4-12 hours

B. 1-3 days

C. 7-10 days

D. >2 months

Correct Answer: B. 1-3 days

Explanation: While coagulative necrosis begins as early as 4 hours, the presence of a brisk neutrophilic infiltrate and the total loss of nuclei and striations specifically characterise the 1-to-3-day window. Evolution of Morphologic Changes: Time Frame Gross Features Light Microscope Findings 0-0.5 hr None None; Electron microscope shows mitochondrial swelling and glycogen loss 0.5-4 hr None Variable waviness of fibres at the borders 4-12 hr Occasional dark mottling Early coagulative necrosis , oedema, and haemorrhage 1-3 days Mottling with a yellow-tan centre Loss of nuclei/striations; brisk neutrophilic infiltrate 3-7 days Hyperemic border; central softening Macrophage phagocytosis begins; early granulation tissue 10-14 days Red-grey depressed borders New blood vessels and collagen deposition 2-8 weeks Gray-white scar Increased collagen and decreased cellularity >2 months Scarring complete Dense collagenous scar

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 497

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 68-year-old woman is admitted with an acute anterior wall myocardial infarction. On hospital day 5, she suddenly develops hypotension and pulseless electrical activity. Bedside echocardiography shows a large pericardial effusion with tamponade physiology. At what time after myocardial infarction does this complication most commonly occur? (Q884940)

A. Within the first 2 days

B. 2-3 weeks

C. 3-7 days

D. After 3 weeks

Correct Answer: C. 3-7 days

Explanation: Myocardial free wall rupture most commonly occurs 3-7 days after MI , when necrotic myocardium undergoes maximal enzymatic degradation and is replaced by soft, friable granulation tissue, making the wall prone to tearing. Mechanical Complication of MI: Myocardial Rupture: Occurs in 1-3% of myocardial infarctions - frequently fatal Types of Rupture: Left Ventricular Free Wall Rupture (Most common): Hemopericardium, cardiac tamponade Often rapidly fatal Ventricular Septal Rupture Papillary Muscle Rupture Timing: Most common 3-7 days post-MI Occurs when: Necrotic myocardium undergoes maximal lysis Infarcted area becomes soft, friable granulation tissue Risk Factors (Especially for Free Wall Rupture): Age > 60 years Female sex First MI Anterior or lateral wall infarction Absence of left ventricular hypertrophy

@Neet_pg_bot

Q4: A 62-year-old man presents with severe substernal chest pain that began 90 minutes ago. ECG shows ST-segment elevation in the inferior leads. Which of the following events is most likely occurring at this time in ischemic cardiac myocytes? (Q884937)

A. ATP reduced to 50% of normal

B. Loss of contractility

C. Irreversible cell injury

D. Microvascular injury

Correct Answer: D. Microvascular injury

Explanation: Microvascular injury typically occurs after more than 1 hour of sustained severe ischemia. Timeline of Ischemic Events in Cardiac Myocytes: The progression from initial oxygen deprivation to permanent tissue death follows a specific chronological order: Immediate Response (Seconds): ATP depletion begins almost instantly after blood flow is interrupted. Early Functional Loss (<2 minutes): The heart muscle loses its ability to contract within 2 minutes. (Option B) Progression of ATP Loss: 10 minutes: ATP levels drop to 50% of normal. (Option A) 40 minutes: ATP levels drop to a critical 10% of normal. The Point of No Return (20–40 minutes): Irreversible cell injury (necrosis) typically sets in during this window. (Option C) Vascular Damage (>1 hour): Damage to the microscopic blood vessels (microvascular injury) occurs after an hour of sustained ischemia.

@Neet_pg_bot

Q5: Which hormone is associated with an increased risk of myocardial infarction in post-menopausal women? (Q884936)

A. Progesterone

B. Estrogen

C. Prolactin

D. Oxytocin

Correct Answer: B. Estrogen

Explanation: After menopause, a decline in estrogen levels is associated with increased risk of myocardial infarction due to loss of its protective cardiovascular effects (favourable lipid profile, anti-inflammatory and vasodilatory effects). Myocardial Infarction (MI): Death of cardiac muscle due to prolonged ischemia Commonly called a heart attack Major cause: Atherosclerosis (most common underlying cause) Sex differences: Males: Higher risk in middle age Females: Relatively protected during reproductive years (estrogen effect) Postmenopause: Risk increases → IHD becomes the leading cause of death in older women Hormone replacement

therapy: Not protective May increase risk (possible prothrombotic effect)

@Neet_pg_bot

Q6: A patient with chronic lung disease presents with pedal oedema, raised JVP, and hepatomegaly. He is diagnosed with isolated right heart failure. What is the structural cause of his right-sided heart failure? (Q884935)

A. Left ventricular hypertrophy

B. Right ventricular hypertrophy and dilatation

C. Mitral stenosis

D. Decreased systemic vascular resistance

Correct Answer: B. Right ventricular hypertrophy and dilatation

Explanation: In patients with chronic lung disease (like COPD or interstitial fibrosis), the right ventricle must pump against increased pulmonary vascular resistance. This leads to Cor Pulmonale . Initially, the right ventricle undergoes hypertrophy (thickening of the wall) to compensate for the pressure. Eventually, the ventricle fails and undergoes dilatation , leading to the clinical signs of systemic venous congestion like pedal oedema, raised Jugular Venous Pressure (JVP), and hepatomegaly. Left ventricular hypertrophy (Option A) : This is the response to systemic hypertension or aortic stenosis. In isolated right heart failure, the left ventricle is typically normal in size or may even be compressed by the bulging interventricular septum. Mitral stenosis (Option C) : While this can lead to right-sided heart failure, it is a left-sided valvular disease. The question specifies "isolated" right heart failure caused by chronic lung disease. Decreased systemic vascular resistance (Option D) : Decreased resistance (as seen in septic shock) would actually decrease the afterload on the left heart. It is increased pulmonary vascular resistance that drives right-sided failure in this scenario.

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 484

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following is a cause of isolated right-sided heart failure? (Q884932)

A. Systemic hypertension

B. Mitral valve stenosis

C. Primary pulmonary hypertension

D. Aortic regurgitation

Correct Answer: C. Primary pulmonary hypertension

Explanation: Isolated right-sided heart failure most commonly results from pulmonary disorders causing pulmonary hypertension (cor pulmonale). This condition directly increases the pressure the right ventricle must work against without primarily involving the left side of the heart. Right-Sided Heart Failure (RHF): Causes: Most common: Left-sided heart failure Isolated RHF → Cor pulmonale (due to lung disease) Parenchymal lung disease Primary pulmonary hypertension Recurrent pulmonary thromboembolism Pulmonary vasoconstriction (OSA, high altitude) Key Differences from Left-Sided HF: Minimal pulmonary congestion Marked systemic & portal venous congestion

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 484

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 68-year-old patient presents with exertional dyspnea. Echocardiography shows preserved ejection fraction with impaired left ventricular relaxation. He is diagnosed with left-sided diastolic heart failure (HFpEF). Which of the following is the most common cause of left-sided diastolic heart failure? (Q884931)

A. Hypertension

B. Cardiac amyloidosis

C. Ischemic heart disease

D. Constrictive pericarditis

Correct Answer: A. Hypertension

Explanation: Chronic hypertension leads to left ventricular hypertrophy and stiffness, making it the most common cause of diastolic heart failure. Left-Sided Heart Failure: Common causes: Ischemic heart disease (most common) Hypertension Aortic or mitral valvular disease Primary myocardial disease Types: Systolic Failure (HFrEF) ↓ Ejection fraction Impaired contractility Diastolic Failure (HFpEF): Preserved EF Stiff, noncompliant LV Commonly due to hypertension Also: fibrosis, amyloidosis, ageing Constrictive pericarditis can mimic

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 484

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A patient with long-standing left-sided heart failure develops progressive dyspnea. Sputum cytology shows findings as shown in the image. What are these cells most appropriately termed? (Q884929)

A. Dust cells

B. Hemosiderin-laden macrophages

C. Foam cells

D. Langhans giant cells

Correct Answer: B. Hemosiderin-laden macrophages

Explanation: The correct answer is Hemosiderin-laden macrophages . These pigment-containing alveolar macrophages are classically known as heart failure cells , formed due to chronic pulmonary congestion with RBC

extravasation and iron accumulation. In left-sided heart failure, the weakened left ventricle causes blood to back up into the pulmonary vasculature, leading to pulmonary hypertension and congestion . The high pressure causes small amounts of blood (RBCs) to leak into the alveoli. Alveolar macrophages phagocytose these RBCs and break down the haemoglobin into hemosiderin , a golden-brown pigment.

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A histologic examination of the heart in an elderly individual reveals several age-related changes. Which of the following is not typically seen in the ageing heart? (Q884928)

A. Lipofuscin deposition in myocytes

B. Transthyretin amyloid deposition

C. Decreased left atrial cavity size

D. Decreased left ventricular cavity size

Correct Answer: C. Decreased left atrial cavity size

Explanation: Ageing is associated with increased left atrial size, not decreased. Effects of Ageing on the Heart: ↑ Prevalence of heart disease with age Major contributors: atherosclerosis, valvular degeneration, myocardial stiffening Chambers: ↑ Left atrial size ↓ Left ventricular cavity size (Option D) Sigmoid septum (basal septal bulge) Valves: Aortic & mitral calcification Leaflet thickening Lambl excrescences Myocardium: ↓ Myocytes, ↑ fibrosis Lipofuscin (brown atrophy) (Option A) Transthyretin amyloid → stiffness (Option B) Coronaries: Tortuosity, calcification Atherosclerosis Aorta: Dilated, tortuous Elastic fragmentation Calcification

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 481

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A histologic section of a normal cardiac valve is examined under microscopy. Which of the following correctly lists the layers of a normal cardiac valve? (Q884927)

A. Intima, media, adventitia

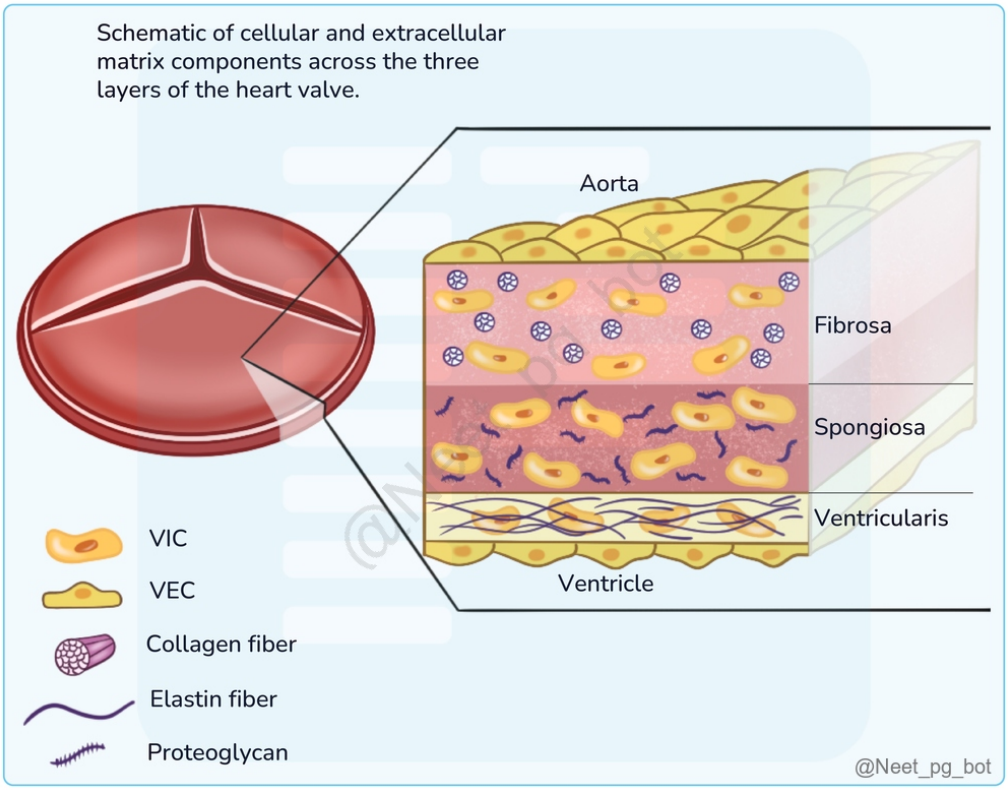
B. Fibrosa, spongiosa, ventricularis

C. Endocardium, myocardium, epicardium

D. Tunica interna, tunica externa

Correct Answer: B. Fibrosa, spongiosa, ventricularis

Explanation: The correct answer is Fibrosa, spongiosa, ventricularis . While blood vessels have the traditional intima/media/adventitia layers, cardiac valves have a specialised three-layer architecture designed for mechanical durability and flexibility. Normal cardiac valves consist of three layers: Fibrosa - Dense collagen; mechanical strength Spongiosa - Loose connective tissue core Ventricularis/Atrialis - Elastin-rich; recoil Endocardium, myocardium, epicardium (Option C) : These are the layers of the heart wall itself, representing the inner lining, the muscle layer, and the outer covering. Tunica interna, tunica externa (Option D) : These are alternate names for the layers of a blood vessel wall.



References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 480

↑ *Back to this question in Part A*

@Neet_pg_bot

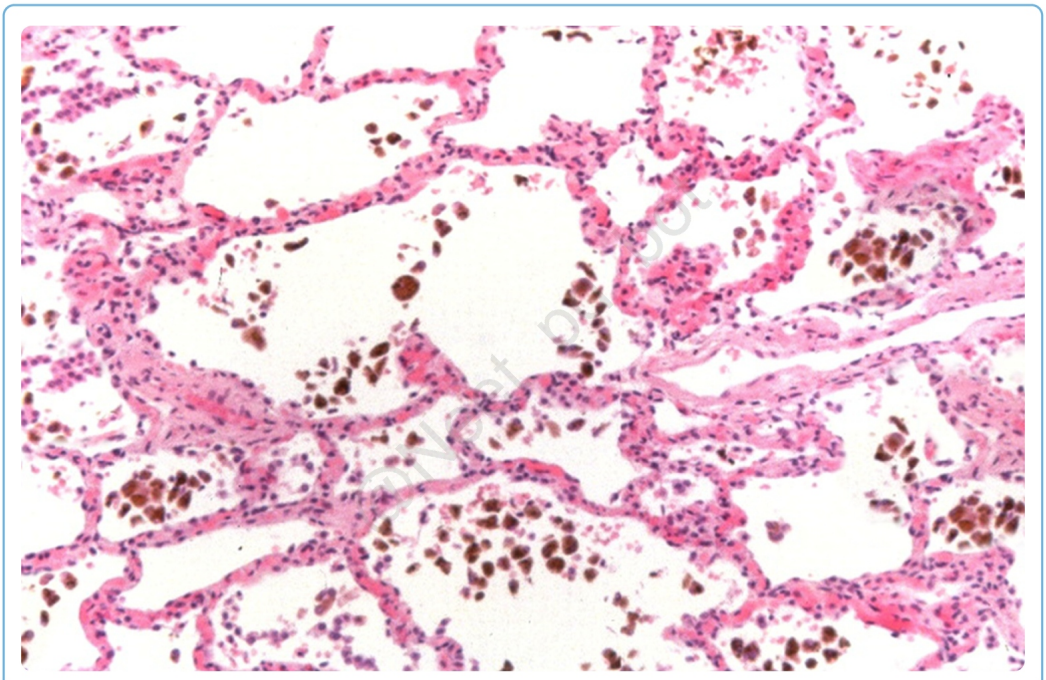
Q12: A 65-year-old male with a history of hypertension and coronary artery disease presents with worsening shortness of breath and orthopnea. Chest X-ray reveals pulmonary congestion. Bronchoalveolar lavage shows hemosiderin-laden macrophages, as shown in the image below. What is the most likely diagnosis? {{caption_text}} (Q845258)

A. Right-sided heart failure

B. Left-sided heart failure

C. Pulmonary embolism

D. Acute myocardial infarction



Correct Answer: B. Left-sided heart failure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms and the histopathological findings of hemosiderin - laden macrophages known as ‘ Heart failure cells ’ are consistent with Left-sided heart failure. This condition is characterized by the heart's inability to pump blood effectively, causing backflow of blood, leading to pulmonary congestion and oedema. In pulmonary edema, the lungs appear wet and boggy, and chest X-ray shows characteristic Kerley B lines. Chronic congestion and microhemorrhages in the lungs result in the accumulation of hemosiderin - laden macrophages (Heart failure cells). These cells can be identified using special stains such as Perl's or Prussian blue , which detect hemosiderin's presence. Right-sided heart failure (Option A): causes systemic congestion, not pulmonary congestion → no hemosiderin-laden macrophages Pulmonary embolism (Option C): causes acute obstruction, not chronic congestion → no heart failure cells Acute myocardial infarction (Option D): can cause left-sided HF, but the finding itself is specific to left-sided HF, not MI directly

References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Pages 530-534

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 58-year-old male presents with complaints of chest pain and shortness of breath. He had a history of MI one month ago, for which he received appropriate

medical management. His vitals are stable, and his physical examination reveals a pericardial rub. An ECG shows diffuse ST-segment elevation. Which of the following is the most likely cause of this condition? (Q845320)

A. Ventricular aneurysm

B. Dressler syndrome

C. Arrhythmia

D. Myocardial rupture

Correct Answer: B. Dressler syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Dressler syndrom: From the given clinical presentation, the most likely cause is Dressler syndrome (autoimmune pericarditis or post-myocardial infarction pericarditis), which is a late complication of myocardial infarction and is characterised by pericardial inflammation. It typically presents weeks to months after the acute myocardial infarction event. Pathophysiology: After myocardial infarction, a necrotic (dead) area develops in the myocardium. In response, the body mounts an immune reaction against this dead tissue, leading to the formation of autoantibodies. These autoantibodies initiate an immune attack that targets the pericardium, resulting in pericardial inflammation. Clinically , this condition may manifest as a pericardial rub, chest pain, and characteristic ECG changes.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 551

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 55-year-old male with a history of hypertension and smoking presents with chest pain and shortness of breath. ECG shows ST-segment elevation in inferior leads. He undergoes PCI but, within hours, develops deteriorating cardiac function. What is the most likely primary mechanism of cardiac deterioration in this patient? (Q845317)

A. Oxidative stress

B. Intracellular calcium overload

C. Activation of coagulation cascade

D. Activation of the complement system

Correct Answer: B. Intracellular calcium overload

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Paradoxical worsening of myocardial damage after restoring blood flow is called reperfusion injury , where reopening a blocked coronary artery post-PCI unexpectedly causes further myocardial damage instead of improvement. Mechanism: Before reperfusion (during ischemia): At the blocked site, there is accumulation of free radicals and also calcium buildup inside ischemic tissue. After reperfusion (after PCI): Restoration of blood flow flushes these free radicals and calcium into the heart tissue. This sudden surge causes further myocardial injury instead of recovery. So the main cause of deterioration is Calcium overload which triggers mitochondrial dysfunction and cell death; worsening the cardiac injury The presence of ' Contraction bands ' in cardiac muscle tissue serves as histological markers of re-perfusion injury. {{caption_text}}

Robbins and Cotran Pathologic Basis of Disease,10th edition, Pages 52, 56

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Which histopathological feature would not be expected in the myocardium within the first 24 hours after the infarction onset? (Q845315)

A. Coagulative necrosis

B. Marginal contraction band necrosis

C. Neutrophilic infiltration

D. Neovascularisation

Correct Answer: D. Neovascularisation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: After Myocardial infarction , histopathological changes occur in a predictable time sequence . Within the first 24 hours , the myocardium mainly shows early necrosis and acute inflammatory changes , while repair processes such as angiogenesis (neovascularization) occur later during healing around 7–10 days after infarction. Coagulative necrosis (Option A): Coagulative necrosis is an early hallmark of myocardial infarction and begins within the first few hours after ischemia. Myocytes lose nuclei and cross-striations and cytoplasm becomes eosinophilic due to protein denaturation. Marginal contraction band necrosis (Option B): Contraction band necrosis may appear early after myocardial ischemia , especially in reperfusion injury and catecholamine excess. It is characterized by hypercontracted sarcomeres forming dense eosinophilic bands within myocardial fibers. These changes can occur within the first few hours to the first day after infarction, so they may be seen within 24 hours. Neutrophilic infiltration (Option C): Neutrophils begin to infiltrate the infarcted myocardium within 6–12 hours after infarction. Their numbers increase markedly by 24 hours . They release proteolytic enzymes , contributing to further tissue damage and removal of necrotic debris.

@Neet_pg_bot

Q17: What histopathological changes are typically observed during the reversible phase of myocardial infarction? Mitochondrial swelling Sarcolemmal disruption Relaxation of myofibrils (Q845301)

A. 1, 2, and 3

B. 1 and 3

C. 2 and 3

D. Only 3

Correct Answer: B. 1 and 3

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Chest pain, shortness of breath, and ST-segment elevation on ECG indicate myocardial infarction (MI). Mitochondrial swelling and relaxation of myofibrils are the histopathological changes observed during the reversible phase of MI . HPE changes in MI Reversible injury Irreversible injury Earliest change in Electron microscopy Relaxation of myofibrils (Statement 3) , Mitochondrial swelling (Statement 1) Sarcolemmal disruption (Statement 2) , Mitochondrial amorphous densities. Earliest change in Light microscopy None The waviness of cardiac fibres and myocyte vacuolisation.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 547

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: In a patient with acute myocardial infarction, which of the following is a characteristic change in LDH isoenzyme levels indicative of myocardial damage in this patient? (Q845299)

A. Elevated LDH2 levels

B. Decreased LDH1/LDH2 ratio

C. Increased LDH2/LDH1 ratio

D. Increased LDH1/LDH2 ratio

Correct Answer: D. Increased LDH1/LDH2 ratio

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: LDH isoenzyme levels in blood: In healthy individuals LDH2>>LDH1 In MI patients LDH1>>LDH2 LDH1, which is predominantly found in heart tissue, is released into the bloodstream when cardiac fibers die during myocardial infarction. Flipping of LDH ratio: Ratio of LDH2/LDH1 >1 in healthy individuals is flipped in MI patients as LDH1/LDH2 >1 Isoenzymes of LDH and CK & their common locations Isoenzymes Location Isoenzymes of LDH LDH - 1 Mainly in heart & RBC LDH - 2 WBC, (small amounts in heart and RBC) LDH - 3 Lungs LDH - 4 Kidneys & Pancreas; Placenta (in pregnancy) LDH - 5 Liver & skeletal muscles

@Neet_pg_bot

Q19: A 58-year-old man presents to the emergency department with sudden-onset chest pain radiating to his left arm and jaw, along with diaphoresis and anxiety. His vital signs show a blood pressure of 160/90 mmHg, heart rate of 110 bpm, and oxygen saturation of 94% on room air. An ECG reveals ST-segment elevation in leads II, III, and aVF, suggestive of acute myocardial infarction (MI). Which of the following biomarkers is most reliable for confirming myocardial injury in this condition? (Q845297)

A. Myoglobin

B. CK-MB (Creatine Kinase-MB)

C. Cardiac-specific troponin I (cTn I)

D. Atrial natriuretic peptide (ANP)

Correct Answer: C. Cardiac-specific troponin I (cTn I)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Cardiac-specific troponins are of different types, like Troponin I (cTNI) and Troponin T (cTnT). cTnI is considered as the most specific cardiac-specific troponin for MI. Troponin levels rise within 2–4 hours after myocardial infarction, peak at 24–48 hours, remain elevated for several days, and gradually fall by the 7th–10th day. Similar rising time is also seen with CK-MB, but it falls within 2-3 days. (Option B ruled out) Myoglobin is the earliest cardiac marker to rise after MI, rising within 2 hours, but it also falls rapidly, returning to normal within 24 hours. Rise of myoglobin is considered non-specific for MI because it can also rise in any cardiac or skeletal muscle injury like a crush injury after RTA. (Option B ruled out)

References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 550

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 50-year-old woman presents to the emergency department with recurrent episodes of chest pain radiating to her left arm and jaw that occur at rest and are not triggered by physical exertion. ECG during an episode shows transient ST-segment

elevation. Troponin levels are normal. Which type of angina is most likely responsible for her symptoms? (Q845263)

A. Stable Angina

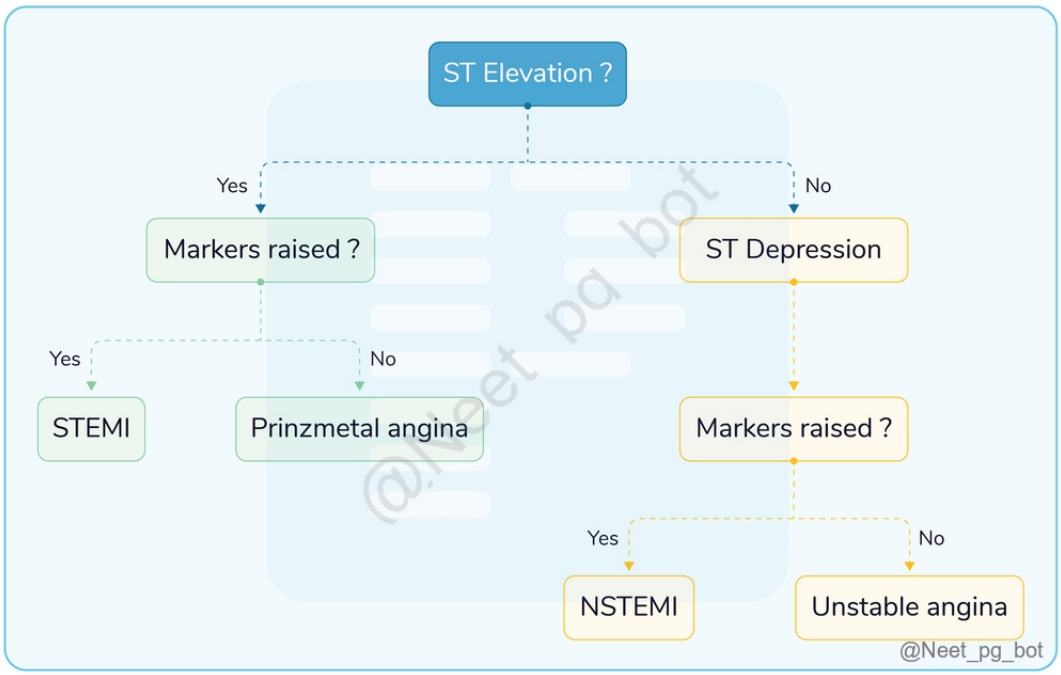
B. Unstable Angina

C. Silent Angina

D. Prinzmetal Angina

Correct Answer: D. Prinzmetal Angina

Explanation: Angina pectoris is characterized by paroxysmal and usually recurrent attacks of substernal or precordial chest discomfort caused by transient myocardial ischemia without the death of myocytes. Type Stable Angina (Option A) Prinzmetal variant angina Unstable or crescendo angina (Option B) Trigger Physical exertion/stress At rest At rest or minimal exertion Cause Chronic coronary stenosis Coronary vasospasm Plaque disruption, ↑ MI risk Treatment response Responds well. Responds well. Need immediate medical intervention. Silent angina (Option C) is asymptomatic myocardial ischemia, detected incidentally on ECG, stress test, or Holter.



