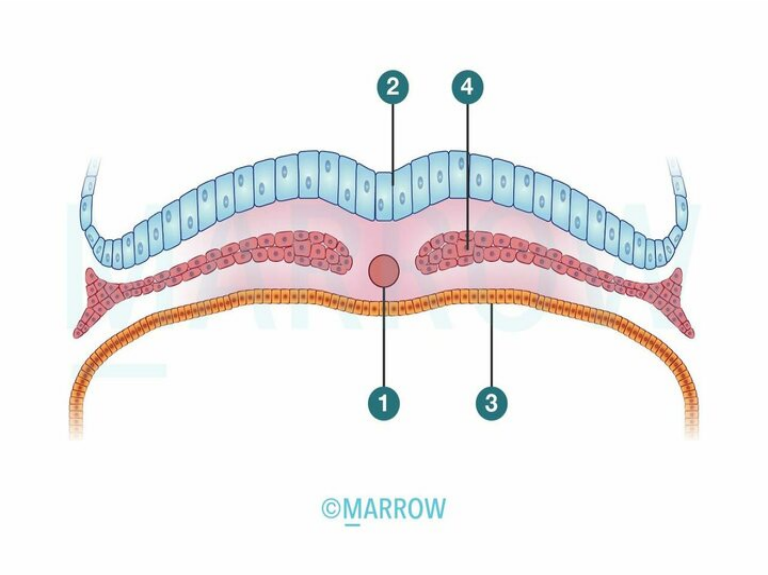
Anatomy AIIMS 2017

Question 1:

Nucleus pulposus is derived from _____.



a) 1

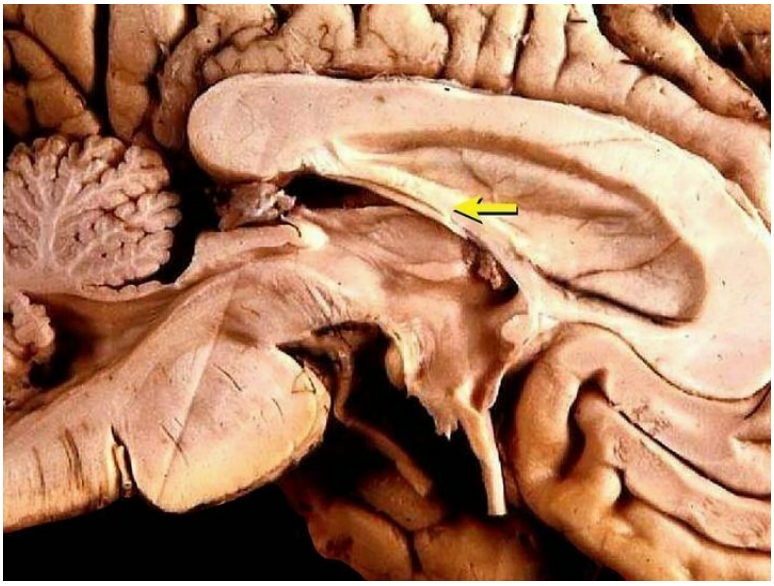
b) 2

c) 3

d) 4

Question 2:

What is the origin of the fibers marked by the arrow?



a) Hippocampus

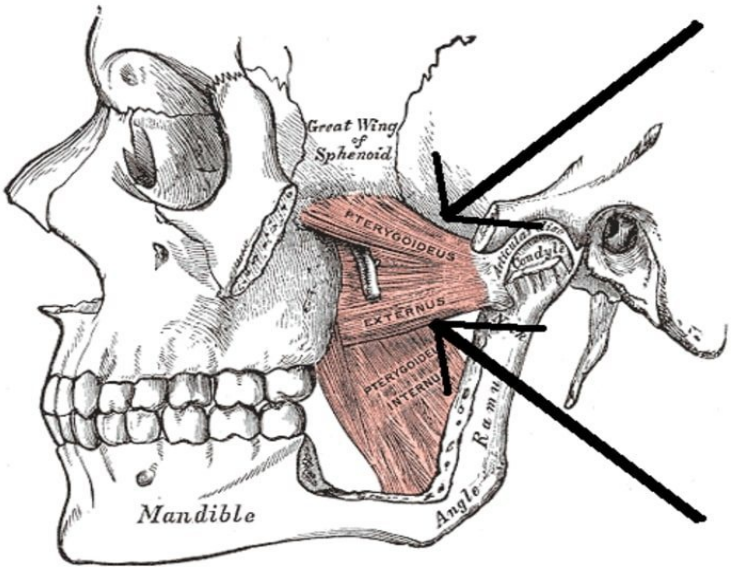
b) Habenular

c) Mamillary body

d) Amygdala

Question 3:

Among the following, what is the function of the marked muscles?



a) Depression

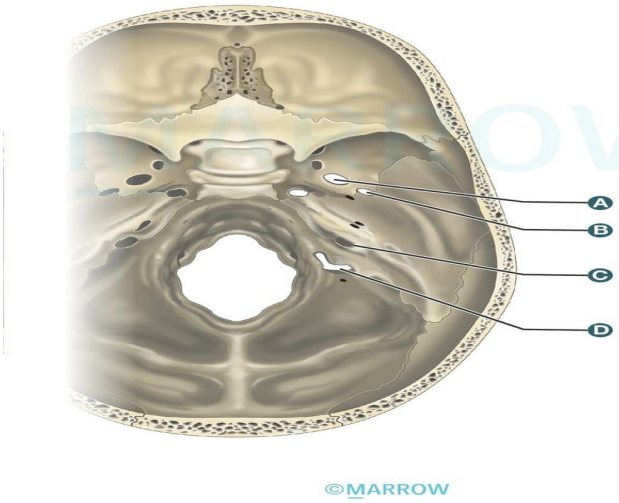
b) Protrusion

c) Elevation

d) Retraction

Question 4:

Which of the marked foramen does the mandibular division of the trigeminal nerve pass through?



a) A

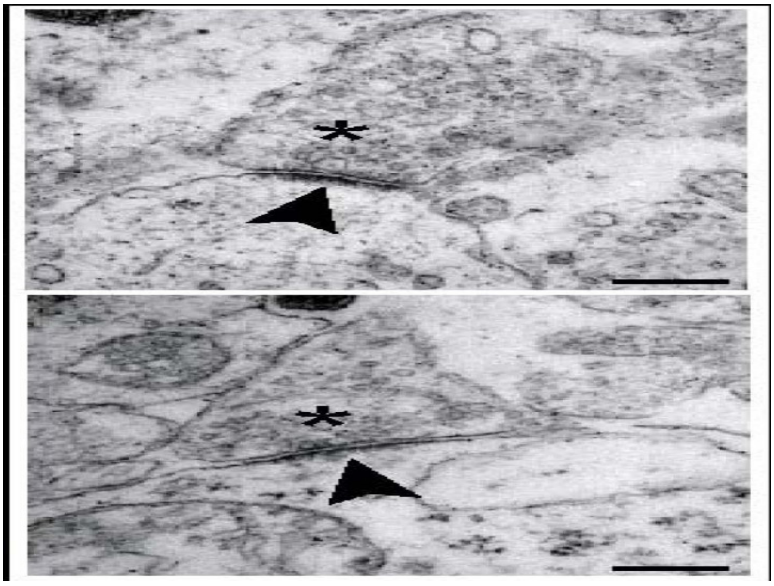
b) B

c) C

d) D

Question 5:

The structure marked with the asterisk in the electron micrograph indicates _____.



a) Mitochondria

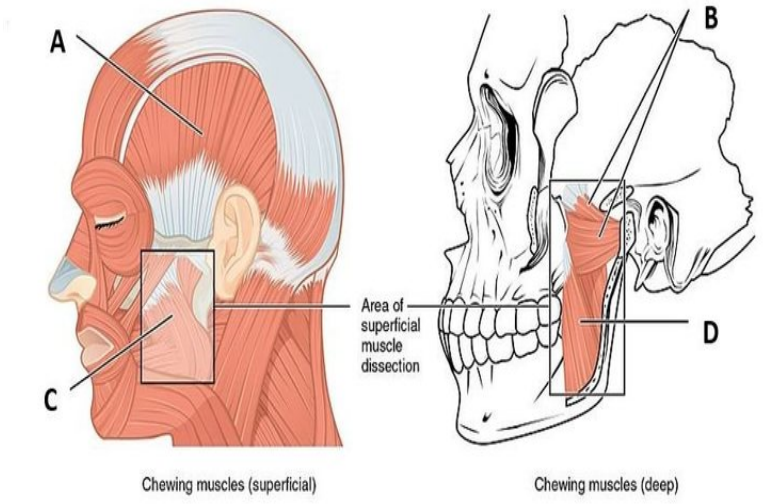
b) Golgi bodies

c) Secretory vesicles

d) Ribosomes

Question 6:

In the image given below, identify the muscle responsible for the opening of the mouth.



a) A

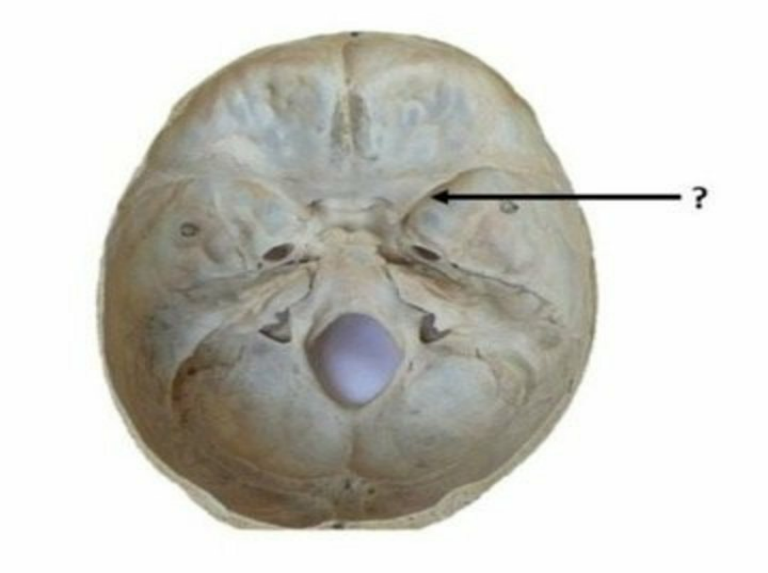
b) B

c) C

d) D

Question 7:

Identify the structure passing through the foramen marked.



a) Abducens nerve

b) Spinal accessory nerve

c) Ophthalmic artery

d) Middle meningeal artery

Question 8:

The talocalcaneonavicular joint is a _____type of joint.

a) Ball and Socket

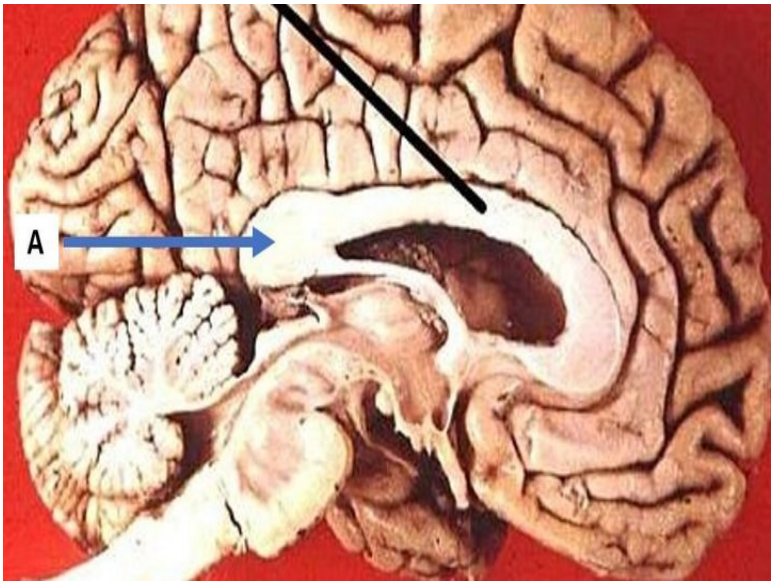
b) Saddle type

c) Plane

d) Ellipsoid

Question 9:

Which of the following is connected to the structure marked as A in the image below?



a) Orbital cortex

b) Hippocampus

c) Striate cortex

d) Optic chiasma

Question 10:

The structure passing through the central tendon of the diaphragm is:

a) Oesophagus

b) Aorta

c) Inferior vena cava

d) Sympathetic Chain

Question 11:

Shape of Trapezius muscle is _____

a) Triangular

b) Quadrilateral

c) Pentagonal

d) Linear

Question 12:

All of the following are true about grey rami communicantes except:

a) Unmyelinated

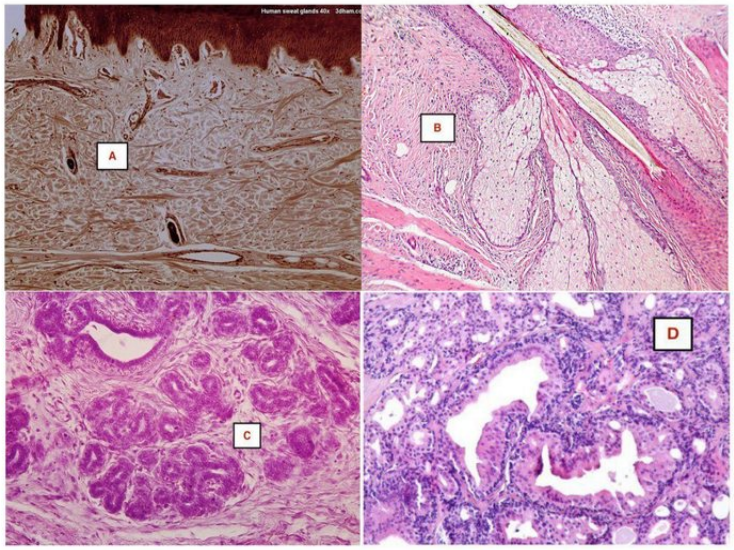
b) Connected to spinal nerve

c) Preganglionic

d) Present medial to white rami communicantes

Question 13:

Which of the following represents a holocrine gland?



a) A

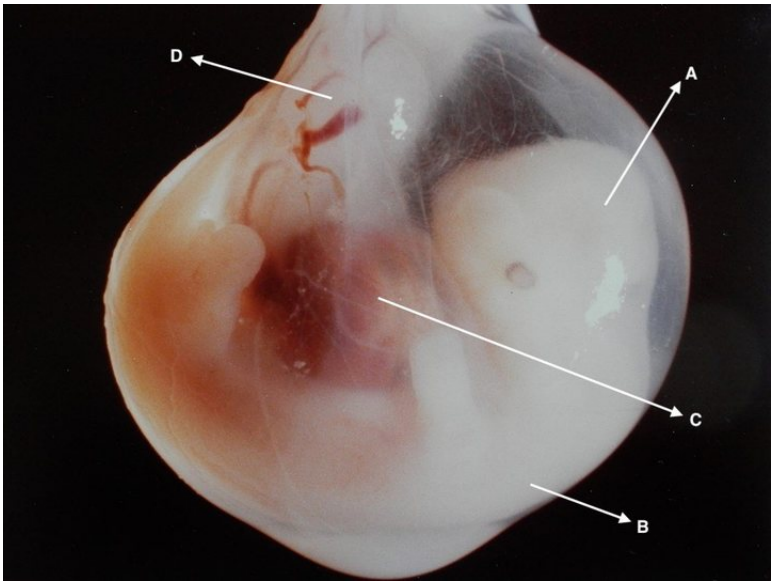
b) B

c) C

d) D

Question 14:

Which of the following structures marked in the below image gives rise to the heart in an adult?



a) A

b) C

c) B

d) D

Question 15:

A 58-year-old woman was undergoing cholecystectomy. During the procedure, the resident accidentally advanced the scissors along the superior border of the epiploic foramen causing injury. Which of the following structures is likely to be injured?

a) Right lobe of liver

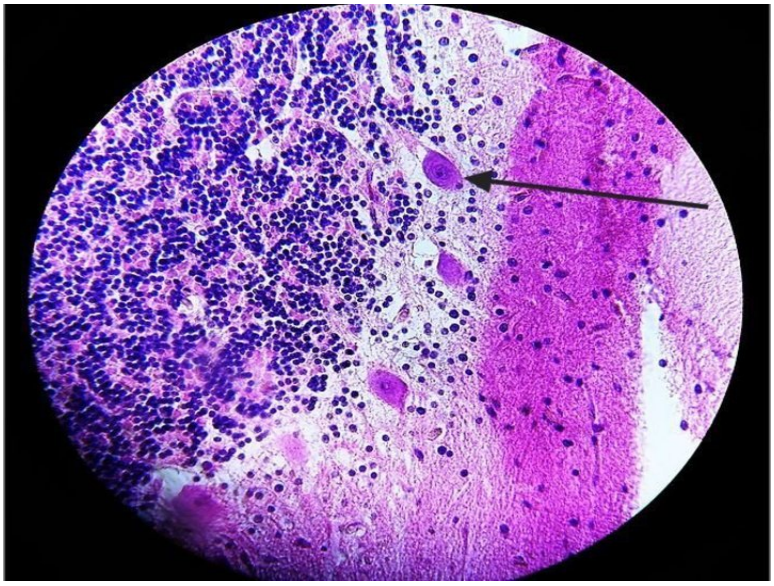
b) Quadrate lobe of liver

c) Caudate lobe of liver

d) Fundus of gall bladder

Question 16:

Which of the following structures does the cell pointed in arrow inhibit?



a) Vestibular nuclei

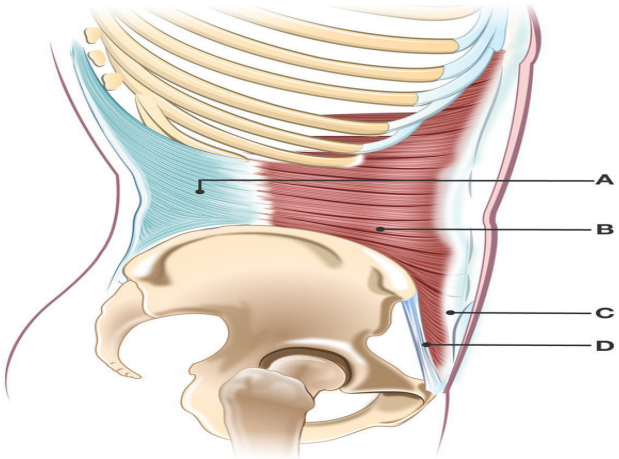
b) Anterior horn of spinal

c) Basal ganglia

d) Deep nuclei of cerebellum

Question 17:

The image below shows the insertion of transversus abdominis muscle. Identify the conjoint tendon:



a) A

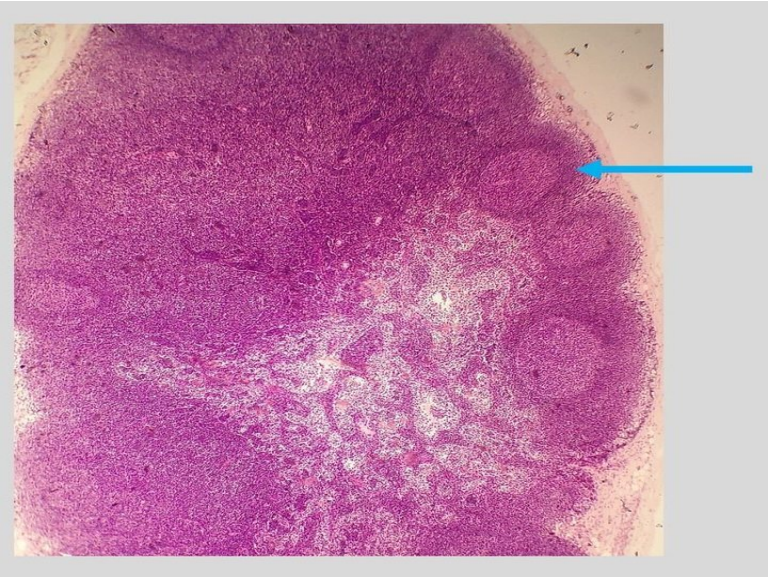
b) B

c) C

d) D

Question 18:

What represents the marked area in the given histology of lymph node?



a) Marginal zone

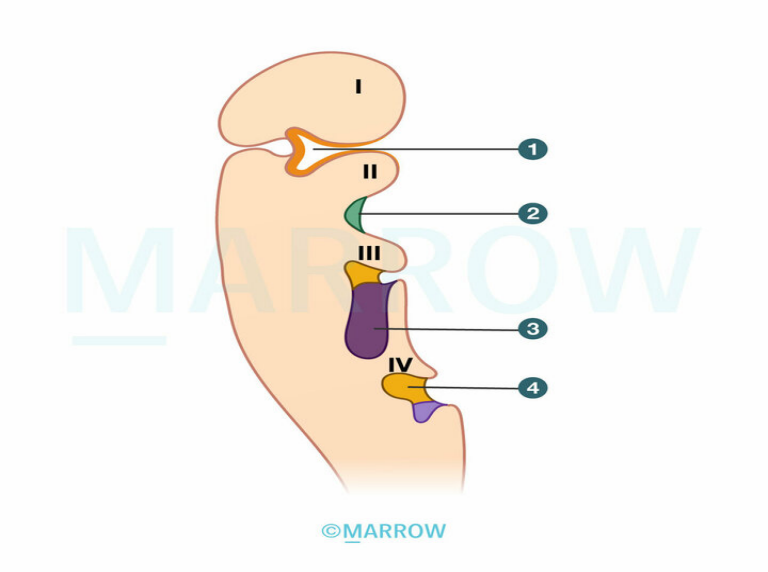
b) Paracortical zone

c) Germinal center

d) Mantle zone

Question 19:

A young patient presented with hypoparathyroidism, absent thymus and tetany. Which of the following marked areas in the picture is defective in this condition?



a) 1

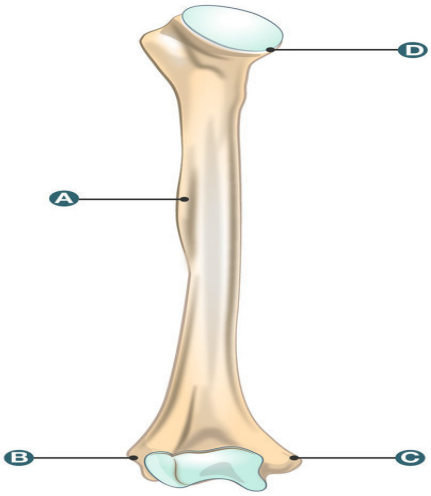
b) 2

c) 3

d) 4

Question 20:

A patient came with complaints of inability to move his 4th and 5th digit, cannot hold a pen and he was not able to hold a paper between fingers. Which of the following sites given below is the probable cause of injury to the nerve in question?



a) A

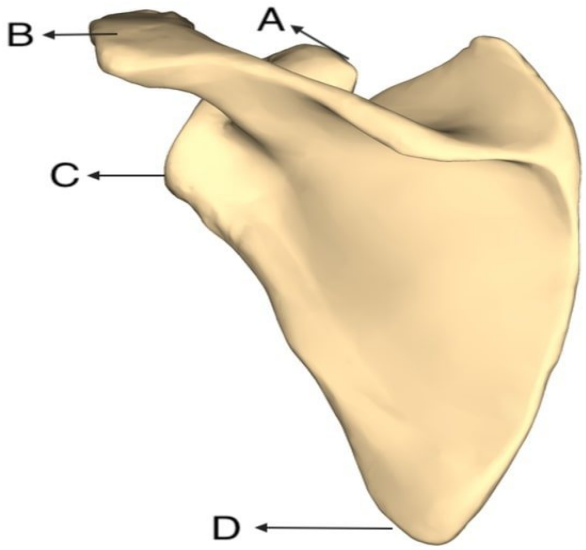
b) B

c) C

d) D

Question 21:

Which of the following structures of the scapula is palpable in the infraclavicular fossa?



a) A

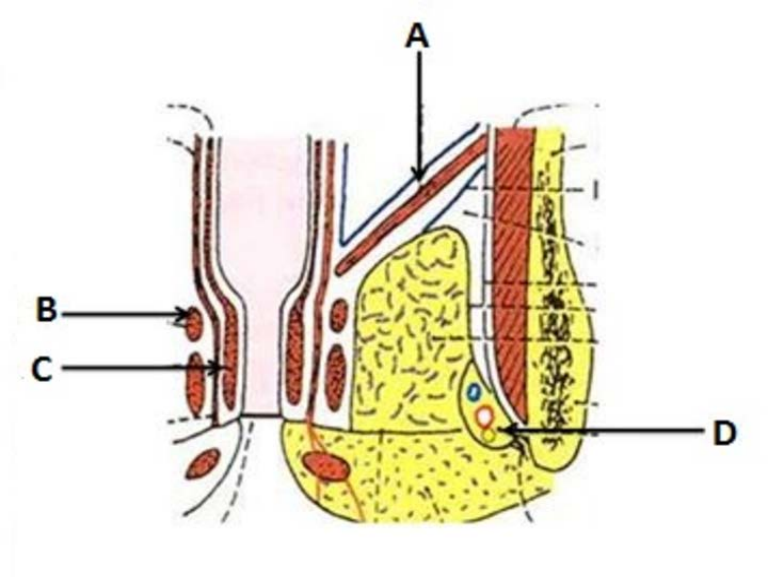
b) B

c) C

d) D

Question 22:

Identify the pelvic diaphragm in the picture given below.



a) A

b) B

c) C

d) D

Question 23:

What is the root value of cremasteric reflex?

a) L1,L2

b) L3,L4

c) S1,S2

d) T8,T9

Answer Key

Question No.	Correct Option
1	a
2	a
3	a
4	a
5	c

6	b
7	a
8	a

15	c
16	d
17	c
18	d
19	c
20	c
21	a
22	a
23	a

Detailed Explanations

Solution to Question 1:

Nucleus pulposus is derived from the notochord (marked as 1).

The other labelled structures are

2 - Ectoderm

3 - Endoderm

4 - Intraembryonic mesoderm

Solution to Question 2:

The arrow indicates the fornix. It arises from the hippocampus and ends in the mamillary body of the hypothalamus.

Fornix is an example of association fiber. It is supplied by the anterior cerebral artery.

Solution to Question 3:

The muscle marked in the above image is the lateral pterygoid muscle and its primary function is depression of the mandible (opening of the mouth).

Bilateral contraction of the lateral pterygoid alone causes depression of the mandible (making it the primary function) whereas, protrusion is the result of bilateral contraction of both the medial and lateral pterygoid muscles.

The lateral pterygoid has the following actions:

• Opening of the jaw (depression): Lateral pterygoid has a specialized role in mandibular opening mediated by its horizontal fibres. When left and right lateral pterygoid muscles contract together, the mandibular condyle is pulled forwards and slightly downwards. This protrusive movement alone has little or no function except in assisting the opening of the jaw (Gray's Anatomy 41st edition).

• Side-to-side movement: When the lateral pterygoid contracts unilaterally along with the adjacent medial pterygoid the jaw is pulled medially. This is used for grinding food between teeth of the same side. This action is mediated by the inferior head of the lateral pterygoid.