References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 543

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: Which of the following statements is incorrect regarding the pathologic changes in right-sided heart failure? (Q845262)

A. Nutmeg liver appearance.

B. Pretibial oedema is the hallmark of right-sided heart failure.

C. Fibrosis in periportal areas of the liver

D. Congestive splenomegaly due to portal hypertension

Correct Answer: C. Fibrosis in periportal areas of the liver

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Periportal fibrosis occurs in chronic liver diseases (hepatitis, alcohol, NAFLD, autoimmune), while right-sided heart failure causes centrilobular fibrosis from chronic congestion, termed cardiac cirrhosis . Options A, B, and D are the pathological changes seen in Right-sided heart failure. Nutmeg liver appearance (Option A): Severe right-sided heart failure causes venous congestion, producing a nutmeg liver with pericentral congestion, periportal pallor, hepatomegaly, elevated liver enzymes, and possible centrilobular necrosis. {{caption_text}} Pretibial oedema (Option B): Pretibial edema, from fluid pooling in dependent areas, is a hallmark of right-sided heart failure. Congestive splenomegaly (Option D): Splenomegaly in right-sided heart failure occurs due to portal hypertension, causing increased portal pressure and platelet sequestration.

Q7 (p. 1657) *Q8 (p. 1658)* *Q9 (p. 1661)* *Q10 (p. 1662)* *Q11 (p. 1663)* *Q12 (p. 1664)*
Q13 (p. 1666)

Q1: Which of the following statements about rheumatic heart disease (RHD) is incorrect? (Q845229)

A. An abnormal immune response to Group A Streptococcus infection causes RHD.

B. RHD commonly affects the pulmonary valve, resulting in valvular stenosis or regurgitation.

C. Chronic inflammation and scarring of heart valves.

D. Prevented with timely treatment of streptococcal infections with antibiotics.

Correct Answer: B. RHD commonly affects the pulmonary valve, resulting in valvular stenosis or regurgitation.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pulmonary valve is the least common valve affected by rheumatic heart disease (RHD). The mitral valve is most commonly affected. RHD is a condition that develops as a complication of untreated or inadequately treated acute rheumatic fever (ARF), which is caused by an abnormal immune response to an infection with Group A beta-hemolytic Streptococcus bacteria (aka Streptococcus pyogenes) (Option A is ruled out). The bacteria trigger an immune response that leads to chronic inflammation and scarring of heart valves (Option C is ruled out) , commonly causing mitral stenosis . Early treatment of streptococcal infections with antibiotics can help prevent initial rheumatic fever and subsequent rheumatic heart disease (Option D is ruled out) .

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 560

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 10-year-old child presents to the clinic with complaints of shortness of breath and fatigue. Upon examination, a diastolic murmur along the left sternal border is detected. An echocardiogram reveals mitral valve stenosis and regurgitation, consistent with Rheumatic heart disease (RHD). What is the most common predisposing condition for this patient to develop RHD? (Q845231)

A. Streptococcal pharyngitis

B. Streptococcal skin infections

C. Streptococcal glomerulonephritis

D. All the above

Correct Answer: A. Streptococcal pharyngitis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Rheumatic heart disease (RHD) is caused by Group A beta-hemolytic streptococcus (GABHS) , also known as Streptococcus pyogenes . Streptococcal pharyngitis is the infection that most commonly predisposes to RHD. RHD can develop 2–3 weeks after an episode of streptococcal pharyngitis. The typical age group affected is 5–15 years, and approximately 3% of children with streptococcal pharyngitis may develop RHD. Streptococcal skin infections (Option B) (e.g., impetigo) are associated with streptococcus but are not linked to RHD. Streptococcal glomerulonephritis (Option C): PSGN is also caused by streptococcus but does not predispose to RHD.

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 560

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 7-year-old child presented to the clinic with fever, joint pain, and rash with a history of sore throat about three weeks ago, which resolved without treatment. Examination reveals a rash characterized by pink to red lesions with well-defined borders and tender, swollen joints. What is the primary mechanism underlying the development of acute rheumatic fever (ARF) in this patient following the untreated sore throat? (Q845232)

A. Direct invasion of tissues by streptococcal bacteria

B. Delayed hypersensitivity reaction to streptococcal exotoxins

C. Cross-reactivity between streptococcal antigens and host proteins

D. Activation of complement by streptococcal toxins

Correct Answer: C. Cross-reactivity between streptococcal antigens and host proteins

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Acute rheumatic fever (ARF): Symptoms / Clinical Features: Fever, Arthralgia / joint pain, Rash, Sore throat (3 weeks ago, indicative of prior streptococcal infection). Causative agent of ARF is Group A beta-hemolytic Streptococcus (GABHS), also called Streptococcus pyogenes. Underlying Mechanism: Molecular Mimicry / Cross-Reactivity: ■■■■■■■ Streptococcus M-protein is the major bacterial antigen. Human glycoproteins are present in the heart, joints, and skin. Similarity between M-protein and human glycoproteins ("twin brothers") leads to mimicry.

@Neet_pg_bot

Q5: Which of the following is a major criterion in the Jones criteria for diagnosing acute rheumatic fever (ARF)? (Q845241)

A. Polyarthralgia involving two or more joints

B. Fever (≥38.5°C)

C. Elevated acute phase reactants

D. Subcutaneous nodules over bony prominences

Correct Answer: D. Subcutaneous nodules over bony prominences

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Jones criteria for diagnosing acute rheumatic fever (ARF): Used for diagnosis of Rheumatic Fever (RF): The presence of two major criteria, or one major criterion + two minor criteria (along with evidence of preceding streptococcal infection), supports the diagnosis of acute rheumatic fever (ARF) according to the Jones criteria. Major criteria Minor criteria Clinical or subclinical evidence of Carditis/Pancarditis (e.g., new murmur) Migratory polyarthritis (Two or more joints involved) Sydenham chorea (involuntary movements, late manifestation) Erythema marginatum (characteristic skin rash) Subcutaneous nodules over bony prominences (Option D) Clinical: Previous rheumatic fever or rheumatic heart disease Fever (≥38.5°C) (Option B) Poly or mono arthralgia (Option A) Laboratory: Elevated acute phase reactants (e.g., CRP, ESR) (Option C) Prolonged PR interval on ECG Supporting evidence of prior streptococcal infection: Proof within past 45 days of: Throat swab culture for Streptococcus Antigen testing for Streptococcus Antibody titers (e.g., ASO titer) {{caption_text}}

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 562

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 54-year-old man with a history of mitral valve prolapse presents to the clinic with fever and malaise following a recent dental procedure. On examination, a new regurgitant murmur is auscultated. Blood cultures are obtained, and subsequent testing reveals the presence of gram-positive cocci in chains. Which of the following organisms is most likely responsible for the new onset murmur in this patient? (Q845246)

A. Staphylococcus aureus

B. Streptococcus viridans

C. Staphylococcus epidermidis

D. Enterococci

Correct Answer: B. Streptococcus viridans

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The presence of gram-positive cocci in chains in blood cultures suggests an infection with a streptococcal species. Streptococcus viridans is a commensal organism found in the oral cavity, upper respiratory tract, and gastrointestinal tract . While normally harmless, it can enter the bloodstream after dental procedures or mucosal injury , leading to subacute infective endocarditis in individuals with underlying valve abnormalities like mitral valve prolapse . Staphylococcus aureus (Option A): Bunch of grapes appearance. Staphylococcus epidermidis (Option C): It is a cocci, but without any specific shape. Enterococci (Option D): Spectacles shaped

@Neet_pg_bot

Q7: Which of the following statements best describes the nature of vegetation in infective endocarditis (IE)? (Q845247)

A. Smooth and non-destructive lesions

B. Typically contain only fibrin and inflammatory cells

C. Prone to embolisation

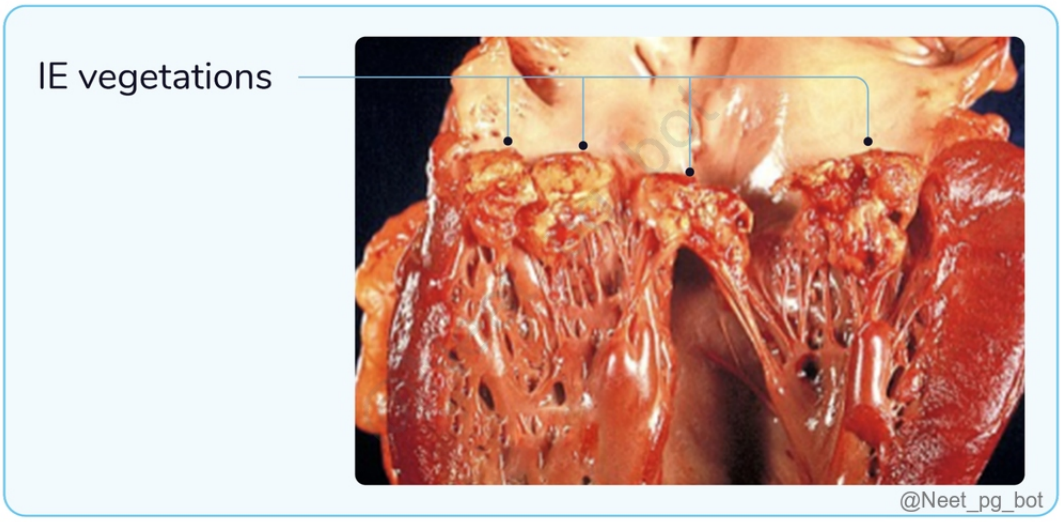
D. Most commonly found on the tricuspid valve

Correct Answer: C. Prone to embolisation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Vegetation in infective endocarditis is large and bulky , typically composed of fibrin, platelets, microorganisms, and inflammatory cells (Option B) Embolization: Due to bulkiness , parts of the vegetation can break off, and these detached fragments are called emboli, which can travel through the bloodstream, causing systemic embolization. Embolization is common but not guaranteed. {{caption_text}} Smooth and non-destructive lesions (Option A): Seen in non-bacterial thrombotic endocarditis (NBTE), not in infective endocarditis. Contain only fibrin and inflammatory cells (Option B): IE vegetations also include microorganisms and platelets. Most commonly found on the tricuspid valve (Option D): True mainly in IV drug users ; overall, the mitral valve is the most commonly affected.



References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Pages 563-564

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 30-year-old man with a history of intravenous drug use presents with fever, chills, and fatigue for the past week. On examination, the patient has multiple lesions on the palms and soles as shown below. The patient also has a new heart murmur.

Blood cultures are positive for Staphylococcus aureus. What are these lesions shown below? {{caption_text}} (Q845249)

A. Splinter hemorrhages

B. Osler nodes

C. Janeway lesions

D. Roth spots

Correct Answer: C. Janeway lesions

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario suggests Infectious endocarditis (IE) occurred as a complication of Rheumatic Heart Disease (RHD). The clinical finding shown in the image is ‘Janeway lesions’ seen in Infective endocarditis, which are painless, erythematous or hemorrhagic lesions on the palms or soles resulting from septic microemboli affecting the small blood vessels in the skin. Splinter hemorrhages (Option A): Painless linear hemorrhages under fingernails Osler nodes (Option B): Painful nodules, commonly on fingers and toes Roth spots (Option D): Retinal hemorrhages: Not specific for IE, as also seen in diabetic/hypertensive retinopathy. Janeway lesions: {{caption_text}} Splinter hemorrhages {{caption_text}} Osler nodes: {{caption_text}} Roth spots: {{caption_text}}

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following is not a predisposing factor for Nonbacterial Thrombotic Endocarditis (NBTE)? (Q845251)

A. Advanced malignancy

B. Antiphospholipid antibody syndrome

C. Systemic lupus erythematosus

D. Traumatic injury to the heart valves

Correct Answer: D. Traumatic injury to the heart valves

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: NBTE = Non-Bacterial Thrombotic Endocarditis Non-bacterial → not caused by any bacterial infection Thrombotic → formation of sterile thrombi (blood clots) Endocarditis → affects the heart valves Thrombi in NBTE form on damaged or hypercoagulable valves, so only conditions that promote thrombus formation can lead to its development. Predisposing Factors: Advanced malignancies, such as pancreatic or lung cancer, where tumors produce mucin that is thrombogenic and promotes valve thrombus formation. ■■■■■■■ Autoimmune Disorders like SLE (Systemic Lupus Erythematosus) or APLA (Antiphospholipid Antibody Syndrome), which cause valve damage or a hypercoagulable state leading to thrombi. Non-Predisposing Factor: Traumatic injury does not predispose to NBTE, as trauma does not produce sterile thrombi on valves.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th edition, Page 564

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Match the following pathologies with the correct pattern of vegetative endocarditis caused by them: 1. Rheumatic Heart Disease a) Small, warty, sterile vegetations along the line of closure of valve leaflets 2. Infective Endocarditis b) Small, bland, sterile vegetation along the line of closure 3.Non-bacterial thrombotic endocarditis (NBTE) c) Small or medium-sized sterile vegetations on both sides of valvular leaflets. 4. Libman-Sacks endocarditis d) Large, bulky, infected, friable, irregular mass along the line of closure or on valvular cusps. (Q845253)

A. 1-a, 2-d, 3-c, 4-b

B. 1-a, 2-d, 3-b, 4-c

C. 1-b, 2-d, 3-c, 4-a

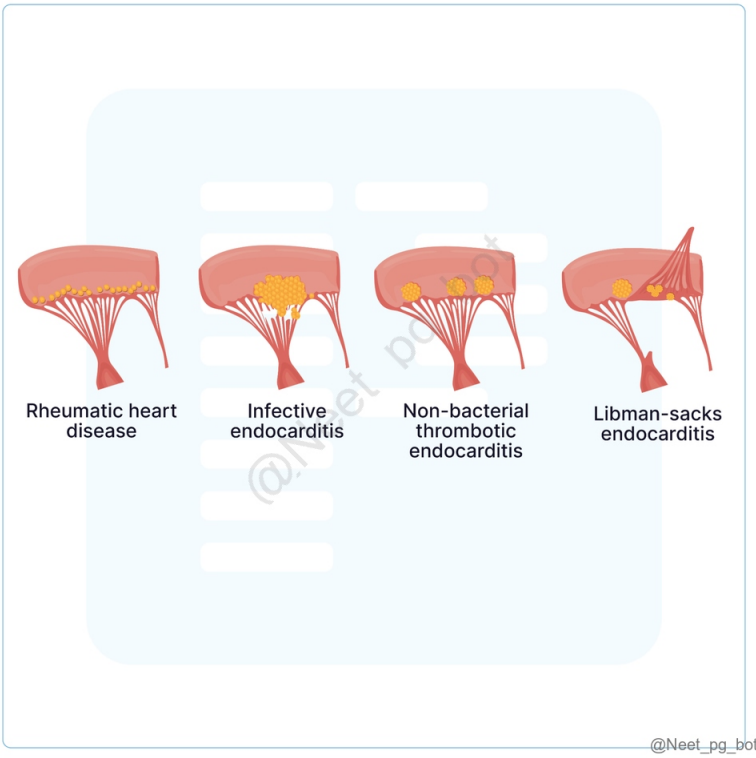
D. 1-d, 2-c, 3-b, 4-a

Correct Answer: B. 1-a, 2-d, 3-b, 4-c

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Condition Vegetations and site Rheumatic heart disease Small, warty, sterile vegetations along the line of closure of valve leaflets. Infective Endocarditis Large, bulky, infected, friable, irregular mass along the line of closure or on valvular cusps, more on the atrial side. They cause damage to cordae tendinae and papillary muscles. Non-bacterial Thrombotic Endocarditis Small, bland, sterile vegetation along the line of closure. Libman-Sacks Endocarditis (Endocarditis of SLE) Small or medium-sized sterile vegetations on either or both sides of valvular leaflets, most commonly on the lower side. {{caption_text}}



References:

Robbins and Cotran Pathologic Basis of Disease,10th edition, Page 562

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following correctly lists the valves in order from most commonly to least commonly affected in chronic rheumatic heart disease? (Q889827)

A. Mitral > Aortic > Tricuspid > Pulmonary

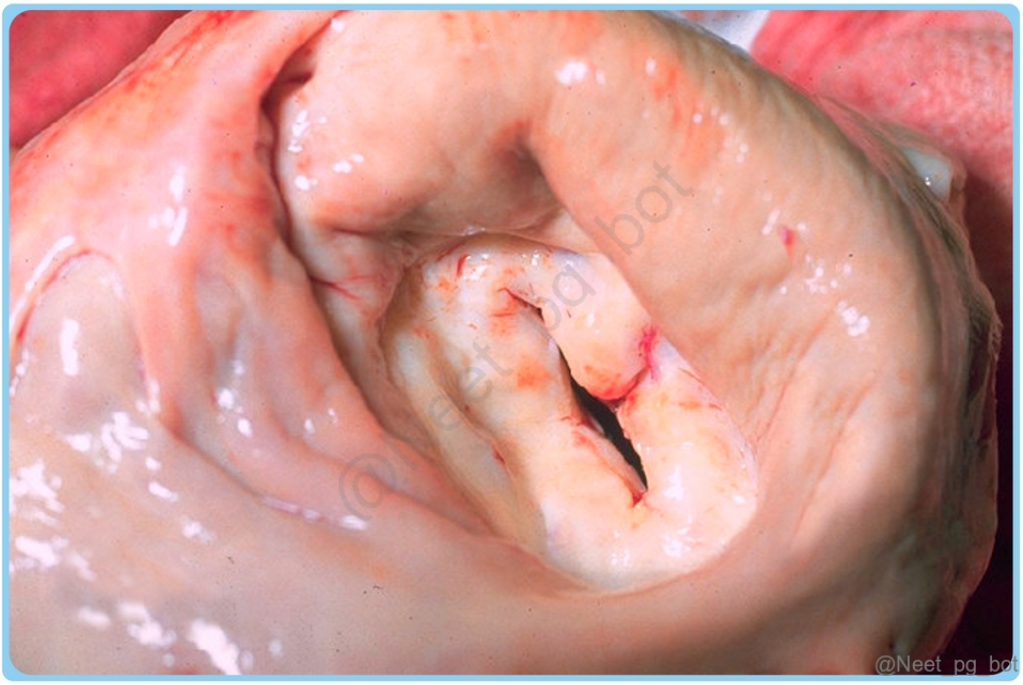
B. Aortic > Mitral > Tricuspid > Pulmonary

C. Mitral > Tricuspid > Aortic > Pulmonary

D. Pulmonary > Tricuspid > Mitral > Aortic

Correct Answer: A. Mitral > Aortic > Tricuspid > Pulmonary

Explanation: Mitral > Aortic > Tricuspid > Pulmonary is correct because the mitral valve is affected in nearly all cases of chronic rheumatic heart disease, followed by the aortic valve. Tricuspid involvement is uncommon, and pulmonary valve involvement is rare. Chronic Rheumatic Heart Disease (RHD): Mitral Valve (Most Commonly Affected): Leaflet thickening Commissural fusion Thickened, shortened, fused chordae tendineae Leads to mitral stenosis ("fish-mouth" valve) Valve involvement pattern: Mitral alone → ~65% Mitral + aortic → ~25% Tricuspid → uncommon Pulmonary → rare



References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 510

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 40-year-old woman with a history of Acute rheumatic fever in childhood had long-standing exertional dyspnea and palpitations. At autopsy, the mitral valve shows

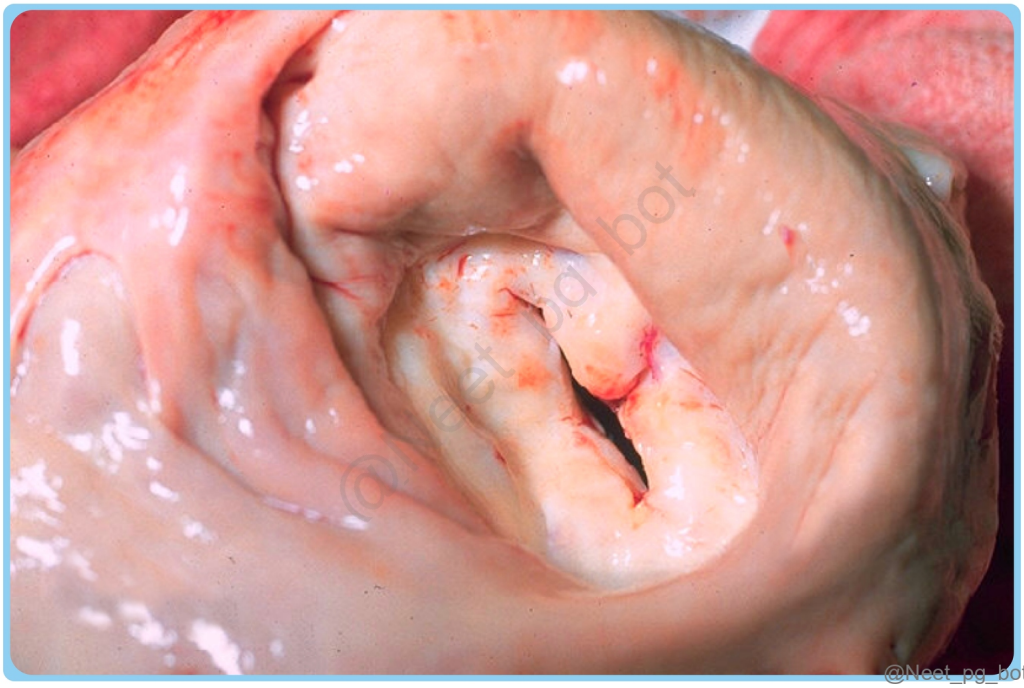
findings as shown. Which pathological process is primarily responsible for this deformity? (Q889828)

A. Vegetation formation

B. Myxomatous degeneration

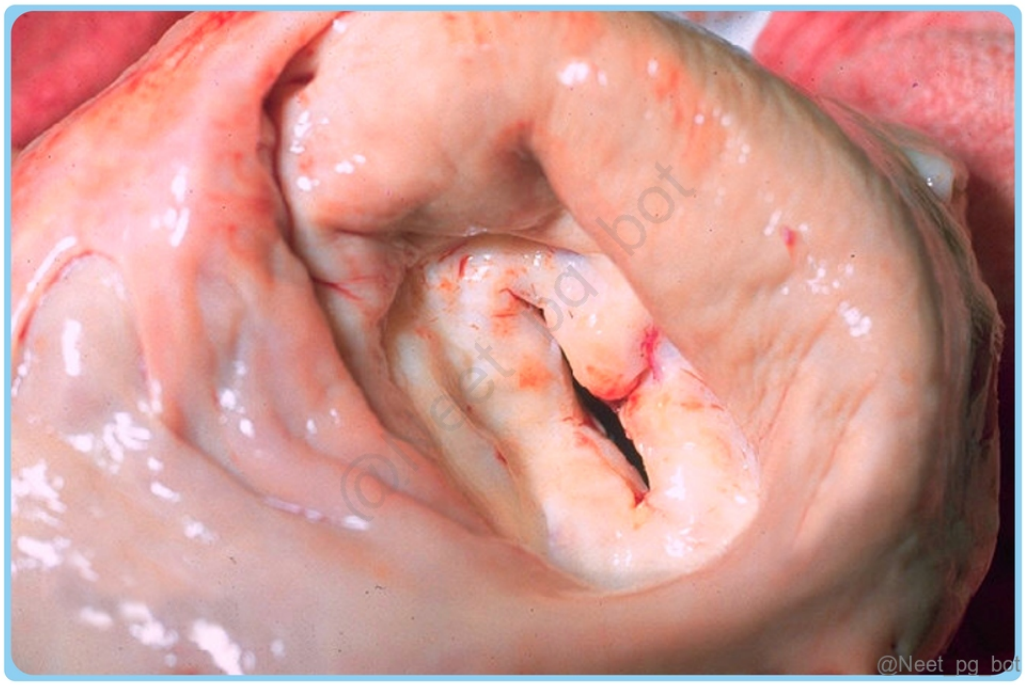
C. Calcification and fibrosis

D. Fibrofatty replacement



Correct Answer: C. Calcification and fibrosis

Explanation: Chronic rheumatic heart disease is characterised by organised inflammation that leads to fibrous thickening of the valve leaflets and commissural fusion . This fusion, often accompanied by calcification, creates the rigid, stenotic, "fish-mouth" deformity typical of the mitral valve in these patients. Gross Features: Commissural fusion + fibrous bridging Leaflet thickening and calcification Classic “fish-mouth” stenosis Vegetation formation (Option A): Seen in acute rheumatic carditis or infective endocarditis; does not produce chronic stenosis. Myxomatous degeneration (Option B): Associated with mitral valve prolapse and regurgitation, not stenosis. Fibrofatty replacement (Option D): Characteristic of arrhythmogenic right ventricular cardiomyopathy, not valvular disease.



References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 511

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which organism is most commonly responsible for infective endocarditis in a previously normal valve? (Q889832)

A. Viridans streptococci

B. Staphylococcus aureus

C. Enterococcus faecalis

D. HACEK organisms

Correct Answer: B. Staphylococcus aureus

Explanation: The most likely organism is Staphylococcus aureus, as it is highly virulent and can infect previously normal valves, causing acute, rapidly destructive infective endocarditis. Infective Endocarditis - Pathogenesis: Predisposing Cardiac Lesions: Rheumatic heart disease (historically most common) Mitral valve prolapse Degenerative calcific stenosis Bicuspid aortic valve Prosthetic valves Congenital heart disease Common Causative Organisms: Native, damaged valves (50–60%): Viridans streptococci (Option A) (oral flora) Most common

overall: Staphylococcus aureus Infects normal or abnormal valves Most common in IV drug users Others: Enterococci HACEK group (oral commensals) (Option D) Gram-negative bacilli Fungi (rare) Prosthetic valve endocarditis: Early (<2 months): S. aureus, S. epidermidis (skin flora) Late (>1 year): Streptococci, S. aureus

Q19 (p. 1685)	*Q20 (p. 1686)*	*Q21 (p. 1687)*	*Q22 (p. 1688)*		

Q1: A 30-year-old woman from a rural area presents with progressively worsening dyspnea on exertion and bilateral lower limb swelling for the past few months. She reports a history of recurrent fevers and weight loss over the past year. Physical examination reveals elevated jugular venous pressure, ascites, and hepatomegaly. Chest X-ray shows an enlarged cardiac silhouette. Echocardiography reveals restrictive filling patterns with apical obliteration and thickened endocardium. What is the most likely diagnosis? (Q845431)

A. Hypertrophic cardiomyopathy

B. Dilated cardiomyopathy

C. Endomyocardial fibrosis

D. Constrictive pericarditis

Correct Answer: C. Endomyocardial fibrosis

Explanation: Congestive heart failure (dominant right-sided symptoms) and echo findings are highly suggestive of endomyocardial fibrosis , a form of restrictive cardiomyopathy. Endomyocardial fibrosis: Endomyocardial fibrosis, mainly affecting children and young adults in tropical regions, causes fibrous thickening of the ventricular endocardium from the apex upward, often involving tricuspid and mitral valves. This fibrosis reduces chamber volume and compliance, leading to restrictive heart function, and is linked to nutritional deficiencies and parasitic-related inflammation. Thrombus formation within the ventricles can also occur.

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 574

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 6-month-old infant presents with progressive heart failure. Echocardiography shows diffuse fibroelastic thickening of the left ventricular endocardium with reduced ventricular compliance. There is a history of intrauterine viral exposure. Which infection is most commonly associated with this condition? (Q889821)

A. Rubella

B. Mumps

C. Epstein-Barr virus

D. Cytomegalovirus

Correct Answer: B. Mumps

Explanation: Intrauterine mumps infection is classically associated with endocardial fibroelastosis in infants. Endocardial Fibroelastosis (EFE): Rare pediatric heart disease Fibroelastic thickening of the left ventricular endocardium Most common in children < 2 years ~1/3 cases associated with: Aortic valve obstruction Other congenital heart defects Etiology: Viral infections (e.g., intrauterine mumps) Tafazzin gene mutation (mitochondrial membrane protein defect) Pathology: Diffuse LV endocardial thickening Leads to reduced compliance → diastolic dysfunction Rapid, progressive heart failure May result in early death if diffuse and severe Rubella (Option A): Associated with congenital heart defects such as patent ductus arteriosus and pulmonary artery stenosis, but not classically with endocardial fibroelastosis. Epstein-Barr virus (Option C): Not associated with endocardial fibroelastosis. Primarily causes infectious mononucleosis and certain lymphoproliferative disorders. Cytomegalovirus (Option D): Can cause congenital infection and myocarditis, but is not the classic association described for endocardial fibroelastosis.

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 522

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 32-year-old man presents with progressive dyspnea. Labs show marked eosinophilia. Imaging shows endomyocardial fibrosis with mural thrombus. Which type of cardiomyopathy is most likely? (Q889817)

A. Dilated cardiomyopathy

B. Hypertrophic cardiomyopathy

C. Restrictive cardiomyopathy

D. Arrhythmogenic RV cardiomyopathy

Correct Answer: C. Restrictive cardiomyopathy

Explanation: The most likely diagnosis is Restrictive cardiomyopathy . The clinical triad of endomyocardial fibrosis , mural thrombi , and marked eosinophilia is characteristic of Loeffler endomyocarditis, a major cause of the restrictive phenotype. This condition is characterised by a primary decrease in ventricular compliance, resulting in impaired ventricular filling during diastole. Loeffler endomyocarditis: Endomyocardial fibrosis + large mural thrombi Marked peripheral eosinophilia Eosinophilic infiltration of multiple organs Pathogenesis: Eosinophil major basic protein → necrosis → thrombus → fibrosis May be associated with myeloid neoplasm Responds to tyrosine kinase inhibitors Dilated cardiomyopathy (Option A) : Ventricular dilation with systolic dysfunction, not fibrosis from eosinophilia. Hypertrophic cardiomyopathy (Option B) : Asymmetric septal hypertrophy without eosinophilia or mural thrombus. Arrhythmogenic RV cardiomyopathy (Option D) : Fibrofatty replacement of the right ventricle, not eosinophil-mediated fibrosis.

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 522

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 13-year-old boy presents with recurrent syncope and palpitations. He has tightly curled woolly hair since birth and diffuse palmoplantar keratoderma since early childhood. ECG shows T-wave inversion in V1-V3, and echocardiography reveals right ventricular dilatation. What is the most likely diagnosis? (Q889814)

A. Carvajal syndrome

B. Naxos disease

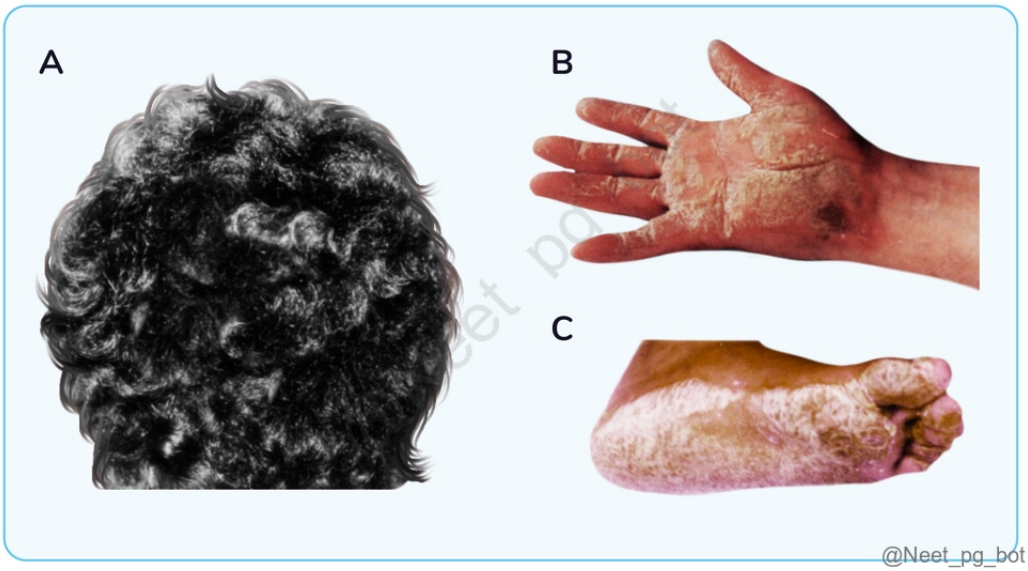
C. Noonan syndrome

D. Isolated ARVC

Correct Answer: B. Naxos disease

Explanation: Naxos disease presents with the classic triad: woolly hair (from birth), palmoplantar keratoderma, and arrhythmogenic right ventricular cardiomyopathy. Naxos disease: Rare autosomal recessive genodermatosis combining: Woolly hair + Palmoplantar keratoderma + Cardiomyopathy . Caused by mutations affecting desmosomal proteins , especially: Plakoglobin gene - classic Naxos. Desmoplakin gene mutations - seen in a

Carvajal syndrome variant with left-ventricular involvement. Clinical features: Hair: Woolly, sparse, curly hair present from birth. Skin: Diffuse palmoplantar keratoderma emerging in infancy. Heart: Arrhythmogenic right ventricular cardiomyopathy (ARVC) typically develops by adolescence, with high penetrance . Early asymptomatic ventricular changes can occur in childhood Management: Close cardiac follow-up with ECG and imaging. Preventive strategies include: Implantable cardioverter-defibrillator (ICD) in symptomatic or high-risk patients Carvajal syndrome (Option A) also presents with woolly hair and palmoplantar keratoderma, but it predominantly involves left ventricular cardiomyopathy rather than right ventricular disease. Noonan syndrome (Option C) is associated with facial dysmorphism, short stature, and pulmonary valve stenosis or hypertrophic cardiomyopathy, not woolly hair with palmoplantar keratoderma. Arrhythmogenic right ventricular cardiomyopathy (Option D) : Isolated ARVC lacks the characteristic cutaneous findings (woolly hair and palmoplantar keratoderma) seen in Naxos disease.



References:

https://ijdvl.com/naxos-disease-a-rare-occurrence-of-cardiomyopathy-with-woolly-hair-and-palmoplantar-keratoderma/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following deficiencies is associated with the development of dilated cardiomyopathy? Thiamine deficiency Selenium deficiency Vitamin B12 deficiency Carnitine deficiency (Q889812)

A. 1, 2 and 4

B. 1 and 3

C. 2 and 3

D. 3 and 4

Correct Answer: A. 1, 2 and 4

Explanation: Dilated cardiomyopathy can result from metabolic and nutritional deficiencies that impair myocardial energy production. Metabolic Causes of DCM: Nutritional deficiency: Thiamine (Vitamin B1) Deficiency : This leads to "Wet Beriberi," characterised by high-output heart failure and significant ventricular dilatation. Selenium Deficiency : Associated with Keshan disease , a specific form of dilated cardiomyopathy originally identified in regions with selenium-poor soil. Carnitine Deficiency : Carnitine is essential for transporting fatty acids into the mitochondria for energy production; a deficiency impairs myocardial metabolism, frequently resulting in a dilated phenotype. Electrolyte deficiency: calcium, phosphate, magnesium Endocrine disorders: thyroid disease, pheochromocytoma Diabetes, obesity Hemochromatosis

Harrison’s Principles of Internal Medicine, 21st Edition, Page 1959

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 48-year-old man presents with progressive dyspnea and echocardiographic evidence of dilated cardiomyopathy; which of the following is the most likely risk factor? (Q889810)

A. Hypertension

B. Alcohol abuse

C. Hyperlipidemia

D. Rheumatic fever

Correct Answer: B. Alcohol abuse

Explanation: Alcohol abuse is a well-established risk factor for dilated cardiomyopathy. Chronic alcohol consumption causes direct myocardial toxicity (via ethanol and acetaldehyde), leading to progressive ventricular dilation and systolic dysfunction. Dilated Cardiomyopathy (DCM): Four-chamber dilation with systolic dysfunction Most common cardiomyopathy (age 20-50 yrs) Causes: Genetic: Most common: Titin (TTN) mutation Others : Lamin A/C, dystrophin AD > X-linked > mitochondrial Myocarditis: Often viral (e.g., Coxsackie B) Toxins: Alcohol (acetaldehyde toxicity, thiamine deficiency) Chemotherapy (doxorubicin) Heavy metals (cobalt) Peripartum cardiomyopathy: Late pregnancy / ≤5 months postpartum Antiangiogenic factors implicated Iron overload: Hemochromatosis or transfusion-related Catecholamine excess / Stress: Pheochromocytoma, cocaine Takotsubo (“broken heart syndrome”) Hypertension (Option A): Typically causes

left ventricular hypertrophy and diastolic dysfunction rather than primary dilated cardiomyopathy. Hyperlipidemia (Option C): Predisposes to atherosclerosis and ischemic heart disease, not primary DCM. Rheumatic fever (Option D): Leads to valvular heart disease, particularly mitral stenosis, not dilated cardiomyopathy.

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 516

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following is the least common type of cardiomyopathy? (Q889806)

A. Dilated cardiomyopathy

B. Hypertrophic cardiomyopathy

C. Restrictive cardiomyopathy

D. Peripartum cardiomyopathy

Correct Answer: C. Restrictive cardiomyopathy

Explanation: Restrictive cardiomyopathy is the least common of the three major pathologic patterns of cardiomyopathy. Among the primary categories, dilated cardiomyopathy is the most common (~90% of cases), while restrictive cardiomyopathy is the rarest. Cardiomyopathies are intrinsic myocardial diseases causing cardiac dysfunction. Primary → Predominantly confined to the myocardium Secondary → Cardiac manifestation of a systemic disorder Etiology: Inflammatory disorders → Myocarditis Immunologic diseases → Sarcoidosis Metabolic disorders → Hemochromatosis Muscular dystrophies Genetic disorders affecting myocardial fibres Major patterns: Dilated Cardiomyopathy (DCM) (Option A): Most common (~90%) Hypertrophic Cardiomyopathy (HCM) (Option B) Restrictive Cardiomyopathy (RCM) Least common Peripartum cardiomyopathy (Option D): A subtype of dilated cardiomyopathy occurring in late pregnancy or the early postpartum period; more common than restrictive cardiomyopathy.

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 516

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 28-year-old male presents with palpitations and dizziness during a soccer match. He is diagnosed with ARVC (Arrhythmogenic Right Ventricular

Cardiomyopathy). Which of the following statements about this condition is true? Statement 1 - It is an autosomal recessive disorder Statement 2 - Associated with NAXOS syndrome Statement 3 - Marked by fatty infiltration and focal fibrosis within the ventricle Statement 4 - It involves mutation in Plakoglobin (Q846623)

A. 1, 2, 3

B. 1, 3, 4

C. 2, 3, 4

D. 1, 2, 3,4

Correct Answer: C. 2, 3, 4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) is an autosomal dominant disorder. (Statement 1 ruled out) The right ventricular wall is markedly thinned due to myocyte loss, with extensive yellowish fatty infiltration and focal fibrosis (Statement 3) . ARVC occurs due to desmosomes mutation. Mutations in genes encoding desmosomal junctional proteins at the intercalated disk (e.g., plakoglobin) (Statement 4) Associated with NAXOS syndrome (Statement 2) , it includes: Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) Woolly hair Palmo-plantar keratoderma (Thick palms and soles due to hyperkeratosis) NAXOS syndrome is an autosomal recessive disorder.

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 572.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 6-month-old infant presents with cyanosis and respiratory distress. Physical examination reveals a murmur and a palpable liver edge. Echocardiography demonstrates multiple intracardiac masses located primarily in the ventricular walls. What is the most likely diagnosis? (Q845436)

A. Rhabdomyoma

B. Cardiac fibroma

C. Myxoma

D. Metastatic neuroblastoma

Correct Answer: A. Rhabdomyoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: RHABDOMYOMA Most common cardiac tumor in adults: Myxoma, occuring more commonly in left atria. Rhabdomyoma is the most common benign tumor in children, which is most commonly found in left ventricle. On histopathology, Myxoma shows Lepidic cells and Rhabdomyoma shows spider cells. Microscopy shows spider cells showing vacuolated cytoplasm comprised of glycogen. These are positive for PAS Stain. Rhabdomyoma is associated with tuberous sclerosis. Tuberous sclerosis is a syndrome which is caused by TSC gene (TSC1 and TSC2 genes). All hamartomas occur under this syndrome, and rhabdomyoma is also considered a hamartoma. The image below shows spider cells. {{caption_text}}

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 579,580

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Identify the true statements regarding atrial myxoma. 1) It is the most common primary tumor of the heart in adults. 2) It is a malignant neoplasm. 3) It is associated with mutations in the GNAS1 gene. 4) 90% of these tumors arise from ventricles. 5) Histologically, it contains lepidic cells (Q845434)

A. 1,2,3

B. 1,2,3,4,5

C. 1,3,4

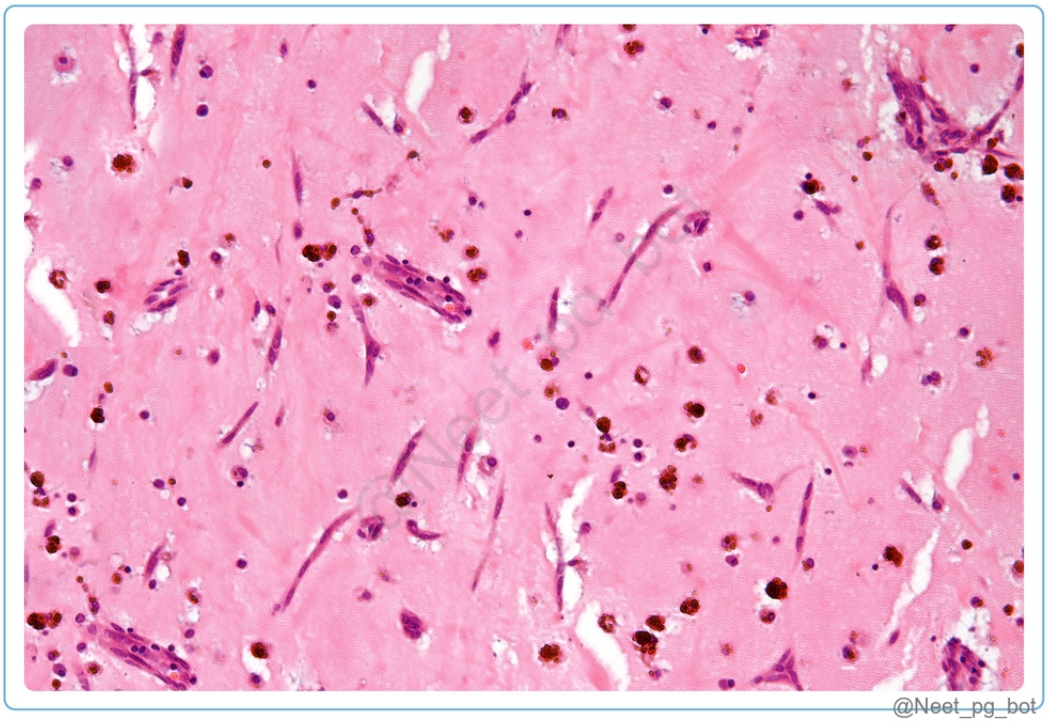
D. 1,3,5

Correct Answer: D. 1,3,5

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Atrial myxoma: The most Common Benign Tumor Of the Heart (Statement 1) It is a benign tumour. Site- Most Commonly arises from Left Atria. Gross Appearance- Gelatinous It is associated with mutations in the GNAS1 gene. (Statement 3) Also associated with McCune-Albright syndrome and Carney Complex. Histologically- Stellate Or Lepidic Cells Seen (Statement 5) {{caption_text}}



References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 579

↑ *Back to this question in Part A*

@Neet_pg_bot

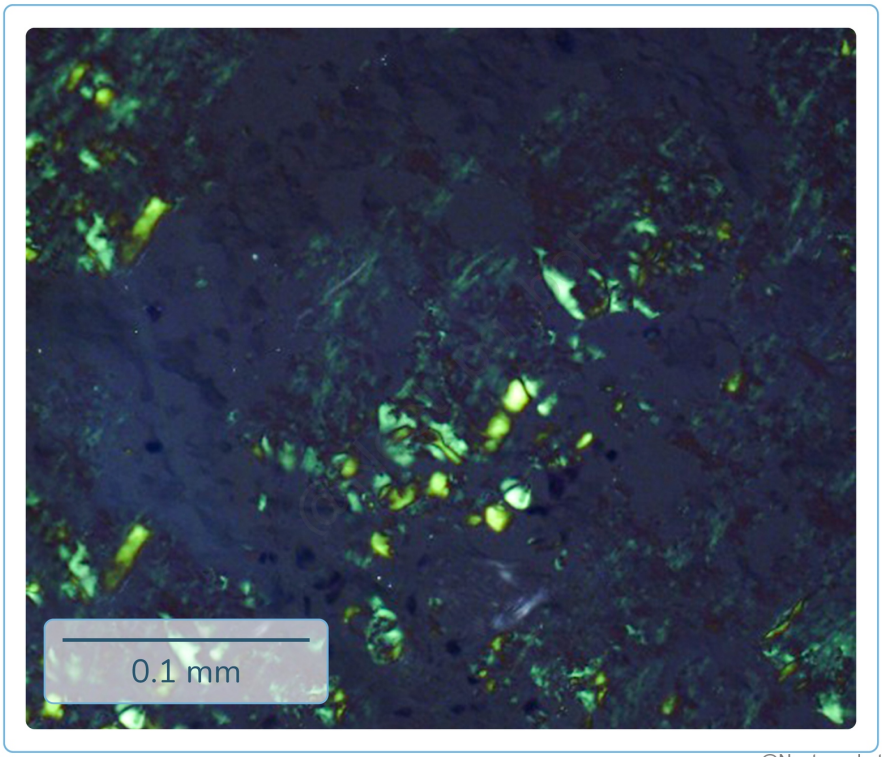
Q11: What is the most likely diagnosis based on the image given below? It is a stained specimen of endomyocardial tissue. {{caption_text}} (Q845433)

A. Hypertrophic cardiomyopathy

B. Dilated cardiomyopathy

C. Cardiac amyloidosis

D. Sarcoidosis



Correct Answer: C. Cardiac amyloidosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The image shows a specimen of endomyocardial tissue. The image shows characteristic extracellular deposition of amorphous material with apple-green birefringence under polarized light on Congo red staining , confirming the diagnosis of Amyloidosis It is the most common cause of Restrictive Cardiomyopathy. Hypertrophic cardiomyopathy (Option A): Banana-shaped heart and Myofiber disarray are seen Dilated cardiomyopathy (Option B): Ninja-star nucleus is seen Sarcoidosis (Option D): Non-caseating granulomas are seen

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 574, 575

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Which viral organism is most commonly associated with myocarditis? (Q845392)

A. Influenza

B. Human immunodeficiency virus (HIV)

C. Coxsackievirus

D. Epstein-Barr virus (EBV)

Correct Answer: C. Coxsackievirus

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Coxsackievirus is a common cause of viral myocarditis, especially in young adults. Other virus includes the Herpes virus and Trichinella Spirali (parasitic). Coxsackievirus is of 2 types: Coxsackie A and Coxsackie B Both are responsible for causing Hand, foot, and mouth disease (HFMD) in children. Coxsackie A is also associated with acute hemorrhagic conjunctivitis .

References:

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 560

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following is not a cause for restrictive cardiomyopathy? (Q845429)

A. Hemochromatosis

B. Amyloidosis

C. Sarcoidosis

D. Alcohol

Correct Answer: D. Alcohol

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Alcohol is not a cause of restrictive cardiomyopathy. Rather, it is a cause of dilated cardiomyopathy. Restrictive cardiomyopathy occurs when something gets deposited and causes restrictions in the movement of the heart, mainly diastolic dysfunction/restriction. CAUSES OF RESTRICTIVE CARDIOMYOPATHY Amyloidosis (Pink extracellular amyloids deposition) (Option B) Hemochromatosis (Iron deposition) (Option A) Radiation Scleroderma Tropical endomyocardial fibrosis Hypereosinophilic syndrome (Löffler’s endocarditis) Sarcoidosis (Option C)

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 574

Harrison’s Principles of Internal Medicine, 21st edition, Page 1968

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 19-year-old boy collapsed during a football game and was brought dead to the hospital. Suspecting a heart condition, a biopsy was done, which showed asymmetric septal hypertrophy. Which of the following histological findings will not be seen in this condition? (Q845425)

A. Massive myocyte hypertrophy

B. Myofibre disarray

C. Fibrotic narrowing of small intramural arteries

D. Ninja star nuclei

Correct Answer: D. Ninja star nuclei

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of a young male who collapsed and died (sudden cardiac death) with a biopsy showing asymmetric septal hypertrophy is suggestive of hypertrophic cardiomyopathy. Histology of HCM includes: Myofibre Hypertrophy (Option A) Myofibre Disarray (Halter-salter appearance) (Option B) Fibrotic narrowing of intramural arteries (Option C) . Ninja star nuclei are seen in Dilated Cardiomyopathy. {{caption_text}} The images below show the gross and histological features of HCM. {{caption_text}}

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Pages 571,573

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 22-year-old man presents to his cardiologist with complaints of exertional chest pain and shortness of breath. His family history is significant for the sudden cardiac death of his brother at the age of 28. Physical examination reveals a harsh

systolic murmur and irregular heart sounds. Which of the following genes is most commonly involved in this condition? (Q845423)

A. Titin

B. Beta-myosin heavy chain

C. Troponin T

D. Alpha-tropomyosin

Correct Answer: B. Beta-myosin heavy chain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypertrophic cardiomyopathy (HCM): HCM is an autosomal dominant condition that occurs due to a mutation in the beta-myosin heavy chain . In HCM, hypertrophy can occur in any part of heart but ir occurs maximally in the interventricular septum. Due to hypertrophy of interventricular septum, left ventricle is narrowed and starts looking like a banana-shaped cavity. Left ventricle is responsible for pumping blood to the body which will be affected due to this narrowing. So in conditions like heavy physical activity, where body wants more blood, it can lead to sudden collapse and sometimes death of patient. Under microscopic examination during autopsy, cardiac muscle fibres shows the classical halter-salter appearance (haphazardly arranged cardiac muscle fibres) Titin (Option A) : Titin mutations are seen in dilated cardiomyopathy.