Muscles of mastication	Nerve supply	Action (On mandible)
Temporalis	Mandibular nerve (CN V3)	ElevationRetraction (posterior fibers)
Masseter	Mandibular nerve (CN V3)	ElevationProtrusion (superficial fibers)
Lateral pterygoid	Mandibular nerve (CN V3)	DepressionSwinging of Jaw(unilaterally)
Medial pterygoid	Mandibular nerve (CN V3)	ElevationProtrusion
Suprahyoid muscles		
Digastric	Facial nerve (CN VII),Mandibular nerve (CN V3)	Depression of mandible and elevation of hyoid bone
Stylohyoid	Facial nerve (CN VII)	Elevation of hyoid bone
Mylohyoid	Mandibular nerve (CN V3)	Elevation of hyoid bone
Geniohyoid	Nerve to geniohyoid	Depression of mandible and elevation of hyoid bone
Infrahyoid muscles		
Omohyoid	Ansa cervicalis (C1-C3)	Fixes or depresses hyoid bone
Sternohyoid	Ansa cervicalis (C1-C3)	Fixes or depresses hyoid bone
Sternothyroid	Ansa cervicalis (C1-C3)	Draws thyroid cartilage downwards
Thyrohyoid	C1 via hypoglossal nerve (CN XII)	Fixes or depresses hyoid bone

Solution to Question 4:

The mandibular nerve passes through the foramen ovale which is marked as A in the above image.

Other foramina marked in the above image:

B - Foramen spinosum

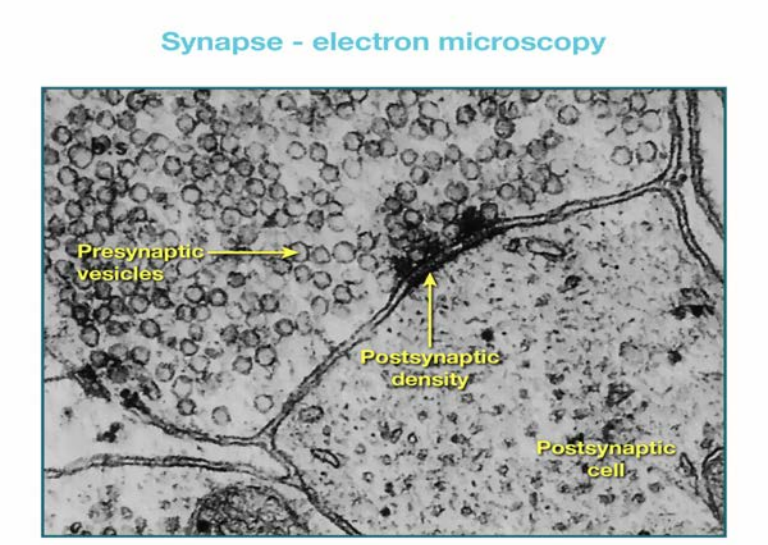
C - Internal acoustic meatus

D - Jugular foramen

Solution to Question 5:

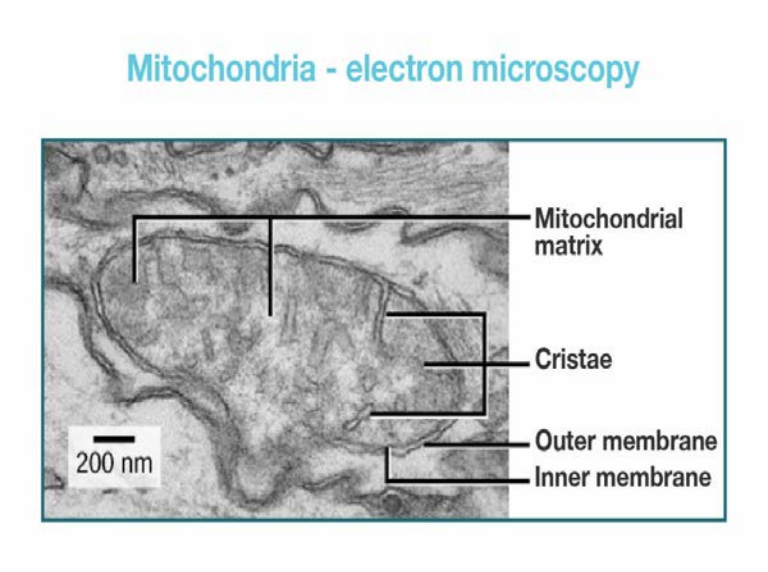
The structure marked with the asterisk in the electron micrograph indicates presynaptic secretory vesicles. The structure marked with the arrowhead is postsynaptic density.

The secretory vesicles are synthesized by the neurons and are involved in electrochemical signalling in the brain and neuromuscular junctions.

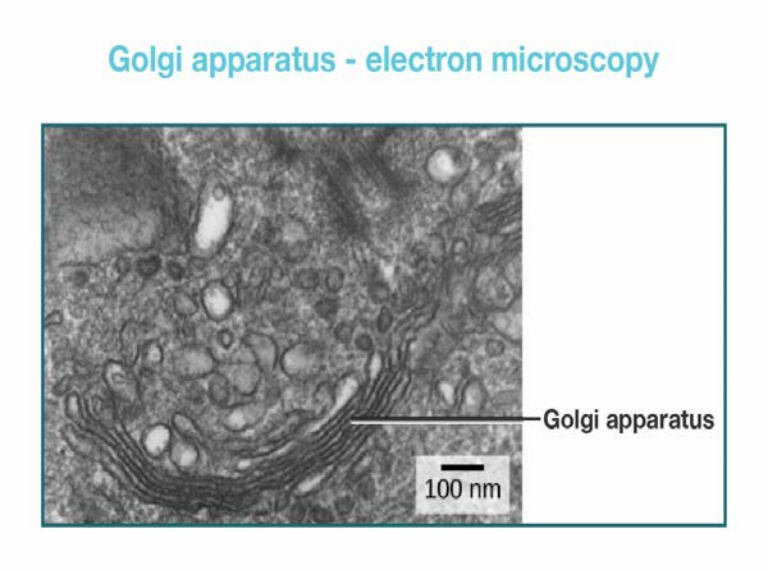


On electron microscopy:

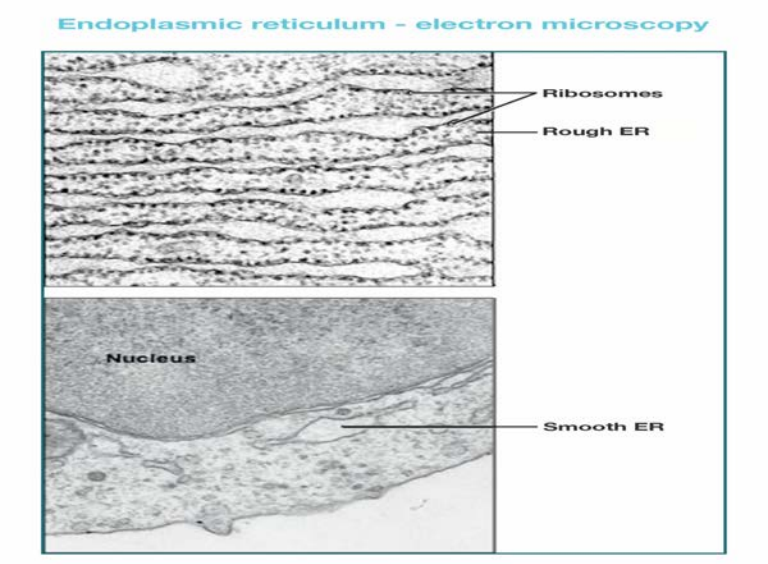
• Mitochondria appear as round or elliptical bodies of 0.5-2.0 micron long on an electron microscope, consisting of an outer and an inner mitochondrial membrane, cristae, and mitochondrial matrix.



• Golgi bodies (or Golgi apparatus) appear as stacks of flatenned membranous cisternae surrounded by clusters of vesicles.



• Ribosomes may be attached to the membrane of the rough endoplasmic reticulum (as shown in the image below), or else, they may exist as monosomes or as a chain of granular structures called polyribosomes associated with mRNA.



Solution to Question 6:

In the given image the structure marked B represents the lateral pterygoid muscle which is responsible for the opening of the mouth.

Lateral pterygoid:

• Origin -

• Upper head - Infratemporal surface and infratemporal crest of the greater wing of the sphenoid bone.

• Lower head - Lateral surface of the lateral pterygoid plate.

• Insertion - It is inserted into the pterygoid fovea, capsule of the temporomandibular joint, and the articular disc.

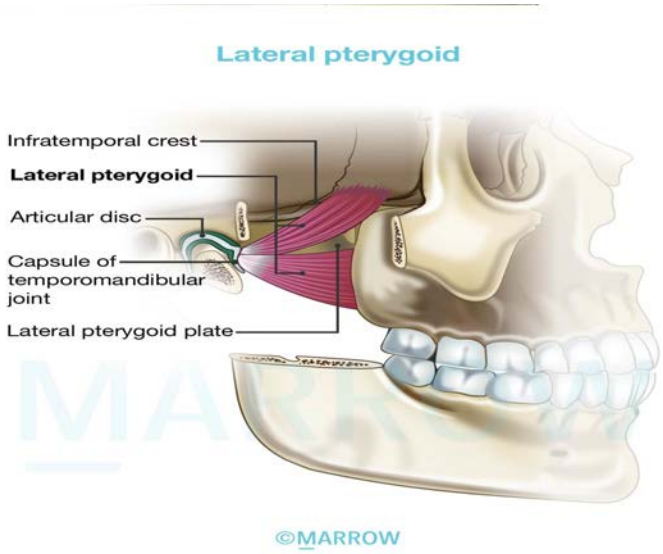
• Nerve supply - Lateral pterygoid nerve which is a branch of the trigeminal nerve.

Other structures marked:

A - Temporalis

C - Masseter

D - Medial pterygoid



Solution to Question 7:

The marked foramen is the superior orbital fissure and the abducens nerve passes through it.

The abducens nerve is the 6th cranial nerve and arises from the brainstem at the pontomedullary junction. It runs through the Dorello's canal which is present at the medial most end of the petrous ridge and then enters the cavernous sinus where it lies lateral to the internal carotid artery. It enters the orbit through the superior orbital fissure within the common tendinous ring and supplies the lateral rectus.

Other options:

Spinal accessory nerve passes through the foramen magnum along with the medulla oblongata and the verterbral arteries

Ophthalmic artery passes through the optic canal along with the optic nerve.

Middle meningeal artery and vein pass through the foramen spinosum along with the meningeal branch of mandibular nerve.

Solution to Question 8:

The talocalcaneonavicular joint is a ball and socket joint.

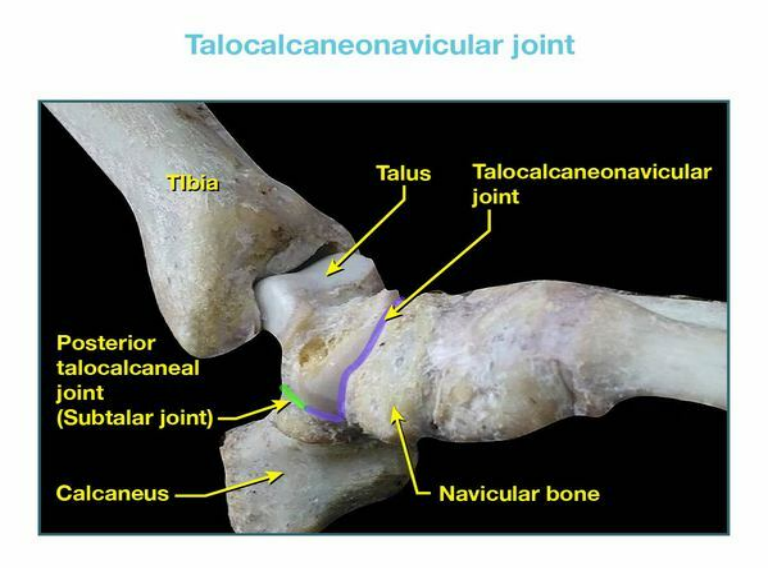
• The ball part is formed by the rounded head of the talus.

• The socket is formed by 3 structures:

• Posterior surface of the navicular

• Anterior articular surface of the calcaneus

• Upper surface of the plantar calcaneonavicular ligament (spring ligament).



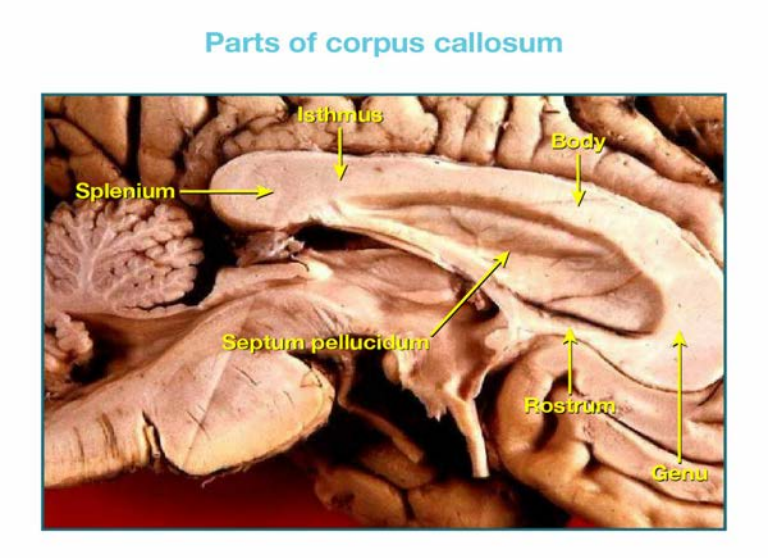
Solution to Question 9:

The structure marked A is the splenium of the corpus callosum and it is connected to the striate cortex.

The body of the corpus callosum arches posteriorly and ends as the thickened posterior portion called the splenium. The fibers from the splenium form the forceps major and arch backward into the occipital lobe (striate cortex).

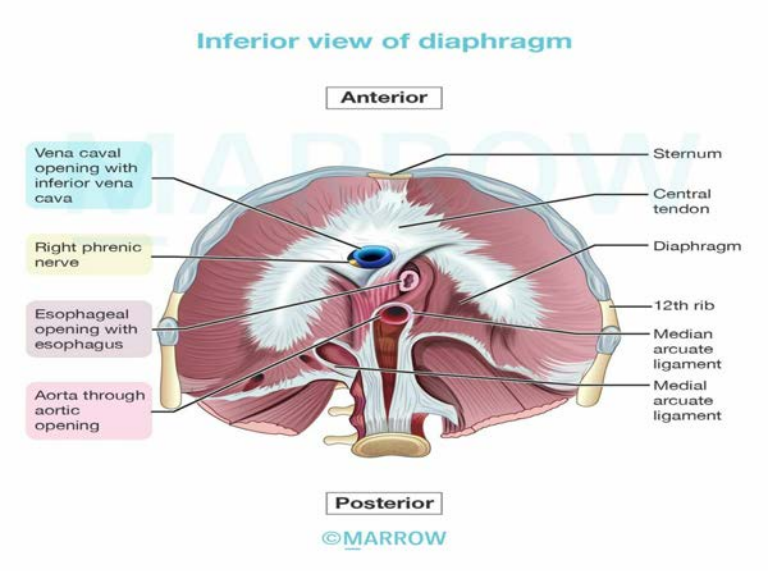
The hippocampus is not connected directly to the splenium, but situated inferior to the splenium.

The image given below shows the parts of the corpus callosum.



Solution to Question 10:

The inferior vena cava passes through the central tendon of the diaphragm.



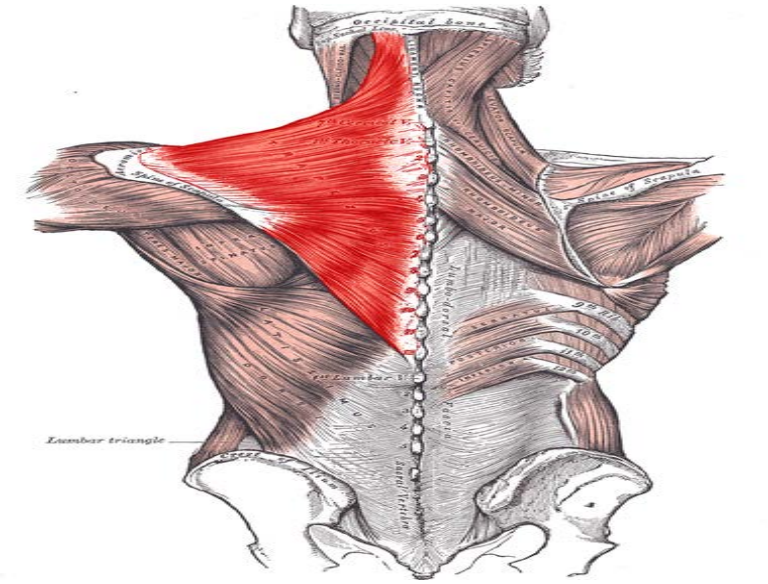
Solution to Question 11:

The trapezius is a broad, flat and triangular muscle

Trapezius muscle shape:

• considering left or right side - triangular shape

• considering both sides together - diamond shaped, hence named “trapezius”

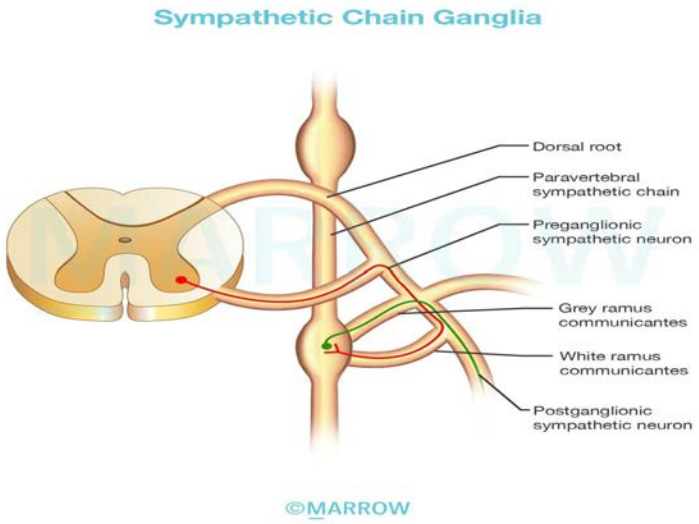


Solution to Question 12:

The grey rami communicantes are not preganglionic fibers. They are postganglionic fibers.

The sympathetic trunks on either side of the vertebral columns consist of a series of ganglia. They are connected to the spinal nerves by white and grey rami communicantes. The cell bodies of the preganglionic sympathetic neurons are located in the lateral horn in the spinal grey matter. They leave the cord in the ventral nerve roots to form spinal nerves. These fibers enter the sympathetic trunk in white rami communicantes. They synapse with the postganglionic sympathetic neurons in the sympathetic ganglia. The axons of the postganglionic neurons return to the spinal nerve through the grey rami communicantes.

Fibers	White rami communicantes	Grey rami communicantes
Location	Preganglionic	Postganglionic
Myelination	Myelinated	Unmyelinated
Principal neurotransmitter	Acetylcholine	Noradrenaline



Solution to Question 13:

The histopathological image marked ‘B’ represents the sebaceous gland, which is a type of holocrine gland.

Holocrine secretions are produced in the cytoplasm of the cell and released by the rupture of the plasma membrane, which destroys the cell and results in the secretion of the product into the lumen.

Examples of holocrine glands are

• Sebaceous glands of the skin and

• Meibomian glands of the eyelid

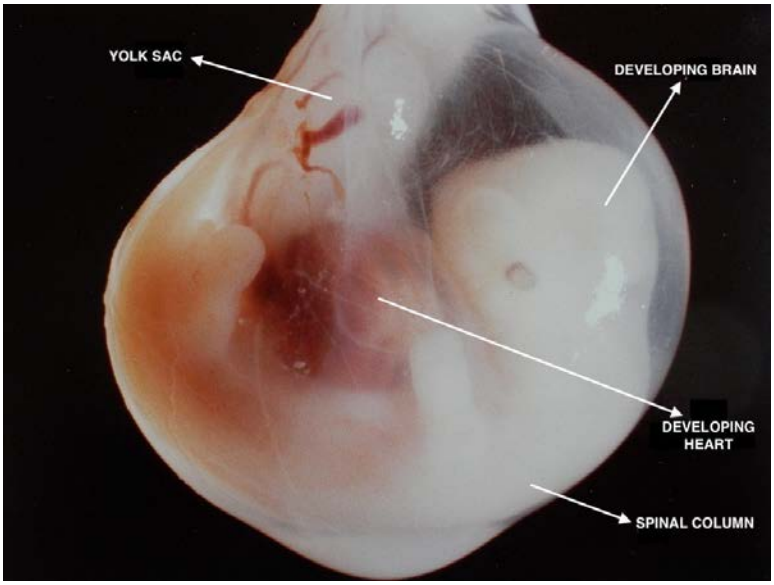
Image A: Sweat glands - Eccrine/merocrine glands; glands remain intact

Image C: Mammary gland - Apocrine gland; apical part sheds to secrete

Image D: Ceruminous gland - Apocrine glands

Solution to Question 14:

The structure marked 'C' in the above image depicts the heart bulge.

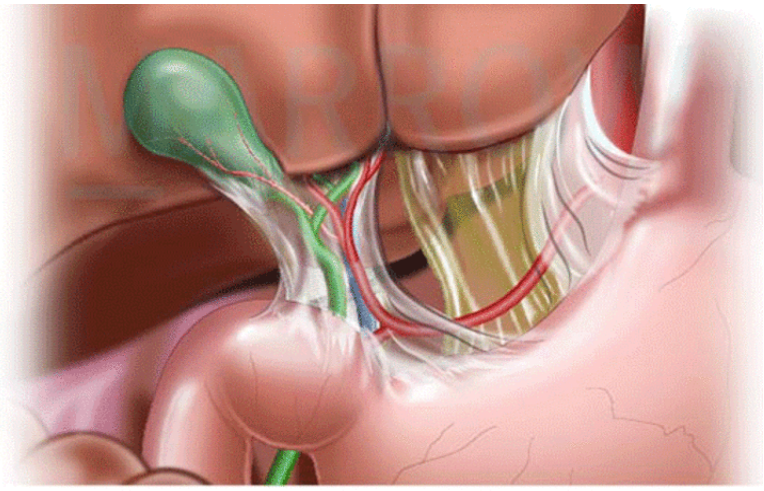


Solution to Question 15:

The superior border of the epiploic foramen (foramen of Winslow) is formed by the caudate lobe of the liver. It is likely to be injured in this case.

Epiploic foramen is a vertical slit of about 3 cm behind the free right border of the lesser omentum. It connects the lesser sac to the greater sac.

Clinical note: Pringle maneuver (as shown below) is a technique where the free margin of the lesser omentum is compressed to obtain rapid control of bleeding from the hepatic artery and portal vein in liver trauma and surgery.



Solution to Question 16:

The image shows a histopathological section of the cerebellum. The cells marked with the arrow are Purkinje cells and they inhibit deep nuclei of the cerebellum.

Solution to Question 17:

The structure marked C is the conjoint tendon.

The conjoint tendon is formed from the lower fibres of internal oblique and the lower part of the aponeurosis of transversus abdominis. It is attached to the pubic crest and extends to a variable extent along the pectineal line.

Transversus Abdominis muscle

Origin: internal surface of 7th -12th costal cartilages, thoracolumbar fascia, iliac crest, connective tissue deep to lateral third of inguinal ligament.

Insertion: Linea Alba with aponeurosis of internal oblique, pubic crest, and pecten pubis via the conjoint tendon.

A: Lumbar fascia

B: Transversus Abdominis

D: Inguinal Ligament

Solution to Question 18:

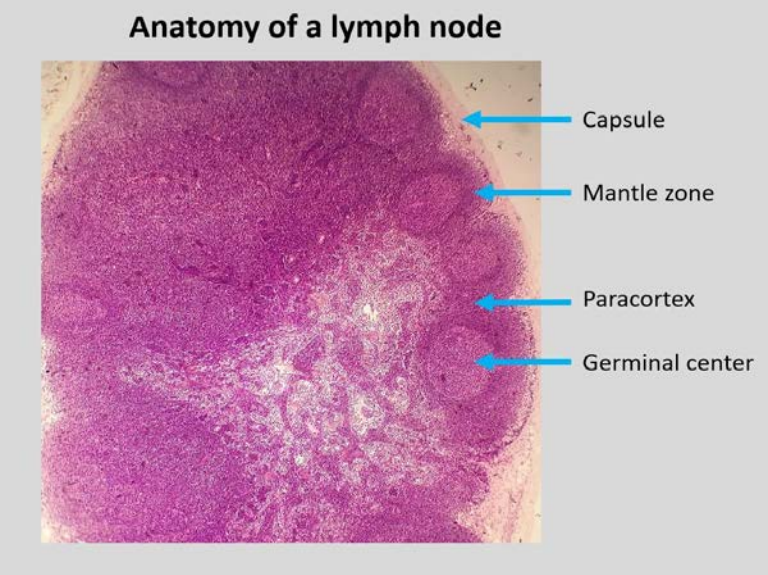
The area marked in the image is the mantle zone of a lymph node.

Lymph node has primary follicle composed of small, quiescent lymphocytes, and a secondary follicle with germinal centre composed mainly of antigen-stimulated B cells.

The mantle zone is produced as surrounding cells are marginalised by the rapidly growing germinal centre. It is populated by mainly quiescent B cells with condensed heterochromatic nuclei and little cytoplasm (hence the deeply basophilic staining of this region in routine preparations), a few helper T cells, Follicular Dendritic cells and macrophages.

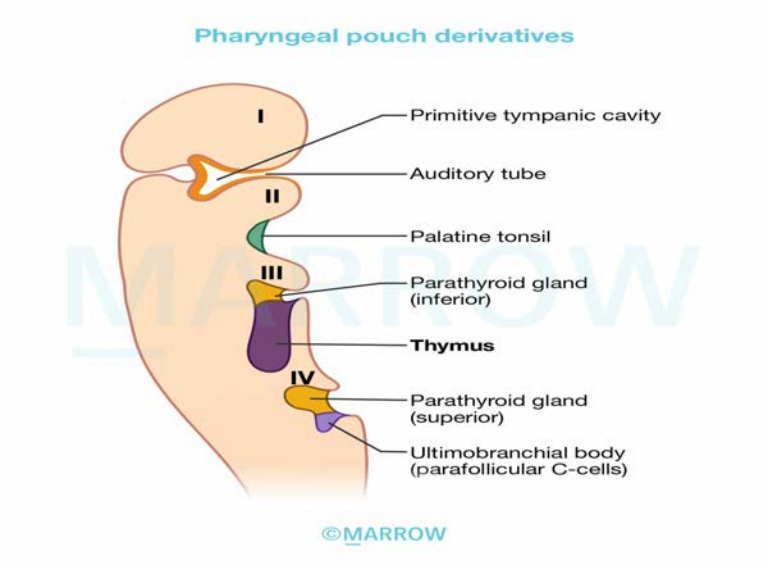
In peripheral lymph nodes, the marginal zone are often inapparent because they are mixed with the mantle zone cells. And often not well developed in lymph nodes.

The paracortex lies between the cortical follicles and the medulla and is populated mainly by T cells, which are not organised into follicles



Solution to Question 19:

The given clinical scenario of hypoparathyroidism, absent thymus, and tetany is suggestive of DiGeorge syndrome. It is caused by defective development of the third and fourth pharyngeal pouch. In the image of pharyngeal pouches, "3" points to the thymus (derivative of 3rd pharyngeal pouch). Since in the above question, the thymus is absent, option 3 will be the most appropriate answer.



DiGeorge syndrome is a complex embryopathy that is caused by the hemizygous interstitial deletion of chromosome 22. It is characterized by multiple developmental defects, including conotruncal defects, hypoparathyroidism, and dysmorphic syndrome. It is also known as velocardiofacial syndrome (palate, facial, and cardiac defects).

It has variable presentations including Cleft palate, Abnormal facies, Thymic aplasia leading to T-cell deficiency, Cardiac defects, and Hypocalcemia secondary to parathyroid aplasia (CATCH-22).

Solution to Question 20:

The given clinical situation suggests an ulnar nerve injury. The most likely site of injury would thus be medial epicondyle (marked as C)

Tests for ulnar nerve lesions are as follows:

• Card test positive

• Claw hand deformity

• Froment's sign positive

• Wartenberg sign

• Palmaris brevis sign

Positive card test is due to weakness of palmar interrosei, causing loss of adduction. As a result, the patient is unable to hold the card firmly between his or her fingers.

Option A: It is the radial groove where radial nerve runs along with profunda brachii artery.

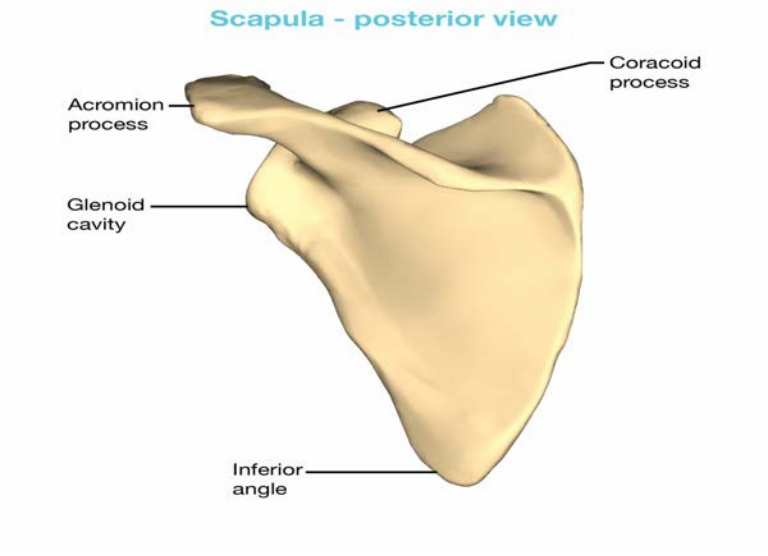
Option D: It is the neck of humerus where axillary nerve runs around.

Option B: It is the lateral epicondyle. Fracture of this part may lead to tardy ulnar nerve palsy, but incidence is less.

Solution to Question 21:

The part of the scapula marked as "A" in this image is palpable and it is the coracoid process.

The apex of the coracoid process lies approximately 2.5cm below the clavicle, immediately lateral to the infraclavicular fossa (deltopectoral triangle). Hence, the coracoid process can be palpated below the clavicle.



Solution to Question 22:

The structure marked "A" is the levator ani muscle which is part of the pelvic diaphragm.

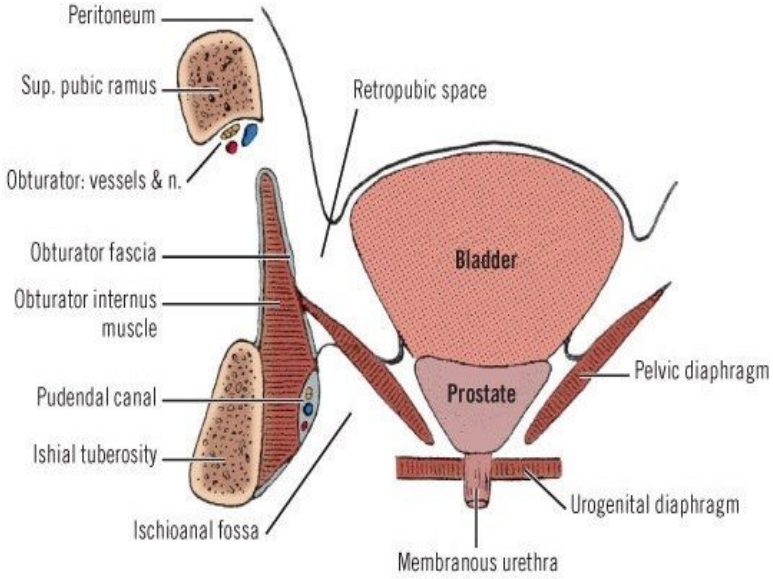
Other structures marked in the above image are

B: External anal sphincter

C: Internal anal sphincter

D: Pudendal canal

Levator ani and ischiococcygeus form the pelvic diaphragm and delineate the lower limit of the true pelvis.

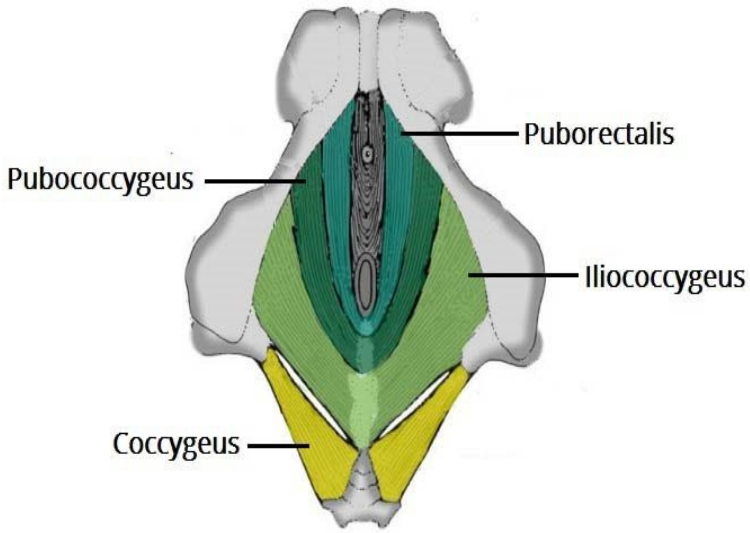


Levator ani is formed by:

• Pubococcygeus

• Iliococcygeus

• Puborectalis.



Solution to Question 23:

Cremasteric reflex is mediated by L1 and L2. In this reflex, there is ipsilateral elevation of the testicle following stroking of the medial thigh.

The cremasteric reflex's afferent and efferent branches:

• Afferent - Femoral branch of genitofemoral nerve

• Efferent - Genital branch of genitofemoral nerve

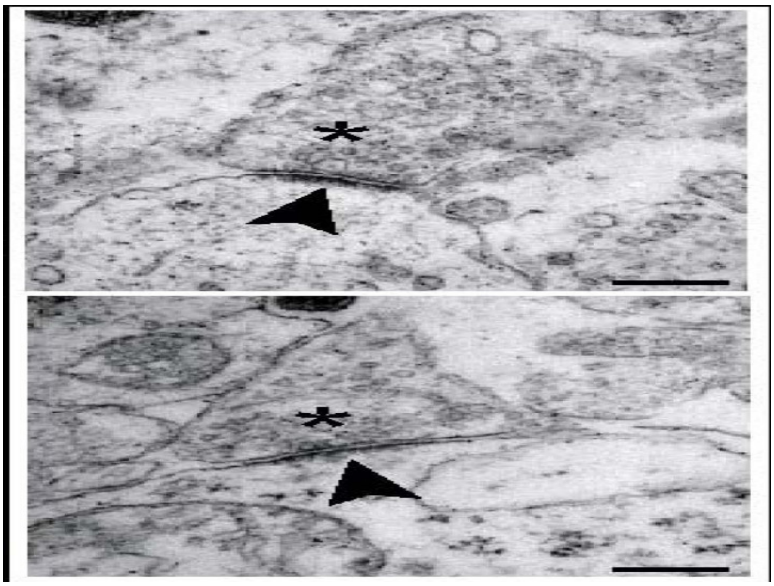
Given below are the various reflexes with their root values.

Deep reflexes	Superficial reflexes
Biceps -C5, C6	Corneal - CN V(A) - CN VII(E) - Pons
Brachioradialis - C5, C6	Conjunctival - CN V (A) - CN VII(E) - Pons
Triceps - C6, C7	Scapular - C5, T1
Finger flexion - C8	Abdominal - T7-T12
Knee jerk - L3,L4	Anal - S3, S4
Ankle -S1, S2	Cremastric -L1, L2
Jaw jerk - CN V (Pons)	Plantar - L5S1

Anatomy AIIMS 2018

Question 1:

The structure marked with the asterisk in the electron micrograph indicates _____.



a) Mitochondria

b) Golgi bodies

c) Secretory vesicles

d) Ribosomes

Question 2:

Inferior thyroid artery is the branch of which of the following?

a) External carotid artery

b) Internal carotid artery

c) Thyrocervical trunk

d) Lingual artery

Question 3:

Neurovascular bundle is absent in which compartment of the leg?

a) Lateral compartment

b) Posterior superficial compartment

c) Posterior deep compartment

d) Anterior compartment

Question 4:

A patient presents to you with inability to form words but can make noises. He also knows what he wants to say. What area of the brain has been damaged in this patient?

a) Wernicke's area

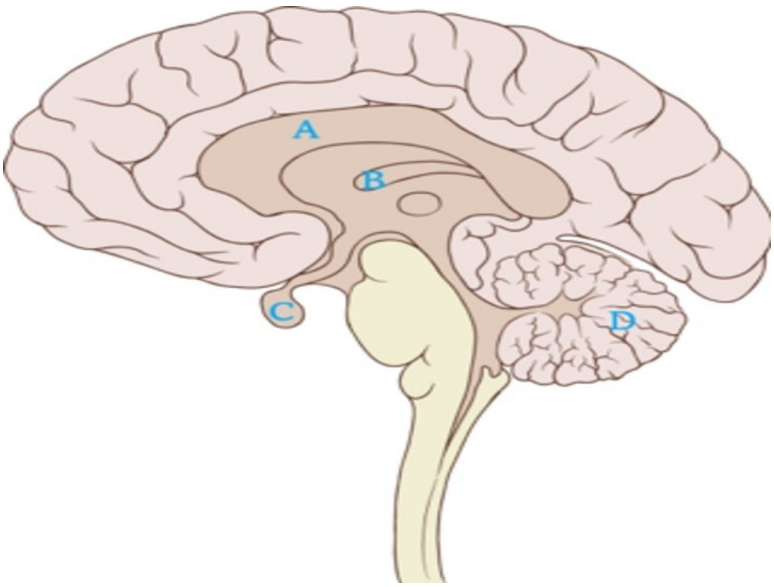
b) Broca's area

c) Heschl's gyrus

d) Striate area

Question 5:

Identify the wrongly marked structure in the diagram



a) A-Corpus Callosum

b) C-Hypothalamus

c) B-Fornix

d) D-Cerebellum

Question 6:

Loss of flexion at the interphalangeal joint of thumb after supracondylar fracture is due to the involvement of?

a) Deep branch of ulnar nerve

b) Median Nerve

c) Posterior interosseous nerve

d) Anterior interosseous nerve

Question 7:

Purkinje cells of cerebellum relay into _____

a) Caudate nucleus

b) Lentiform nucleus

c) Dentate nucleus

d) Red nucleus

Question 8:

Which of the following sensations is not perceived by the spinal nucleus of the trigeminal nerve?

a) Temperature

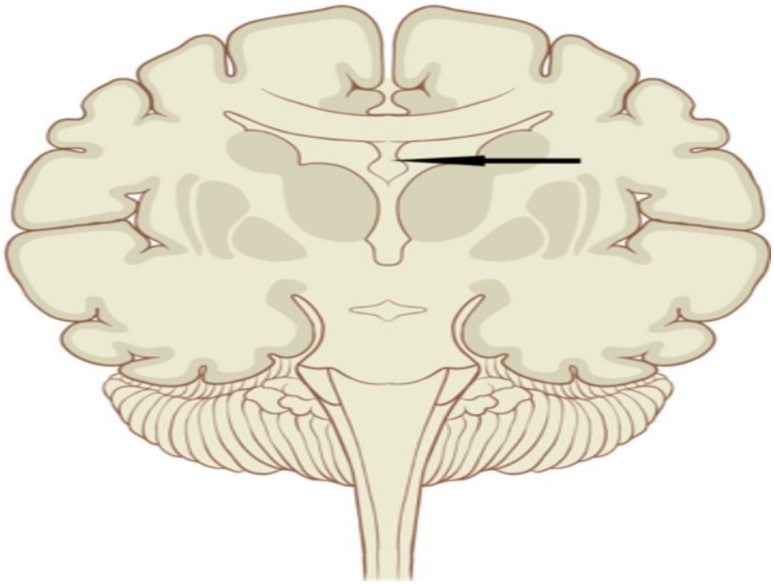
b) Pain

c) Touch

d) Proprioception

Question 9:

The structure marked in the given picture arises from the _____.



a) Mamillary body

b) Hippocampus

c) Thalamus

d) Amygdala

Question 10:

Which of the following arteries does not supply the corresponding region of the dura mater?

a) Middle meningeal artery – Anterior cranial fossa

b) Accessory meningeal branch of maxillary artery – Middle cranial fossa

c) Meningeal branch of internal carotid artery – Posterior cranial fossa

d) Meningeal branch of anterior and posterior ethmoid artery – Anterior cranial fossa

Question 11:

All of the following take part in the formation of the wrist joint, except:

a) Scaphoid

b) Triquetrum

c) Distal end of radius

d) Distal end of ulna

Question 12:

Which of the following nerves is not involved in olfaction?

a) Trigeminal nerve

b) Vagus nerve

c) Glossopharyngeal nerve

d) Hypoglossal nerve

Question 13:

Which of the following is the most conspicuous sign of breast cancer?

a) Peau d'orange

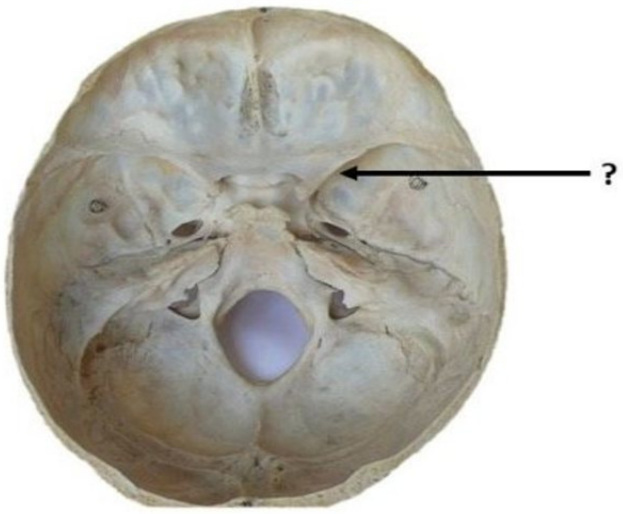
b) Nipple retraction

c) Puckering

d) Both nipple retraction and puckering

Question 14:

Identify the cranial nerve that passes through the marked foramen marked in the image below.



a) Oculomotor nerve

b) Olfactory nerve

c) Optic nerve

d) Facial nerve

Question 15:

Which of the following veins drain into brachiocephalic vein?

a) Hemiazygous vein

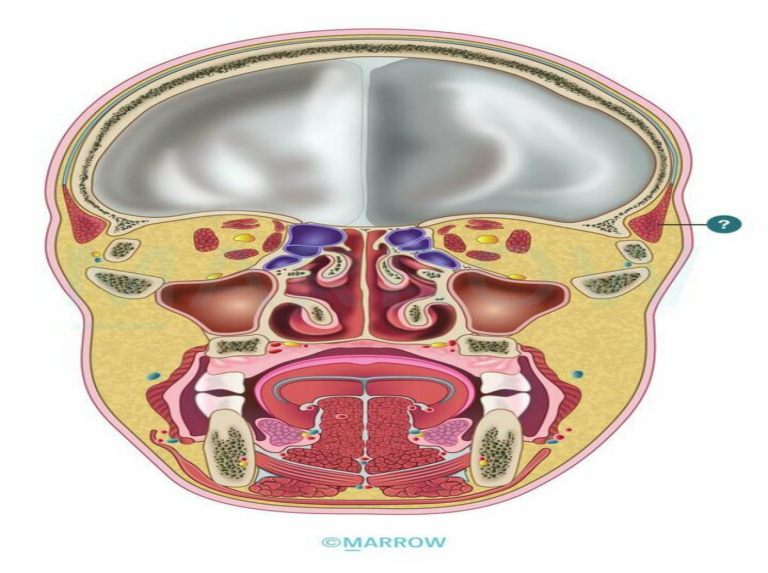
b) Superior thyroid veins

c) Right superior intercostal vein

d) Left superior intercostal vein

Question 16:

What is the main action of the muscle marked below?



a) Elevation

b) Depression

c) Protrusion

d) Retraction

Question 17:

Ligamentum flavum has high levels of:

a) Type 1 collagen

b) Type 2 collagen

c) Reticular fibres

d) Elastin fibres

Question 18:

Which muscle is not involved in the inversion of foot?

a) Tibialis anterior

b) Tibialis posterior

c) Peroneus longus

d) Extensor hallucis longus

Question 19:

Which of the following is normally seen in lumbar spine?

a) Scoliosis

b) Kyphosis

c) Lordosis

d) Recurvatum

Question 20:

Type I collagen is not seen in _____.

a) Bone

b) Ligament

c) Aponeurosis

d) Elastic cartilage

Question 21:

The correct pair of lymph node level in the neck and anatomical boundaries amongst the following are:

a) Level 3 - Cricoid to clavicle

b) Level 4 - Hyoid to cricoid

c) Level 5 - Base of skull to cricoid

d) Level 6 - Hyoid to clavicle

Question 22:

Meissner corpuscles are present in:

a) Papillary dermis

b) Reticular dermis

c) Basal epidermis

d) Stratum lucidum

Answer Key

Question No.	Correct Option
1	c
2	c
3	b
4	b
5	b
6	d
7	c
8	d
9	b
10	c
11	d
12	d
13	a
14	a
15	d
16	a
17	d
18	c

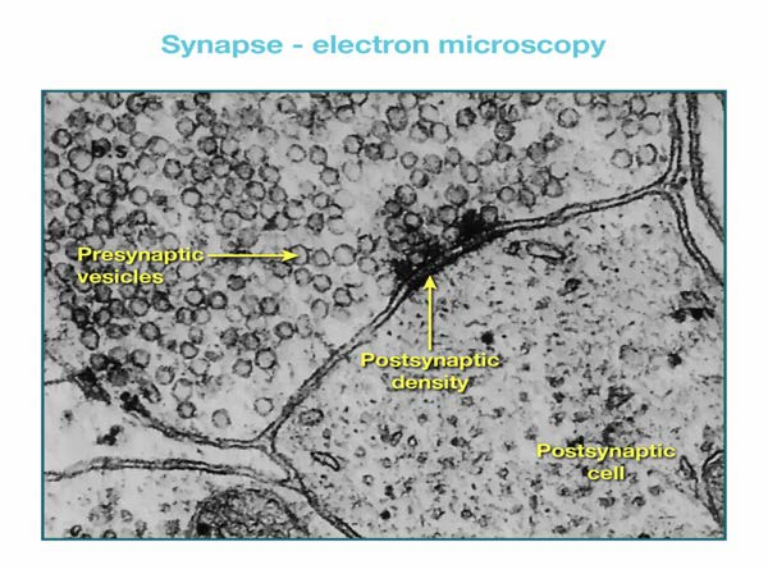
19	c
20	d
21	d
22	a

Detailed Explanations

Solution to Question 1:

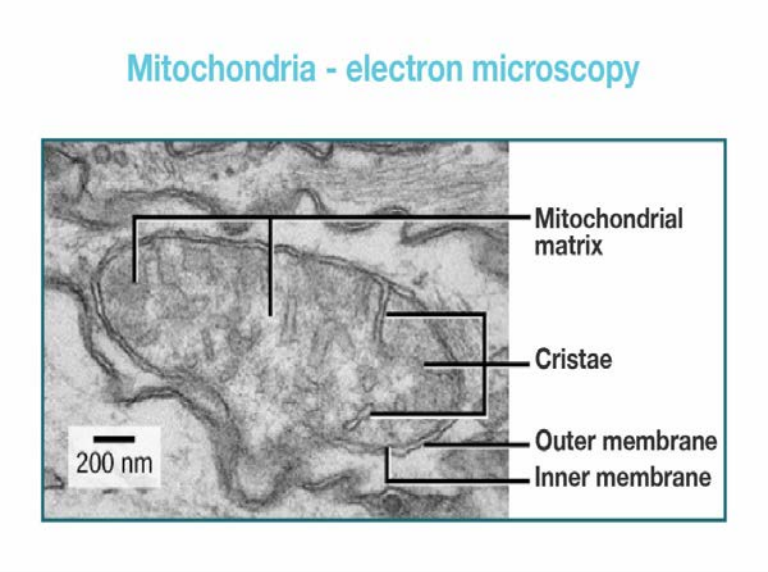
The structure marked with the asterisk in the electron micrograph indicates presynaptic secretory vesicles. The structure marked with the arrowhead is postsynaptic density.

The secretory vesicles are synthesized by the neurons and are involved in electrochemical signalling in the brain and neuromuscular junctions.

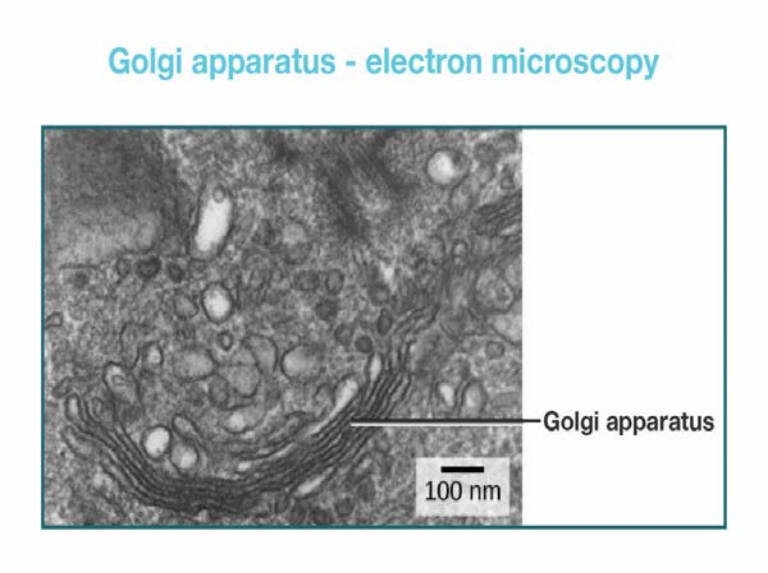


On electron microscopy:

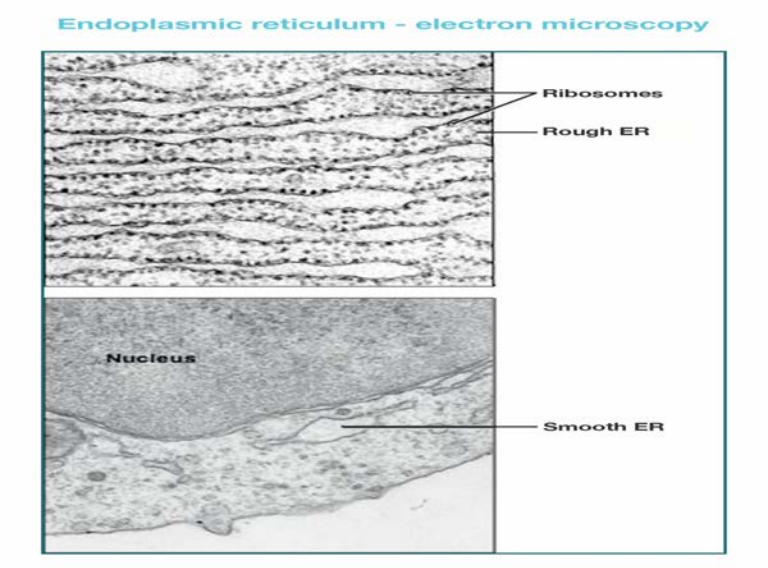
• Mitochondria appear as round or elliptical bodies of 0.5-2.0 micron long on an electron microscope, consisting of an outer and an inner mitochondrial membrane, cristae, and mitochondrial matrix.



• Golgi bodies (or Golgi apparatus) appear as stacks of flatenned membranous cisternae surrounded by clusters of vesicles.



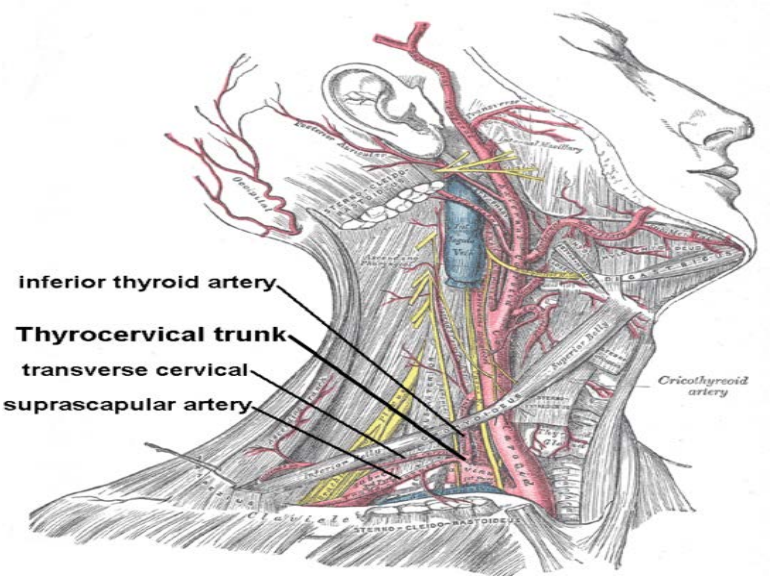
• Ribosomes may be attached to the membrane of the rough endoplasmic reticulum (as shown in the image below), or else, they may exist as monosomes or as a chain of granular structures called polyribosomes associated with mRNA.



Solution to Question 2:

Inferior thyroid artery is a branch of thyrocervical trunk, which in turn, is a branch of the first part of the subclavian artery. The inferior thyroid artery loops upwards anterior to the medial border of the scalenus anterior, turns medially just below the sixth cervical transverse process, and then descends on longus colli to the lower border of the thyroid gland.

Relations between the terminal branches and recurrent laryngeal nerve are very variable and of considerable surgical importance.



Solution to Question 3:

Posterior superficial compartment of the leg does not contain any neurovascular bundle.

The posterior compartment of the leg is divided into the deep and superficial parts by the transverse intermuscular septum.

The contents of the posterior superficial compartment are gastrocnemius, plantaris, and soleus muscle.

Neurovascular components in various compartments of leg are as follows:

• Anterior compartment: Anterior tibial artery and Deep fibular/peroneal nerve

• Posterior deep compartment: Tibial nerve and posterior tibial vessels in the deep plane.

• Lateral Compartment: Superficial peroneal/fibular nerve and peroneal/fibular vessel. Peroneal artery is a branch of posterior tibial artery.

Note: MRI is the best imaging modality for evaluating the soft tissues of the leg.