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 572

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following conditions is characterised by transient left ventricular dysfunction, often triggered by emotional or physical stress, presenting with symptoms mimicking acute coronary syndrome but with normal coronary arteries on angiography? (Q845401)

A. Acute Myocardial Infarction (AMI)

B. Takotsubo Cardiomyopathy (TCM)

C. Hypertrophic Cardiomyopathy (HCM)

D. Dilated Cardiomyopathy (DCM)

Correct Answer: B. Takotsubo Cardiomyopathy (TCM)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Takotsubo cardiomyopathy also known as BROKEN HEART SYNDROME, is a dilated cardiomyopathy following extreme psychological or emotional stress. This stress leads to excessive release of catecholamines in body. Catecholamines can act on all the chambers of heart but maximum receptors for catecholamines are present in left ventricle. The left ventricle is dilated with apical ballooning resembling a JAPANESE POT named TAKOTSUBO used for catching Octopus. Because LV is dilated and blood is not reaching rest of the body, the patient presents with symptoms resembling acute coronary syndrome such as chest pain. It mimics heart attack or MI but there is no blockage found on coronary angiography as this is not a coronary artery disease.

References:

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 575

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 55-year-old woman presents to the emergency department with sudden-onset chest pain and shortness of breath following the news of death of her son. An electrocardiogram shows ST-segment elevation in the anterior leads, and cardiac biomarkers are elevated. Coronary angiography reveals no significant coronary artery disease. Which of the following is the most likely underlying mechanism in this patient? (Q845400)

A. Excessive release of catecholamines

B. Viral myocarditis

C. Autoimmune response

D. Genetic predisposition

Correct Answer: A. Excessive release of catecholamines

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Excessive release of catecholamines is the most likely underlying mechanism for the development of Takotsubo cardiomyopathy in this patient. Emotional or physical stress, such as the news of a family member's death, can trigger a surge of catecholamines (e.g., adrenaline and noradrenaline). In Takotsubo cardiomyopathy (aka Broken Heart Syndrome), excessive catecholamines act on left ventricle (LV), leading to left ventricle

dilatation. Dilated left ventricle cannot contract properly, leading to a hampered blood supply to the body.

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 570

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Which of the following genes is most commonly associated with inherited forms of dilated cardiomyopathy? (Q845398)

A. BRCA1 gene

B. TTN gene

C. CFTR gene

D. SCN5A gene

Correct Answer: B. TTN gene

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: TTN gene mutation, which is specific to inherited dilated cardiomyopathy is the correct option. TTN gene encodes for titin protein which is the largest protein of human body with over 30000 amino acids. Defect in titin protein can lead to dilated cardiomyopathy. Microscopically it shows a classical Ninja star nucleus appearance .

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 569

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 45-year-old male with a history of intravenous drug abuse, presenting with fever, malaise, and a new-onset heart murmur, reports recent injection site infections. On examination, there are multiple healing scars on the upper extremities, and a grade III/VI holosystolic murmur is auscultated at the left sternal border. His temperature is 38.5°C, heart rate is 110 bpm. Which criterion amongst the following is a major criterion for the condition diagnosed? (Q845397)

A. Fever of unknown origin lasting more than 7 days

B. IV drug abuse

C. Predisposing cardiac condition such as a prosthetic heart valve

D. Positive blood cultures for typical microorganisms persistently isolated from blood cultures

Correct Answer: D. Positive blood cultures for typical microorganisms persistently isolated from blood cultures

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The diagnosis in a 45-year-old male with a history of intravenous drug abuse, presenting with fever, malaise, and a new-onset heart murmur is Infective Endocarditis. Duke's Criteria: Major Criteria Minor Criteria Positive blood cultures for typical microorganisms persistently isolated from blood cultures (2 cultures > 12 hrs apart, single positive culture for Coxiella) Predisposing cardiac conditions such as a prosthetic heart valve (Option C), IV drug abuse (Option B) Evidence of endocardial involvement on echocardiography (vegetations or abscesses) Fever (≥38.0°C) (Option A) New valvular regurgitation Vascular phenomena (e.g., emboli, Janeway lesions) Immunological phenomena (e.g., glomerulonephritis, Osler's nodes) Microbiological evidence not meeting major criteria (e.g., positive blood culture but not persistently positive) For diagnosis, either of the following should be present: 2 major criteria OR 1 major criteria and 3 minor criteria OR 5 minor criteria

References:

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 563

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: Which of the following is not a major criterion according to Jones Criteria for Rheumatic Heart Disease? (Q845395)

A. Polyarthritis

B. Carditis

C. Subcutaneous nodules

D. Fever

Correct Answer: D. Fever

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Jones Criteria: Major Criteria Minor Criteria Carditis (Pancarditis) (Option B) Polyarthritis (Option A) Sydenham's chorea (involuntary movements) Subcutaneous nodules (usually painless) (Option C) Erythema marginatum (skin rash) Clinical Fever Polyarthralgia Prolonged PR interval Lab Increased ESR Increased CRP The presence of either two major criteria or one major criterion plus two minor criteria, along with evidence of a preceding streptococcal infection, supports the diagnosis of acute rheumatic fever according to the Jones Criteria.

References:

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 561

↑ *Back to this question in Part A*

Q21: Which of the following findings is most likely present in the myocardial biopsy of a Rheumatic Heart disease patient? (Q845394)

A. Fibrous thickening of the endocardium

B. Areas of lymphocytic infiltrates, Anitschkow cells and fibroblasts in all layers of the heart

C. Calcific nodules on the valve leaflets

D. Disruption of the endothelial lining of blood vessels

Correct Answer: B. Areas of lymphocytic infiltrates, Anitschkow cells and fibroblasts in all layers of the heart

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Areas of lymphocytic infiltrates, plump macrophages and fibroblasts in all layers of the heart are the characteristic features of Rheumatic Heart Disease. Aschoff bodies , characterized by areas of lymphocytic infiltrates, plump macrophages (Anitschkow cells) , and fibroblasts, are commonly found in all layers of the heart (maximum in myocardium) of patients with Rheumatic Heart Disease. Anitschkow cells: Appearance of nuclei: Caterpillar chromatin pattern: Zig-zag nucleus "Owl eye" appearance: If nucleus is cut from center and is appearing round.

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 564

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: Which of the following statements best describes the vegetation found in Infective Endocarditis compared to other conditions? (Q845393)

A. Vegetations in Infective Endocarditis are typically small, friable, sterile and composed of fibrin, and platelets.

B. Vegetations in Infective Endocarditis are large, verrucous, and primarily consist of fibrin, inflammatory cells, and microorganisms.

C. Nonbacterial Thrombotic Endocarditis (NBTE) commonly presents with small, non-sterile vegetations composed mainly of fibrin and platelets.

D. Libman-Sacks Endocarditis is characterised by tiny, marantic vegetations consisting of fibrin and micro-organisms.

Correct Answer: B. Vegetations in Infective Endocarditis are large, verrucous, and primarily consist of fibrin, inflammatory cells, and microorganisms.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Vegetations of Infective endocarditis are very large and bulky, which sometimes fall off and form emboli via blood vessels to different parts of body. They comprises of fibrin and inflammatory cells with microorganisms within. Rheumatic heart disease Infective Endocarditis Non-bacterial Thrombotic Endocarditis (Option C) Libman-Sacks Endocarditis (Option D) Small and warty Large and bulky (Option B) (Option A ruled out) Small and friable Medium sized Along lines of closure Upper surface of cusps Along lines of closure Both surface of valves (M/C-lower surface) Sterile Non-sterile (Infected) Sterile Sterile Emboli - Emboli +/- Emboli +++ Emboli -

Q13 (p. 1700)	*Q14 (p. 1701)*	*Q15 (p. 1702)*	*Q16 (p. 1704)*	*Q17 (p. 1704)*	*Q18 (p. 1708)*

Q1: A 55-year-old female presents with hematuria, hemoptysis, and sinusitis. Renal biopsy reveals pauci-immune necrotising crescentic glomerulonephritis. What is the most likely diagnosis? (Q845459)

A. Wegener's Granulomatosis

B. Goodpasture Syndrome

C. Systemic Lupus Erythematosus (SLE)

D. Microscopic Polyangiitis (MPA)

Correct Answer: A. Wegener's Granulomatosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of a 55-year-old female with hematuria, hemoptysis, sinusitis, and renal biopsy showing pauci-immune necrotising crescentic glomerulonephritis is suggestive of Wegener’s granulomatosis. Rapidly Progressive Glomerulonephritis (RPGN) classification: Type I (Anti-GBM disease) → Anti-GBM antibodies → Goodpasture’s Type II (Immune complex) → SLE, IgA nephropathy, PSGN Type III (Pauci-immune) → ANCA-associated vasculitis (GPA , MPA, EGPA) Wegener's Granulomatosis (Granulomatosis with Polyangiitis-GPA): It is characterised by pauci-immune necrotising granulomatous vasculitis affecting small- to medium-sized vessels. It causes Necrotizing granulomas in 3 key organs : Respiratory tract (upper + lower) → sinusitis, otitis media, nasal septal perforation, hemoptysis Kidneys → crescentic glomerulonephritis (RPGN type III) → hematuria Blood vessels → systemic small vessel vasculitis In GPA, there is a presence of anti-neutrophil cytoplasmic antibodies (ANCA), specifically cytoplasmic ANCA (c-ANCA) targeting proteinase 3 (PR3) and sometimes p-ANCA targeting myeloperoxidase (MPO) . Another classical triad of GPA (ENT triad): E: Ear → otitis media N: Nose → nasal septal perforation (“saddle-nose”) T: Throat/mouth → strawberry gums Goodpasture Syndrome (Option B): It causes RPGN I and shows Anti-glomerular basement membrane antibodies (anti-GBM antibodies). SLE (Option C): It is a multi-system disorder causing RPGN II and has Anti-Nuclear antibodies (ANA). Microscopic polyangiitis (Option D) (MPA): It can also cause RPGN III, but it doesn't show other symptoms like hemoptysis and sinusitis

Robbins and Cotran, Pathologic Basis of Disease, 10th Edition, Page 514.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 3-year-old child presents with persistent high fever, bilateral conjunctival erythema, strawberry tongue, erythema of palms and soles, desquamating rash, and cervical lymphadenopathy. This presentation is classically referred to as which of the following? (Q889802)

A. Mucocutaneous lymph node syndrome

B. Polyarteritis nodosa

C. Takayasu arteritis

D. Henoch-Schönlein purpura

Correct Answer: A. Mucocutaneous lymph node syndrome

Explanation: Kawasaki disease , also known as mucocutaneous lymph node syndrome , is an acute febrile medium-vessel vasculitis that primarily affects children younger than 5 years. Kawasaki disease: Clinical (Mucocutaneous LN syndrome): Persistent high fever Bilateral non-exudative conjunctivitis Strawberry tongue Polymorphous rash with desquamation Erythema of palms and soles Cervical lymphadenopathy Complications: Coronary arteritis → aneurysm, thrombosis, MI, rupture ~20% untreated patients develop cardiac complications Treatment: IV immunoglobulin (IVIG) + aspirin Markedly reduces coronary complications Polyarteritis nodosa (Option B) : Medium-vessel necrotising vasculitis; does not present with mucocutaneous lymph node syndrome. Takayasu arteritis (Option C) : Large-vessel granulomatous vasculitis in patients <50 years; characterised by weak pulses, not mucocutaneous features. Henoch-Schönlein purpura (Option D) : IgA-mediated small-vessel vasculitis; presents with palpable purpura, abdominal pain, and renal involvement.

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 468

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Anti-endothelial cell antibodies are most commonly associated with which of the following conditions? (Q889800)

A. Polyarteritis nodosa

B. Kawasaki disease

C. Takayasu arteritis

D. Granulomatosis with polyangiitis

Correct Answer: B. Kawasaki disease

Explanation: The presence of anti-endothelial cell antibodies (AECA) is a classic association for Kawasaki disease and is thought to contribute to the vascular damage seen in the coronary arteries. Kawasaki disease: Acute febrile medium-vessel vasculitis 80% <5 years old Transmural inflammation Self-limited but clinically significant due to coronary artery involvement Pathogenesis: Likely triggered by a viral infection in genetically susceptible children Delayed-type hypersensitivity → Cytokine release Polyclonal B-cell activation Autoantibodies to endothelial & smooth muscle cells Polyarteritis nodosa (Option A): A medium-vessel necrotizing vasculitis often associated with immune complex deposition and hepatitis B infection, not classically associated with AECA. Takayasu arteritis (Option C): A large-vessel granulomatous vasculitis that is primarily T-cell mediated , not characteristically associated with AECA. Granulomatosis with polyangiitis (Option D): Associated with c-ANCA (PR3-ANCA) , not anti-endothelial cell antibodies.

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Page 468

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 27-year-old woman presents with fatigue, weak upper limb pulses, and visual disturbances. Imaging reveals narrowing of major branches of the aorta. She is diagnosed with Takayasu arteritis. Which of the following statements is correct? (Q889799)

A. The renal artery is spared

B. It commonly involves the aortic arch

C. B-cell mediated disease

D. It is a medium vessel granulomatous vasculitis

Correct Answer: B. It commonly involves the aortic arch

Explanation: Takayasu arteritis classically affects the aortic arch and its major branches , leading to diminished upper limb pulses (“pulseless disease”). Takayasu arteritis: Granulomatous large-vessel vasculitis (Option D) Affects the aorta (especially the aortic arch) & major branches Occurs mainly in patients <50 years Also called “pulseless disease” T-cell-mediated autoimmune aetiology (Option C) Common vessels: Aortic arch (most common) Great vessels Pulmonary arteries (~50%) Coronary & renal arteries May involve the entire aorta Morphology: Transmural thickening of the vessel wall Intimal hyperplasia → luminal narrowing/obliteration Granulomatous inflammation with giant cells Patchy medial necrosis Late stage: fibrosis of all layers Aortic root dilation → aortic regurgitation (occasionally) Clinical features: Weak/absent upper limb pulses (“pulseless disease”) ↓ BP in arms Visual & neurologic symptoms Renal artery stenosis (Option A) → hypertension

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Pages 465, 466

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 68-year-old woman presents with new-onset temporal headache, jaw claudication, and transient vision loss. ESR is elevated. Which of the following statements is correct regarding this condition? (Q889798)

A. A negative temporal artery biopsy excludes the diagnosis

B. The disease uniformly affects the entire length of the artery

C. A negative biopsy does not exclude the diagnosis

D. The aorta is spared

Correct Answer: C. A negative biopsy does not exclude the diagnosis

Explanation: The clinical presentation of a temporal headache, jaw claudication, and vision loss in an elderly patient with an elevated ESR is classic of Giant Cell (Temporal) Arteritis . Giant cell arteritis has segmental (skip) lesions, so that biopsy may miss affected areas. If clinical suspicion is high, treatment (corticosteroids) is started immediately to prevent permanent blindness, even if the biopsy is initially negative. Giant cell arteritis: Chronic

granulomatous vasculitis of large- and medium-sized arteries Commonly involves the temporal, vertebral, and ophthalmic arteries Can involve the aorta (giant cell aortitis) (Option D) Risk: sudden irreversible blindness Morphology: Patchy lesions → biopsy ≥1 cm required (Option B) Intimal thickening → luminal narrowing Granulomatous inflammation in the media Fragmentation of the internal elastic lamina Multinucleated giant cells (~75%) Healed lesions → fibrosis & medial scarring Clinical features: Age >50 years Fever, fatigue, weight loss Temporal headache & scalp tenderness Jaw claudication Ocular symptoms → diplopia or vision loss Diagnosis: Temporal artery biopsy (negative biopsy does not exclude due to patchy involvement) (Option A and C) Treatment: Immediate corticosteroids Anti-TNF therapy in resistant cases Tocilizumab (anti-IL-6 receptor) in refractory or steroid-dependent cases

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Pages 464, 465

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 72-year-old woman presents with temporal headache, scalp tenderness, and transient visual disturbances. ESR is markedly elevated. Temporal artery biopsy confirms Giant cell arteritis. Which of the following statements is incorrect regarding this condition? (Q889797)

A. It commonly affects individuals older than 50 years

B. It is characterised by granulomatous inflammation with giant cells

C. It can also involve veins

D. Risk of vision loss

Correct Answer: C. It can also involve veins

Explanation: Giant cell arteritis is a large- and medium-sized arterial vasculitis and does not involve veins. Giant cell arteritis: Chronic granulomatous vasculitis of large- and medium-sized arteries Commonly involves the temporal, vertebral, and ophthalmic arteries Risk: sudden irreversible blindness (Option D) Pathogenesis: T-cell-mediated immune response to the vessel wall antigen Key cytokines: IFN-γ, IL-17 Associated with MHC class II haplotypes Morphology: Patchy lesions → biopsy ≥1 cm required Intimal thickening → luminal narrowing Granulomatous inflammation in the media (Option B) Fragmentation of the internal elastic lamina Multinucleated giant cells (~75%) Healed lesions → fibrosis & medial scarring Clinical features: Age >50 years (Option A) Fever, fatigue, weight loss Temporal headache & scalp tenderness Jaw claudication Ocular symptoms → diplopia or vision loss Diagnosis: Temporal artery biopsy (negative biopsy does not exclude due to patchy involvement) Treatment: Immediate corticosteroids Anti-TNF therapy in resistant cases Tocilizumab (anti-IL-6 receptor) in refractory or steroid-dependent cases

References:

Robbins, Cotran & Kumar, Pathologic Basis of Disease, 11th Edition, Pages 464, 465

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 25-year-old girl with a history of asthma presents with wheezing and rhinitis. Lab reports show eosinophilia and antibodies against neutrophil myeloperoxidase. What is the most likely diagnosis? (Q845462)

A. Churg-Strauss syndrome

B. PAN

C. Buerger's disease

D. Wegener granulomatosis

Correct Answer: A. Churg-Strauss syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of a 25-year-old girl, k/c/o asthma with wheezing, rhinitis, and antibodies against neutrophil myeloperoxidase is suggestive of Churg Strauss syndrome. Eosinophilic Granulomatosis with Polyangiitis (EGPA / Churg–Strauss): p-ANCA: p-ANCA (perinuclear ANCA) shows antibody clustering around the nucleus on immunofluorescence, with the target antigen being myeloperoxidase (MPO), which is why it is also called MPO-ANCA. Diseases associated with p-ANCA (MPO-ANCA): Microscopic polyangiitis Eosinophilic granulomatosis with polyangiitis (EGPA/Churg–Strauss) Sometimes, Granulomatosis with polyangiitis (GPA/Wegener's). Clinical features of EGPA: Asthma → hallmark of EGPA (not seen in GPA or MPA) Eosinophilia → classic clue (not present in GPA or MPA) Allergic rhinitis → part of atopic background p-ANCA positive → consistent with EGPA Polyarteritis Nodosa (Option B) is a systemic necrotizing vasculitis that primarily affects medium-sized arteries. It is associated with Hepatitis B, fibrinoid necrosis and is ANCA negative. Buerger's disease (Option C): It is strongly associated with heavy smoking. It primarily affects the extremities and presents with claudication, raynaud's phenomenon, gangrene, and ischemic ulcers. It does not involve asthma, eosinophilia, or MPO antibodies. Wegener Granulomatosis (Option D): May show p-ANCA, but usually c-ANCA (PR3-ANCA) and does not cause eosinophilia or asthma

References:

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 515

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 30-year-old male patient presents with recurrent oral ulcers, genital ulcers, and skin lesions on the lower extremities. He also complains of blurred vision and pain in his right eye. On examination, there are multiple oral and genital ulcers with posterior uveitis evident on ophthalmologic evaluation. Which of the following is false regarding the condition? (Q845461)

A. HLA B27 positivity

B. Painful scarring genital ulcers

C. Erythema nodosum

D. Positive pathergy test

Correct Answer: A. HLA B27 positivity

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Based on the clinical presentation along with examination finding this patient is most likely suffering from Behcet's disease which is not associated with HLA B27 Behcet's disease Associations HLA-B51 Clinical features A clinical triad of recurrent oral aphthous ulcers + genital ulcers + uveitis is seen Oral Aphthous Ulcers : Hallmark feature Genital Ulcers : Painful and may leave scars after healing. (Option B) Uveitis : Most serious manifestation due to its potential for causing blindness. Other Symptoms: Joint pain (arthritis), skin lesions (erythema nodosum) (Option C) , vascular manifestations (thrombophlebitis, deep vein thrombosis), and neurological involvement Diagnosis Pathergy test (A skin test for Behcet's disease) (Option D)

References:

Harrison's Principles of Internal Medicine, 21st edition, Pages 2817, 2818

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 45-year-old female presents with rapidly progressive hematuria, hemoptysis, and peripheral neuropathy. Serological testing reveals the presence of perinuclear anti-neutrophil cytoplasmic antibodies (p-ANCA) targeting myeloperoxidase (MPO). What is the most likely diagnosis based on these serological findings? (Q845460)

A. Microscopic Polyangiitis

B. Granulomatosis with Polyangiitis

C. Eosinophilic Granulomatosis with Polyangiitis

D. Goodpasture Syndrome

Correct Answer: A. Microscopic Polyangiitis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of rapidly progressive hematuria, hemoptysis, peripheral neuropathy, and MPO positivity points towards the diagnosis of microscopic polyangiitis. Microscopic Polyangiitis (MPA): MPA is a small-vessel vasculitis showing multi-organ involvement. p-ANCA (MPO-ANCA) positivity is the hallmark of MPA. Multi-organ involvement : Kidneys → rapidly progressive glomerulonephritis (RPGN III) → hematuria Lungs → alveolar capillaritis → hemoptysis Nerves → mononeuritis multiplex → peripheral neuropathy No granulomas (this differentiates it from GPA/Churg-Strauss) Granulomatosis with Polyangiitis (Option B) is typically c-ANCA (PR3-ANCA) positive, though p-ANCA may also be seen, and can present with hematuria, hemoptysis, and neuropathy. It is characterized by granuloma formation with ENT involvement such as nasal septal perforation and strawberry gums. Eosinophilic Granulomatosis with Polyangiitis (EGPA) (Option C), formerly known as Churg-Strauss Syndrome, is a p-ANCA–positive small vessel vasculitis characterized by peripheral eosinophilia along with asthma or allergic rhinitis as defining features. Goodpasture Syndrome (Option D) is characterized by rapidly progressive glomerulonephritis (RPGN) with hemoptysis, caused by anti-GBM antibodies rather than ANCA, and is limited to the kidney and lung without neuropathy or systemic vasculitis.

@Neet_pg_bot

Q11: A 10-year-old child presents with palpable purpura on the lower extremities, arthralgia, and abdominal pain. Laboratory tests show elevated serum IgA levels and red blood cell casts in urine. What is the most likely diagnosis? (Q845457)

A. Henoch-Schönlein Purpura

B. Systemic Lupus Erythematosus

C. Kawasaki Disease

D. Rheumatic Fever

Correct Answer: A. Henoch-Schönlein Purpura

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of a 10-year-old child with palpable purpura, arthralgia, abdominal pain, elevated serum IgA levels, and RBC casts in urine is suggestive of Henoch-Schonlein purpura (HSP). Clinical features (PAAARpura): P: Palpable purpura (typically lower extremities and buttocks) A: Arthralgia / joint pain A: Abdominal involvement (pain, nausea, GI bleeding possible) A: Associated with elevated IgA (causative immunoglobulin) R: Renal involvement (hematuria, red blood cell casts) Pathophysiology: HSP is a Small-vessel vasculitis mediated by IgA immune complex deposition. IgA deposits weaken vessel walls, leading to purpura and bleeding. Because the platelet count is normal, also called as non-thrombocytopenic purpura .

Robbins and Cotran, Pathologic Basis of Disease, 10th Edition, Page 509.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Which of the following is a characteristic feature of Buerger disease? (Q845456)

A. Segmental fibrinoid necrosis of the media with focal transmural necrotising lesions

B. Segmental thrombosing vasculitis affecting small and medium-sized arteries

C. Granulomatous inflammation of vessel walls

D. Adventitial mononuclear infiltrates with perivascular cuffing of the vasa vasorum

Correct Answer: B. Segmental thrombosing vasculitis affecting small and medium-sized arteries

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Segmental thrombosing vasculitis affecting small and medium-sized arteries is the hallmark feature of Buerger's disease. It involves inflammation and thrombosis of small and medium-sized arteries , particularly in the distal extremities , leading to ischemia and tissue damage. {{caption_text}} In the above image, the lumen is occluded by thrombin-containing abscesses, and the vessel wall is infiltrated with leukocytes. Segmental fibrinoid necrosis of the media with focal transmural necrotising lesions (Option A) is a hallmark feature of polyarteritis nodosa (PAN). Granulomatous inflammation of vessel walls (Option C) is a hallmark of large-vessel vasculitides, such as giant cell arteritis (GCA) and Takayasu arteritis. Adventitial mononuclear infiltrates with perivascular cuffing of the vasa vasorum (Option D) in syphilitic aortitis, part of tertiary syphilis.