Solution to Question 4:

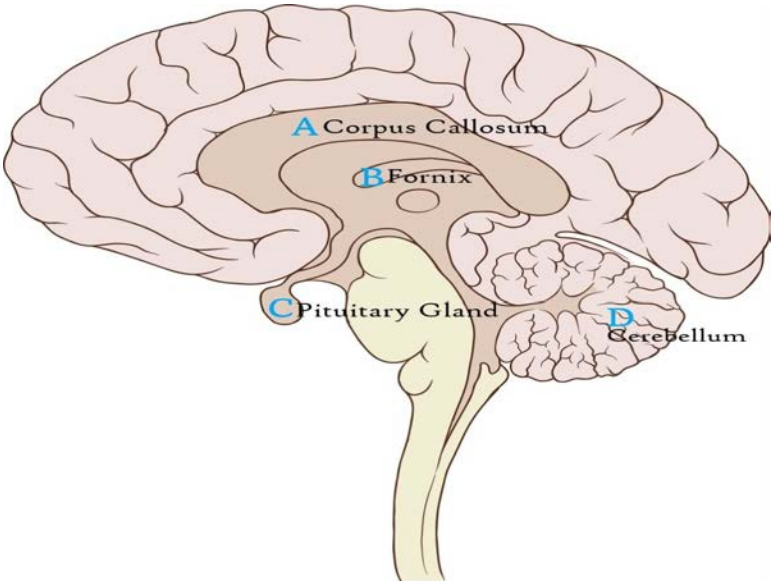
The given clinical scenario is suggestive of Broca's aphasia in which the Broca's area will be affected.

In Broca's aphasia/ Motor aphasia / Non-fluent aphasia, areas 44 and 45 in the prefrontal and premotor facial regions of the cerebral cortex are affected. The affected individuals will have difficulty forming verbal or written words. The comprehension aspect of speech is preserved but the person cannot repeat or name the words and lacks fluency.

Patients in whom the area is severely affected may have very few words to express all of their emotions.

Solution to Question 5:

The image shows the midsagittal section of the brain. The wrongly marked structure is C-hypothalamus. The structure marked as C corresponds to the pituitary gland.



Solution to Question 6:

Loss of flexion at the interphalangeal (IP) joint of the thumb, is due to the involvement of the anterior interosseous nerve (AIN).

Flexion of thumb occurs at 2 joints:

• IP joint: Flexor pollicis longus (FPL) supplied by the anterior interosseous nerve (a branch of the median nerve, C7 and C8).

• MCP joint: Flexor pollicis brevis (FPB) supplied by the recurrent motor branch of the median nerve.

Other options:

• Deep branch of ulnar nerve > ulnar claw hand

Solution to Question 7:

Purkinje cells of the cerebellum relay into the dentate nucleus which is one of the deep cerebellar nuclei.

The input to the Purkinje cells come from the climbing fibres. The output of Purkinje cells is inhibitory to the deep cerebellar nuclei.

Options A and B: Caudate and lentiform nuclei are part of the basal ganglia.

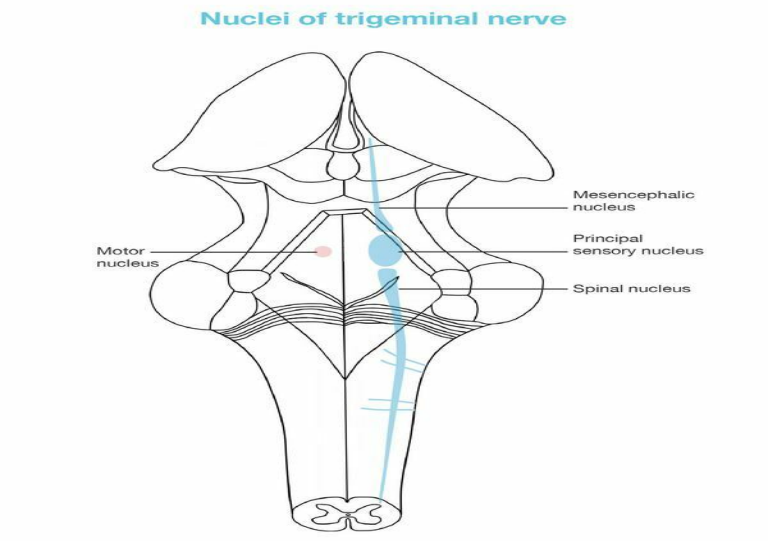
Option D: Red nucleus receives afferents from the cerebellum and plays a role in modulating signals to the upper motor neurons of the cerebral cortex.

Solution to Question 8:

Proprioception is perceived by the mesencephalic nucleus of the trigeminal nerve, not the spinal nucleus.

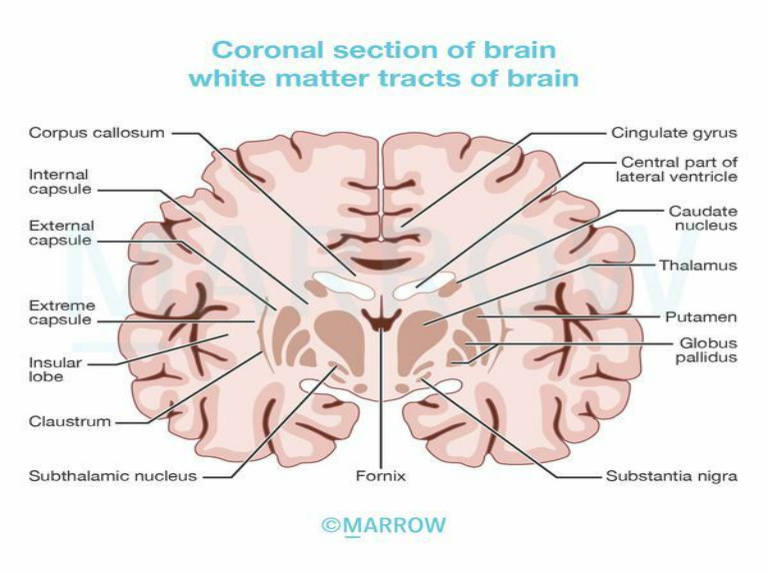
The trigeminal nerve consists of 4 nuclei: 3 sensory (Mesencephalic, spinal, and principal sensory nucleus) and 1 motor.

Nucleus	Location	Function
Mesencephalic Nucleus	Composed of a column ofuni polar nervecells situated in th e midbrain and extends inferi orly into the pons as far as th e main sensory nucleus	Receives the sensation ofpro prioceptionfrom the muscles of mastication and from the f acial and extraocular muscles
Principal sensory nucleu s	Posterior part of the pons lat eral to the motor nucleus	Receives the sensations oftou ch and pressurefrom the face
Spinal nucleus	Continuous superiorly with t he main sensory nucleus and extends inferiorly the whole of the medulla oblongatatill t he 2ndCervical Segment	Receives the sensation ofpain and temperaturefrom the fac e and some fibers oftouch
Motor nucleus	The pons medial to the main sensory nucleus	Supplies the muscles of masti cation, the tensor tympani, t he tensor veli palitini and the mylohyoid and the anterior belly of digastric muscle



Solution to Question 9:

This is a coronal section of the brain and the marked structure is the fornix. It arises from the hippocampus and ends in the mammillary body of the hypothalamus.



Solution to Question 10:

The meningeal branch of the internal carotid artery (ICA) does not supply the posterior cranial fossa. It supplies the anterior cranial fossa.

The dura mater is supplied by meningeal arteries that pass along the inner periosteum (endosteum) of the skull over the endosteal layer of the dura and supply the following regions.

Region	Arteries
Anterior cranial fossa	Meningeal branches of anterior and posterior ethmoid arteriesMeningeal branchesofinternal carotid arteriesA branch of themiddle meningealartery
Middle cranial fossa	Middle meningeal artery and accessory meningeal branches of the maxillary arteryA branch of the ascending pharyngeal arteryBranches of the internal carotid arteryA recurrent branch of the lacrimal artery
Posterior cranial fossa	Meningeal branches of the occipital arteryPosterior meningeal branches of the vertebral arteryDorsal meningeal and tentorial arteries arising from the meningohypophyseal trunk

Solution to Question 11:

The distal end of the ulna does not take part in the formation of the radiocarpal joint.

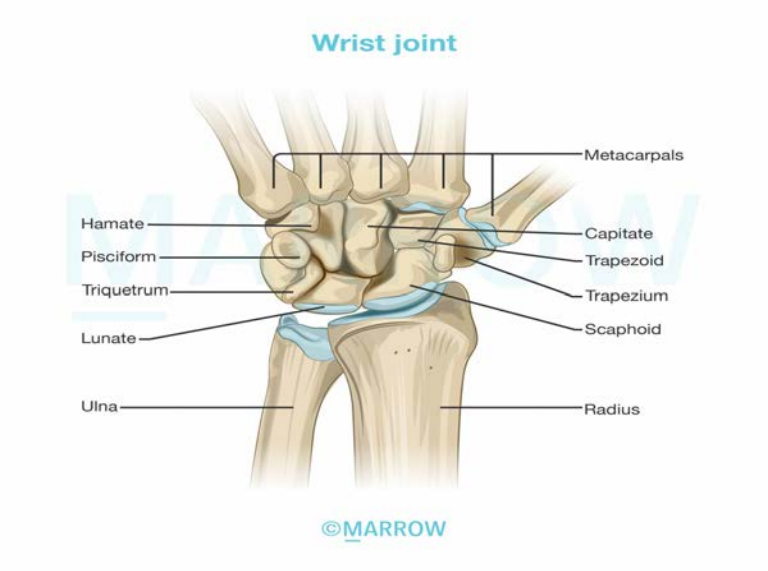
The radiocarpal joint (Wrist joint) is a synovial, biaxial, and ellipsoid joint formed by the articulation of:

• The distal end of the radius

• Articular disc of the triangular fibrocartilage

• Scaphoid, lunate and triquetrum

In the neutral position of the wrist, only the scaphoid and lunate are in contact with the radius and articular disc; the triquetrum comes into apposition with the disc only in full adduction of the wrist joint.



Solution to Question 12:

The hypoglossal nerve is purely motor cranial nerve and is not involved in olfaction.

The other three cranial nerves—trigeminal, glossopharyngeal, and vagus nerves are mixed cranial nerves and contribute to olfaction.

Vagal nerve stimulation modifies the electrical activity of the olfactory bulb.

Solution to Question 13:

The most conspicuous sign of breast cancer is Peau d' orange appearance.

Peau d'orange (orange peel like texture), is the edematous swollen and pitted breast skin due to obstruction of the subcutaneous lymphatics.

Solution to Question 14:

The marked structure is the superior orbital fissure and the oculomotor nerve passes through this fissure.

Superior orbital fissure is divided into three compartments by the common tendinous ring. The oculomotor nerve passes through its intermediate compartment.

Solution to Question 15:

The left superior intercostal vein drains into the left brachiocephalic vein.

Tributaries of the brachiocephalic vein:

• Left and right internal thoracic veins

• Left and right inferior thyroid veins

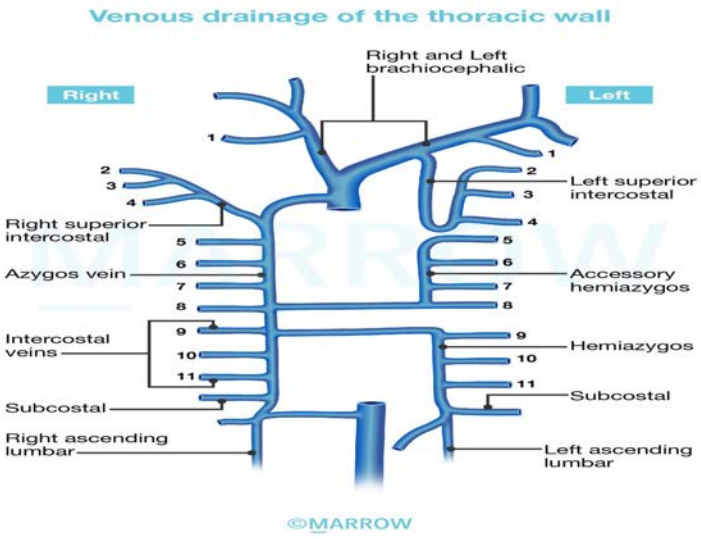
• Left superior intercostal vein drains into the left brachiocephalic vein.

The right superior intercostal vein drains into the azygos vein.

Option A - Hemiazygous vein drains into the azygous vein.

Option B - Superior thyroid veins drain directly into internal jugular veins.

Option C - Right superior intercostal vein drains into the azygous vein.



Solution to Question 16:

The muscle marked in the image is the temporalis and its main action is elevation of the mandible.

Other actions are:

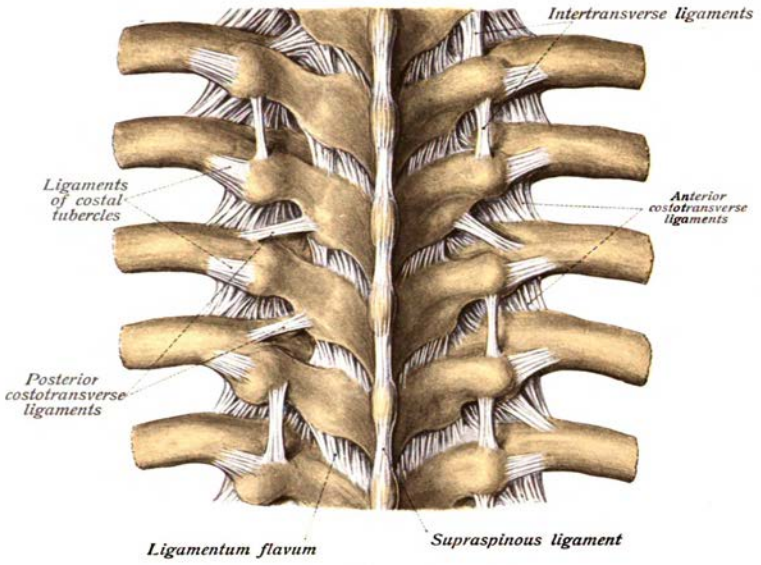
• It helps in the side-to-side grinding movements of the mandible.

• The posterior fibres which are horizontal, help in the retraction of the mandible.

Solution to Question 17:

Ligamentum flavum has high levels of elastin fibres.

The ligamenta flava are a series of ligaments that connect the ventral parts of the laminae of adjacent vertebrae. They predominantly contain elastic tissue and form part of the posterior surface of the vertebral canal. The high content of elastin allows it to be stretched by 80% without damage. The ligamentum flava resist separation of the laminae in flexion and assist in extension back to the anatomical position.



Solution to Question 18:

Peroneus longus muscle is not involved in the inversion of the foot. It causes eversion and plantar flexion.

Inversion of the foot is a movement in which the medial border of the foot is elevated so that the sole faces medially.

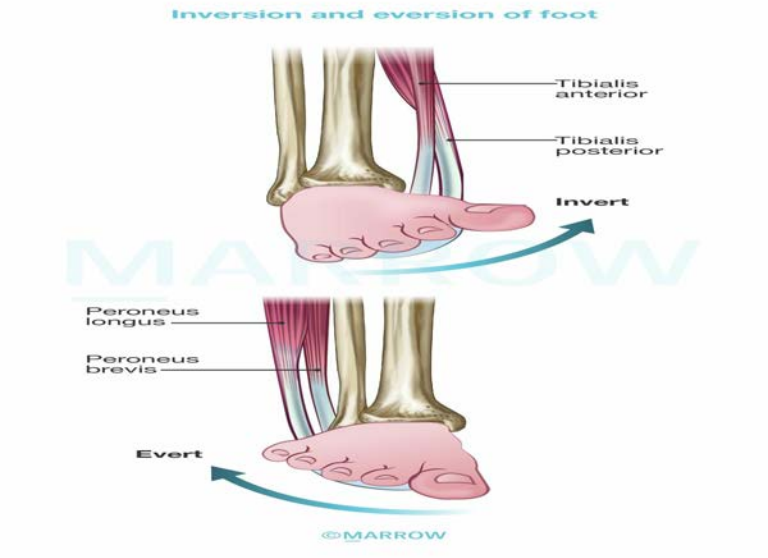
• Tibialis anterior - Causes dorsiflexion and inversion of the foot

• Tibialis posterior - Causes plantar flexion and inversion of the foot

• Extensor hallucis longus - Causes extension of the great toe, dorsiflexion of the foot, and inversion of the foot (minimal action)

Eversion of the foot is a movement where the lateral border of the foot is elevated so that the sole faces laterally. Peroneus longus, peroneus brevis, and peroneus tertius are the muscles involved.

These movements take place, mainly at the talocalcaneal and the talocalcaneonavicular joints, and partly at the transverse tarsal joint.



Solution to Question 19:

Lordosis is normally seen in lumbar spine.

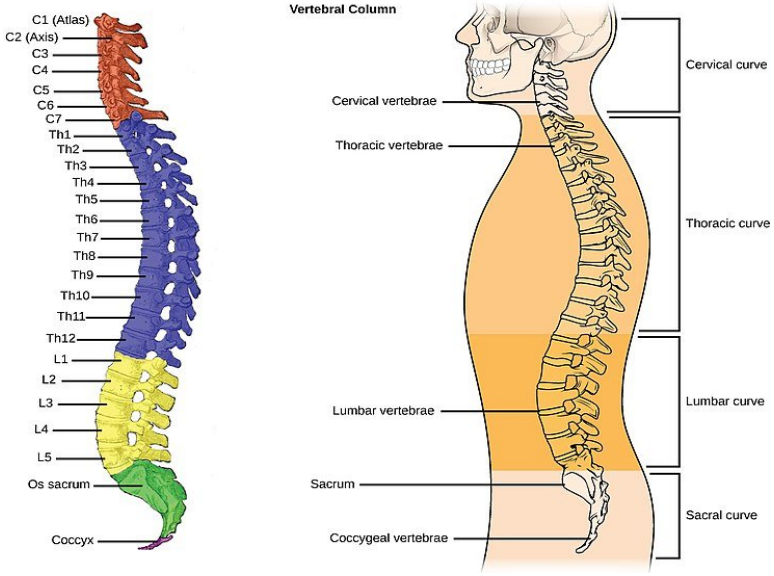
In adults,

• The cervical curve is a lordosis (convex forwards),

• The thoracic curve is a kyphosis (convex dorsally),

• The lumbar curve is also a lordosis,

• The pelvic curve is concave anteroinferiorly.



Solution to Question 20:

Cartilage is made up of type II collagen.

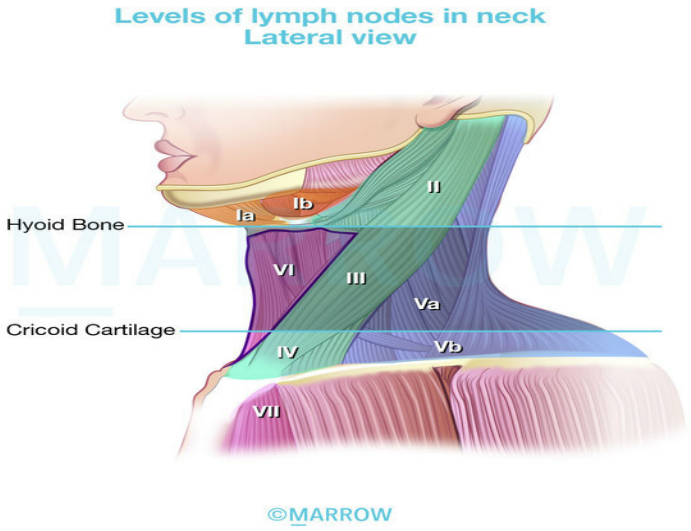
Type I collagen (fibrocartilage), Type II collagen (hyaline and elastic).

There are nearly 28 types of collagen. The important ones are given below with mnemonic:

Bone, Ligament, Tendon, Aponeurosis	Type I Collagen [B-ONE]
Hyaline and Elastic Cartilage	Type II Collagen [Car-Two-Lage]
Reticular Tissue	Type III Collagen [Re-Three-Cular]
Basement Membrane	Type IV Collagen [Floor-Four]

Solution to Question 21:

The correct pair of lymph nodes and levels among the following options are level 6- Hyoid to clavicle.



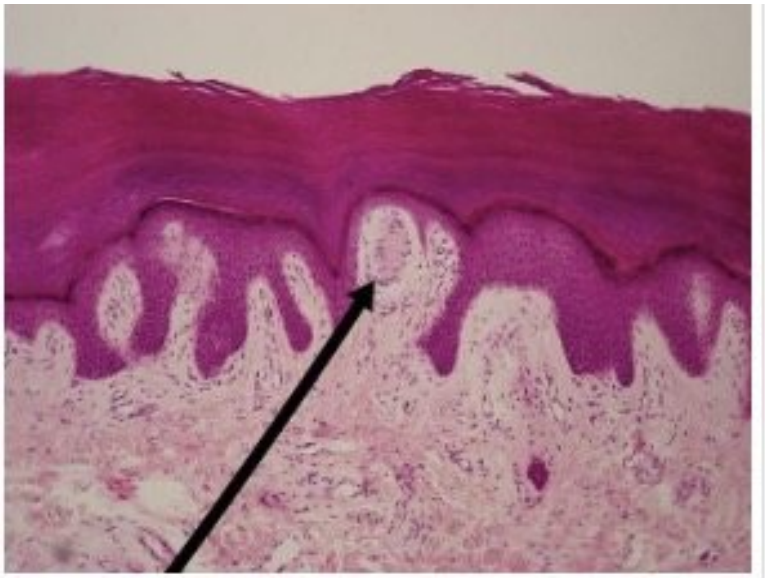
Levels of lymph nodes

Level	Lymph node
1a	Submental
1b	Submandibular
2	Upper jugular
3	Middle jugular
4	Lower jugular
5	Posterior triangle
6	Anterior group
7	Mediastinal

Solution to Question 22:

Meissner corpuscles are present in the papillary dermis. These corpuscles are rapidly adapting mechanoreceptors particularly sensitive to the movement of objects over the skin's surface and low-frequency vibrations. Their acute sensitivity plays a crucial role in tasks such as reading Braille text.

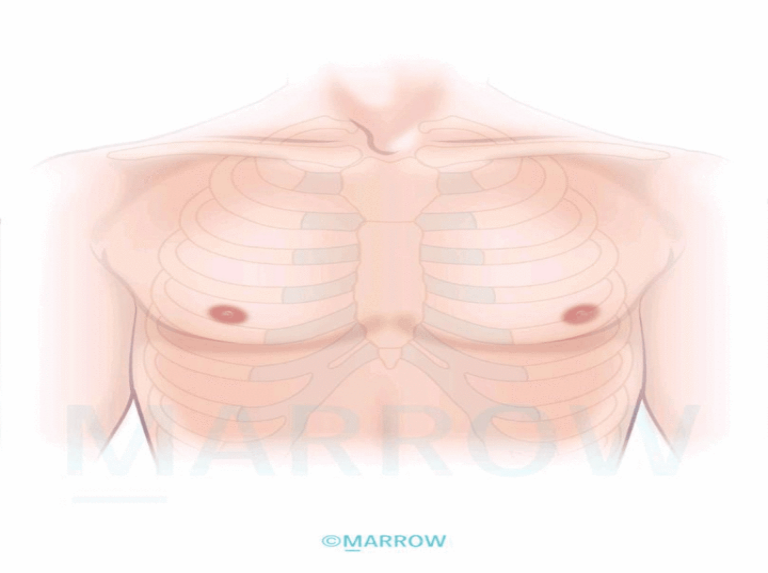
It is an elongated encapsulated nerve ending of a large myelinated sensory nerve fiber (type Aβ). Each corpuscle consists of a connective tissue capsule and a central core composed of stacked modified Schwann cells. Meissner's corpuscles are found in nonhairy areas of the skin, especially in fingertips, lips, and other regions where spatial touch perception is highly developed.



Anatomy AIIMS 2019 (May & Nov)

Question 1:

The region marked corresponds to the surface marking for which of the following structures:



a) Thoracic duct

b) Right atrium

c) Inferomedial bronchopulmonary segments

d) Hilum

Question 2:

The action of the muscle attached to the marked area?

a) Flexion

b) Adduction

c) Abduction

d) Extension

Question 3:

Which of the following finger has two dorsal interossei muscles?

a) Index finger

b) Little finger

c) Middle finger

d) Ring finger

Question 4:

The structure that divides the liver in Couinaud's classification system is:

a) Portal vein

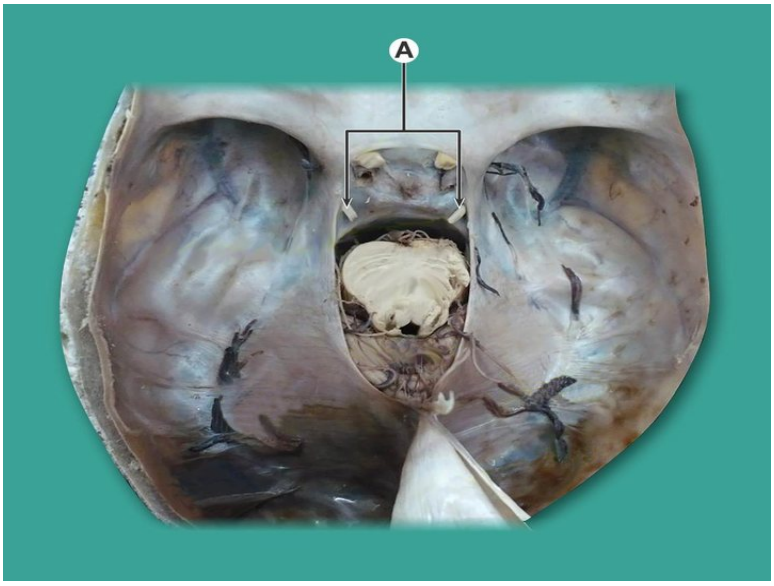
b) Hepatic artery

c) Bile duct

d) Cystic duct

Question 5:

Which of the following muscle is not supplied by the structure marked A?



a) Superior rectus

b) Superior oblique

c) Medial rectus

d) Levator palpebrae superioris (LPS)

Question 6:

The wrong statement regarding the levator ani muscle is:

a) Supports pelvic viscera

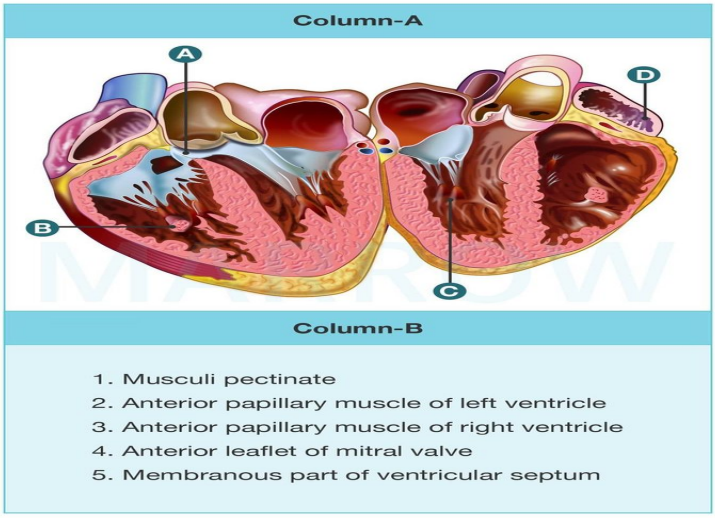
b) Converge downwards and medially

c) Consists of iliococcygeus and pubococcygeus

d) Attached to pelvic brim

Question 7:

In the given section of the heart, match the marked (A, B, C & D) structures.



a) A-5, B-2, C-1, D-4

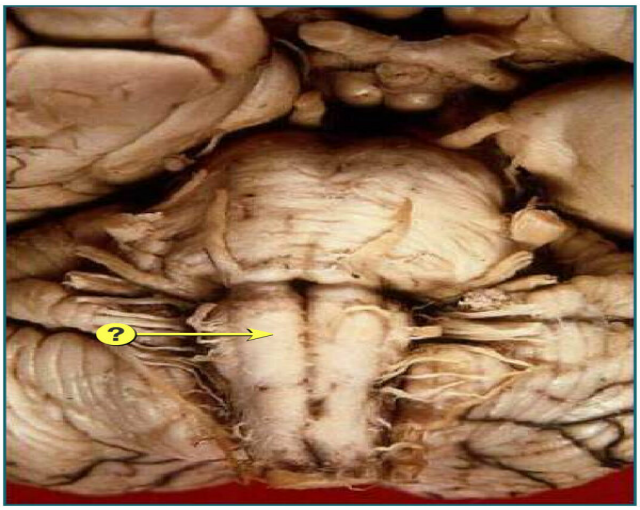
b) A-1, B-2, C-5, D-3

c) A-5, B-3, C-2, D-1

d) A-1, B-2, C-4, D-5

Question 8:

A lesion of the structure marked in the image below causes?



a) Contralateral hemiplegia

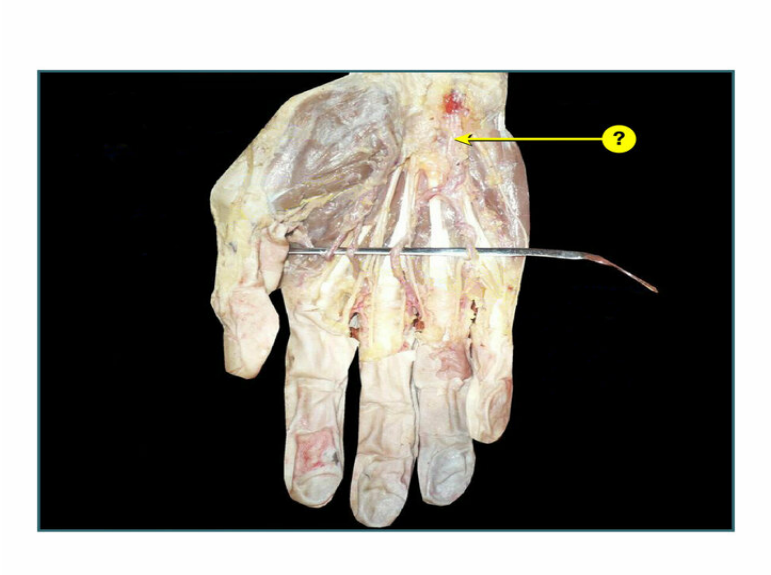
b) Ataxia

c) Tinnitus

d) Ipsilateral facial palsy

Question 9:

Identify the structure marked in the image given below:



a) Ulnar nerve

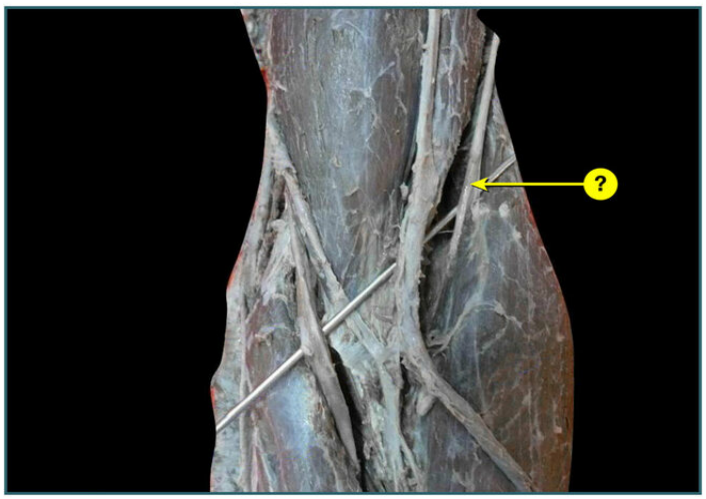
b) Ulnar artery

c) Superficial radial artery

d) Median nerve

Question 10:

True regarding the lesion of the structure marked by the arrow is:



a) Ape thumb deformity

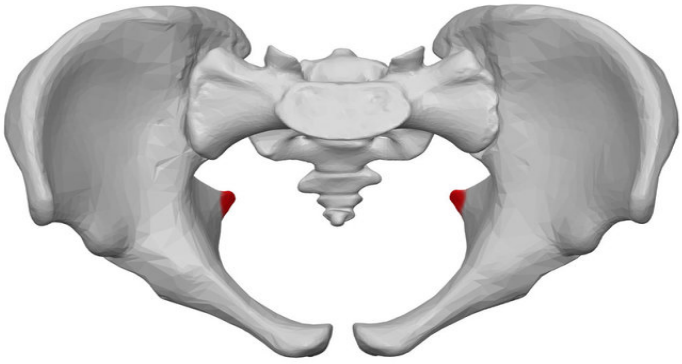
b) Claw hand

c) Claudication

d) Wrist drop

Question 11:

Which of the following structures given below is related to the structure highlighted (red) in the image?



a) Pudendal nerve

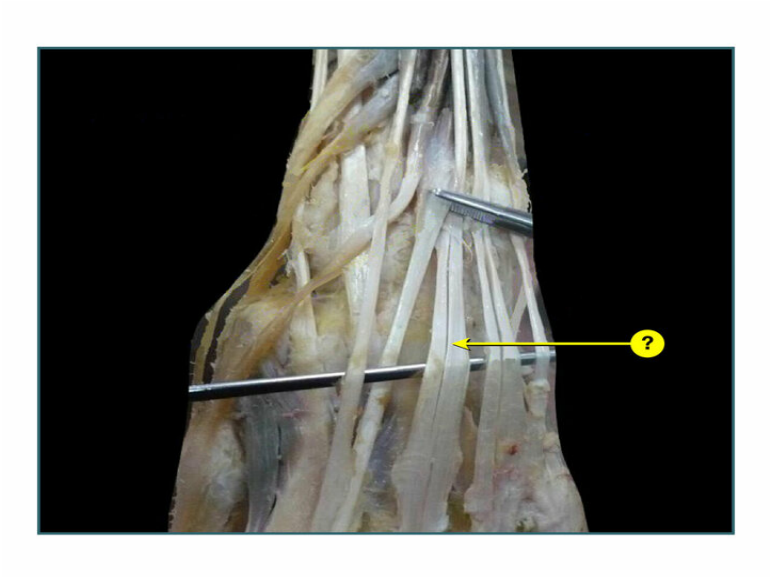
b) Sciatic nerve

c) Obturator nerve

d) Femoral nerve

Question 12:

All of the following form the marked structure except:



a) 2nd Dorsal interossei

b) Lumbricals

c) Extensor digitorum

d) 2nd Palmar interossei

Question 13:

Which of the following structures of brachial plexus do not give branches?

a) Roots

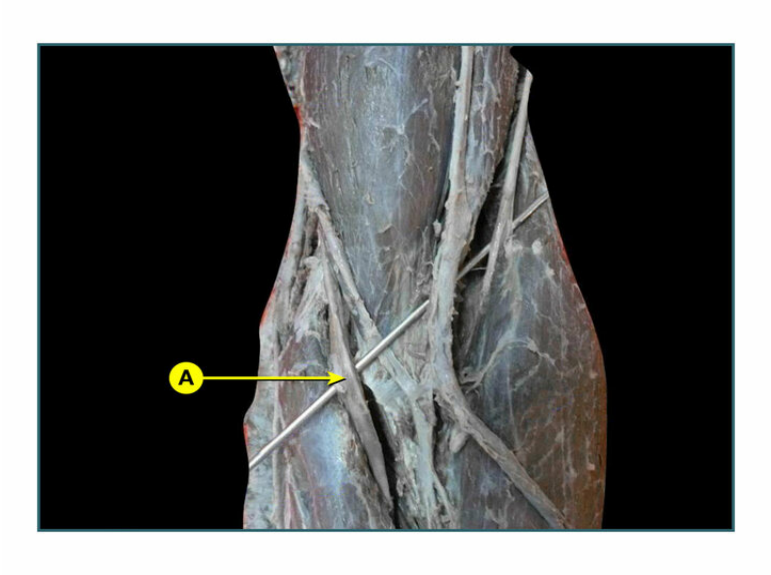
b) Cords

c) Trunks

d) Divisions

Question 14:

Lesion of the structure marked 'A' causes:



a) Loss of sensation of the nail of index finger

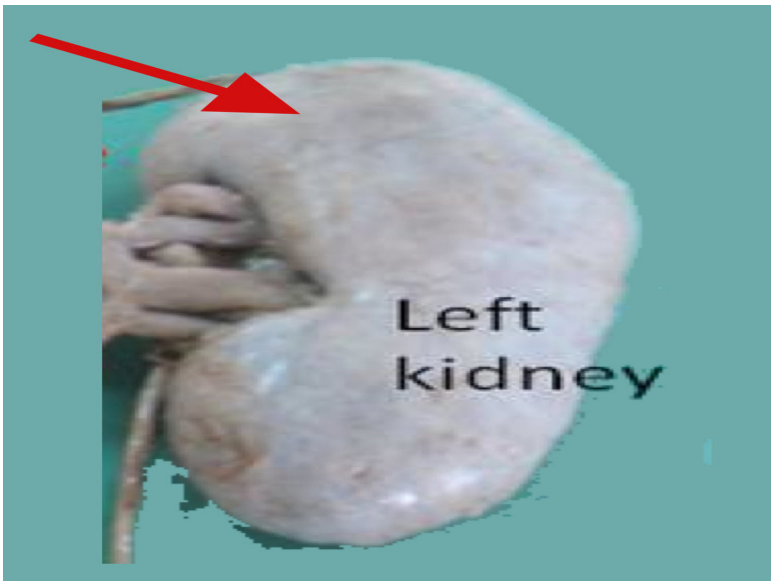
b) Hypothenar muscles wasting

c) Loss of sensation at the tip of radial tubercle

d) Loss of sensation of the 4th interdigital cleft

Question 15:

Which of the following is related to the marked area in the image?



a) Stomach

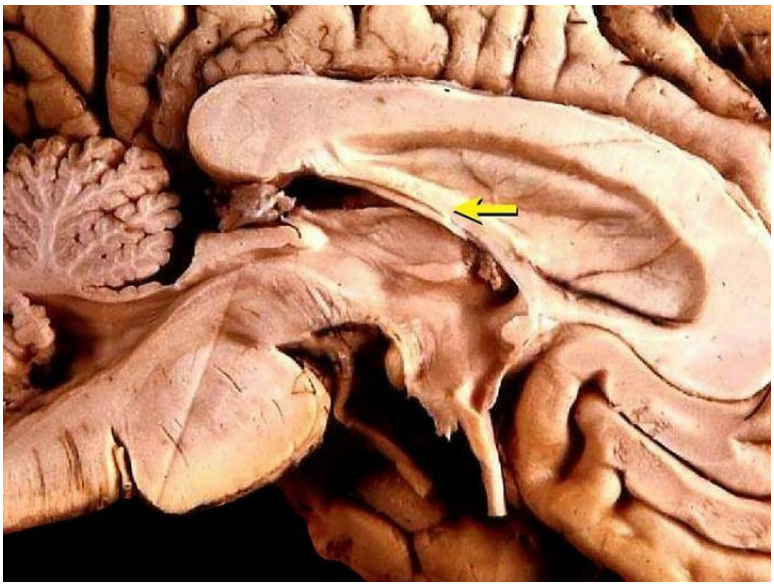
b) Spleen

c) 2nd part of duodenum

d) Pancreas

Question 16:

The blood supply to the structure marked in the image is by:



a) Vertebral artery

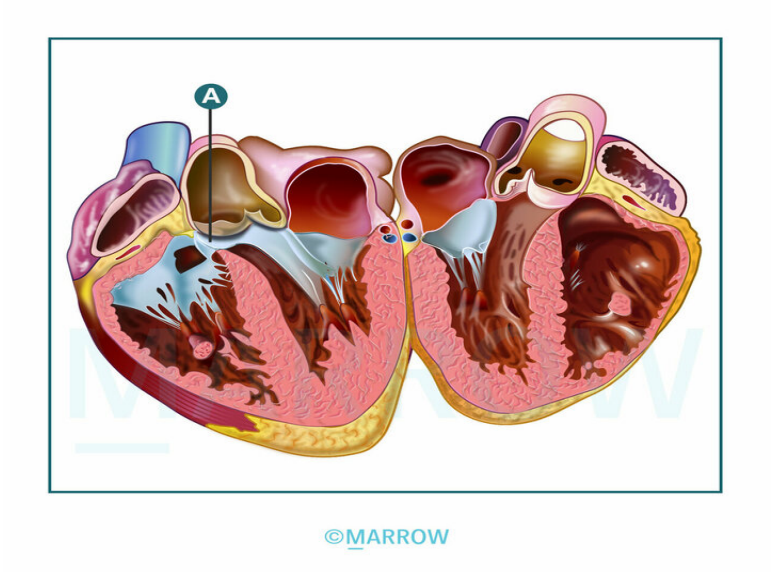
b) Internal carotid artery

c) Anterior cerebral artery

d) Middle cerebral artery

Question 17:

Marked structure is derived from the_____



a) Endocardial cushions

b) Septum primum

c) Left venous valve

d) Bulbous venosus

Question 18:

All of the following supply the marked structure except :

a) Right coronary artery

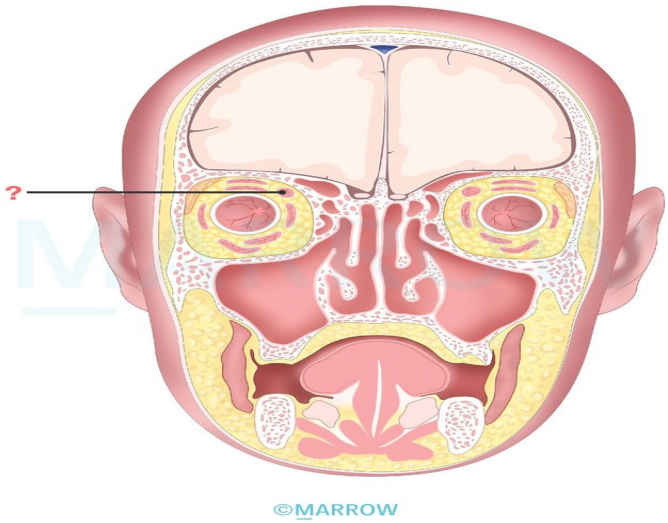
b) Anterior interventricular artery

c) Marginal artery

d) Diagonal artery

Question 19:

What is the nerve supply of the structure marked in the image below?



a) Oculomotor nerve

b) Trochlear nerve

c) Trigeminal nerve

d) Abducens nerve

Answer Key

Question No.	Correct Option
1	b
2	c
3	c
4	a
5	b
6	d
7	c

8	a
9	b
10	d
11	a
12	d
13	d
14	a
15	a
16	c
17	a
18	d
19	b

Detailed Explanations

Solution to Question 1:

The region marked corresponds to the surface marking for the right atrium.

The costal margin, xiphoid process, and the mid-clavicular line are seen in this image. The examiner draws a laterally convex line that extends from a level below the 2nd costal cartilage (as clued in by the sternal angle) i.e., 3rd costal cartilage to about 3 spaces below i.e., the 6th costal cartilage. This line is about 1.2 cms lateral to the sternal edge. These suggest that the region marked corresponds to the surface marking for the right atrium.

The projection of the cardiac borders, of an average adult, onto the anterior thoracic wall forms a trapezoid. This can be mapped out using the percussion method by looking for cardiac dullness.

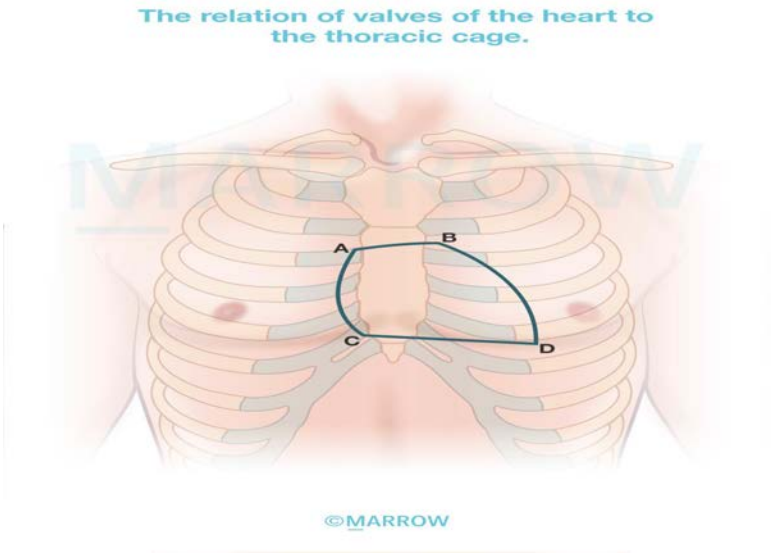
The varying heart borders and the corresponding surface markings are as follows:

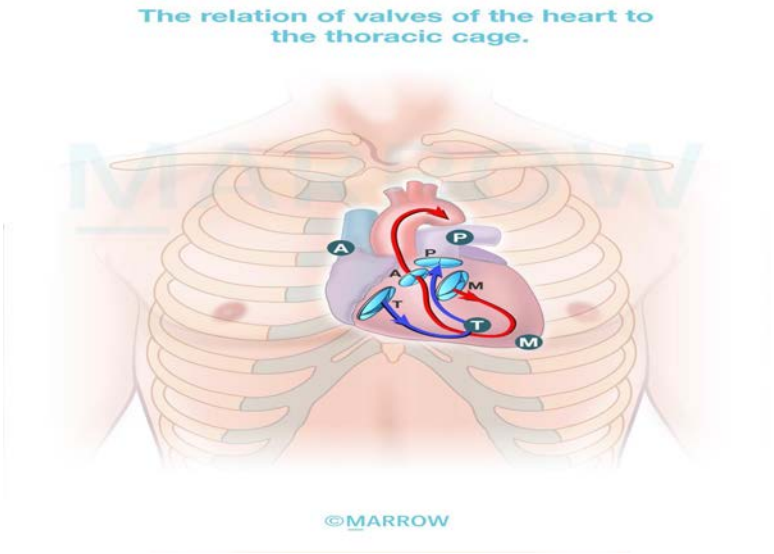
• Upper border: Slopes gently from the second left costal cartilage to the third right costal cartilage. It corresponds to the left atrium.

• Right border: Convex to the right and runs from the third to the sixth right costal cartilages, 1–2 cm lateral to the sternal edge. It corresponds to the right atrium.

• Inferior border or acute border: Runs leftwards from the 6th right costal cartilage to the cardiac apex which is located approximately 9 cm lateral to the midline, often in the left 5th intercostal space or level with the 5th or 6th rib. It corresponds to the right ventricle.

• Left border or obtuse border: Convex laterally on the left. It extends superomedially from the cardiac apex to meet the second left costal cartilage about 1 cm from the left sternal edge. It corresponds to the left ventricle.





Solution to Question 2:

The image shows the greater trochanter and the muscle fibers of the gluteus medius and the gluteus minimus attach(insert) here and their function is to abduct the thigh and their anterior fibers rotate the thigh medially.

Both are innervated by the superior gluteal nerve (L4, L5, S1)

Greater and Lesser trochanters:

• Greater trochanter

• Large and quadrangular

• Junction of the neck and shaft

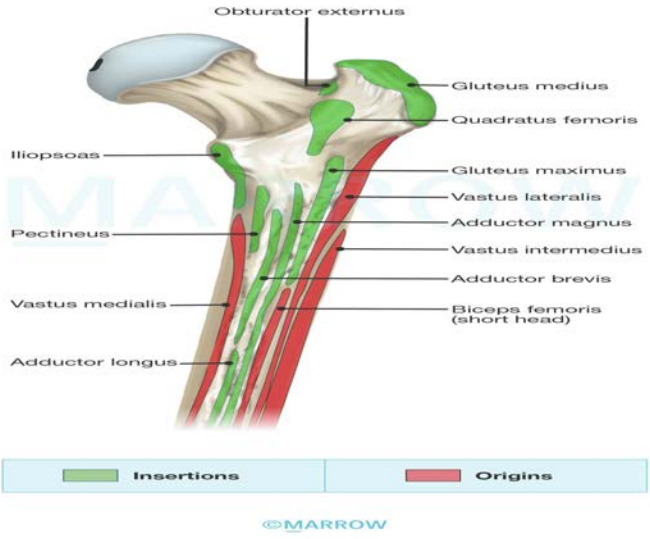
• Lesser trochanter

• Conical projection

• Posteromedial to shaft

• Posteroinferior to junction with the neck.

• Surface marking: Greater trochanter lies approximately a hand's breadth below the iliac tuberculum, the surface is palpable, especially when the muscles are relaxed, Lesser trochanter is not palpable.



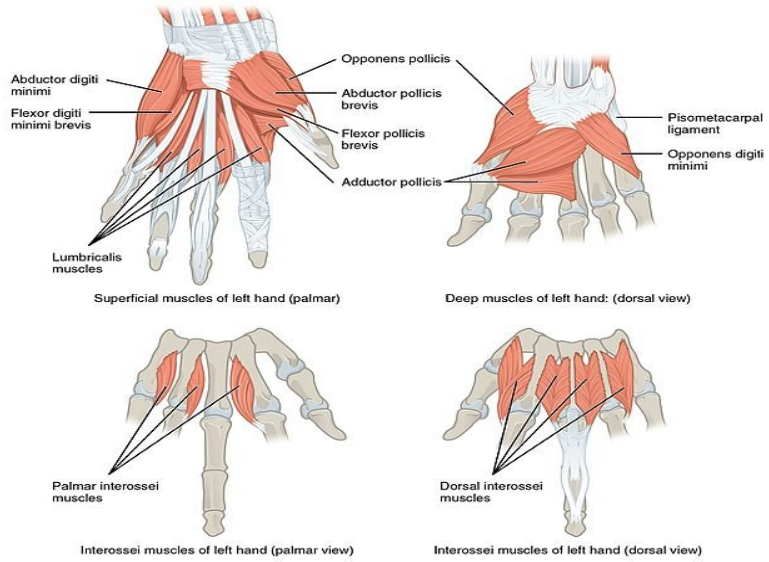
Solution to Question 3:

The Middle Finger has two Dorsal interossei as seen in the image below.

Dorsal Interossei causes Abduction of fingers from the Middle/3rd finger:

Muscle	Palmar Interossei	Dorsal Interossei
Origin	First arises from the base of 1 st metacarpal; Other three fr om the anterior surface of sh afts of 2nd, 4th, and 5th met acarpals	Contiguous sides of shafts of metacarpal bones
Insertion	Proximal phalanges of thumb and index, ring, and little fin gers and dorsal extensor exp ansion of each finger	Proximal phalanges of index, middle, and ring fingers and dorsal extensor expansion
Nerve sup ply	Deep branch of the ulnar ner ve	
Nerve root s	C8; T1	

Muscle	Palmar Interossei	Dorsal Interossei
Action	Palmar interosseiadductfingerstoward the centerof the third finger & flexes the metacarpophalangeal joints and extend interphalangeal joints	Dorsal interosseiabductfingersfrom the centerof the third finger flexes metacarpophalangeal joints and extend interphalangeal joints



Solution to Question 4:

The structure that divides the liver in Couinaud's classification system is the portal vein.

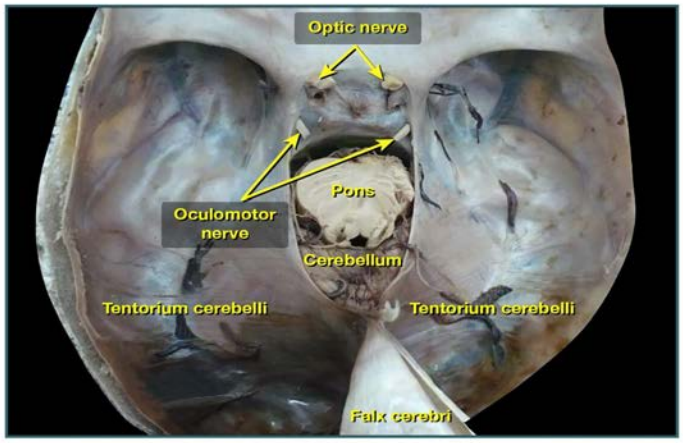
Solution to Question 5:

The structure marked in the image is the oculomotor nerve and it does not supply the superior oblique muscle. Superior oblique muscle is supplied by the trochlear nerve.

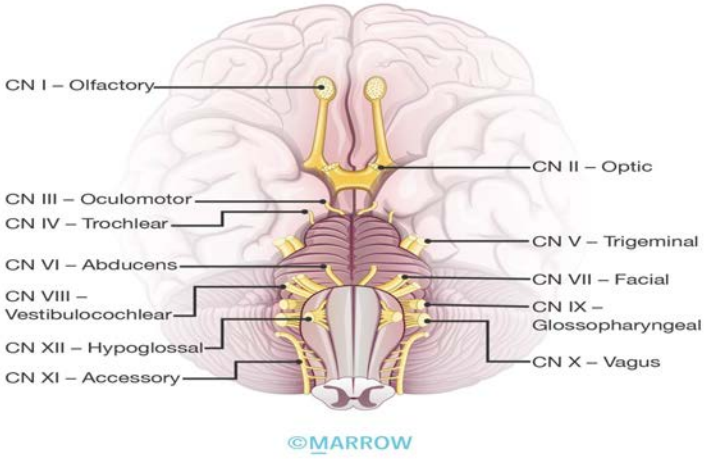
All the extraocular muscles are innervated by the oculomotor (III) nerve except:

- Lateral rectus which is supplied by abducens (VI) nerve
- Superior oblique which is supplied by trochlear (IV) nerve

Optic and Oculomotor nerves



Origin of cranial nerves at the base of the brain



Solution to Question 6:

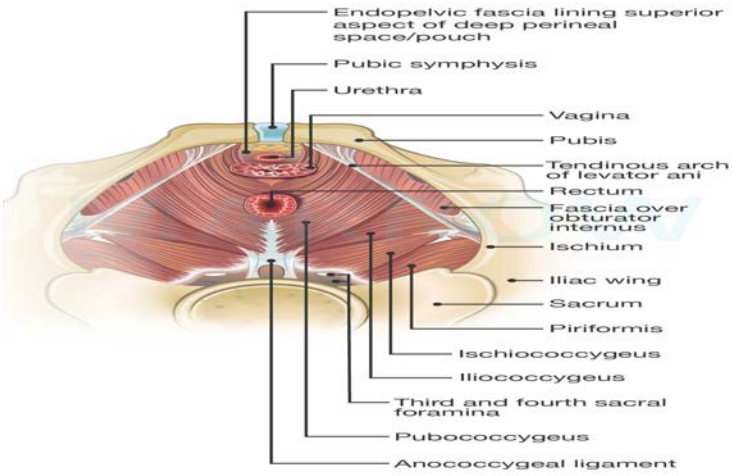
Levator Ani Muscle is not attached to the pelvic brim. It takes its origin from the body of the pubis, the arcus tendinous of the levator ani (a thickened part of the obturator fascia), and the ischial spine.

• Insertion :- The coccyx and the anococcygeal raphe or ligament.

• Nerve supply :- The branches of the anterior rami of sacral nerves S3 and S4 and the perineal branch of the pudendal nerve.

• Supports and raises the pelvic floor.

• Consists of the puborectalis, pubococcygeus, and iliococcygeus.



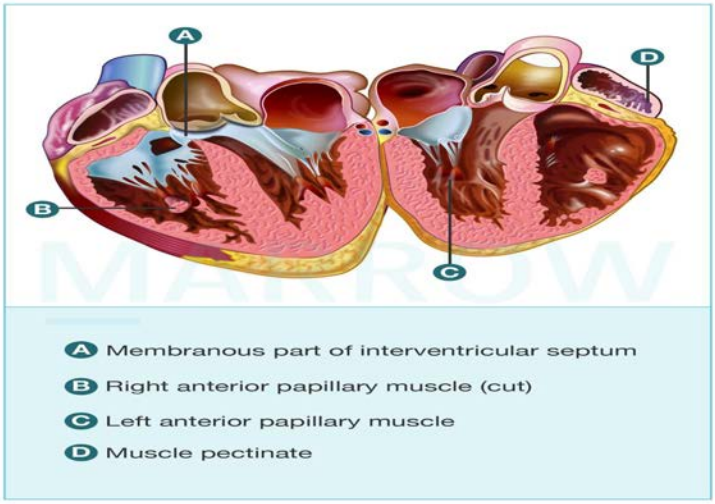
Pelvic floor

©MARROW

Solution to Question 7:

The image shows a cut and reflected section of the heart.

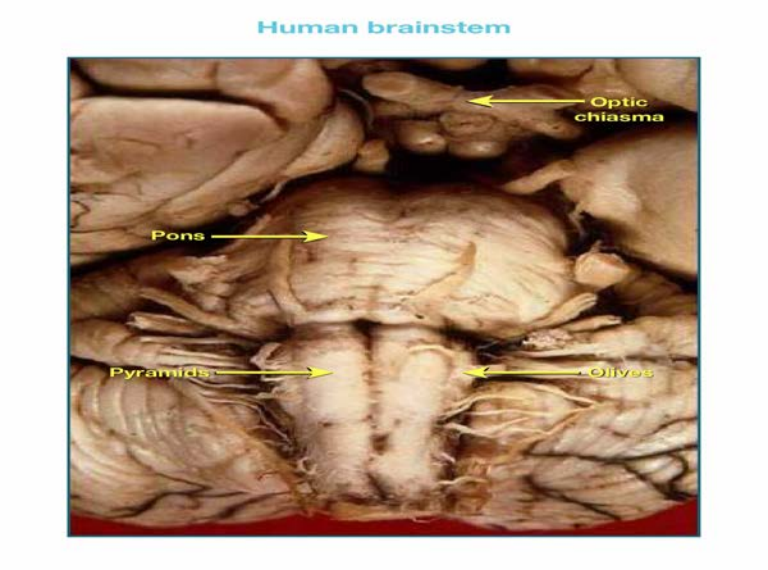
The ventricles can be identified based upon the wall thickness. Left ventricle has thicker walls. The correct match is:

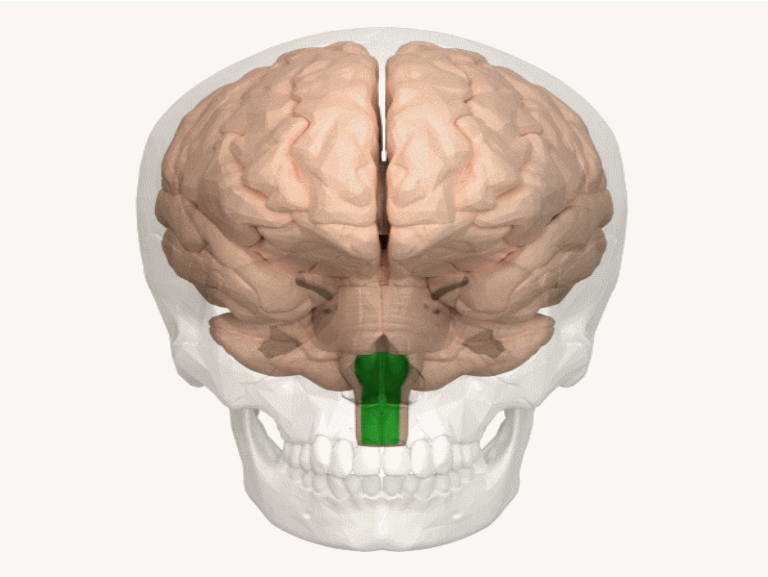


©MARROW

Solution to Question 8:

The structure marked in the image is the pyramid containing the pyramidal tracts. A lesion here leads to contralateral hemiplegia.

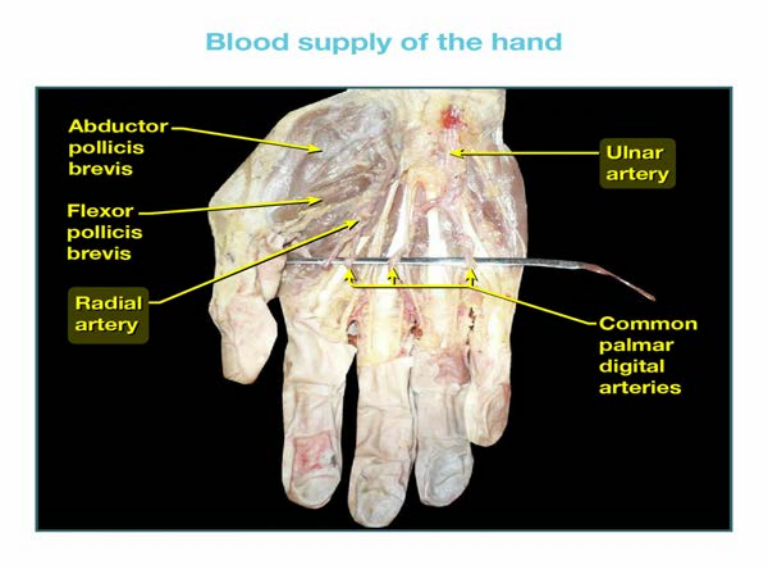


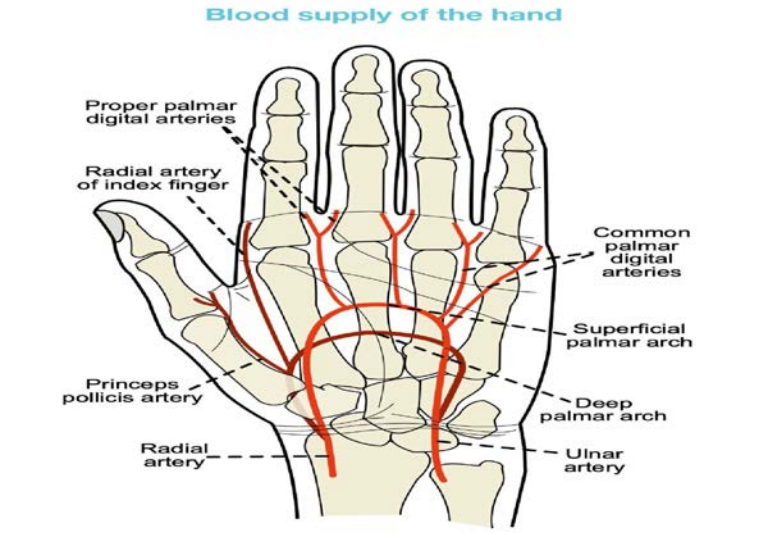


Solution to Question 9:

The structure marked in the image is the ulnar artery, seen contributing to the superficial palmar arch.

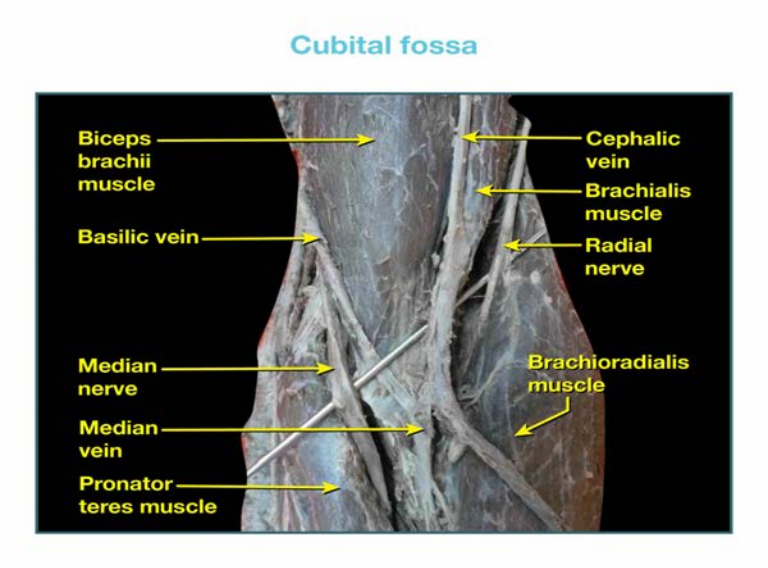
It passes deep to the Guyon's canal in the wrist and contributes to the superficial and deep palmar arch.

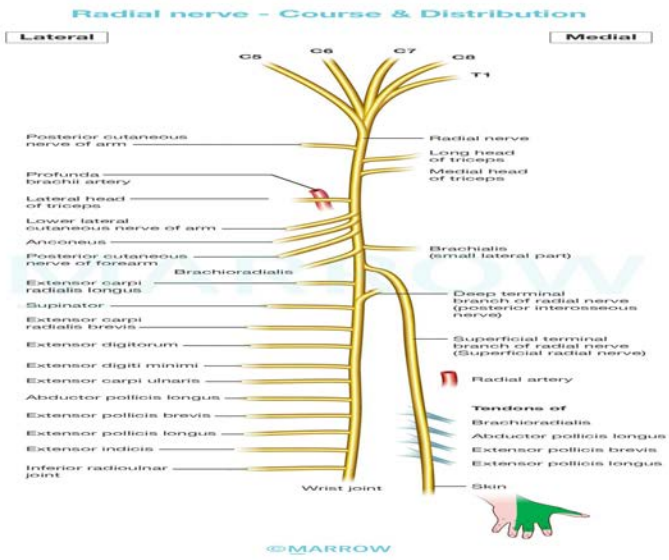




Solution to Question 10:

The structure marked in the image is the radial nerve demonstrated in the cubital fossa. A lesion of the radial nerve leads to a wrist drop.





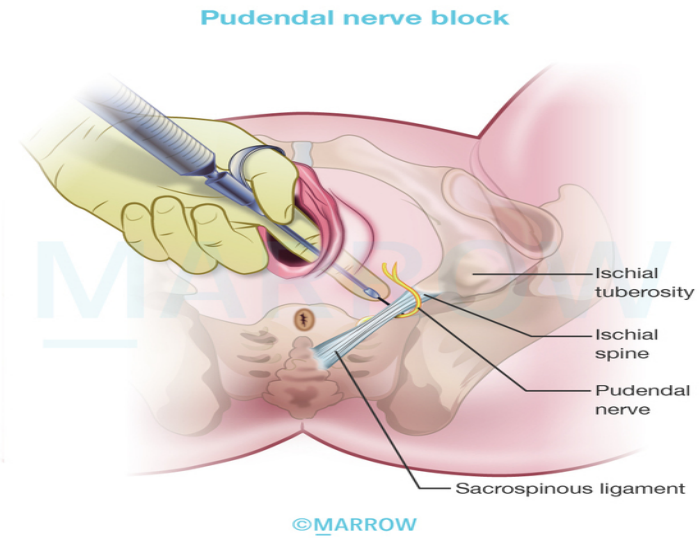
Ape thumb deformity is seen in a lesion of the median nerve.

Claw hand deformity is seen in a lesion of the ulnar nerve.

Solution to Question 11:

The structure marked in red is the ischial spine and the pudendal nerve is related to it.

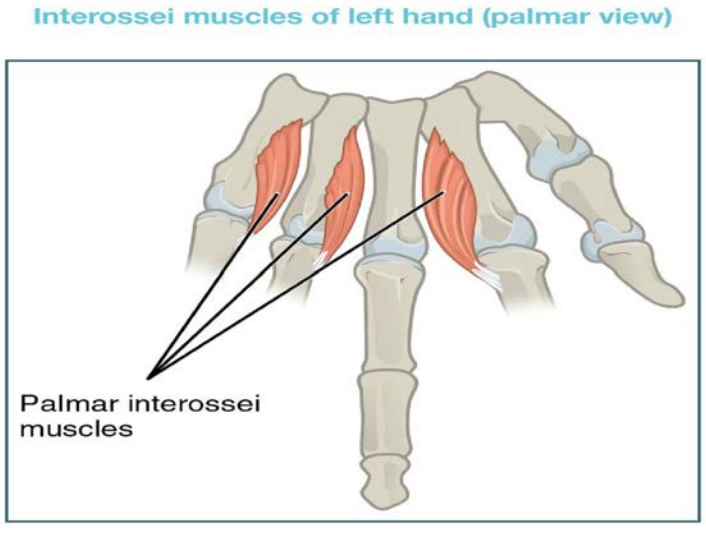
The pudendal nerve originates from the sacral plexus S2-S4. It exits out of the pelvis by passing through the greater sciatic foramen. It then enters the perineum below the pelvic floor by passing around the ischial spine. The ischial spine is used as a landmark for pudendal nerve block.



Solution to Question 12:

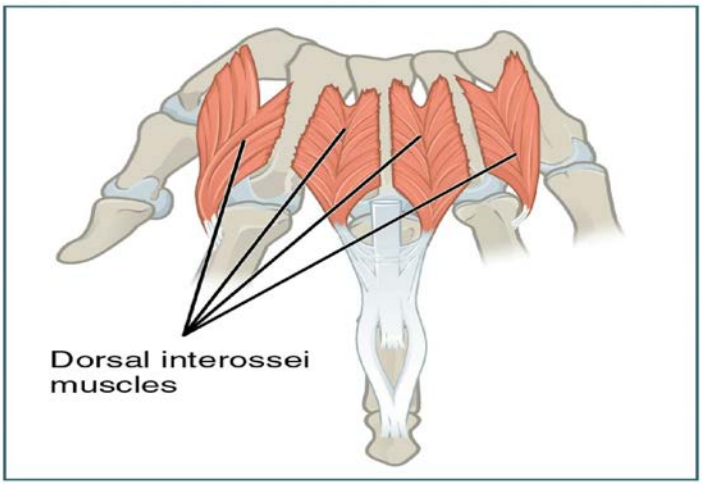
The structure marked in the image is the dorsal digital expansion of the middle finger. Palmar interossei do not attach to the middle finger and therefore it does not contribute to the dorsal digital expansion of the middle finger.

Palmar interossei are unipennate muscles originating from their own metacarpal bone. Their function is adduction. The middle finger does not need adduction and hence does not have palmar interossei.



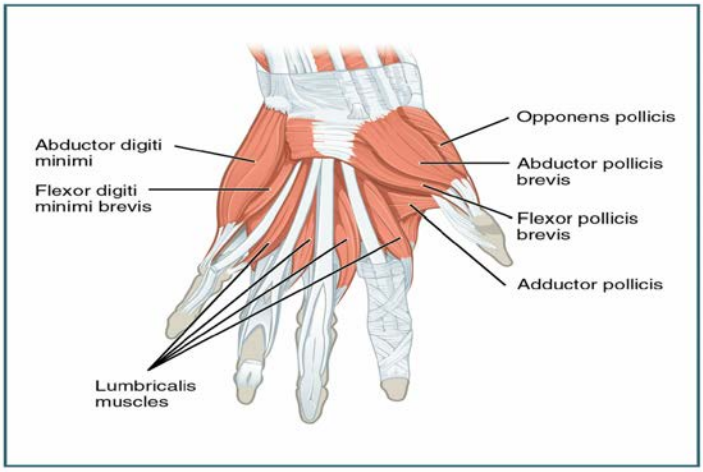
Dorsal interossei are bipennate muscles originating from the adjacent metacarpal bone. They attach to the middle three fingers on both sides and do not attach on the thumb and little finger. Their function is abduction. The thumb and little finger have other muscles for abduction.

Interossei muscles of left hand (dorsal view)



The lateral 2 lumbricals are unipennate and medial 2 lumbricals are bipennate. Their function is flexion at metacarpophalangeal joints.

Superficial muscles of the hand (palmar view)



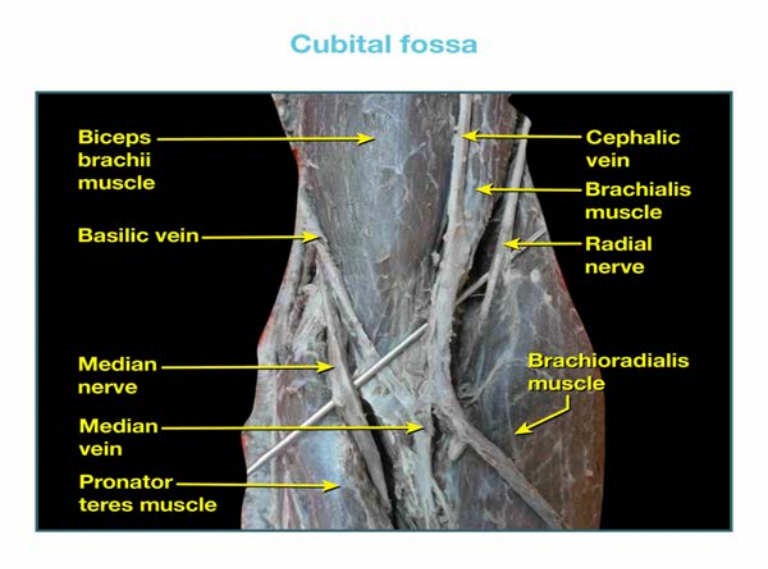
Solution to Question 13:

The divisions in the brachial plexus do not give any branches.

However, the roots, trunks, and cords of the brachial plexus give out direct branches.

Solution to Question 14:

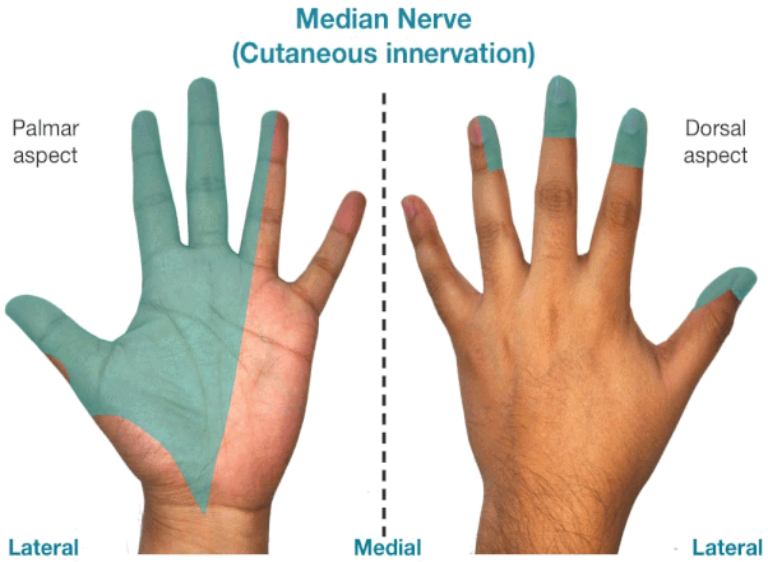
The structure marked 'A' in the diagram is median nerve in the cubital fossa. A lesion of the median nerve causes loss of sensation of the nail of the index finger.



Median nerve cutaneous supply:

• Lateral 2/3rd of the palm by superficial cutaneous branch

• Lateral 3½ fingers (palmar aspect and dorsal aspect of nailbeds) by palmar digital nerves



Contents of cubital fossa: (From medial to lateral) - “MBBR”

• Median nerve

• Brachial artery

• Biceps brachii tendon

• Radial nerve

Solution to Question 15:

The marked area in the image of the left kidney is related to the stomach.

The anterior relations of the right kidney:

The anterior relations of the left kidney:

The posterior relations of the kidneys:

• One vessel - subcostal vessels

• Two ligaments - medial and lateral arcuate ligaments

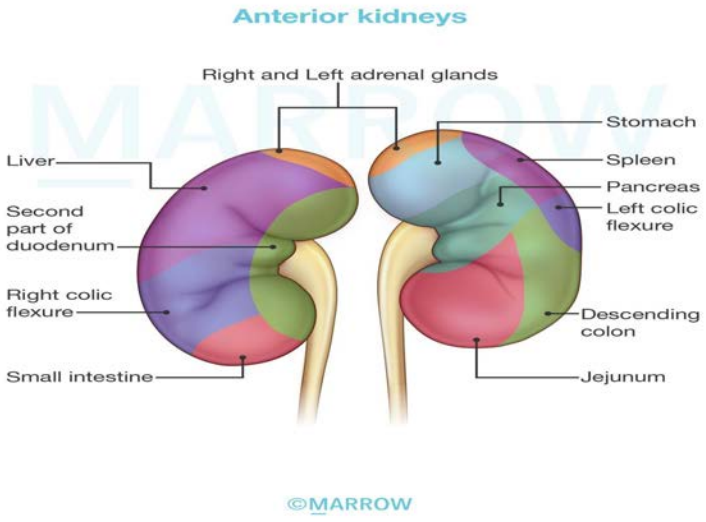
• Three nerves - subcostal, iliohypogastric, and ilioinguinal nerves

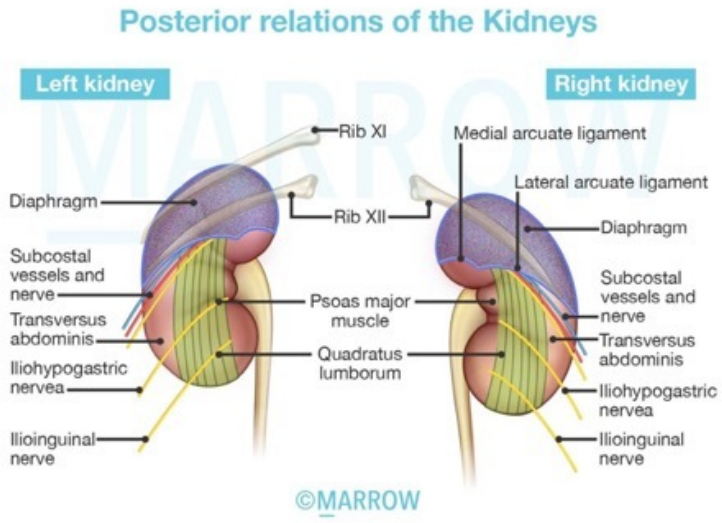
• Four muscles - diaphragm, psoas major, quadratus lumborum, and transverse abdominis.

• The right kidney is related to the 12th rib and the left kidney is related to the 11th and 12th ribs

Intraperitoneal	Right lobe of liverSmall intestine
Retroperitoneal	Right suprarenal gland2ndpart of duoednumHepatic flexure of colon

Intraperitoneal	StomachJejunumSpleen
Retroperitoneal	Left suprarenal glandPancreasSplenic vesselsSplenic flexure and beginning of descending colon

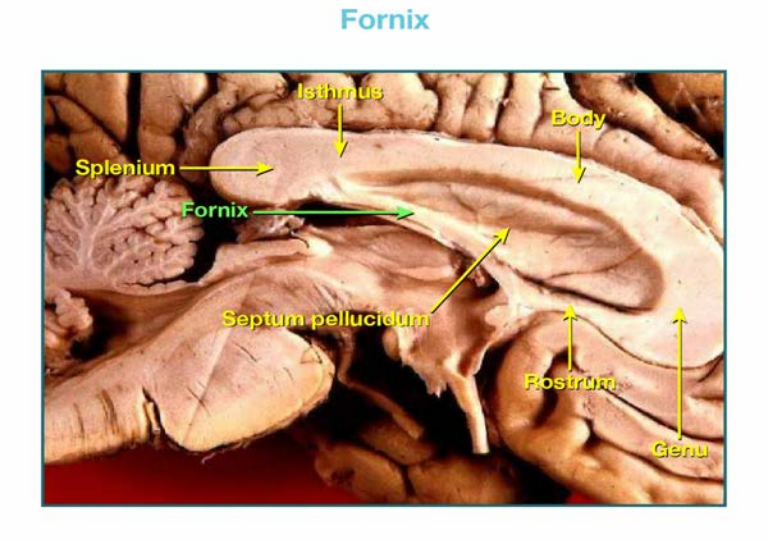




Solution to Question 16:

The marked structure is fornix which is supplied by the anterior cerebral artery.

The anteromedial central branches from the anterior cerebral artery supply the fornix along with optic chiasma, lamina terminalis, hypothalamus, para-olfactory areas, and cingulate gyrus.



Solution to Question 17:

The structure marked is the membranous part of the interventricular septum. It is derived from endocardial cushions.

Endocardial cushions are soft tissue masses that protrude in the atrioventricular and conotruncal regions.

• Atrioventricular cushions are derived from overlying endocardial cells.

• The conotruncal cushions are derived from the neural crest cells.

Endocardial cushions contribute to the formation of:

• Atrial septa

• Ventricular septa (membranous portion)

• Atrioventricular canals

• Atrioventricular valves

• Aortic and pulmonary channels

Defects in endocardial cushion formation can result in cardiac malformations, including ASDs, VSDs, and defects involving the great vessels (transposition of the great vessels, common truncus arteriosus, and tetralogy of Fallot).

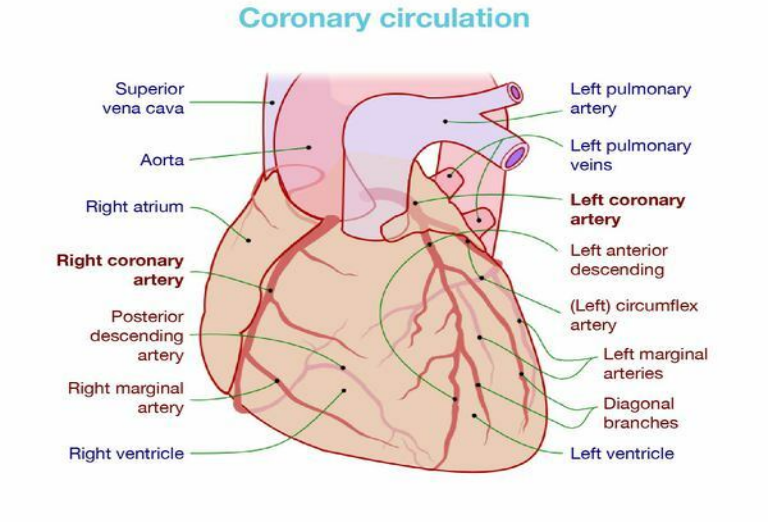
Solution to Question 18:

The structure marked is the right ventricle. It is not supplied by the diagonal artery.

The diagonal artery is a branch of the anterior interventricular artery supplying the left ventricle. This is present in about 30-50% of the population.

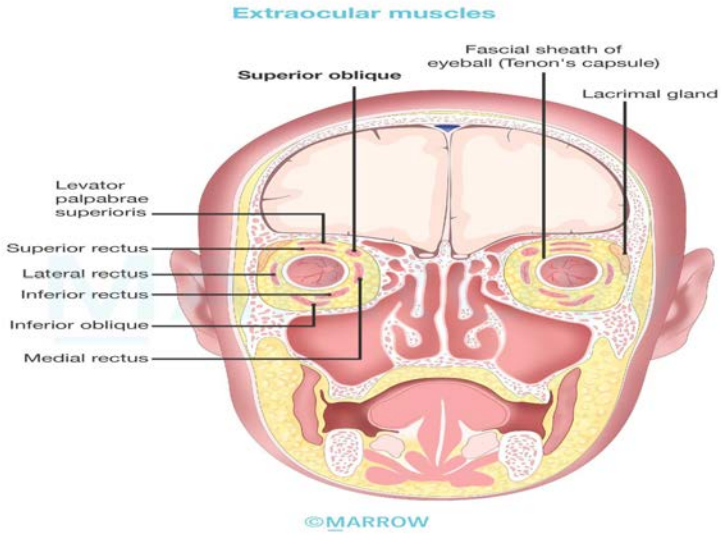
The right ventricle is mostly supplied by the right coronary artery and its branches such as the marginal artery.