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 521

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 42-year-old male heavy smoker presents with a history of recurrent episodes of pain and discolouration in his fingers and toes, particularly when exposed to cold temperatures. On examination, you notice superficial migratory thrombophlebitis in his lower extremities. Doppler ultrasound reveals segmental occlusions in the arteries of his lower limbs. Considering his clinical presentation, which of the following is the most likely diagnosis? (Q845455)

A. Thromboangiitis Obliterans

B. Raynaud's Phenomenon

C. Atherosclerosis

D. Giant Cell Arteritis

Correct Answer: A. Thromboangiitis Obliterans

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Thromboangiitis Obliterans (Buerger's Disease): Clinical Features: Segmental arterial occlusion in medium-sized vessels (medium-vessel vasculitis) Pain and discoloration of the digits that worsen with cold exposure can initially mimic Raynaud's phenomenon , but: Raynaud's phenomenon: Does not cause arterial occlusion and is not strongly associated with smoking (Option B ruled out) Superficial migratory thrombophlebitis is characteristic. Pathophysiology: Thrombo - blood clot Angitis - inflammation of blood vessels Obliterans - occlusion of blood vessels due to clot + inflammation Etiology: This has a strong association with heavy smoking, as tobacco triggers inflammatory and thrombotic processes in the blood vessels. Intermittent claudication due to insufficient blood supply during activity can potentially progress to digital ischemia, ulceration, or gangrene Treatment: The most important treatment is complete cessation of smoking, which provides symptomatic relief and helps prevent disease progression.

References:

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 521

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 3-year-old child presents with a high fever persisting for five days, along with bilateral conjunctival injection, strawberry tongue, and rash on the trunk and extremities. There is also swelling and erythema of the hands and feet. What is the most likely diagnosis? (Q845452)

A. Measles

B. Scarlet fever

C. Henoch-Schönlein purpura

D. Kawasaki disease

Correct Answer: D. Kawasaki disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Based on the clinical presentation, the child is suffering from Kawasaki disease, which is an acute, febrile, usually self-limited illness of infancy and childhood associated with large- to medium-sized vessel arteritis . Kawasaki disease, the most common vasculitis in children, is mediated by anti-endothelial cell antibodies and can lead to coronary artery involvement, including aneurysms, coronary arteritis, and myocardial infarction. Clinical Features (Mnemonic: CREAM-F.): C onjunctivitis (non-exudative & non-purulent). R ash (Polymorphous, non-vesicular). E dema (or erythema) of hands & feet. A denopathy (Cervical, often unilateral & non-suppurative). M ucosal involvement (strawberry tongue). F ever (Most important constitutional symptom) . A diagnosis of Kawasaki disease is confirmed when a patient presents with ≥4 of 5 criteria + fever . The image below shows the strawberry tongue. {{caption_text}} Measles (Option A): P resents with a prodrome of fever , cough , coryza , and conjunctivitis followed by a maculopapular rash spreading from head to toe. Scarlet fever (Option B): Measles classically presents with the “three Cs”: coryza , cough , and conjunctivitis , along with Koplik spots on the buccal mucosa. Henoch-Schönlein purpura (Option C): HSP) is the most common pediatric vasculitis, an IgA-mediated small-vessel vasculitis, typically presenting with features such as purpura.

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 513

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 52-year-old woman presents with a 3-month history of muscle aches, joint pain, and numbness in her hands and feet and blood in stools. She also reports experiencing episodes of abdominal pain and nausea. Physical examination reveals decreased sensation in the distal extremities and decreased peripheral pulses. Laboratory tests show elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Nerve conduction studies indicate peripheral neuropathy. What is the most likely diagnosis? (Q845449)

A. Polyarteritis nodosa (PAN)

B. Wegener's granulomatosis

C. Churg-Strauss syndrome

D. Giant cell arteritis

Correct Answer: A. Polyarteritis nodosa (PAN)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms, including fever, fatigue, weight loss, blood in stools, abdominal pain, and skin manifestations (livedo reticularis), along with the laboratory findings of elevated inflammatory markers, are all consistent with polyarteritis nodosa , a medium-vessel vasculitis that can affect multiple organ systems. Polyarteritis Nodosa (PAN): PAN is a Medium-vessel vasculitis, which is often seen in Hepatitis B-positive individuals. Clinical Features: Multi-organ involvement : almost every medium vessel can be affected Most commonly: renal vessels Others: GI tract, peripheral nerves, skin, muscles Pulmonary vessels are spared due to which pulmonary symptoms are absent in PAN. Peripheral neuropathy : due to ischemic nerve injury Raised inflammatory markers : ESR, CRP Histopathology: Fibrinoid necrosis of vessel walls (pink amorphous material) Segmental transmural inflammation : Segmental → only parts of vessel affected Transmural → full thickness of the vessel wall involved in affected segments {{caption_text}} Wegener's granulomatosis (Option B): Shows granulomas; often involves kidneys and lungs Churg-Strauss syndrome (Option C): Characterized by eosinophilic infiltration Giant Cell Arteritis (Option D): Large-vessel vasculitis characterized by giant cells, usually affecting individuals over 50 years of age, and commonly involves the temporal artery.

Robbins and Cotran, Pathological Basis of Disease, 10th Edition, Page 513

↑ *Back to this question in Part A*

Q16: A 28-year-old female presents to the outpatient department with complaints of fatigue, weight loss, and intermittent claudication in her upper limbs. On further questioning, she reports occasional headaches and dizziness. Physical examination reveals absent pulses in both brachial arteries and decreased blood pressure in the upper extremities compared to the lower extremities. Laboratory investigations show elevated ESR & CRP, and Doppler ultrasound shows diffuse narrowing and irregularities in the brachial and subclavian arteries. What is the most likely diagnosis? (Q845448)

A. Rheumatoid arthritis

B. Takayasu arteritis

C. Polyarteritis nodosa

D. Microscopic polyangiitis

Correct Answer: B. Takayasu arteritis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation is suggestive of Takayasu arteritis. Takayasu arteritis: Patient age is a key differentiating factor in vasculitis, helping distinguish Takayasu arteritis, which typically affects individuals under 50 years, from Giant Cell Arteritis, which usually occurs in those over 50 years. Symptoms: Predominantly upper limb involvement Pulseless disease → absent brachial pulses Neurological symptoms: headache, dizziness Subclavian artery narrowing: Subclavian artery is the most commonly affected vessel in Takayasu Arteritis. Doppler confirms brachial and subclavian artery stenosis Rheumatoid arthritis (Option A): primarily affects the joints and no upper limb arterial involvement . Polyarteritis nodosa (Option C): Medium-vessel vasculitis; multi-system involvement , often Hepatitis B-associated; not limited to upper limbs Microscopic polyangiitis (Option D): Small vessel vasculitis; associated with ANCA antibodies ,

Robbins and Cotran, Pathologic Basis of Disease, 10th edition, Page 512

↑ *Back to this question in Part A*

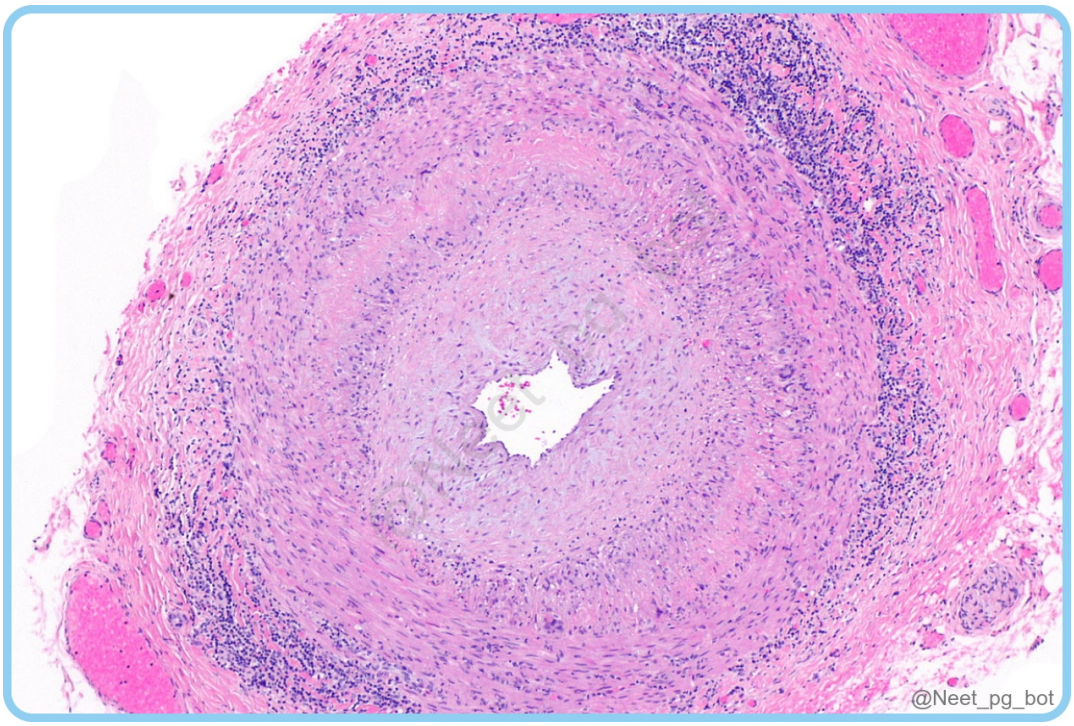
Q17: An arterial biopsy of an elderly male was performed and is shown below. What is the most likely diagnosis? {{caption_text}} (Q845445)

A. Giant cell arteritis

B. Takayasu arteritis

C. Polyarteritis nodosa

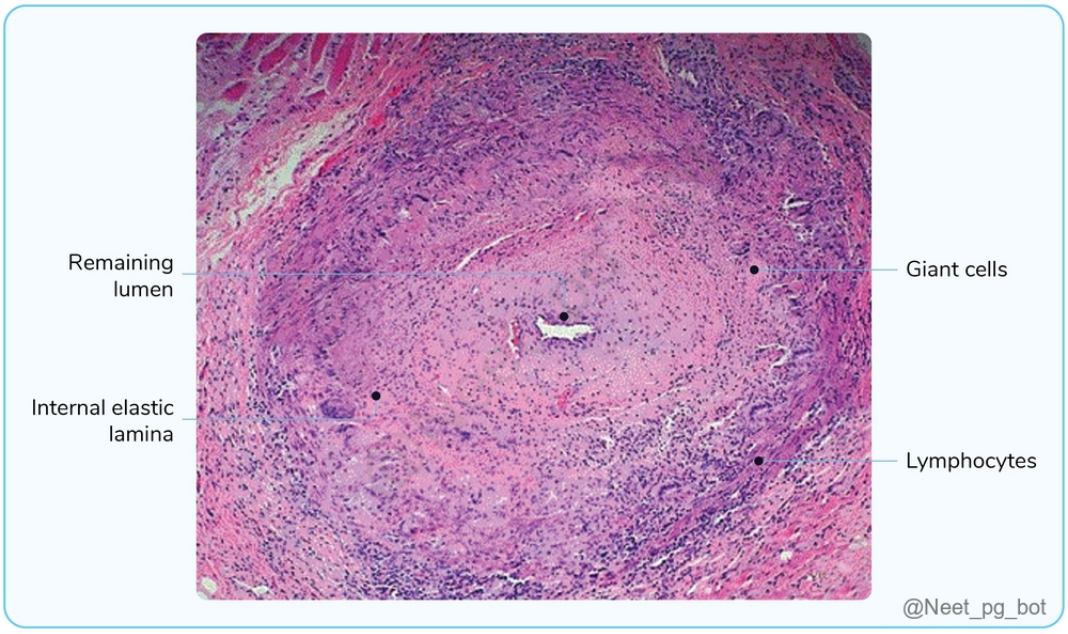
D. Microscopic polyangiitis



Correct Answer: A. Giant cell arteritis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: An arterial biopsy obtained from an elderly patient showing narrowed lumen , chronic inflammation (blue-coloured lymphocytes), giant cells (present in the arterial wall) and internal elastic lamina fragmentation suggests giant cell arteritis. Giant Cell Arteritis (GCA) , also known as Temporal Arteritis Key Histopathological Features of GCA: Giant cells in the arterial wall Chronic inflammatory infiltrate (lymphocytes) Narrowed lumen due to intimal thickening Commonly affects patients >50 years old {{caption_text}} Takayasu arteritis (Option B) Can show giant cells but typically <50 years old Polyarteritis nodosa (Option C) Shows fibrinoid necrosis (pink necrotic material). {{caption_text}} Microscopic polyangiitis (Option D) AKA leukocytoclastic vasculitis which shows broken white blood cells. {{caption_text}}



Remaining lumen
Internal elastic lamina
Giant cells
Lymphocytes

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 68-year-old woman presents to the emergency department with a three-week history of progressively worsening temporal headaches, jaw pain, and visual disturbances. On examination, her right temporal artery appears swollen and tender to palpation. Which of the following statements regarding this condition are false? (Q845441)

A. Involves large to medium-sized arteries

B. It is the most common cause of vasculitis in adults

C. It occurs as a result of a B cell-mediated immune response

D. It is associated with polymyalgia rheumatica

Correct Answer: C. It occurs as a result of a B cell-mediated immune response

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of a 68-year-old woman with worsening temporal headaches (classical symptom), jaw pain (most specific symptom), visual disturbances (most dangerous complication), and tender and swollen right temporal artery points towards the diagnosis of giant cell arteritis. Temporal arteritis/Giant cell arteritis: Giant cell (temporal) arteritis involves large- to medium-sized arteries. (Option A ruled out) Epidemiology: Most common type of vasculitis in adults (usually >50 years old) (Option B ruled out) It is frequently associated with polymyalgia rheumatica. (Option D ruled out) It is a T-cell-mediated immune response (Option C) Biopsy findings: Giant cells Granulomas Fragmentation of internal elastic lamina Special stain : Verhoeff-Van Gieson stain (to visualize elastic lamina) Fragmentation of internal elastic lamina: Elastic lamina is mostly present everywhere but fragmented in some places.

Q1: Which of the following syndromes can lead to pulmonary hemorrhage in a patient and show p-ANCA positivity? (Q844207)

A. Monckeberg's Sclerosis

B. Microscopic polyangiitis

C. Wegener granulomatosis

D. Polyarteritis nodosa

Correct Answer: B. Microscopic polyangiitis

Explanation: Microscopic polyangiitis is a type of small-vessel vasculitis associated with p-ANCA (perinuclear antineutrophil cytoplasmic antibodies) and can lead to pulmonary hemorrhage. Incorrect Options: Monckeberg's Sclerosis (Option A): Monckeberg's sclerosis does not cause pulmonary hemorrhage or p-ANCA positivity. Wegener granulomatosis (Option C): Wegener granulomatosis, now called Granulomatosis with Polyangiitis (GPA), is predominantly associated with c-ANCA. Polyarteritis nodosa (Option D): Polyarteritis nodosa (PAN) is not associated with p-ANCA positivity.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following statements regarding rheumatic fever are correct? (Q879221)

A. Characterized by the presence of Aschoff bodies

B. Caused by Group B β-hemolytic Streptococci

C. Manifests only as myocarditis

D. Associated with aortic valve rupture

Correct Answer: A. Characterized by the presence of Aschoff bodies

Explanation: Rheumatic heart disease (RHD) is a chronic sequel of acute rheumatic fever (ARF) , which follows infection with Group A β-hemolytic Streptococcus (Streptococcus pyogenes) . Its hallmark is Aschoff bodies in the myocardium - distinctive granulomatous lesions that confirm rheumatic carditis. It develops as a complication of untreated or inadequately treated acute rheumatic fever (ARF), which is caused by an abnormal immune response to an infection with Group A beta-hemolytic Streptococcus bacteria. (Option B ruled out) The bacteria trigger an immune response that leads to chronic inflammation and scarring of heart valves, commonly affecting the mitral valve. Order of valves affected in RHD : Mitral > aortic > tricuspid > pulmonary. Manifests only as myocarditis (Option C) : RHD involves all three layers of the heart (pancarditis) - endocarditis (valvulitis), myocarditis (Aschoff bodies), and pericarditis ("bread-and-butter" appearance). Associated with aortic valve rupture (Option D) : Chronic RHD causes valvular fibrosis and stenosis, most often mitral stenosis, not rupture. Aortic valve involvement causes regurgitation, not rupture.

Robbins & Cotran, Pathologic Basis of Diseases, 10th Edition, Pages 561

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 65-year-old man was admitted to the emergency ward with severe, sudden-onset chest pain radiating to the left arm and profuse sweating. The ECG showed ST-segment elevation in precordial leads. The person succumbed after 3 hours. During the autopsy, his heart was taken out and immersed in a solution. The normal area of the heart turned brick-red, whereas the infarcted portion turned pale. Which of the following is a likely component of the solution? (Q859250)

A. Formalin

B. Triphenyl tetrazolium chloride

C. Ethanol

D. Glutaraldehyde

Correct Answer: B. Triphenyl tetrazolium chloride

Explanation: Triphenyl tetrazolium chloride (TTC) is a histochemical stain that differentiates viable from non-viable myocardium by reacting with dehydrogenases in active mitochondria. Viable myocardial tissue stains brick-red, while infarcted tissue, lacking dehydrogenase activity, remains pale and unstained. {{caption_text}} Incorrect Options: Formalin (Option A) is a fixative used for tissue preservation. It cannot differentiate between viable and infarcted myocardium. Ethanol (Option C) is a solvent and fixative used in histological procedures. It does not specifically stain or differentiate between viable and infarcted myocardial tissue. Glutaraldehyde (Option D) is a fixative used in electron microscopy. While it preserves cellular structures, it does not differentiate between viable and infarcted tissues.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 505.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: How is thrombosis initiated? (Q858519)

A. Platelet activation

B. Endothelial injury

C. Coagulation cascade

D. Vasoconstriction of vessels

Correct Answer: B. Endothelial injury

Explanation: Thrombosis is initiated by endothelial injury, which exposes underlying collagen and pro-coagulant factors, leading to platelet activation and adhesion. This triggers the coagulation cascade, resulting in thrombus

formation. Endothelial injury is considered the primary event that starts the sequence leading to thrombosis. Virchow’s triad is a concept used to explain the three primary factors that contribute to the development of thrombosis Endothelial Injury : Damage to the inner lining of blood vessels (endothelium) can lead to the exposure of underlying tissues, such as collagen and tissue factor, which activate the clotting process. Conditions like atherosclerosis, trauma, or inflammation can cause endothelial injury. Abnormal Blood Flow (Stasis or Turbulence) : Disruptions in normal blood flow, such as slow or stagnant blood flow (stasis) or turbulent flow, can promote clot formation. This is commonly seen in conditions like atrial fibrillation, prolonged immobility, or varicose veins. Hypercoagulability : An increased tendency of the blood to clot, which can be due to genetic factors (such as factor V Leiden mutation), acquired conditions (such as cancer or pregnancy), or certain medications that contribute to thrombosis.

@Neet_pg_bot

Q5: Which of the following features does the histology of the reperfused myocardium show? (Q854873)

A. Wavy fibres

B. Neutrophils in cardiac muscle

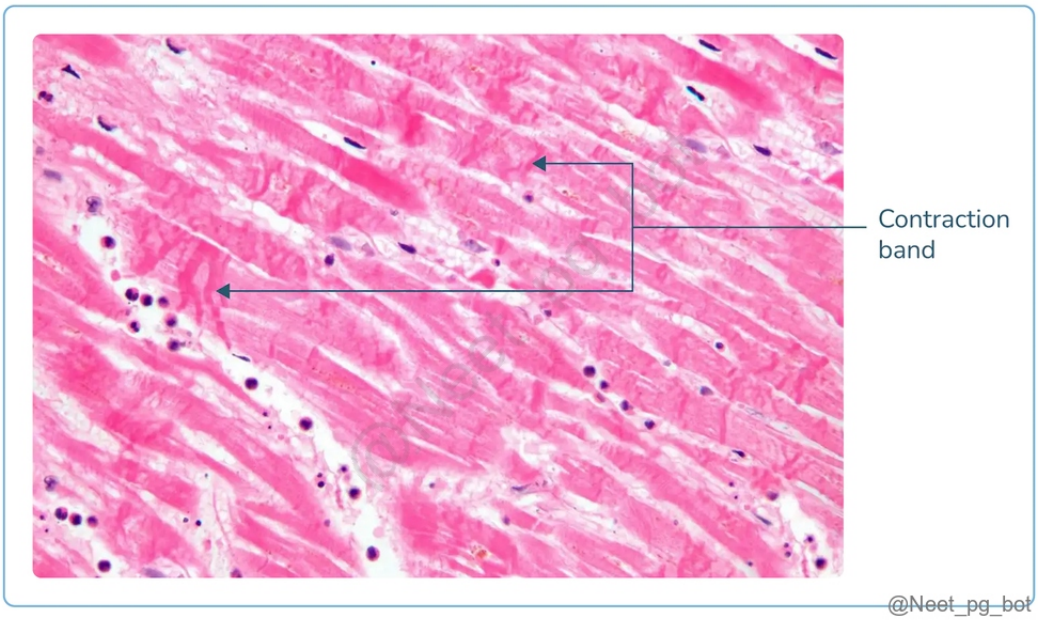
C. Swelling of cells

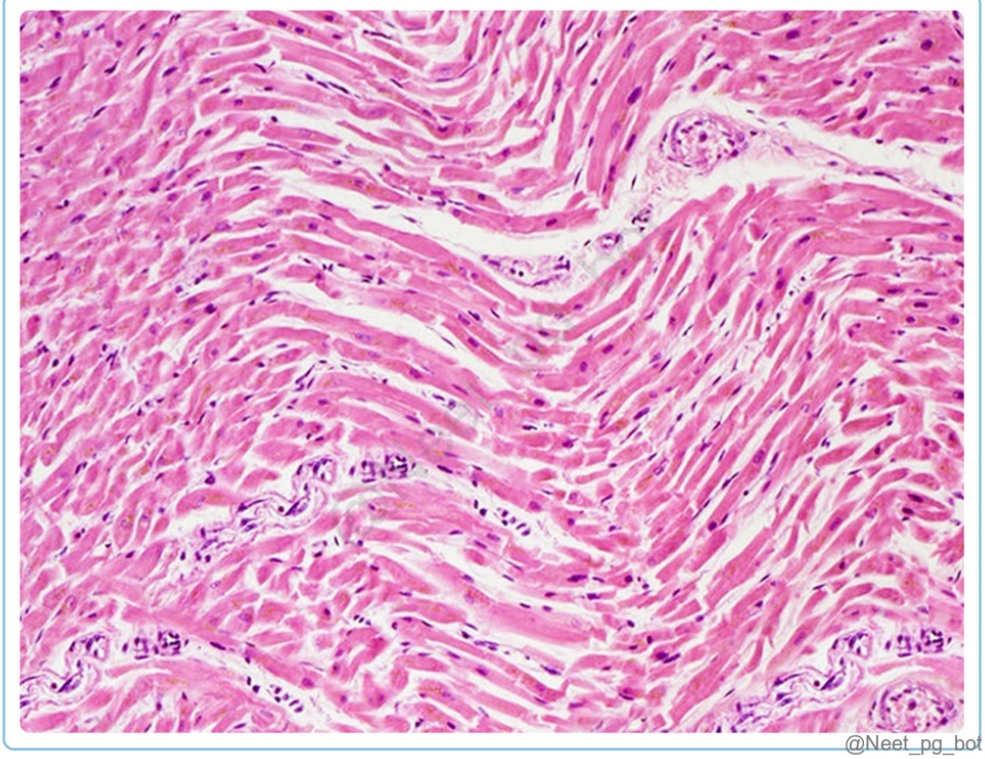
D. Eosinophilic contraction band

Correct Answer: D. Eosinophilic contraction band

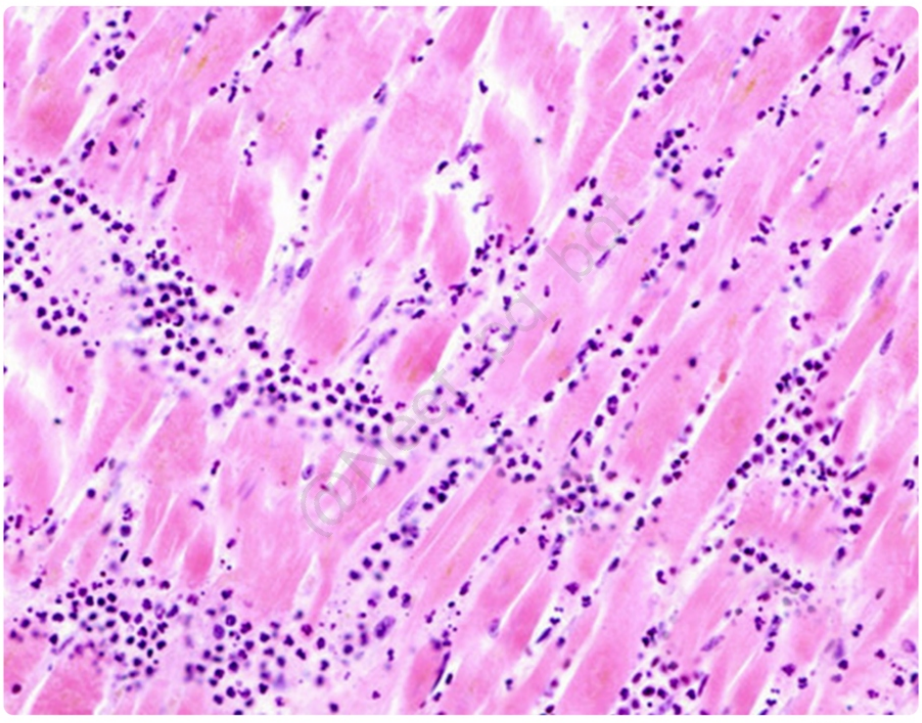
Explanation: Eosinophilic contraction bands are a hallmark feature of reperfusion injury in the myocardium. Reperfusion injury: Intracellular calcium overload is the most likely the primary mechanism responsible for the reperfusion injury in this patient. During PCI, reperfusion of the occluded coronary artery can lead to a sudden influx of calcium into cardiomyocytes, known as calcium paradox , which can cause cell injury and dysfunction. This phenomenon is characterised by increased mitochondrial calcium levels, leading to mitochondrial permeability transition pore opening, mitochondrial dysfunction, and cell death. The presence of 'Contraction bands' in cardiac muscle tissue serves as histological markers of reperfusion injury. {{caption_text}} Morphological features of myocardium in MI: Time Gross Features Light Microscope Electron Microscope Reversible Injury 0– 1/2 hour None None Relaxation of myofibrils; glycogen loss; mitochondrial swelling Irreversible Injury 1/2 –4 hours None Usually none; variable waviness of fibres at the border; myocyte vacuolisation {{caption_text}} Sarcolemmal disruption; mitochondrial amorphous densities (Calcium in mitochondria) 4–12 hours Occasional dark mottling Early coagulative necrosis, oedema, haemorrhage 12–24 hours Dark mottling Ongoing coagulative necrosis; pyknosis of nuclei; myocyte hypereosinophilia; marginal contraction band necrosis; early neutrophilic infiltrate 1–3 days Mottling with yellow-tan infarct centre

Coagulative necrosis, with loss of nuclei and striations; brisk interstitial infiltrate of neutrophils (Acute inflammation) {{caption_text}} 3–7 days Hyperemic border; central yellow-tan softening Beginning disintegration of dead myofibers, with dying neutrophils; early phagocytosis of dead cells by macrophages at the infarct border (Chronic inflammation) 7–10 days Maximally yellow-tan and soft, with depressed red-tan margins Well-developed phagocytosis of dead cells; granulation tissue at margins (Repair) {{caption_text}} 10–14 days Red-gray depressed infarct borders Well-established granulation tissue with new blood vessels and collagen deposition 2–8 weeks Grey-white scar, progressive from the border toward the core of the infarct Increased collagen deposition, with decreased cellularity >2 months Scarring complete Dense collagenous scar {{caption_text}}





@Neet_pg_bot



@Neet_pg_bot

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 52,56,547

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 3-year-old child has been brought to the hospital with complaints of fever, rash, and swelling of her hands and feet for the past 5 days. There is desquamative skin rash, edema of hands and feet, erythema of palms and soles, oral erythema, and cervical lymphadenopathy. What is the likely condition? (Q854849)

A. Kawasaki disease

B. Measles

C. Scarlet fever

D. Henoch-Schonlein purpura

Correct Answer: A. Kawasaki disease

Explanation: The classic features of this disease are the swelling of hands and feet, rash, and the other symptoms described in the case, making Kawasaki disease the most likely diagnosis. It is an acute, febrile, usually self-limited illness of infancy and childhood associated with large- to medium-sized vessel arteritis . 80% of the patients are younger than 4 years of age. It presents with fever, conjunctival injection, desquamative rash, erythema of palms and soles, oral erythema (strawberry tongue), and cervical lymphadenopathy. Coronary arteritis can result in aneurysms that rupture or thrombose, causing myocardial infarction . In genetically susceptible persons, a variety of infectious agents (mostly viral) have been posited to trigger the disease. The vasculitis may result from a delayed-type hypersensitivity response directed against cross-reactive or newly uncovered vascular antigens. Subsequent cytokine production and polyclonal B-cell activation result in autoantibodies to ECs and SMCs that precipitate the vasculitis. Clinical Features Mnemonic: CREAM-F. C onjunctivitis (non-exudative & non-purulent). R ash (Polymorphous, non-vesicular). E dema (or erythema of hands & feet). A denopathy (Cervical, often unilateral & non-suppurative). M ucosal involvement (Erythema or fissures or crusting at times, referred to as strawberry tongue). F ever (Most important constitutional symptom) . The image below shows the strawberry tongue. {{caption_text}} Measles (Option B) is a viral infection characterised by a maculopapular rash, Koplik spots in the mouth, and fever. It does not present with the swelling of hands and feet or the specific oral erythema seen in Kawasaki disease. Scarlet fever (Option C) is caused by a group A Streptococcus infection , typically presenting with a sandpaper-like rash, fever, and sore throat. It does not cause the desquamative rash or the extensive lymphadenopathy seen in Kawasaki disease. Henoch-Schonlein purpura (Option D) is a small vessel vasculitis commonly presenting with purpura, abdominal pain, and arthritis. The signs of erythema of palms and soles and the specific rash described are not characteristic of this condition.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 513

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Large, friable, irregular vegetation on heart valves is seen in which condition? (Q854841)

A. Infective endocarditis

B. Rheumatic heart disease

C. Libman-Sacks endocarditis

D. Non-bacterial thrombotic carditis

Correct Answer: A. Infective endocarditis

Explanation: Infective endocarditis is characterised by the presence of large, friable, and irregular vegetations on heart valves. These vegetations are composed of a mixture of microorganisms, fibrin, and inflammatory cells.

Condition Vegetations and site Rheumatic heart disease (Option B) Small, warty, sterile vegetations along the line of closure of valve leaflets. Infective Endocarditis Large, bulky, infected, friable, irregular mass along the line of closure or on valvular cusps, more on the atrial side. Non-bacterial Thrombotic Endocarditis (Option D) Small, bland, sterile vegetation along the line of closure. Libman-Sacks Endocarditis (Option C) Small or medium-sized sterile vegetations on either or both sides of valvular leaflets, most commonly on the lower side.

Robbins & Cotran Pathologic Basis of Disease, 10th Edition, Page 562

↑ *Back to this question in Part A*

@Neet_pg_bot

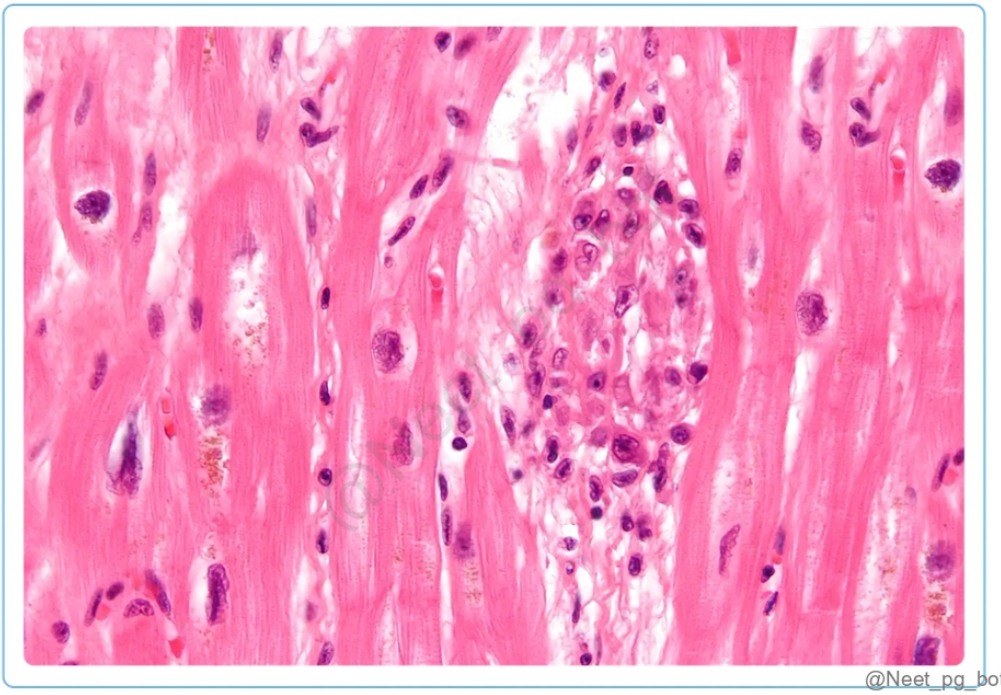
Q8: A 34-year-old female patient presented to the outpatient department with migratory arthritis, and examination revealed a pan-systolic murmur. An echocardiography was performed, which was suggestive of mitral regurgitation. A biopsy specimen was obtained, and the image is provided below. What is the most likely lesion shown in the histopathology slide? {{caption_text}} (Q856158)

A. Aschoff’s bodies

B. Epithelioid granuloma

C. Granulomatous vasculitis

D. Granuloma inguinale



Correct Answer: A. Aschoff’s bodies

Explanation: Aschoff's bodies are the hallmark histopathological findings in rheumatic fever . This patient’s symptoms of migratory arthritis, pan-systolic murmur, and mitral regurgitation, along with the characteristic granulomatous lesions, point to rheumatic heart disease caused by rheumatic fever . Histopathological features of RHD Aschoff bodies They are focal areas of inflammation with infiltration of lymphocytes, plasma cells and activated macrophages or histiocytes. An endomyocardial biopsy showing Aschoff's bodies helps in confirming the diagnosis of RHD. {{caption_text}} Anitschkow cells They are activated macrophages with elongated and wavy nuclei commonly found within Aschoff bodies. They appear as caterpillars in longitudinal sections (hence also called Caterpillar cells) and owls in cross sections. {{caption_text}} Fibrinoid necrosis This is seen in areas of the valves affected by inflammation. Granulation tissue is seen in cases of repair. It comprises proliferating blood vessels, inflammatory cells and fibroblasts. Epithelioid granuloma (Option B) is a characteristic feature of tuberculosis and other granulomatous diseases (like sarcoidosis). These granulomas are not typically seen in rheumatic fever. Granulomatous vasculitis (Option C) refers to a condition where there is inflammation of the blood vessels, and granulomas form in the vessel walls. This is typically seen in diseases like Wegener's granulomatosis or Takayasu arteritis , not rheumatic fever. Granuloma inguinale (Option D) is a sexually transmitted infection caused by Klebsiella granulomatis . It causes ulcerative lesions in the genital area and does not lead to heart murmurs, mitral regurgitation, or migratory arthritis.

Robbins and Cotran, Pathologic Basis of Disease, 10th Edition, Page 56

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A child is presenting with palpable blanching purpura, abdominal pain, and pain in the knee joint resulting from arthritis. Urine examination showed hematuria and proteinuria. What is the most likely diagnosis? (Q856146)

A. Immune thrombocytopenic purpura

B. Dengue

C. Churg-Strauss syndrome

D. Henoch-Schonlein purpura

Correct Answer: D. Henoch-Schonlein purpura

Explanation: The child’s presentation of palpable blanching purpura, abdominal pain, arthritis (joint pain), hematuria and proteinuria is most consistent with Henoch-Schonlein purpura (HSP). Henoch-Schönlein Purpura (IgA vasculitis) Definition It is a systemic vasculitis characterised by inflammation of small blood vessels , primarily affecting children, but can also occur in adults. Etiology Often follows upper respiratory tract infections Pathology Immune complex deposition of IgA in small blood vessels leads to inflammation Clinical features Inflammation of small blood vessels primarily affects children but can also occur in adults. Associated with elevated serum IgA levels Skin : Palpable purpura, most prominently on the lower limbs and buttocks. Musculoskeletal : Arthralgia or arthritis, often transient and non-deforming. Gastrointestinal : Abdominal pain, nausea, vomiting, and sometimes gastrointestinal bleeding, Intussusception is a severe but rare complication. Renal : Hematuria, proteinuria, and red blood cell casts in urine. It can progress to IgA nephropathy in severe cases. Management Supportive care : Hydration, rest, and pain management with NSAIDs for arthralgia. Glucocorticoids : For severe abdominal pain, renal involvement, or systemic symptoms. Intussusception : Surgical intervention if required. Nephritis : Immunosuppressants (e.g., cyclophosphamide) in severe cases. Immune thrombocytopenic purpura (Option A) is characterised by isolated thrombocytopenia without significant involvement of other systems. The purpura is typically non-blanching and is not associated with arthritis, abdominal pain, or renal symptoms. Dengue (Option B) often presents with high fever, rash, severe headache, and retro-orbital pain. While petechiae can occur, Dengue is not commonly associated with purpura or renal involvement. Churg-Strauss syndrome (Option C) is also called Eosinophilic Granulomatosis with Polyangiitis and is a vasculitis that is associated with asthma , eosinophilia , and granulomatous inflammation . It is part of the group of ANCA-associated vasculitis . It normally does not present with palpable purpura or renal involvement, as seen in HSP.

Robbins and Cotran, Pathologic Basis of Disease, 10th Edition, Page 509

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: What is the gold standard investigation for the diagnosis of myocarditis? (Q856719)

A. Endo-myocardial biopsy

B. Magnetic Resonance Imaging

C. Brain Natriuretic Peptide

D. LDH1 to LDH2 ratio

Correct Answer: A. Endo-myocardial biopsy

Explanation: Endo-myocardial biopsy is considered the gold standard investigation for the diagnosis of myocarditis. It involves obtaining a small tissue sample from the endocardium or the myocardium to examine it under a microscope. This biopsy allows for direct visualization of the cardiac tissue and assessment of cellular inflammation, the presence of viral particles, and other histopathological changes characteristic of myocarditis. Myocarditis It is a diverse group of pathologic entities in which infectious microorganisms and/or a primary inflammatory process cause myocardial injury. Pathogenesis Infections: Viruses (e.g., Coxsackievirus, Echovirus, Influenza, HIV, Cytomegalovirus) Chlamydiae (e.g., Chlamydophila psittaci) Rickettsiae (e.g., Rickettsia typhi, Typhus fever) Bacteria (e.g., Corynebacterium diphtheriae, Neisseria meningococcus, Borrelia) Fungi (e.g., Candida) Protozoa (e.g., Trypanosoma cruzi [Chagas disease], toxoplasmosis) Helminths (e.g., Trichinosis) Immune-Mediated Reactions Postviral Poststreptococcal (Rheumatic fever) Systemic lupus erythematosus Drug hypersensitivity (e.g., methyldopa, sulfonamides) Transplant rejection Immune checkpoint inhibitor therapies Unknown Sarcoidosis Giant cell myocarditis Clinical features It can be asymptomatic (recovery without sequelae) Heart failure Arrhythmias Sudden death Symptoms include fatigue, dyspnea, palpitations, precordial discomfort, and fever. Magnetic Resonance Imaging (Option B) can offer valuable supportive evidence for diagnosing myocarditis, but it is not regarded as the gold standard. Cardiac MRI can reveal myocardial oedema, inflammation, and tissue characterization through specific sequences like T2-weighted imaging and late gadolinium enhancement. Brain Natriuretic Peptide (BNP) (Option C) is a hormone secreted by the heart in response to increased stretching of the cardiac chambers, commonly observed in conditions like heart failure. Although BNP levels can be elevated in myocarditis due to associated cardiac dysfunction, it is not a specific test for diagnosing myocarditis. LDH1 to LDH2 ratio (Option D) is not a specific diagnostic marker for myocarditis. Lactate dehydrogenase (LDH) is an enzyme present in various tissues, including the heart. In myocarditis, LDH levels may be elevated due to myocardial injury.

@Neet_pg_bot

Q11: A patient presented with complaints of dyspnea on exertion for 1 month. Echocardiography showed the presence of mitral stenosis and left ventricular

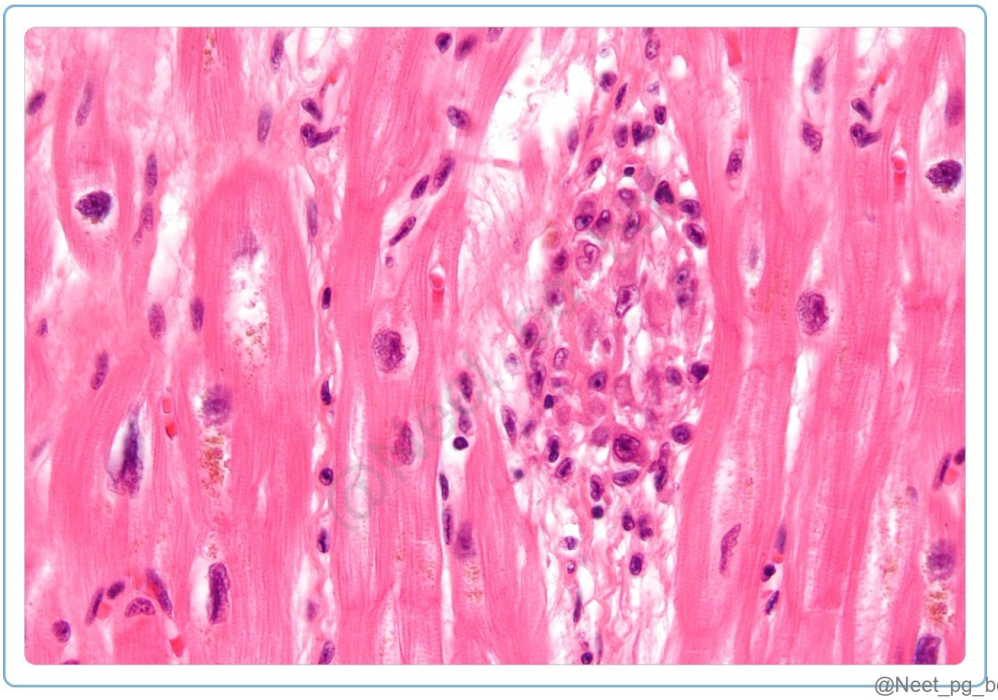
hypertrophy. Identify the histopathological finding given below and the probable diagnosis. (Q855407)

A. Aschoff body; Rheumatic heart disease

B. Calcification of valve; Mitral stenosis

C. Granuloma; Sarcoidosis

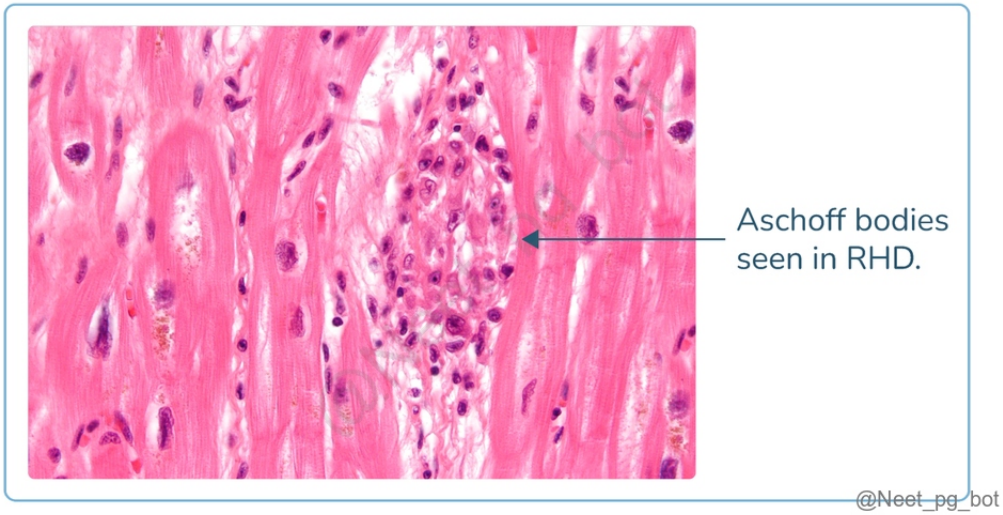
D. Non-caseating granuloma; Tuberculosis



Correct Answer: A. Aschoff body; Rheumatic heart disease

Explanation: The given scenario, featuring dyspnea on exertion for one month, mitral stenosis and left ventricular hypertrophy, along with histopathological evidence of Aschoff bodies, is consistent with a diagnosis of Rheumatic Heart Disease (RHD). It is caused by an autoimmune reaction following a Group A Streptococcus infection. Predisposing factor: Acute Rheumatic fever typically occurs 2-3 weeks after the onset of Streptococcal pharyngitis (Group A beta-hemolytic Streptococci). Pathogenesis: Acute rheumatic fever (ARF) results from an immune response to group A streptococcal antigens, particularly the M proteins, which can cross-react with host proteins, including cardiac self-antigens. This molecular mimicry produces antibodies and activates CD4+ T cells that ultimately cause inflammation and tissue damage, particularly in the heart. Histopathological findings: Involve changes in the heart valves due to chronic inflammation and scarring. They include: Aschoff bodies: Consist of areas of chronic inflammation infiltrated with lymphocytes, plasma cells, and activated macrophages or histiocytes known as Anitshkow cells. Anitshkow cells: These are activated macrophages with a characteristic “caterpillar-like appearance” due to the presence of a central, slender and wavy nucleus. Fibrinoid necrosis results from the deposition of fibrin and inflammatory cells and is seen in areas of the valves affected by inflammation. {{caption_text}} {{caption_text}} Complications of RHD: Valvular stenosis and regurgitation Heart failure

Arrhythmias, particularly atrial fibrillation in the setting of mitral stenosis Pulmonary arterial hypertension (PAH) Recurrence of acute rheumatic fever Cardio-embolic stroke Cardiomyopathy Infective endocarditis Ruptured heart valve. Calcification of valve; Mitral stenosis (Option B): Mitral stenosis is a narrowing of the mitral valve opening, caused by valve calcification, which restricts blood flow from the left atrium to the left ventricle, leading to symptoms such as shortness of breath, fatigue, and heart palpitations. {{caption_text}} Granuloma; Sarcoidosis (Option C): Sarcoidosis is an inflammatory condition marked by the development of granulomas. While the exact cause remains unknown, it is thought to result from an abnormal immune response, potentially triggered by genetic and environmental factors. Histologically, it presents with non-caseating granuloma or naked granuloma (lymphocytic collar absent). Asteroid bodies (stellate, pink-staining inclusions in giant cells) are commonly found but not specific. {{caption_text}} Non-caseating granuloma; Tuberculosis (Option D): Tuberculosis is a bacterial infection caused by Mycobacterium tuberculosis, characterized histologically by a granulomatous inflammatory response with both caseating and non-caseating tubercles. {{caption_text}}



@Neet_pg_bot

Q12: Which of the following histopathological findings is not seen 12 hours after an ischemic injury to the heart? (Q857177)

A. Karyorrhexis of myocytes

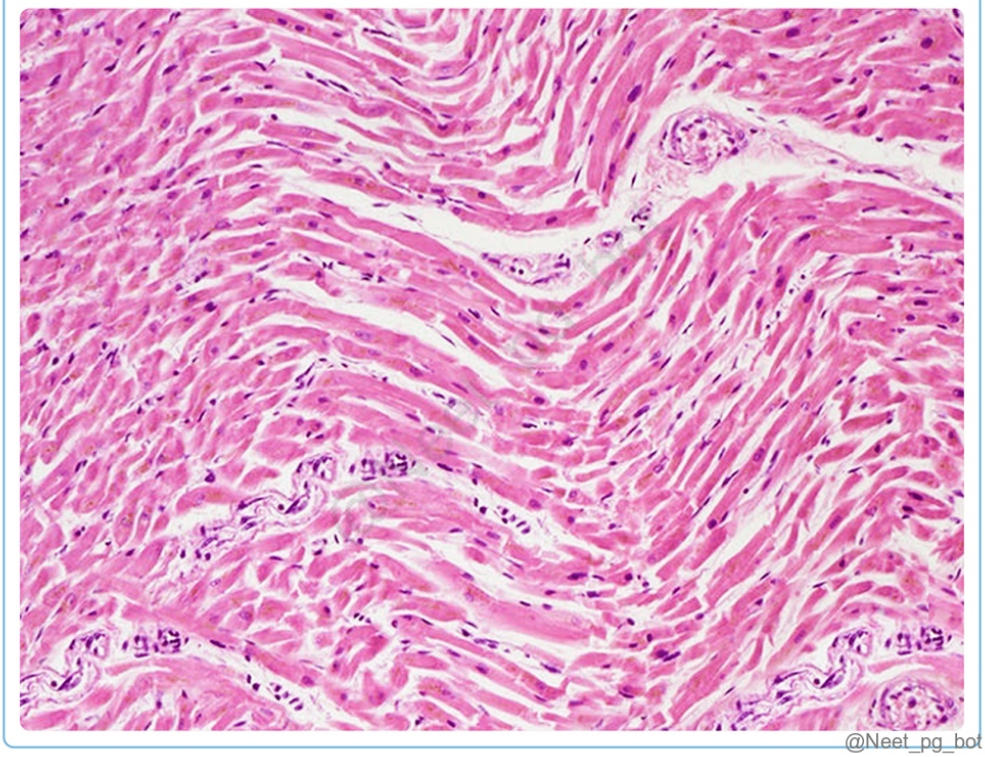
B. Neocapillary invasion of myocytes

C. Hyper-eosinophilia of myocytes

D. Coagulation necrosis of myocytes

Correct Answer: B. Neocapillary invasion of myocytes

Explanation: Neocapillaries appear as part of granulation tissue , which develops 7–10 days after MI. Too early to see new vessel formation at 12 hours. Time Gross Features Light Microscope Electron Microscope Reversible Injury 0– 1/2 hour None None Relaxation of myofibrils; glycogen loss; mitochondrial swelling Irreversible Injury 1/2 –4 hours None Usually none; variable waviness of fibres at the border; myocyte vacuolisation {{caption_text}} Sarcolemmal disruption; mitochondrial amorphous densities (Calcium in mitochondria) 4–12 hours Occasional dark mottling Early coagulative necrosis, oedema, haemorrhage 12–24 hours Dark mottling Ongoing coagulative necrosis; pyknosis of nuclei; myocyte hypereosinophilia; marginal contraction band necrosis; early neutrophilic infiltrate 1–3 days Mottling with yellow-tan infarct centre Coagulative necrosis, with loss of nuclei and striations; brisk interstitial infiltrate of neutrophils (Acute inflammation) {{caption_text}} 3–7 days Hyperemic border; central yellow-tan softening Beginning disintegration of dead myofibers, with dying neutrophils; early phagocytosis of dead cells by macrophages at the infarct border (Chronic inflammation) 7–10 days Maximally yellow-tan and soft, with depressed red-tan margins Well-developed phagocytosis of dead cells; granulation tissue at margins (Repair) {{caption_text}} 10–14 days Red-gray depressed infarct borders Well-established granulation tissue with new blood vessels and collagen deposition. 2–8 weeks Grey-white scar, progressive from the border toward the core of the infarct Increased collagen deposition, with decreased cellularity. >2 months Scarring complete Dense collagenous scar {{caption_text}}



@Neet_pg_bot

Q13: A 65-year-old man dies due to a myocardial infarction. Which stains can be used to see the infarct in the heart while conducting an autopsy? (Q858094)

A. Oil Red O

B. Triphenyl tetrazolium chloride

C. Sudan black B

D. Masson's trichrome

Correct Answer: B. Triphenyl tetrazolium chloride

Explanation: Triphenyl tetrazolium chloride (TTC) is a stain commonly used in autopsies to identify myocardial infarction (MI). In myocardial infarction (MI), within the first 4 hours , gross examination may not show any visible infarcted area. However, immersion of tissue slices in TTC solution can highlight the necrotic area. This histochemical stain imparts a brick-red colour to intact, non-infarcted myocardium with preserved lactate dehydrogenase activity. Conversely, infarcted tissue appears as an unstained pale zone because of leakage of dehydrogenases through the damaged membranes of dead cells. {{caption_text}} {{caption_text}} Incorrect Options: Oil Red O (Option A) stain optimally detects lipids in frozen sections by staining them bright red and is commonly used to detect fat accumulation or atherosclerotic plaques, but it is not used for identifying infarcts in myocardial tissue. Sudan black B (Option C) is a lipid-specific stain primarily used to identify lipid-rich substances by staining them black , but it does not detect myocardial infarction. Masson's trichrome (Option D) stain is used to differentiate collagen fibres (stain blue) from other tissue components. It is not specific for visualising glycogen.