The anterior interventricular artery gives off 1-2 anterior right ventricular branches.



Solution to Question 19:

The structure marked in the image is the superior oblique muscle. It is innervated by the trochlear nerve.



There are seven extraocular muscles present in the eye. They are:

• Levator palpebrae superioris - Which elevates the upper eyelids

• Four recti muscles - Superior, inferior, medial, and lateral recti

• Two obliques - Superior and inferior oblique

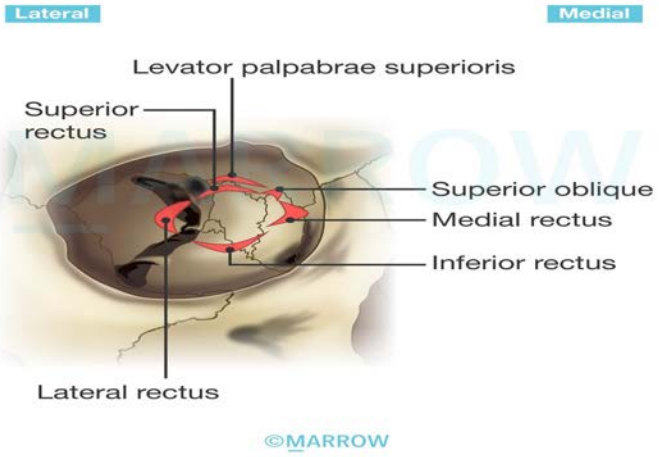
The muscles originate from the back of the orbit in a common tendinous ring called the annulus of Zinn and are inserted into the sclera.

All the extraocular muscles are innervated by the oculomotor (III) nerve except:

• Lateral rectus which is supplied by abducens (VI) nerve

• Superior oblique which is supplied by trochlear (IV) nerve

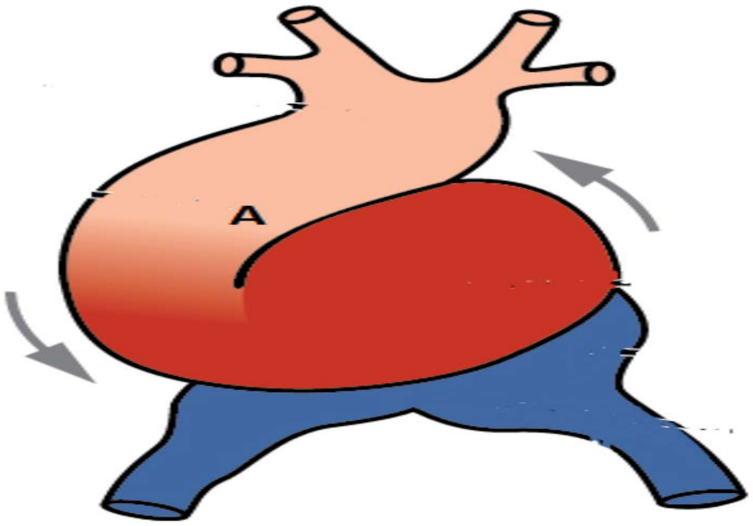
Origin of extraocular muscles in orbit



Anatomy AIIMS 2020 (May and Nov INI-CET)

Question 1:

Given is a model of embryological development of the heart. Which structure develops from the area marked as "A" ?



a) Atria

b) Left Ventricle

c) Infundibulum

d) Interventricular septum

Question 2:

A muscle is attached to the area marked in the given image. What is the action of this muscle on the hip joint?

a) Flexion and medial rotation

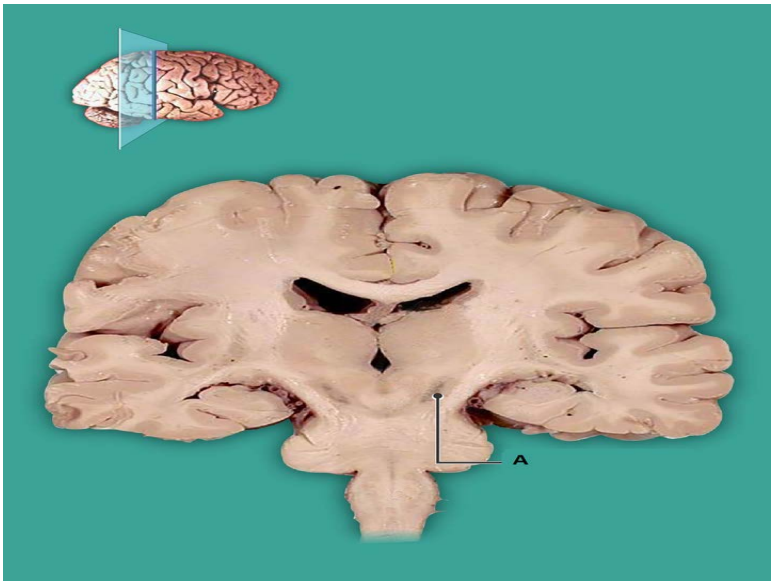
b) Adduction and lateral rotation

c) Abduction and medial rotation

d) Extension and lateral rotation

Question 3:

Neurotransmitter secreted by the area marked in the given image is?



a) Acetylcholine

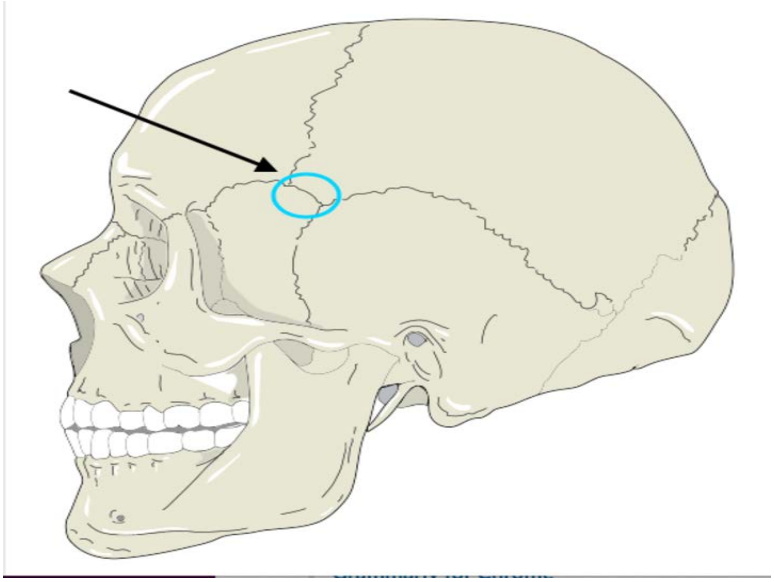
b) Dopamine

c) Glutamine

d) Noradrenaline

Question 4:

Which of the following arteries passes in close proximity to the area marked by the arrow in the given image?



a) Internal carotid artery

b) Middle meningeal artery

c) Anterior cerebral artery

d) Deep temporal artery

Question 5:

Where are the Ito cells in the liver located?

a) Space of disse

b) Space of moll

c) Sinusoids

d) Bile canaliculi

Question 6:

Which of the following features differentiates the exocrine pancreas from the parotid gland?

a) Basal lamina lining the serous acini

b) Absence of striated duct

c) Presence of serous acini with acidophilic tip

d) Presence of apical acinar villi

Question 7:

Medial lemniscus is a continuation of which of the following structures?

a) Spinothalamic tract

b) Spinocerebellar tract

c) Spinotectal tract

d) Fasciculus gracilis

Question 8:

The type of fibers present in the fornix are:

a) Association and commisural fibers

b) Association and projection fibers

c) Commissural and projection fibers

d) Association fibers

Question 9:

Decussation of the superior cerebellar peduncle occurs at which level?

a) Pons

b) Midbrain

c) Diencephalon

d) Medulla

Question 10:

The pretracheal layer of deep cervical fascia encloses all of the following except:

a) Oesophagus

b) Sternocleidomastoid

c) Sternohyoid

d) Thyroid gland

Question 11:

All of the following are the contents of the carotid sheath except?

a) Sympathetic chain

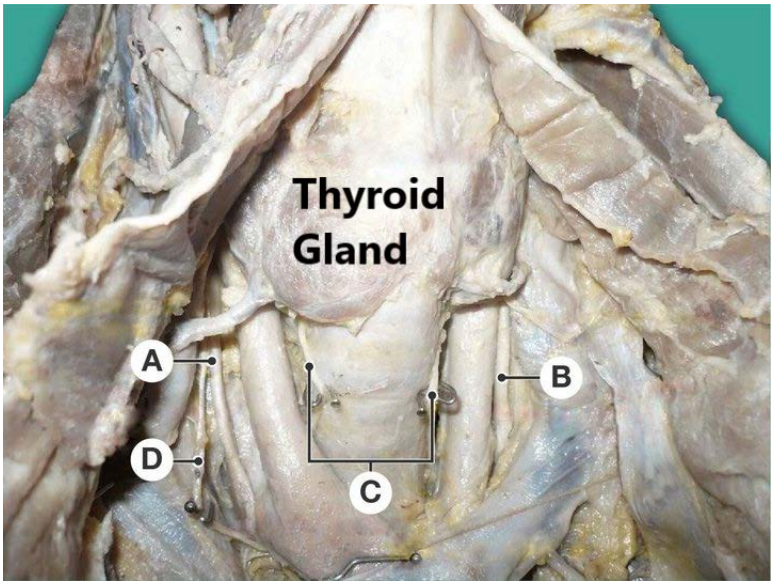
b) Carotid artery

c) Internal jugular vein

d) 10th cranial nerve

Question 12:

A patient presented with paradoxical respiration. Which of the following nerves is most likely to be affected?



a) A

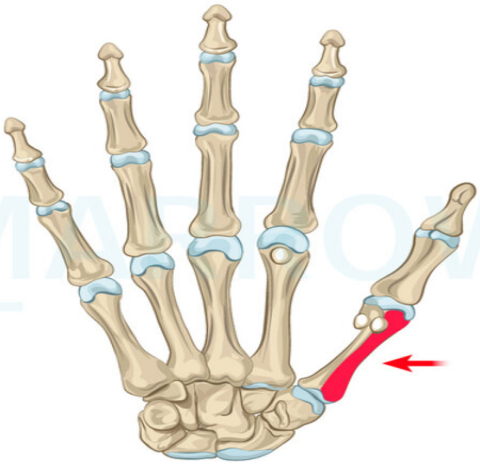
b) B

c) C

d) D

Question 13:

Which of the following muscles is attached to the area marked in the image below?



a) Abductor pollicis longus

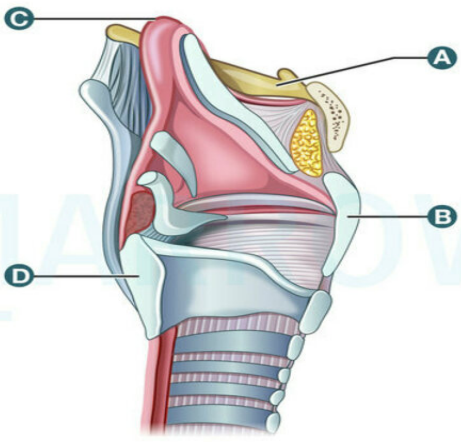
b) Palmar interossei

c) Opponens pollicis

d) Flexor pollicis brevis

Question 14:

Which of the following marked structures does not form part of the laryngeal skeleton?



a) A

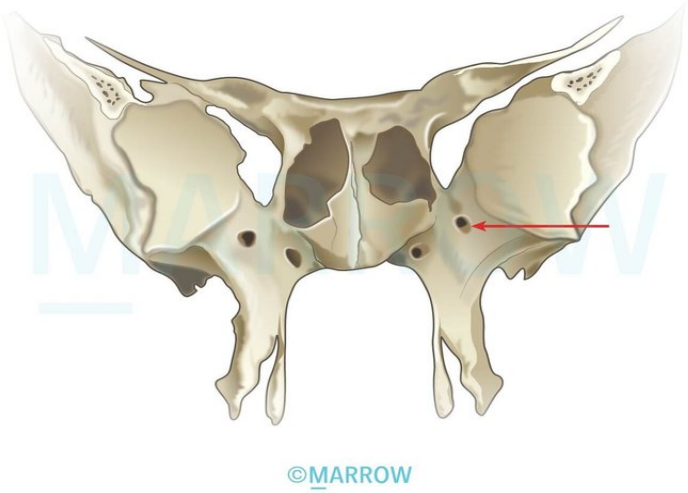
b) B

c) C

d) D

Question 15:

Identify the foramen marked in the image below.



a) Foramen rotundum

b) Foramen ovale

c) Vidian canal

d) Foramen spinosum

Question 16:

Reticular fibres are not present in which of the following structures?

a) Thymus

b) Lymph node

c) Bone marrow

d) Spleen

Question 17:

Which of the following muscles is not involved in the overhead abduction of the arm?

a) Serratus anterior

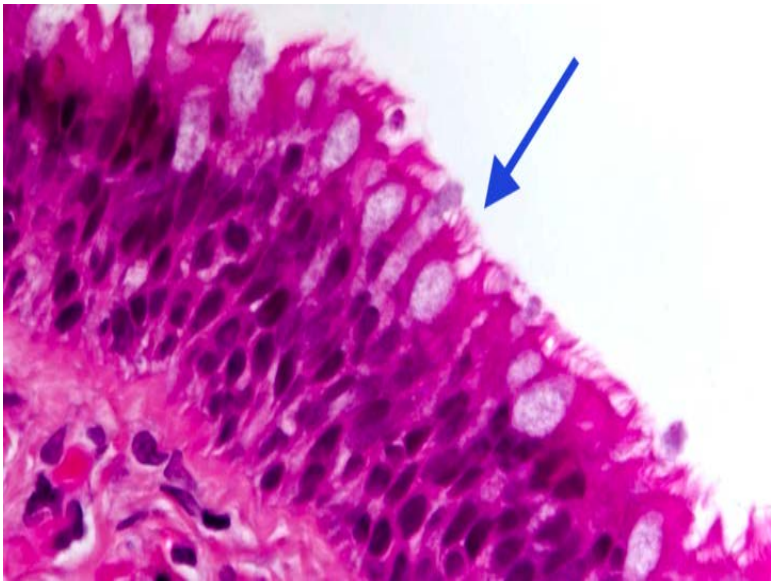
b) Deltoid

c) Trapezius

d) Pectoralis major

Question 18:

The structures marked in the image below are found in the epithelial lining of all of the following sites, except:



a) Oviduct

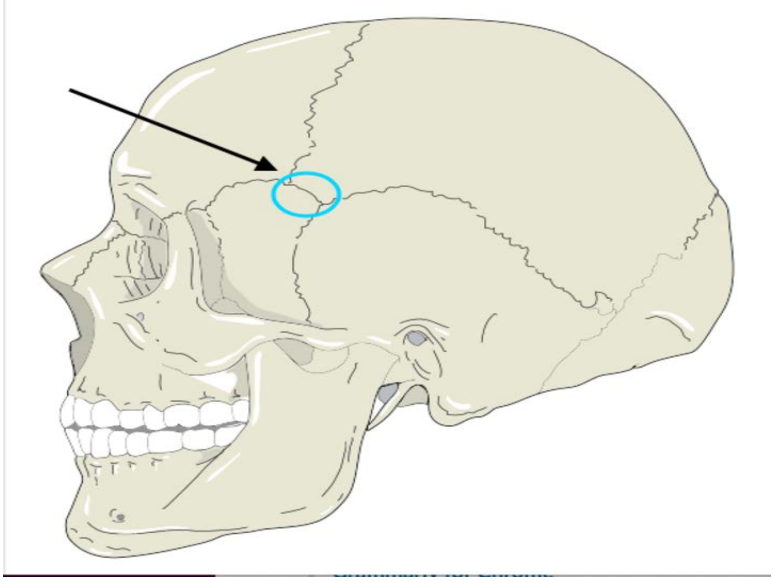
b) Epididymis

c) Bronchi

d) Ependyma

Question 19:

Which of the following bony structures is present behind the marked area?



a) Post clivus

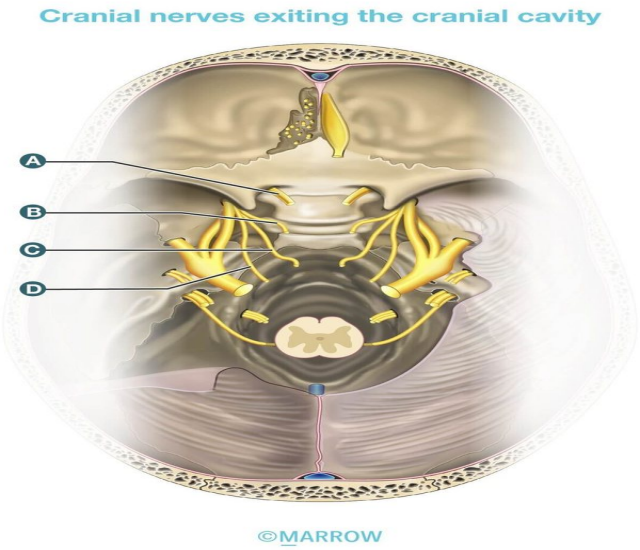
b) Lesser wing of sphenoid

c) Sella turcica

d) Carotid canal

Question 20:

All of the following nerves are involved in the movement of the eyeball except:



a) A

b) B

c) C

d) D

Question 21:

The middle radioulnar joint is an example of a:

a) Plane synovial

b) Primary cartilaginous

c) Secondary cartilaginous

d) Fibrous joint

Question 22:

What is the action of the muscle at the hip, which is attached to the marked area in the image below.

a) Abduction and external rotation

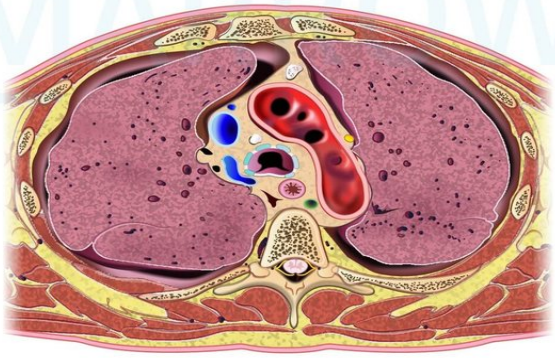
b) Extension and lateral rotation

c) Extension, adduction, and lateral rotation

d) Flexion and abduction

Question 23:

Identify the level of the cross-section shown in the image below.



a) T_1 - T_2

b) T_2 - T_3

c) T_3 - T_4

d) T_4 - T_5

Question 24:

A patient is unable to abduct his arm. Which of the following root values is likely to be affected?

a) C_4

b) C_5

c) C_6

d) C_7

Answer Key

Question No.	Correct Option

Detailed Explanations

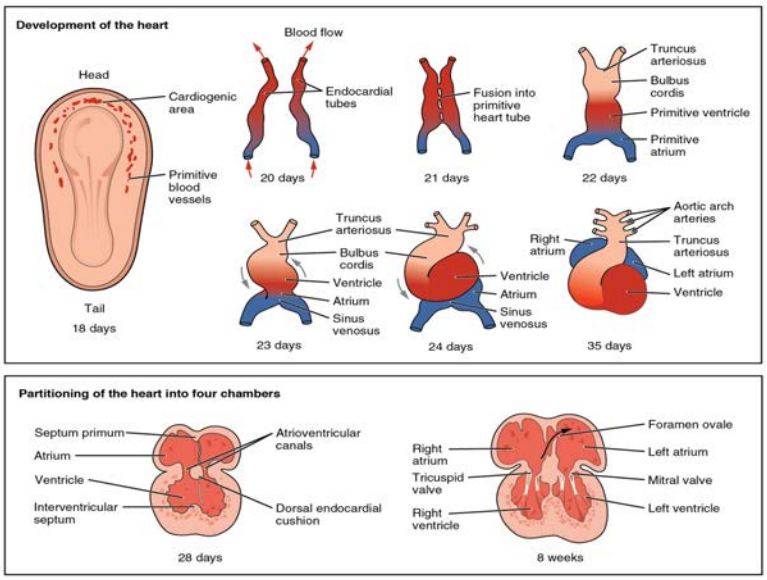
Solution to Question 1:

The structure marked is conus cordis (middle part of bulbus cordis). The infundibulum of the heart develops from this structure.

The model shows the embryologic stage of the heart at which both the heart tubes have fused and are undergoing dextro-looping or bending. This happens around day 23 of intrauterine life.

Heart tube and its derivatives	
Part of the heart tube	Derivative structure in the he art

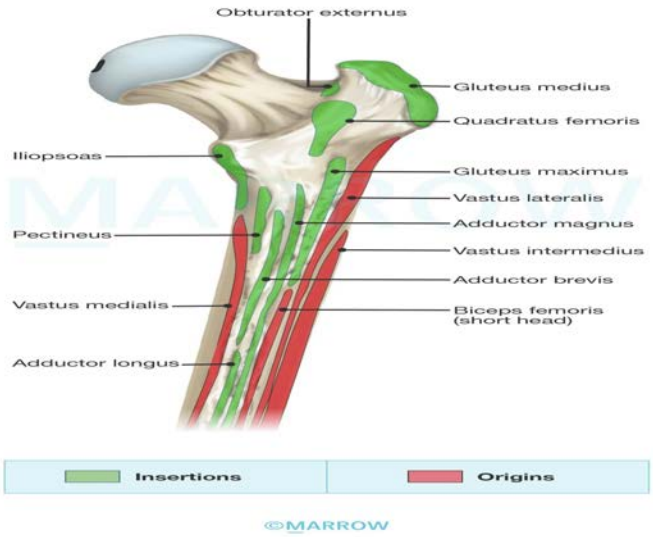
Heart tube and its derivatives	
Bulbus cordisProximal 1/3Middle 1/3 (conus cordis)Distal 1/3 (truncus arteriosus)	Trabeculated part of Rt.ventricleOutflow tract of Rt. and Lt.ventriclesRoot and proximal portions of aorta and pulmonary artery
Primitive ventricle	Trabeculated part of the Lt.ventricle
Primitive atrium	The common atrium that splits to Rt. and Lt.atrium



Solution to Question 2:

The area marked in the given image is the gluteal tuberosity. The muscle that is inserted here is the gluteus maximus which causes extension and lateral rotation of the hip joint.

Gluteus maximus inserts onto iliotibial tract (3/4th part) and deep fibers (1/4th) attach on gluteal tuberosity (marked in image). It is supplied by the inferior gluteal nerve. It is the chief extensor of the lower limb at the hip joint. It additionally also causes lateral rotation, abduction.



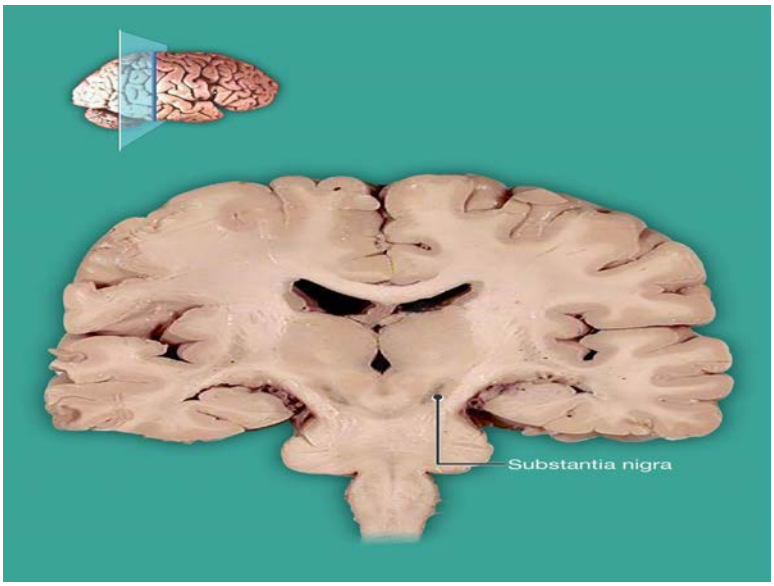
Solution to Question 3:

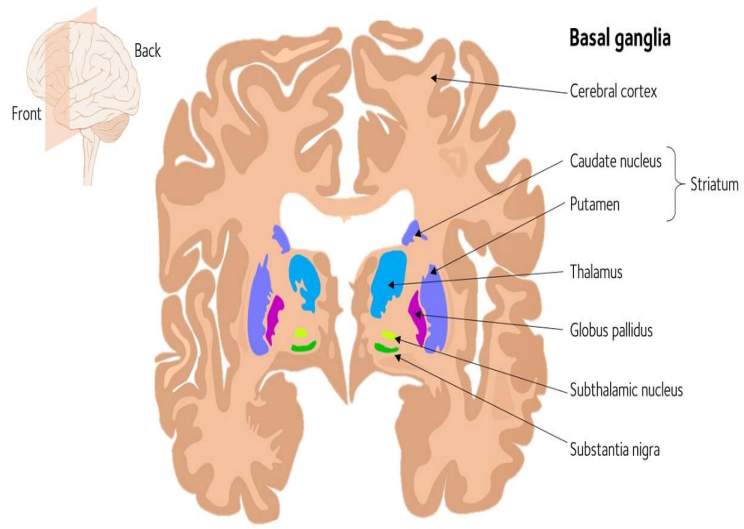
The area marked in the given image is substantia nigra (meaning- dark substance). The neurotransmitter secreted by this area is dopamine.

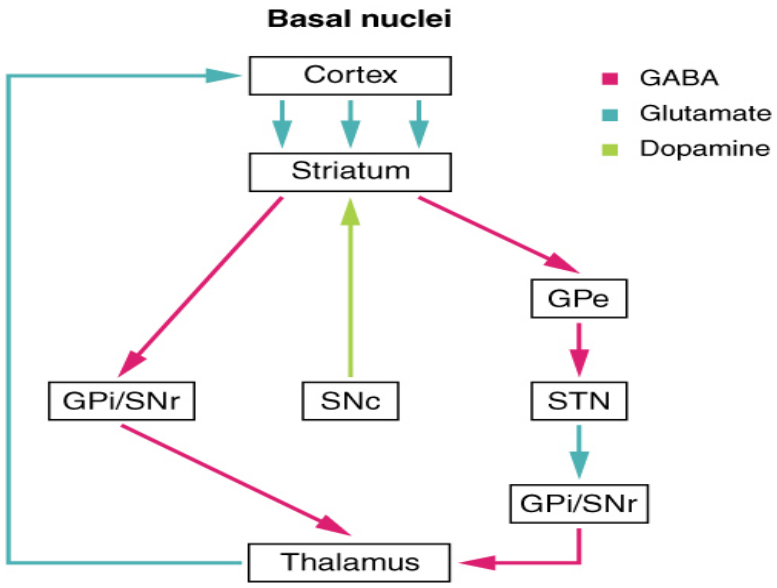
Substantia nigra is a part of the nigrostriatal pathway. Degeneration of dopaminergic neurons is implicated in Parkinson's disease.

Other dopaminergic pathways include:

- Mesocortical
- Mesolimbic
- Tuberoinfundibular







Solution to Question 4:

The area marked by an arrow in the given image is pterion and the artery that passes in close proximity to this area is the middle meningeal artery.