↑ *Back to this question in Part A*

@Neet_pg_bot

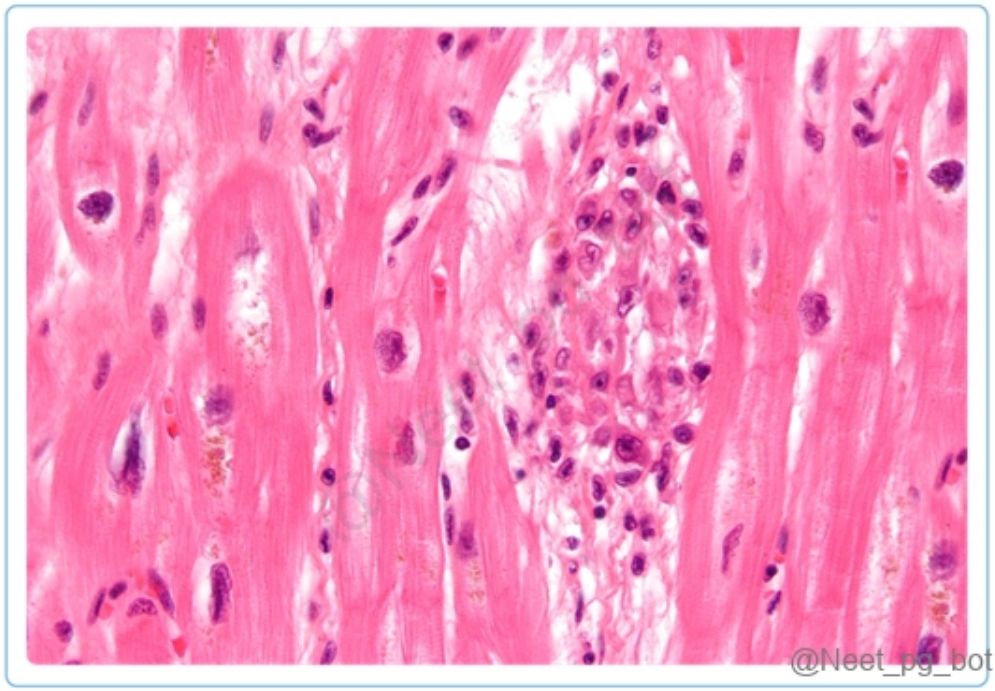
Q14: A 34-year-old female patient presented to the outpatient department with migratory arthritis, and examination revealed a pan-systolic murmur. An echocardiography was performed, which was suggestive of mitral regurgitation. A biopsy specimen was obtained, and the image is provided below. What is the most likely lesion shown in the histopathology slide? (Q858083)

A. Aschoff's bodies

B. Epithelioid granuloma

C. Granulomatous vasculitis

D. Granuloma inguinale



Correct Answer: A. Aschoff’s bodies

Explanation: This patient's symptoms of migratory arthritis, pan-systolic murmur (mitral regurgitation), and Aschoff bodies on biopsy are indicative of rheumatic fever , a complication of Group A Streptococcus throat infection. Histopathological features of RHD: Aschoff bodies are focal areas of inflammation with infiltration of lymphocytes, plasma cells and activated macrophages or histiocytes. An endomyocardial biopsy showing Aschoff's bodies helps in confirming the diagnosis of RHD. Anitschkow cells or Caterpillar cells are activated macrophages with elongated and wavy nuclei commonly found within Aschoff bodies. Fibrinoid necrosis is seen in areas of the valves affected by inflammation. Note: Granulation tissue is seen in cases of repair. It comprises proliferating blood vessels, inflammatory cells and fibroblasts. {{caption_text}} Incorrect Options: Epithelioid granuloma (Option B) is typically seen in granulomatous conditions like tuberculosis or sarcoidosis . The clinical presentation given does not align with these conditions. Granulomatous vasculitis (Option C) refers to inflammation of blood vessels with granuloma formation, often seen in diseases like Wegener’s granulomatosis , but again, the clinical signs do not point to these disorders. Granuloma inguinale (Option D), also called Donovanosis, is a sexually transmitted infection caused by Klebsiella granulomatis and typically presents with genital ulcers.

Robbins and Cotran Pathologic Basis of Disease,10th Edition, Page 561

↑ *Back to this question in Part A*

@Neet_pg_bot

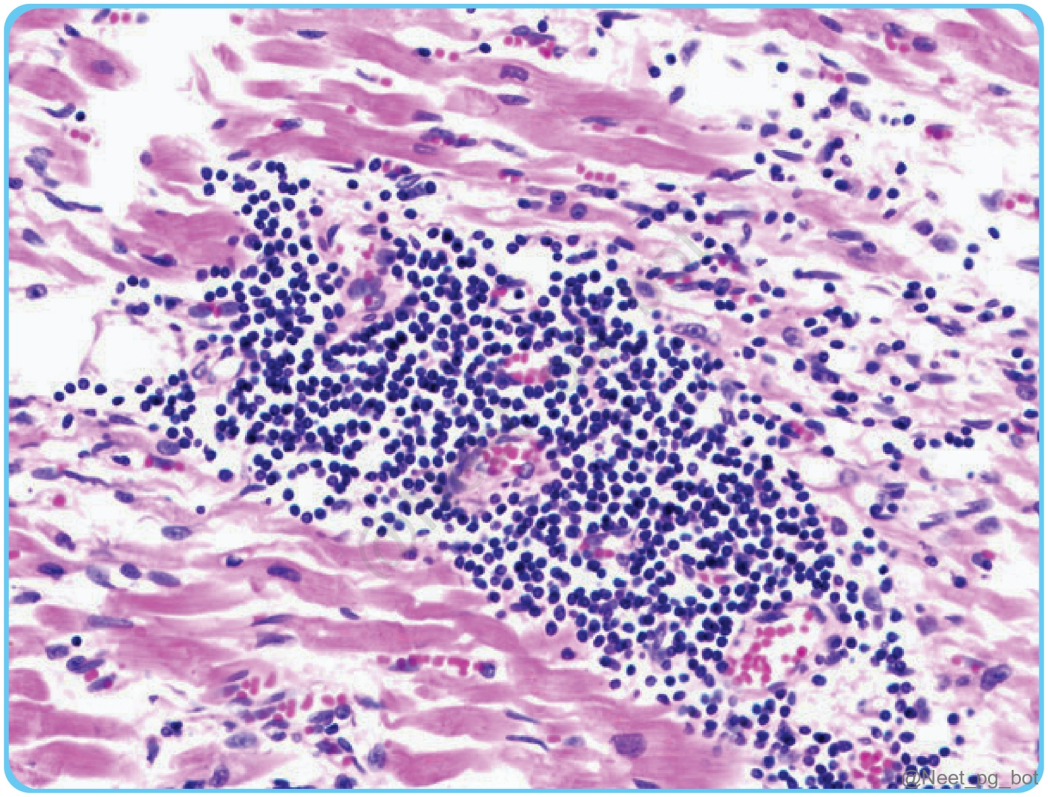
Q15: A 5-year-old child presents with fever, fatigue, and left ventricular dysfunction. An endomyocardial biopsy is shown below. What is the most likely diagnosis? (Q855420)

A. Acute rheumatic fever

B. Chagas cardiomyopathy

C. Pyogenic myocarditis

D. Lymphocytic myocarditis



Correct Answer: D. Lymphocytic myocarditis

Explanation: The clinical scenario of a child with complaints of fever, fatigue & LV dysfunction & biopsy showing lymphocytic infiltration is suggestive of Lymphocytic myocarditis , an inflammatory condition of the heart muscle characterised by the infiltration of lymphocytes, which are immune cells involved in viral or autoimmune responses. Etiology: Viral infections (e.g., enteroviruses, adenoviruses) Postviral reactions Autoimmune diseases (e.g., systemic lupus erythematosus, rheumatoid arthritis) Idiopathic cases (unknown cause) Pathological finding: Lymphocytic infiltration : Predominantly, lymphocytes infiltrate the myocardium, especially in the left ventricle. Myocyte necrosis : The inflammation leads to the death of myocardial cells. Fibrosis : Chronic cases may develop fibrosis and scarring in the heart tissue. Dilated cardiomyopathy : Severe cases can lead to heart enlargement and dysfunction. Prognosis: The prognosis depends on the underlying cause, extent of myocardial damage, and response to treatment. Viral myocarditis can resolve with supportive care, but severe cases may lead to heart failure or require a heart transplant. Chronic forms may lead to dilated cardiomyopathy .

https://pmc.ncbi.nlm.nih.gov/articles/PMC6198272/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following is the earliest marker to rise in a case of myocardial infarction (MI)? (Q860196)

A. CKMB (Creatine Kinase-MB)

B. Troponin

C. LDH

D. Heart fatty acid binding protein

Correct Answer: D. Heart fatty acid binding protein

Explanation: H-FABP(Heart fatty acid binding protein) is the earliest marker to rise in a case of myocardial infarction (MI). Cardiac Markers Cardiac Troponin (Troponin T and I) (Option B ruled out) Preferred biochemical markers due to their sensitivity and specificity. Troponin levels: Increase within 3-6 hours. Peak at around 36 hours. Remains elevated for 7-10 days after STEMI. Troponin should be measured at presentation and repeated at 1-3 hours (high-sensitivity assays) or 3-6 hours (conventional assays). Cardiac troponin levels remain elevated for several days after an acute myocardial infarction (AMI), making them unreliable for detecting reinfarction. Creatine Phosphokinase (CK) and CK-MB (Option A ruled out) CK rises within 4-8 hours. Peaks by 24 hours. Returns to normal within 48-72 hours. CK-MB elevated: Cardiac surgery Myocarditis Electrical cardioversion CK-MB levels normalise within 48 to 72 hours, so a subsequent rise can confirm reinfarction. Lactate Dehydrogenase (LDH) (Option C ruled out) Increase in the blood 6 to 12 hours after ACS. Peak within 24 to 72 hours. Normalise within 8 to 14 days. LDH is no longer used to diagnose myocardial infarction because it is not specific to cardiac myocytes. Heart-type Fatty Acid-Binding Protein (H-FABP) (Option D) It is the earliest marker to rise in a case of myocardial infarction (MI). It has higher sensitivity than troponin and CK-MB for detecting AMI within 4 hours of symptom onset, but its specificity is lower.

@Neet_pg_bot

Q17: A 35-year-old patient presents with colicky abdominal pain, joint pain, and palpable purpura. Urinalysis shows only red blood cells with no other significant findings. Which of the following is the likely diagnosis? (Q860153)

A. IgA vasculitis

B. Granulomatosis with polyangiitis

C. Microscopic polyangiitis

D. Behçet's disease

Correct Answer: A. IgA vasculitis

Explanation: The scenario of colicky abdominal pain, joint pain, palpable purpura, and hematuria without proteinuria suggests Henoch-Schönlein Purpura (IgA Vasculitis). It is an IgA-mediated small vessel vasculitis characterized by inflammation of small blood vessels. The exact cause of HSP is unclear, but it is thought to involve an abnormal immune response, where IgA immune complexes deposit in blood vessel walls, causing inflammation and damage. It is more common in children but can occur in adults. It is characterized by Henoch Schonlein purpura (palpable purpura) Purpuric rash in lower limbs Abdominal pain Arthralgia Renal (hematuria) It is associated with elevated serum IgA levels. Urinalysis: The presence of red blood cells cast in urine. Granulomatosis with polyangiitis (GPA) (Option B) , also known as Wegener's granulomatosis , is an autoimmune condition that primarily affects the small- to medium-sized blood vessels, leading to granulomatous inflammation and necrosis. It involves respiratory symptoms and renal issues, while Henoch-Schönlein Purpura (HSP) is more likely here due to abdominal pain, joint pain, and palpable purpura, which are hallmark features of HSP with IgA deposition. Microscopic polyangiitis (MPA) (Option C) is a small-vessel vasculitis primarily affecting the kidneys and lungs, often presenting with rapidly progressive glomerulonephritis and pulmonary symptoms like hemoptysis, along with ANCA positivity. Behcet's disease (Option D) is a systemic vasculitis that presents with oral and genital ulcers, ocular involvement, and skin lesions like erythema nodosum.

Robbins and Cotran, Pathological Basis of Diseases, 10th Edition, Page 509.

↑ *Back to this question in Part A*

@Neet_pg_bot

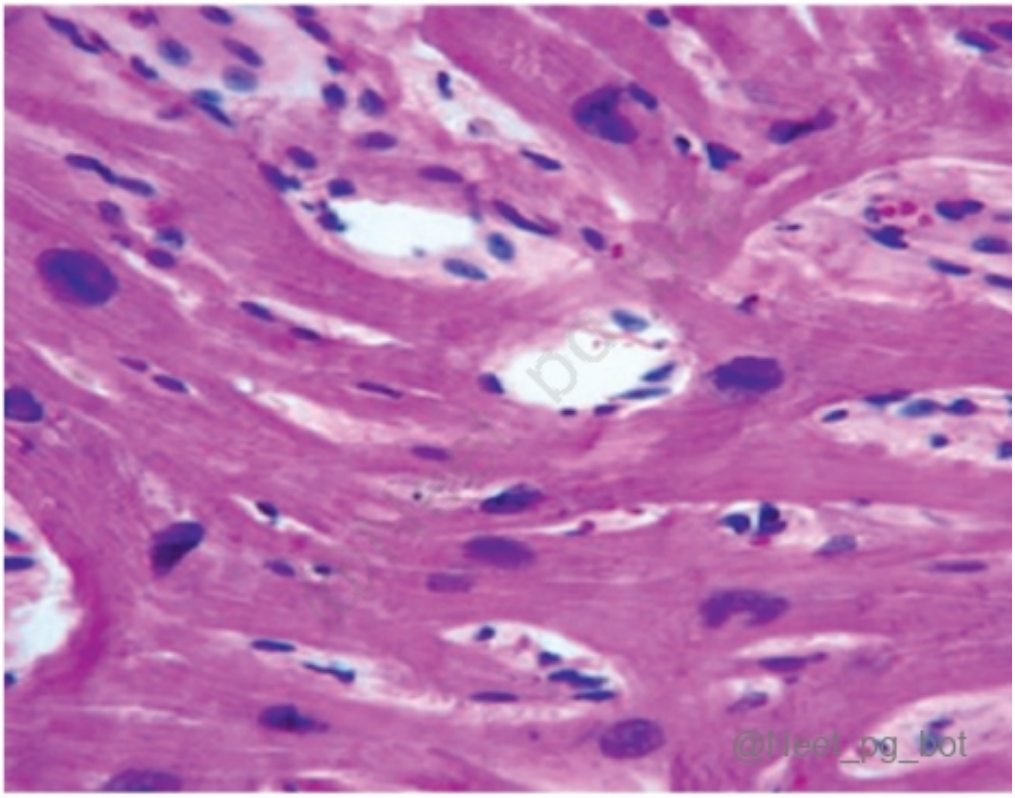
Q18: A 30-year-old football player is brought to the emergency department after he collapsed due to sudden cardiac arrest. Based on the biopsy findings of his cardiac tissue, what is the most likely cause of his death? (Q844091)

A. Hypertrophic obstructive cardiomyopathy

B. Dilated cardiomyopathy

C. Restrictive cardiomyopathy

D. Arrhythmogenic cardiomyopathy



Correct Answer: A. Hypertrophic obstructive cardiomyopathy

Explanation: The biopsy shows myocyte hypertrophy with disarray, which is characteristic of HOCM. HOCM is a genetic disorder (usually autosomal dominant) involving mutations in sarcomeric proteins. It commonly affects young athletes and is the most frequent cause of sudden cardiac death in this population. The histologic hallmark is myocyte disarray with interstitial fibrosis, leading to arrhythmias. Obstruction of the left ventricular outflow tract may or may not be present, but sudden death is usually due to ventricular arrhythmia. Incorrect Options : Option B) Dilated cardiomyopathy – Shows ventricular dilation and thin walls, not myocyte disarray; usually causes heart failure rather than sudden death in athletes. Option C) Restrictive cardiomyopathy – Characterized by fibrosis or amyloid deposition, with normal wall thickness; arrhythmic sudden death is less common. Option D) Arrhythmogenic cardiomyopathy – Shows fibrofatty replacement of right ventricular myocardium, not myocyte disarray in the left ventricle.

@Neet_pg_bot

Q19: A 20-year-old athlete suddenly collapsed while playing football and was taken to the hospital, where he was declared dead. His autopsy image is given below. Which of

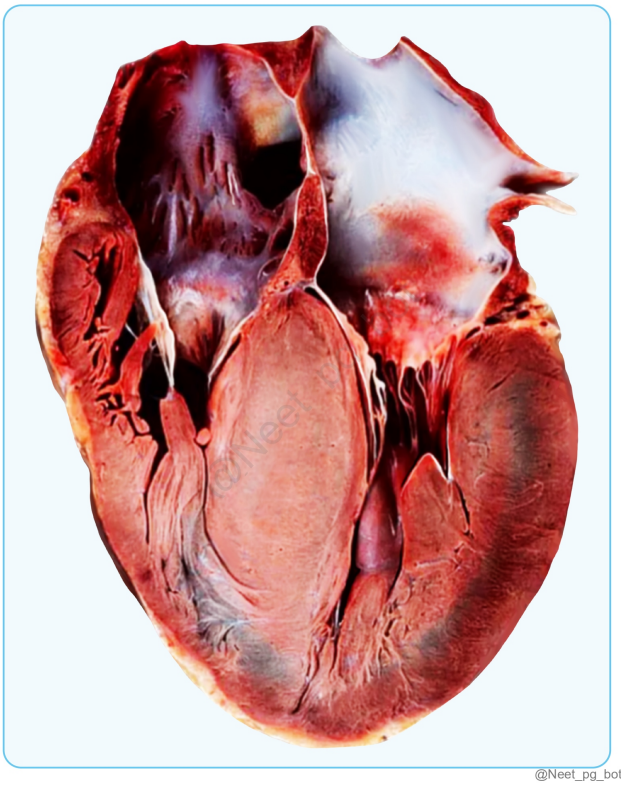
the following is the most likely cause of death? (Q855424)

A. Valvular heart disease due to RHD

B. Sudden cardiac death due to arrhythmia

C. Sudden cardiac death due to hypertrophic cardiomyopathy

D. Sudden cardiac death due to atherosclerosis



Correct Answer: C. Sudden cardiac death due to hypertrophic cardiomyopathy

Explanation: The autopsy image reveals signs of cardiac hypertrophy, indicating hypertrophic cardiomyopathy (HCM) as a likely cause of death, which is a common contributor to Sudden Cardiac Death (SCD) in young athletes due to abnormal thickening of the heart muscle, particularly in the left ventricle. Sudden Cardiac Death (SCD) Sudden Cardiac Death (SCD) is defined as unexpected death occurring within an hour of symptom onset due to cardiac causes, including unwitnessed deaths in individuals who seemed healthy within the last 24 hours. Risk Factors Structural Heart Disease: The presence of structural heart issues or inherited arrhythmia syndromes significantly increases SCD risk. Major Risk Factors: Coronary Heart Disease (CHD) Heart Failure Diabetes Hypertension Smoking Family History of SCD In Athletes Younger Athletes: The leading causes of SCD are inherited cardiac conditions, particularly Hypertrophic Cardiomyopathy (HCM). (Option C) Older Athletes: Risks are primarily associated with atherosclerotic coronary artery disease (CAD). Precipitating Factors SCD and Sudden Cardiac Arrest (SCA) frequently occur at specific times (e.g., mornings, winter months) and in public places. Vigorous exertion, especially in men, can trigger SCD; however, regular exercise may reduce this risk. Underlying Heart Disease The most common cause of SCD is Ventricular fibrillation Many SCD cases are linked

to coronary artery disease (CAD), but non-ischemic cardiomyopathies and other heart conditions also contribute. Common mechanisms leading to SCD include: Acute Myocardial Infarction Bradyarrhythmias Ventricular scars leading to arrhythmias Commotio Cordis Commotio cordis is a specific cause of SCD, often resulting from an impact to the left chest by a hard object, such as a baseball, during sports. This can induce ventricular fibrillation and cardiac arrest in an otherwise structurally normal heart. Valvular heart disease due to RHD (Option A): The autopsy image shows no significant abnormalities in the heart valves, excluding valvular heart disease as the cause of death. RHD, which results from untreated or inadequately treated streptococcal infections, leads to inflammation and scarring of the heart valves. However, typical signs of RHD, such as thickened or damaged valves, are not observed in this image. Sudden cardiac death due to arrhythmia (Option B): Sudden cardiac death (SCD) is an unexpected and rapid loss of heart function, typically caused by a life-threatening arrhythmia. In athletes, the most frequent cause of SCD is hypertrophic cardiomyopathy (HCM), which is characterized by abnormal thickening of the heart muscle. Sudden cardiac death due to atherosclerosis (Option D): Atherosclerosis involves the accumulation of plaques in the arteries, which narrows and restricts blood flow. Although atherosclerosis can lead to heart attacks and sudden cardiac death, the autopsy image shows no signs of significant plaque buildup or obstruction in the coronary arteries.

@Neet_pg_bot

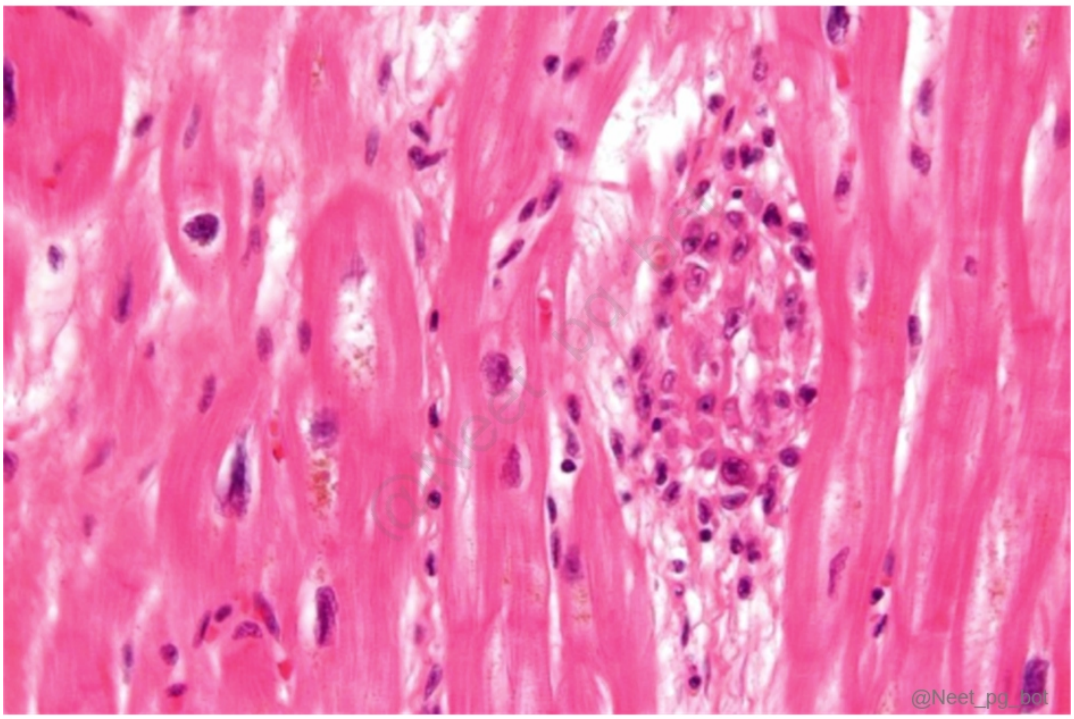
Q20: A 34-year-old female patient presented to the outpatient department with migratory arthritis , and examination revealed a pan-systolic murmur . An echocardiography was performed, which was suggestive of mitral regurgitation . A biopsy specimen was obtained, and the image is provided below. What is the most likely lesion shown in the histopathology slide? (Q799426)

A. Aschoff’s bodies

B. Epithelioid granuloma

C. Granulomatous vasculitis

D. Granuloma inguinale



Correct Answer: A. Aschoff’s bodies

Explanation: Correct Option A - Aschoff’s bodies : The patient's presentation with migratory arthritis, a pan-systolic murmur, and mitral regurgitation is suggestive of rheumatic heart disease. Aschoff's bodies are characteristic histopathological features seen in rheumatic heart disease. Aschoff's bodies are focal areas of chronic inflammation within the myocardium. They consist of a central focus of fibrinoid necrosis, surrounded by Anitschkow cells. Incorrect Options: Option B - Epithelioid granuloma: Epithelioid granulomas are associated with granulomatous diseases such as tuberculosis and sarcoidosis. Option C - Granulomatous vasculitis: Granulomatous vasculitis typically involves inflammation and damage to blood vessels. Option D - Granuloma inguinale: Granuloma inguinale, also known as Donovanosis, is a sexually transmitted infection characterized by genital ulcers.

Q1: A 20-year-old male presented with cough and breathing difficulty and was diagnosed with emphysema after radiographic examination. Which of the following genetic conditions should be suspected as a possible cause? (Q845463)

A. Cystic fibrosis

B. Asthma

C. Alpha-1 antitrypsin deficiency

D. Bronchiectasis

Correct Answer: C. Alpha-1 antitrypsin deficiency

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Alpha-1 antitrypsin deficiency is a genetic condition characterised by low levels or dysfunctional alpha-1 antitrypsin protein. Alpha-1 antitrypsin deficiency: It is an autosomal recessive disorder caused by mutations in the alpha-1 antitrypsin gene located on Chromosome 14 . The condition primarily affects the lungs, leading to panacinar emphysema and the liver, causing cirrhosis due to abnormal protein accumulation. Cystic fibrosis (Option A) is a genetic disorder caused by CFTR gene mutations, leading to thick mucus, chronic lung infections, and bronchiectasis. While it causes obstructive lung disease, emphysema is not typical. Asthma (Option B) is a chronic inflammatory condition causing reversible airway obstruction and episodic wheezing, coughing, and breathlessness. It does not typically result in emphysema or structural lung damage. Bronchiectasis (Option D) is a condition of permanently dilated bronchi due to chronic infections or inflammation. While it causes cough and sputum production, it does not primarily lead to emphysema.

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 679, 680

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Match the following types of emphysema with their characteristic features: Types of Emphysema Characteristic Features 1) Centriacinar emphysema A) Uniformly affects the entire acinus, commonly associated with alpha 1 antitrypsin deficiency 2) Panacinar emphysema B) Predominantly involves the upper lobes, often associated with bullae formation. Alveolar ducts and sacs are spared 3) Paraseptal emphysema C) Associated with scarring and fibrosis, often seen in patients with chronic inflammation or recurrent infections 4) Irregular emphysema D) Involves the distal airways and is often associated with spontaneous pneumothorax (Q845464)

A. 1-a, 2-c, 3-b, 4-d

B. 1-b, 2-a, 3-d, 4-c

C. 1-a, 2-b, 3-c, 4-d

D. 1-d, 2-b, 3-a, 4-c

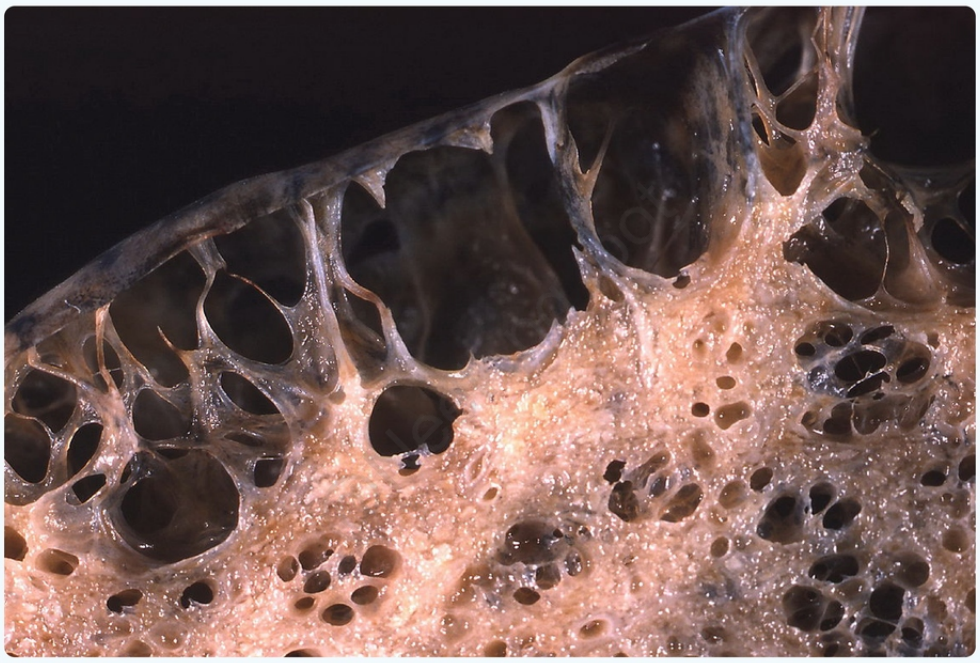
Correct Answer: B. 1-b, 2-a, 3-d, 4-c

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Emphysema is classified according to its anatomic distribution within the lobule. Based on the segments of the respiratory units that are involved, emphysema is subdivided into four major types: Features Centriacinar (M/C) Panacinar Paraseptal Irregular Involves Proximal acinus Proximal & distal acini Distal acinus Irregular involvement Site Upper lobes especially apical segments Lower zones & anterior margins of the lung. More severe at the base of the lung. The upper half of the lungs (more severe). Airspaces can form cyst-like structures. Any part of the lung can be involved. Aetiology Smokers Chronic bronchitis α1-antitrypsin deficiency Spontaneous pneumothorax Depends on involvement, most found in autopsy The image below shows centriacinar emphysema. The image below shows paraseptal emphysema.

@Neet_pg_bot



The image shows paraseptal Emphysema

@Neet_pg_bot

The image below shows panacinar emphysema

@Neet_pg_bot

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Pages 679, 680

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following mechanisms is not involved in the development of emphysema? (Q845465)

A. Toxic injury and inflammation leading to variable degrees of parenchymal destruction.

B. Protease-antiprotease imbalance with a relative deficiency of protective antiproteases.

C. The presence of T and B cells in affected parts of the lung indicates a robust adaptive immune response.

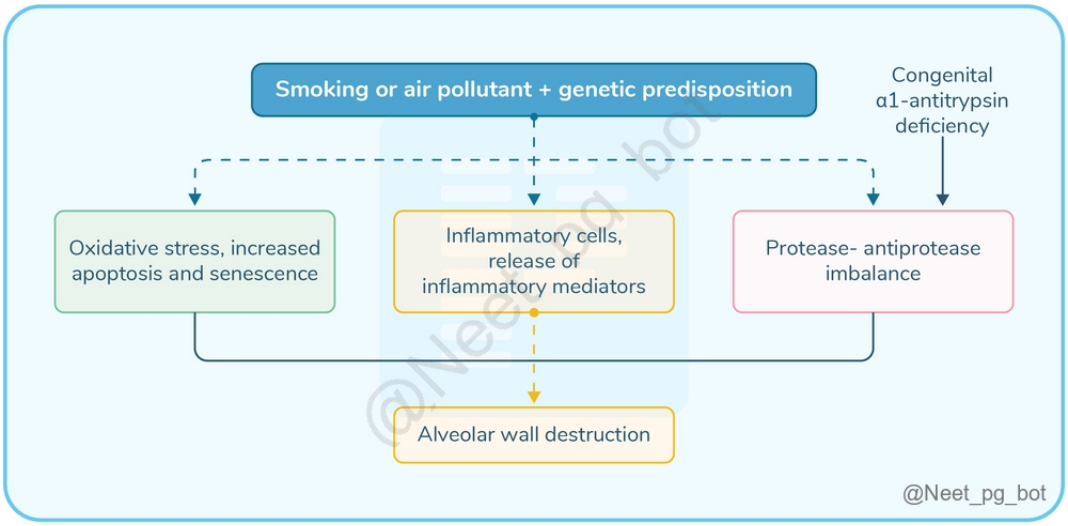
D. Oxidative stress induced by substances in tobacco smoke, alveolar damage, and inflammatory cells.

Correct Answer: C. The presence of T and B cells in affected parts of the lung indicates a robust adaptive immune response.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Chronic inflammation in emphysema does lead to the accumulation of T and B cells in affected parts of the lung, but the role of adaptive immunity is currently uncertain. Therefore, it's not considered a defining feature of the disease. Pathophysiology of emphysema: Inhaled cigarette smoke and other noxious particles cause damage to respiratory epithelium and inflammation, resulting in parenchymal destruction, which is a hallmark of emphysema. In patients with emphysema, there is often a relative deficiency of protective antiproteases, which allows proteases released from inflammatory cells and epithelial cells to break down connective tissue components, contributing to tissue destruction. Substances in tobacco smoke, alveolar damage, and inflammatory cells all produce oxidants, which contribute to tissue damage, endothelial dysfunction, and inflammation, further exacerbating the pathology of emphysema.



References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 680

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 65-year-old man has been a heavy smoker for the past 40 years and presents with complaints of progressive shortness of breath, especially with exertion, and a chronic cough with occasional scanty sputum production. Physical examination reveals a barrel-shaped chest, decreased breathing sounds, and a prolonged expiratory phase. Based on the clinical presentation and history, what is the most likely diagnosis? (Q845466)

A. Chronic bronchitis

B. Emphysema

C. Pulmonary fibrosis

D. Asthma

Correct Answer: B. Emphysema

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's history of heavy smoking, chronic cough with occasional scanty sputum production , progressive shortness of breath, especially with exertion and physical examination showing barrel-shaped chest, decreased breath sounds, and a prolonged expiratory phase is highly suggestive of COPD with emphysema. Clinically significant emphysema is largely confined to smokers and patients with α1-antitrypsin deficiency. Chronic bronchitis (Option A) presents insidiously with slowly increasing dyspnea on exertion and chronic cough with sputum production, slight at first but increasing over time. Pulmonary fibrosis (Option C) is characterized by progressive scarring of the lungs, leading to decreased lung compliance and restrictive lung disease. Asthma (Option D) is characterized by reversible airflow obstruction, wheezing, and chest tightness, but the patient's history of heavy smoking and clinical presentation is not typical of asthma.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 679

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 45-year-old male patient presents with a history of chronic cough, increased sputum production, and shortness of breath. He reports that these symptoms have been present for several years and have gradually worsened over time. The patient is a lifelong smoker, having smoked one pack of cigarettes per day for the past 20 years. What is the likely diagnosis? (Q845469)

A. Emphysema

B. Asthma

C. Chronic bronchitis

D. Lung cancer

Correct Answer: C. Chronic bronchitis

Explanation: The patient's symptoms of chronic cough, increased sputum production, and shortness of breath, combined with his history of long-term smoking, are highly suggestive of chronic bronchitis. Emphysema (Option A): is characterized by the destruction of the alveoli in the lungs, leading to airflow obstruction. While emphysema

can co-occur with chronic bronchitis, the patient's primary symptoms of chronic cough and increased sputum production indicate more chronic bronchitis. Asthma (Option B): c haracterized by intermittent symptoms that worsen with triggers rather than the persistent, progressive symptoms described in the case. Lung cancer (Option D): Lung cancer can also present with cough and shortness of breath, but the gradual, chronic nature of the patient's symptoms makes lung cancer a less likely diagnosis compared to chronic bronchitis.

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 681

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following is not true regarding chronic bronchitis? (Q845472)

A. Reid index >0.4

B. The most common cause is smoking

C. The most common cause of exacerbation is Haemophilus influenzae.

D. Recurrent, episodic attacks of wheezing, prolonged expiration, dyspnea (shortness of breath), and chest tightness.

Correct Answer: D. Recurrent, episodic attacks of wheezing, prolonged expiration, dyspnea (shortness of breath), and chest tightness.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Recurrent, episodic attacks of wheezing, prolonged expiration, dyspnea (shortness of breath), and chest tightness are seen in asthma. Chronic bronchitis is defined clinically as persistent cough with sputum production for at least 3 months in at least 2 consecutive years in the absence of any other identifiable cause. Reid's Index: RI = Thickness of submucosal gland layer / overall thickness of the wall The Reid index (normally 0.4) is increased in chronic bronchitis (>0.4), usually in proportion to the severity and duration of the disease. The primary or initiating factor in the genesis of chronic bronchitis is exposure to noxious or irritating inhaled substances such as tobacco smoke (90% of those affected are smokers, making it the commonest cause) and dust from grain, cotton, and silica. (Option B) The most common cause of exacerbation in COPD is Haemophilus influenzae and the second most common cause is Moraxella. (Option C)

References:

Robbins and Cotran Pathologic Basis of Disease, 10th Edition, Page 681

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 32-year-old female presents with recurrent episodes of wheezing, coughing, and shortness of breath. On further testing, a diagnosis of asthma was made. Which of the following best describes the underlying pathophysiological changes seen in this patient's condition? (Q845474)

A. Reduced goblet cell secretion

B. Thinning of the basement membrane

C. Increase in airway inflammation and remodeling

D. Decreased submucosal gland activity

Correct Answer: C. Increase in airway inflammation and remodeling

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation of recurrent wheezing, coughing, and shortness of breath suggests airway inflammation and remodelling , which are characteristic of asthma. These changes contribute to airway hyperresponsiveness and the symptoms experienced by the patient. Pathophysiology of Asthma: Atopic asthma , the most common form of the disease, is caused by a Th2-mediated IgE response to environmental allergens in genetically predisposed individuals. (Type 1 hypersensitivity) Airway inflammation is central to the disease pathophysiology and causes airway dysfunction partly through the release of potent inflammatory mediators and partly through the remodelling of the airway wall. As the disease becomes more severe, there is increased local secretion of growth factors, which induce mucous gland enlargement , smooth muscle proliferation , angiogenesis , and fibrosis . Images A & B Comparison of a normal airway and an airway involved in asthma. The asthmatic airway is marked by the accumulation of mucus in the bronchial lumen secondary to Increase in the number of mucus-secreting goblet cells in the mucosa (Option A) Hypertrophy of submucosal glands (Option D) , intense chronic inflammation due to the recruitment of eosinophils, macrophages, and other inflammatory cells. The basement membrane is thickened (Option B), and there is hypertrophy and hyperplasia of smooth muscle cells.

@Neet_pg_bot

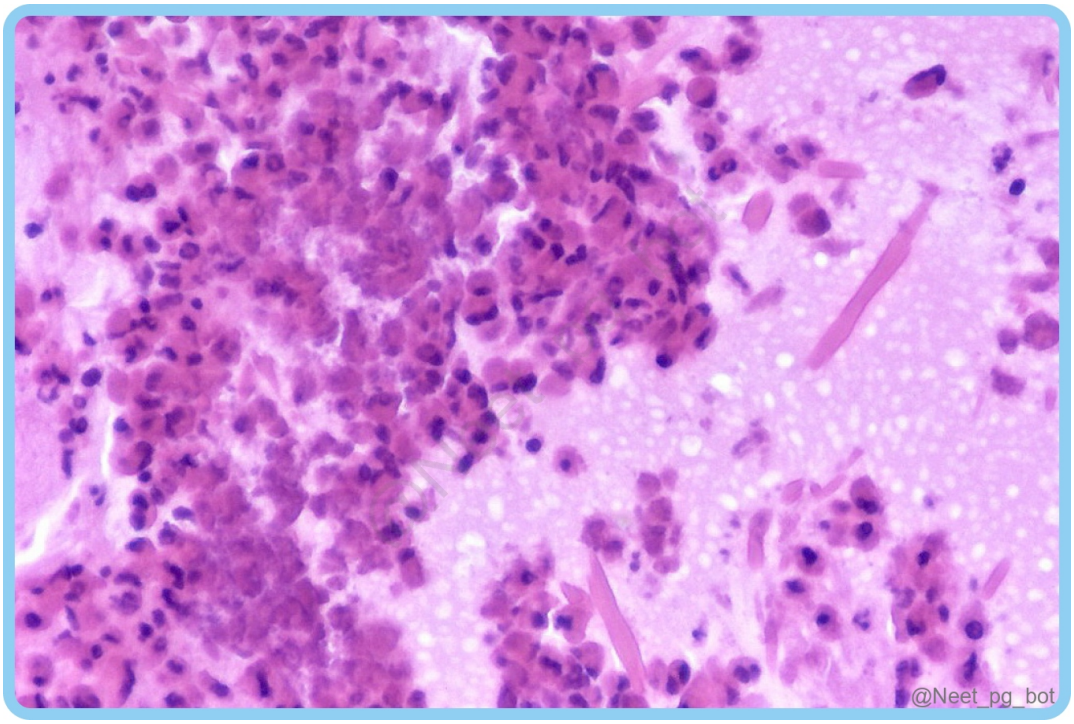
Q8: A 45-year-old male has a history of recurrent wheezing, coughing, and shortness of breath. His sputum microscopy, shown in the image below, reveals the following finding. Which best describes this finding? (Q845476)

A. Extrusion of mucus plugs from the subepithelial mucous gland ducts or bronchioles.

B. Ciliated columnar cells sloughed from the bronchial mucosa.

C. Polypoid plugs of loose organizing connective tissue within the bronchioles.

D. They are composed of Galectin 10.



Correct Answer: D. They are composed of Galectin 10.

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The clinical presentation points towards a diagnosis of bronchial asthma, with sputum culture showing Charcot-Leyden crystals Charcot-Leyden crystals: They are microscopic, needle-shaped crystals that are often found in the sputum of asthma patients, particularly during exacerbations . They are primarily composed of galectin-10 (derived from the eosinophils) also known as Charcot-Leyden crystal protein (CLC). Strong inducers of inflammation and mucus production. Extrusion of mucus plugs from the subepithelial mucous gland ducts or bronchioles describes the Curschmann spirals. They are a characteristic finding in asthma. (Option A) Ciliated columnar cells sloughed from the bronchial mucosa describe the Creola bodies seen in bronchial asthma. (Option B) Polypoid plugs of loose organizing connective tissue within the bronchioles, alveolar ducts, and alveoli describe Masson bodies , which are seen in cryptogenic organising pneumonia. (Option C)

Q9: A 30-year-old patient presents with a history of recurrent wheezing, coughing, and shortness of breath. Upon further investigation, it is found that the patient has a family history of allergies and asthma. Which genetic factor is most likely co-related to the severity of this condition? (Q845477)

A. Variant IL-4 receptor gene

B. IL-13 polymorphism

C. ADAM33 polymorphism

D. YKL40 gene mutation

Correct Answer: D. YKL40 gene mutation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The YKL40 (a chitinase-like glycoprotein) gene mutation has been found to be correlated with the severity of asthma. YKL40 levels are associated with inflammation and tissue remodelling in the airways, contributing to the progression and severity of asthma symptoms. Genetic Factors in Asthma: A susceptibility locus for asthma located on chromosome 5q , near the gene cluster, encoding the cytokines IL-3, IL-4, IL-5, IL-9, and IL-13 and the IL-4 receptor. Polymorphisms in the IL13 gene have the strongest and most consistent associations with asthma or allergic disease. The IL-4 receptor gene variants are associated with atopy , elevated total serum IgE , and asthma. Variants associated with the genes encoding IL-33 ADAM33 polymorphism.

@Neet_pg_bot

Q10: A 35-year-old male presents to the emergency department with complaints of chronic cough with production of purulent sputum, intermittent hemoptysis, and recurrent respiratory infections over the past several years. He reports a history of childhood respiratory infections and no significant past medical history. Physical examination reveals coarse crackles and rhonchi on auscultation of the chest. Chest X-ray shows bilateral bronchial wall thickening and tram-line shadows. Which of the

following is unlikely to be a cause for this condition? (Q845478)

A. Primary ciliary dyskinesia

B. Bronchial Asthma

C. Cystic fibrosis

D. Kartagener syndrome

Correct Answer: B. Bronchial Asthma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical findings along with radiographic findings are suggestive of bronchiectasis and bronchial asthma is not a cause. Bronchiectasis is the permanent dilation of the bronchi and bronchioles. Aetiology of Bronchiectasis: Congenital or hereditary conditions (Options A, C, and D) Cystic fibrosis Primary ciliary dyskinesia Kartagener syndrome Severe necrotising pneumonia Caused by bacteria, viruses, or fungi This may be a single severe episode or recurrent infection Bronchial obstruction Tumor Foreign body Idiopathic (50% of the cases) Dysfunctional host immunity to infectious agents leads to chronic inflammation

@Neet_pg_bot

Q11: Which of the following statements accurately describes the pathophysiology of Kartagener's syndrome? (Q845479)

A. Mutation in the CFTR gene leading to impaired ciliary function.

B. Autosomal dominant inheritance pattern affecting the cilia in the respiratory tract.

C. The primary defect involves dynein arm proteins, leading to impaired ciliary motility.

D. Characterized by an excess of cilia in the respiratory epithelium.

Correct Answer: C. The primary defect involves dynein arm proteins, leading to impaired ciliary motility.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Kartagener’s syndrome is a rare genetic disorder that is part of the broader spectrum of primary ciliary dyskinesia (PCD). The primary defect lies in the dynein arm proteins; there is impaired ciliary motility. This impairment leads to ineffective clearance of mucus, debris, and pathogens from the respiratory tract, sinuses, and other ciliated surfaces in the body. Kartagener’s syndrome is characterised by a triad of: Bronchiectasis. Situs inversus Sinusitis. Infertility can be seen in males due to sperm dysmotility (Asthenospermia). Mutation in the CFTR gene leading to impaired ciliary motility (Option A): Cystic fibrosis is a genetic disorder caused by CFTR gene mutations, leading to thick mucus buildup in the lungs and digestive system. Autosomal dominant inheritance pattern affecting the cilia in the respiratory tract (Option B): Kartagener's syndrome follows an autosomal recessive inheritance pattern, not autosomal dominant. Additionally, it affects the structure and function of cilia throughout the body, not just in the respiratory tract. Characterized by an excess of cilia in the respiratory epithelium (Option D): Kartagener's syndrome is characterized by defects in ciliary structure and function, leading to impaired ciliary motility rather than an excess of cilia.

@Neet_pg_bot

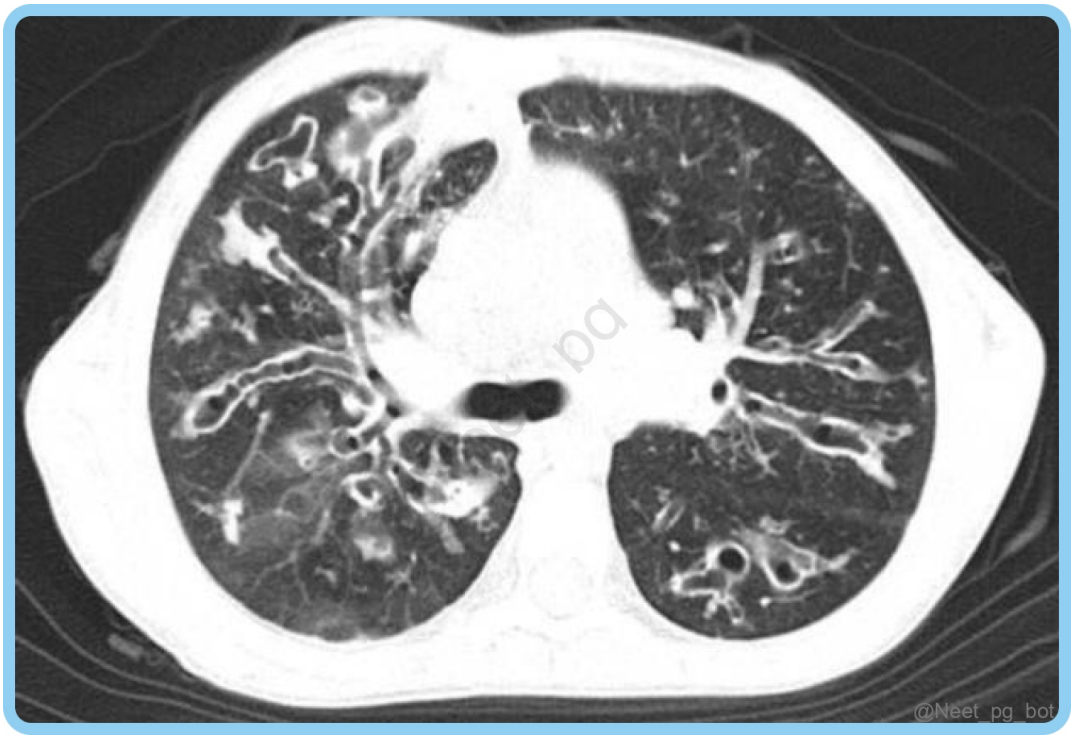
Q12: A 45-year-old male presents with a chronic cough productive of copious sputum. He reports frequent respiratory infections over the past several years. Physical examination reveals digital clubbing and coarse crackles on auscultation. An HRCT is done and shown below. Which of the following is the most likely diagnosis? (Q845480)

A. Tuberculosis

B. Asthma

C. Chronic obstructive pulmonary disease

D. Bronchiectasis



Correct Answer: D. Bronchiectasis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The clinical presentation of a male with chronic cough, copious sputum, past history of frequent respiratory infections, clubbing, coarse crackles on auscultation, and HRCT showing thickened and dilated bronchi (tram-track appearance) is suggestive of bronchiectasis. Bronchiectasis is characterised by the irreversible dilation and distortion of bronchi , typically due to chronic inflammation and recurrent infections. The image below shows bronchiectasis with markedly dilated bronchi in the upper and lower lobes. {{caption_text}} Tuberculosis (Option A): HRCT shows cavitary lesions, tree-in-bud nodules, or consolidations, not the bronchial dilation seen in bronchiectasis. Asthma (Option B): HRCT is usually normal or may show bronchial wall thickening but not bronchial dilation. COPD (Option C): HRCT shows emphysematous changes (air trapping, bullae) and airway narrowing but lacks the tram-track or signet ring appearance seen in bronchiectasis.