The pterion is an H shaped sutural junction between four bones of the skull:

• Frontal bone

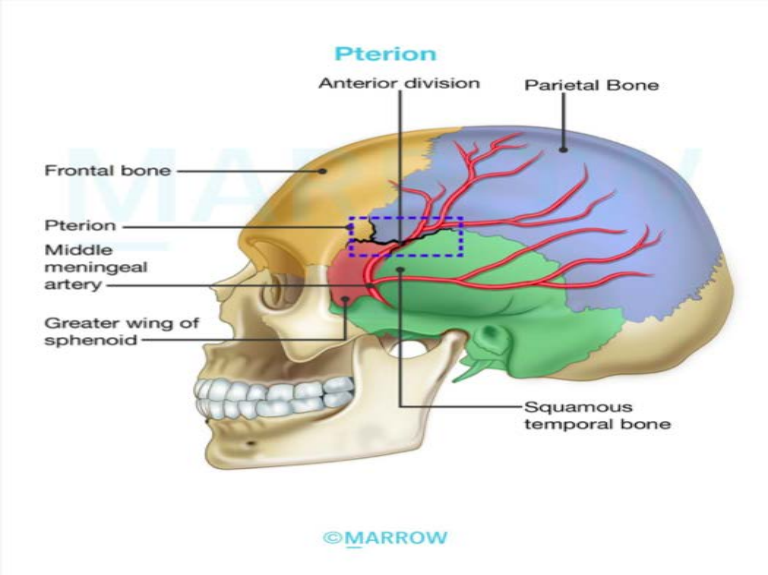
• Squamous part of the temporal bone

• Greater wing of the sphenoid bone

• Parietal bone.

It is an important structure as it overlies the anterior branch of the middle meningeal artery and lateral fissure of the cerebral hemisphere. The bone in this area is thin and any injury to this area

may lead to rupture of the middle meningeal artery leading to extradural hematoma.



Solution to Question 5:

Ito cells/Hepatic stellate cells are located in the space of Disse. They are mesenchymal in origin.

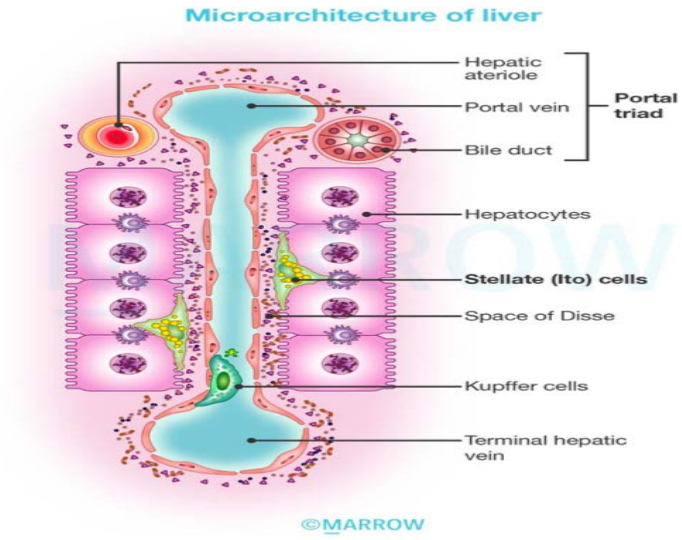
The space of Disse or the perisinusoidal space (or space of Disse) is a location in the liver between hepatocytes and the liver sinusoid.

Significance of Ito cells:

Ito cells are in a dormant state for the majority of the duration. They store the fat-soluble vitamin A in their lipid droplets and are a signi■cant source of growth factors involved in liver homeostasis and regeneration.

When there is liver injury, Ito cells get activated. They replace damaged hepatocytes with collagenous scar tissue and secrete intralobular matrix components, including collagen type III (reticular) ■bres. This leads to hepatic ■brosis.

Note: A narrow space which separates limiting plate (a sleeve of modified hepatocytes) from the connective tissue of the portal area is known as space of moll.



Solution to Question 6:

Absence of striated duct in exocrine pancreas differentiates it from the parotid gland.

The exocrine pancreas is comprised entirely of serous acini. Hence, its general structure is similar to that of the parotid gland, but the two are easily distinguished by:

• The parotid gland has striated and intercalated intralobular ducts, whereas the pancreas has only the intercalated type.

• The excretory ducts of the parotid gland are striated columnar, whereas the excretory duct of the pancreas is a simple columnar.

Solution to Question 7:

Medial lemniscus is a continuation of fasciculus gracilis.

Posterior column–medial lemniscal pathway:

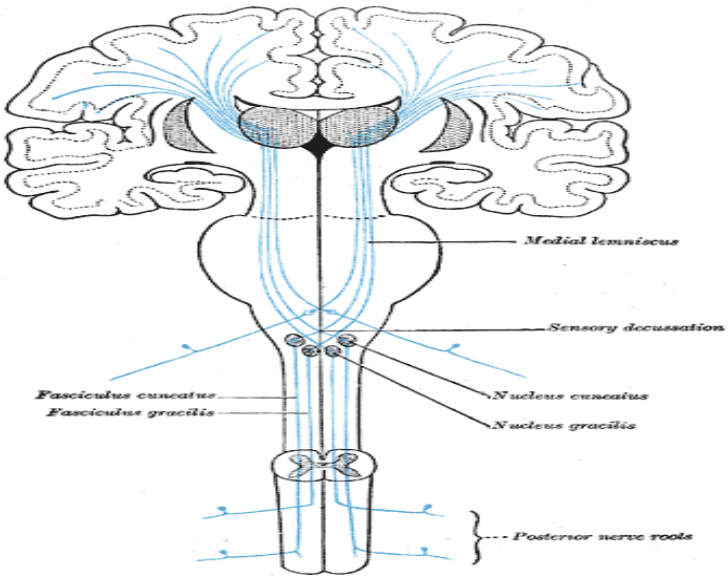
First-order axons carrying discriminative touch and vibration sensations enter the dorsal horn and continue traveling upward in the posterior white column as the fasciculus gracilis and fasciculus cuneatus.

Fibers of these fasciculi synapse on the second-order neurons of the ipsilateral nuclei gracilis and cuneatus in the medulla oblongata, respectively.

Axons of these second-order neurons then cross over as the internal arcuate fibers to form the medial lemniscus in the contralateral medulla.

These second-order axons ascend through the brainstem to reach the third-order neuronal cell bodies in the ventral posterior lateral nucleus of the thalamus. Axons from the third-order neurons then project through the posterior limb of the internal capsule to reach the primary

somatosensory cortex.



Solution to Question 8:

The fibers present in the fornix are association fibers except for the hippocampal commissure of fornix which has commissural fibers. Hence the most appropriate answer is option A. i.e both association and commissural fibers.

Association fibers connect various cortical regions within the same hemisphere whereas commissural fibers connect corresponding regions of two hemispheres.

Fornix arises from the hippocampus and ends in the mamillary body of the hypothalamus. It is supplied by the anterior cerebral artery.

Note: The function of the commissure of the fornix is to connect the hippocampal formations of the two sides.

Solution to Question 9:

The decussation of the superior cerebellar peduncle occurs in the midbrain, at the level of the inferior colliculus.

The midbrain has four decussations:

• At the level of the superior colliculus:

• Ventral tegmental decussation of the rubrospinal tract

• Dorsal tegmental decussation of the tectospinal tract

• At the level of the inferior colliculus:

• Decussation of superior cerebellar peduncles

• Decussation of trochlear nerve

Solution to Question 10:

All the above structures are enclosed by the pretracheal layer of deep cervical fascia except sternocleidomastoid. It is enclosed by the investing layer of deep cervical fascia.

The deep cervical fascia of the neck is organized into the following layers:

• The investing layer, which surrounds all structures in the neck

• The prevertebral layer, which surrounds the vertebral column and the deep muscles associated with the back.

• The pretracheal layer, which encloses the viscera of the neck

• The carotid sheath, which receives a contribution from the other three fascial layers

In the neck, the pretracheal fascia covers the strap muscles i.e sternohyoid, omohyoid, sternothyroid, thyrohyoid. It splits to enclose the thyroid gland. It also surrounds the trachea and the esophagus including the recurrent laryngeal nerve present in the groove between them.

Solution to Question 11:

The sympathetic chain is not the content of the carotid sheath. It lies posterior to the carotid sheath and anterior to the transverse processes of the cervical vertebrae in the neck.

The carotid sheath is a layer of loose connective tissue formed by adjacent portions of the investing layer of deep cervical fascia, the pretracheal fascia, and the prevertebral fascia.

Contents of carotid sheath:

• Common and internal carotid arteries,

• Internal jugular vein,

• Vagus nerve

• Ansa cervicalis

Note: The glossopharyngeal, accessory, and hypoglossal nerves lie within the upper part of the carotid sheath.

Solution to Question 12:

Paradoxical respiration occurs due to the damage of the phrenic nerve, which is marked as D, in the given image.

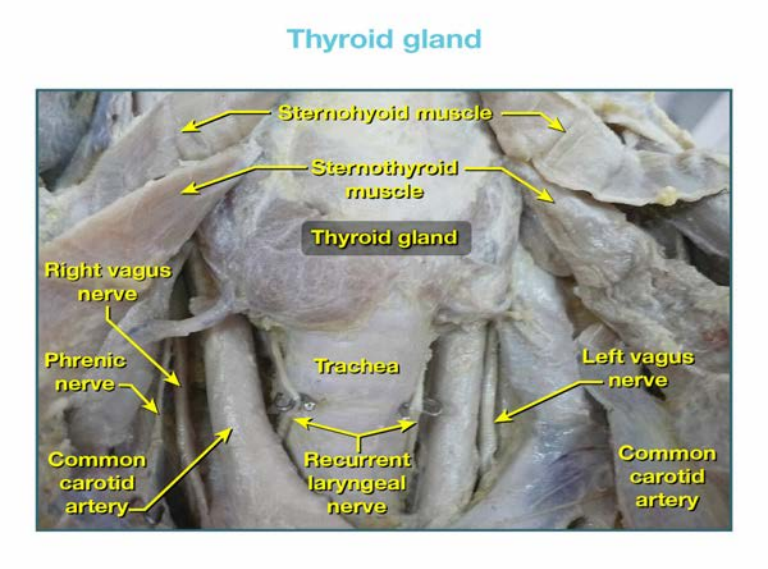
The structures marked in the image are:

A. Right vagus nerve

B. Left vagus nerve

C. Recurrent laryngeal nerve

D. Right phrenic nerve



Paradoxical movements in the chest are as follows:

• Paradoxical respiration - the abnormal movement of the chest wall or abdominal wall, where they move in during inspiration instead of moving out. It is seen in flail chest.

• Paradoxical movement of the diaphragm - normally, the diaphragm moves down during inspiration. However, in cases of phrenic nerve palsy, the affected side of the diaphragm moves upward (paradoxical respiration) due to diaphragmatic paralysis. The gold standard investigation to detect this is the electrical or magnetic stimulation of the phrenic nerve with a recording of the compound muscle action potential and/or the transdiaphragmatic pressure. This can be observed on ultrasound or fluoroscopy.

Solution to Question 13:

The area marked in the image is the palmar aspect of the first metacarpal. The opponens pollicis muscle is inserted at this site.

Opponens pollicis:

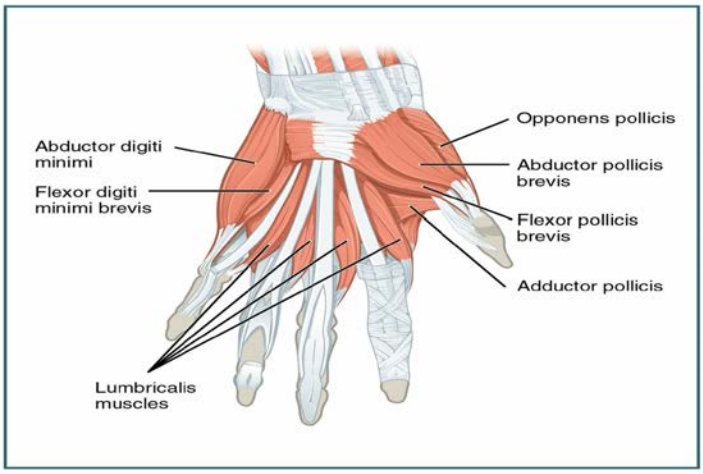
Origin: Tubercle of the trapezium and flexor retinaculum

Insertion: Whole length of the lateral border and adjoining lateral half of the palmar aspect of the first metacarpal.

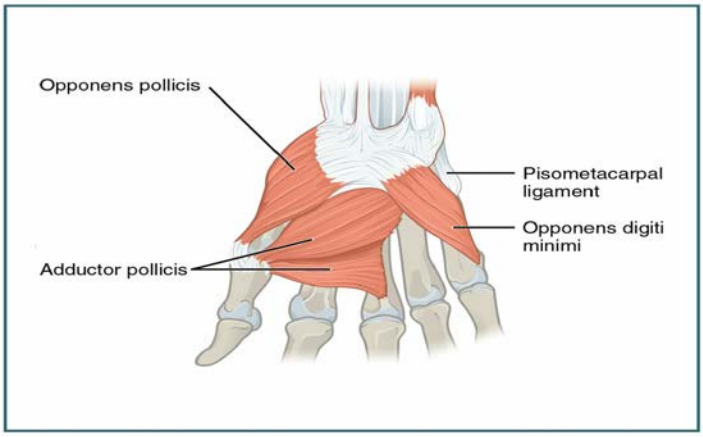
Action: Flexes the metacarpal bone of the thumb.

The image below shows various intrinsic muscles of the hand.

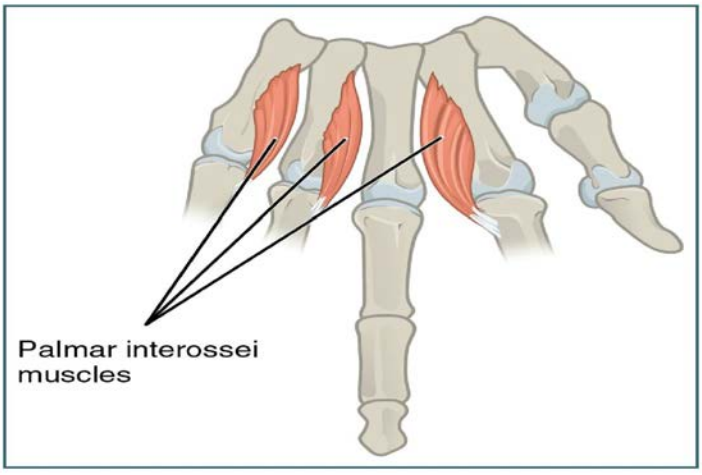
Superficial muscles of the hand (palmar view)

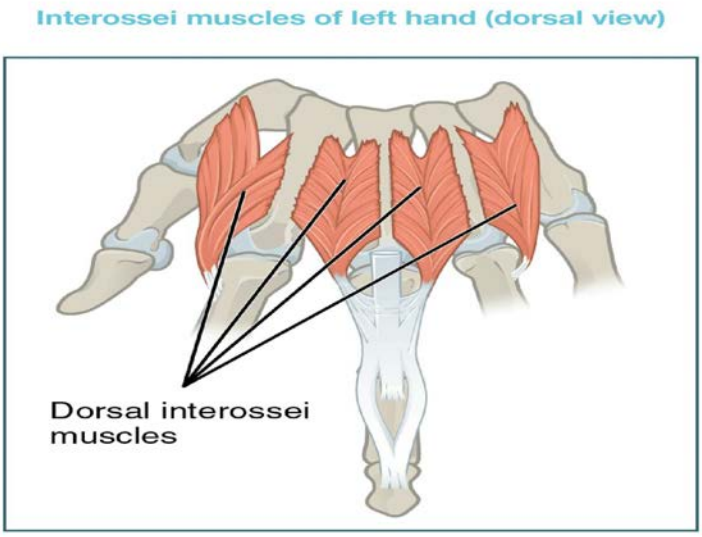


Deep muscles of the hand (palmar view)



Interossei muscles of left hand (palmar view)





Solution to Question 14:

The structure marked as 'A', is the hyoid bone, which is not a part of the laryngeal skeleton.

The structures marked in the image are:

• Hyoid bone

• Thyroid cartilage

• Epiglottis

• Cricoid cartilage

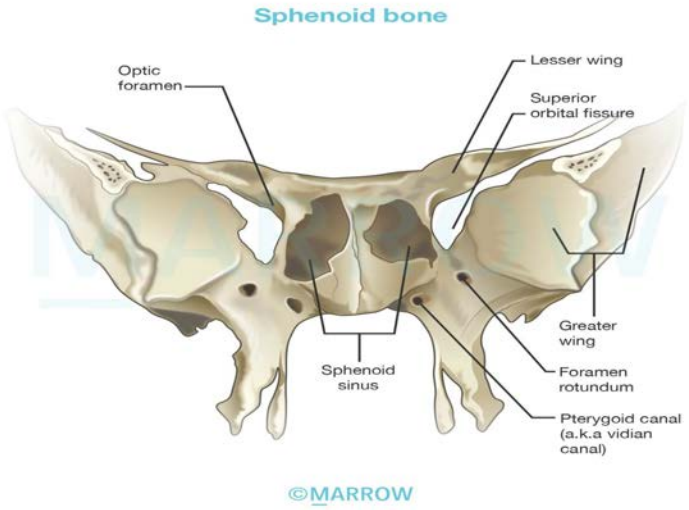
The laryngeal skeleton is formed by a series of cartilages that are connected by ligaments and fibrous membranes:

• The thyroid, cricoid, and the greater part of the arytenoid cartilages consist of hyaline cartilage.

• The corniculate, cuneiform, tritiate, and epiglottic cartilages and the apices of the arytenoid cartilage consist of elastic cartilage.

Solution to Question 15:

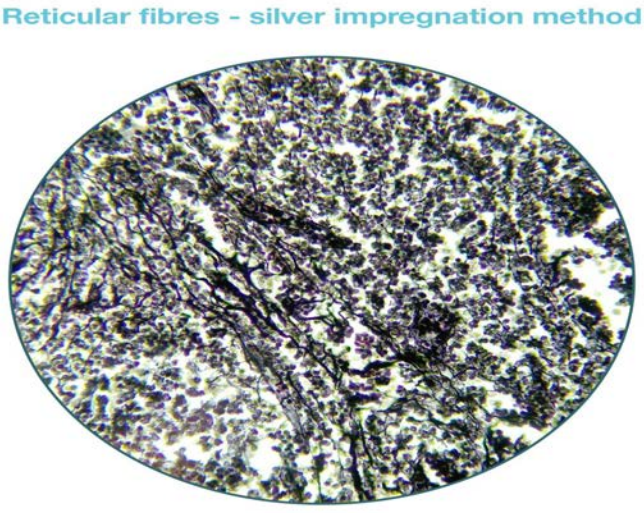
The image shows the sphenoid bone. The foramen marked is the foramen rotundum. Maxillary branch of trigeminal nerve passes through it.



Solution to Question 16:

Reticular fibres are not present in the thymus.

Reticular fibres are fine, anastomosing fibres composed of mainly type III collagen. They differ from type I collagen fibres in that, they are finer and are arranged in the form of a network (reticulum). The fibres appear black in colour on staining with silver impregnation. Due to this affinity to silver salts, they are also known as argentophil fibres.



Reticular fibres are mainly found in:

• All lymphoid organs like spleen, lymph node, and bone marrow (except thymus).

• Glands, liver and kidneys.

• The basement membrane of all epithelia.

• Smooth muscle and nerve cells.

Solution to Question 17:

Pectoralis major is mainly involved in adduction and medial rotation of the arm and is not involved in the abduction of the arm.

Glenohumeral abduction is about 120° or more. The glenohumeral arthrodesis restricts the abduction at about 45°. Further abduction occurs at the sterno and acromioclavicular articulations, and contralateral vertebral flexion.

Muscles involved in the abduction of the shoulder:

• The first 15° of abduction is initiated by the supraspinatus muscle.

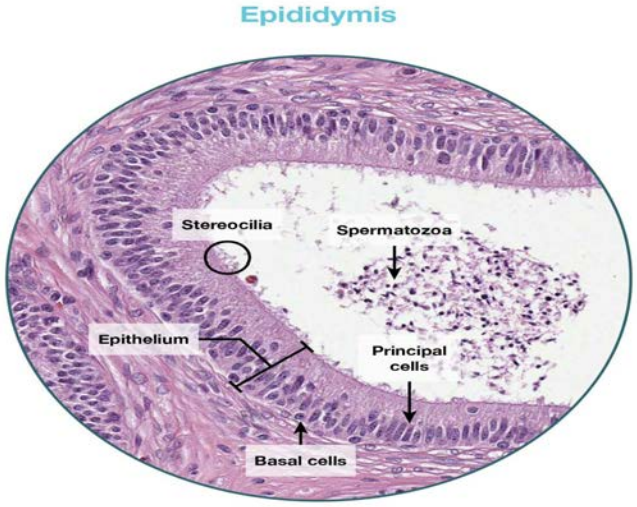
• 15° to 90° of abduction is carried out mainly by the middle fibers of the deltoid muscle.

• Abduction of the arm, beyond 90°, is carried out by the movement of the shoulder girdle caused by the action of trapezius and serratus anterior.

Solution to Question 18:

The image shows an arrow mark pointing towards the cilia. All the structures given in the options have a ciliated lining epithelium except epididymis, which is lined by pseudostratified columnar epithelium with stereocilia.

The given image is a histological section of the epididymis showing the pseudostratified columnar epithelium with stereocilia.



Cilia are minute hair-like projections, while stereocilia are very long, thick microvilli measuring about 5–10 μm in length.

Ciliated epithelium:

• The epithelium bears cilia, which moves in a coordinated fashion, and help in the movement of the mucus, or propel the movement of any other structures such as ova or spermatozoa.

• The ciliated columnar epithelium is found in most of the respiratory tract, the uterus, and the uterine tube (oviduct), efferent ductules of the testis, parts of the middle ear and auditory tube; the ependyma lining the central canal of the spinal cord and the ventricles of the brain.

• The pseudostratified ciliated columnar epithelium is seen in the trachea and in large bronchi.

Solution to Question 19:

The structure marked in the image is pterion, and the bony structure that is present behind it is the lesser wing of the sphenoid.

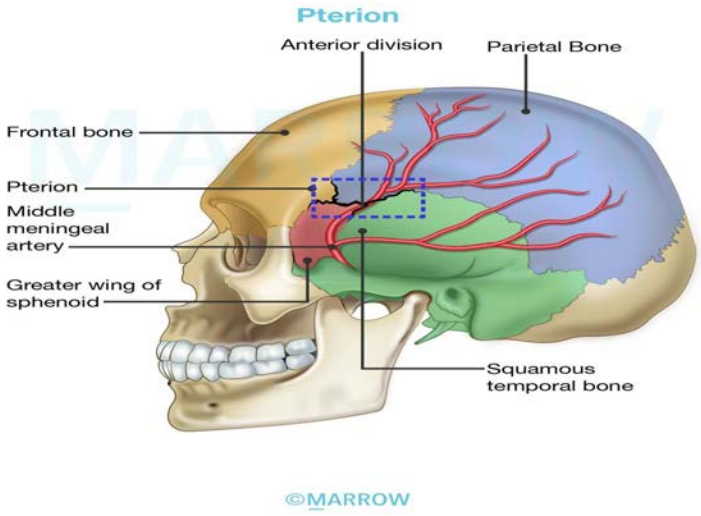
The pterion is an H-shaped sutural junction between four bones of the skull:

• Frontal bone

• Squamous part of the temporal bone

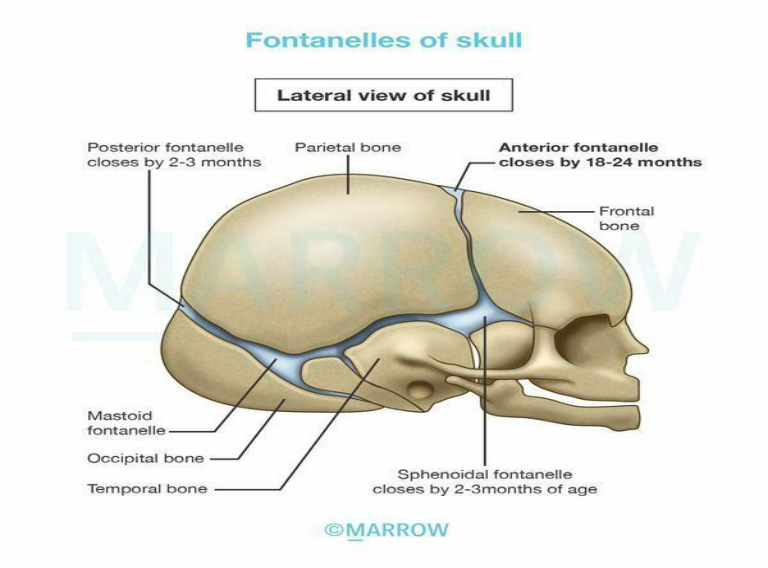
• Greater wing of the sphenoid bone

• Parietal bone



The pterion overlies the anterior branch of the middle meningeal artery and lateral fissure of the cerebral hemisphere. The bone in this area is thin and any injury to this area may lead to rupture of the middle meningeal artery leading to extradural hematoma.

The pterion also corresponds to the site of the anterolateral (sphenoidal) fontanelle of the neonatal skull, which closes in the third month after birth.



Solution to Question 20:

The nerve marked as 'A' is the optic nerve (II CN), and is not involved in the movement of the eyeball.

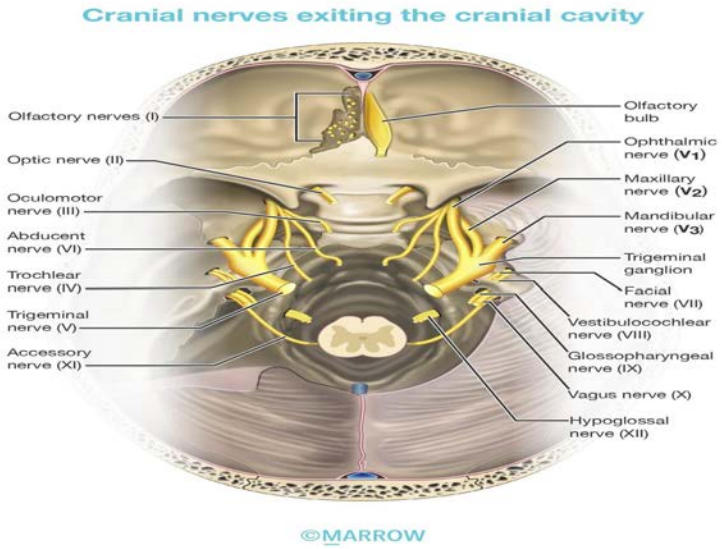
The nerves marked in the image are:

• Optic nerve (II CN)

• Oculomotor nerve (III CN)

• Abducens nerve (VI CN)

• Trochlear nerve (IV CN)



Extraocular muscles involved in the movement of the eyeball:

• Superior rectus, inferior rectus, medial rectus, inferior oblique, and levator palpebrae superioris muscles - supplied by the oculomotor (III) nerve.

• Lateral rectus - supplied by abducens (VI) nerve.

• Superior oblique - supplied by trochlear (IV) nerve.

Solution to Question 21:

The middle radioulnar joint is an example of a fibrous joint (syndesmosis).

The radius and ulna are united with each other by three joints:

• Proximal (superior) radioulnar joint

• Middle radioulnar joint

• Distal (inferior) radioulnar joint

Proximal and distal radioulnar joints are uniaxial pivot joints (synovial) and are involved in pronation and supination movements of the forearm.

The middle radioulnar joint is a fibrous joint (syndesmosis). The radius and ulna, in the middle, are connected by two syndesmoses namely:

• The oblique cord - extends from the lateral side of the ulnar tuberosity to the radius, distal to the radial tuberosity.

• Interosseous membrane - a broad, thin collagenous structure, which runs perpendicular to the oblique cord. It extends distomedially between the interosseous borders of the radius and ulna.

Based on the structure, joints are classified into three types:

• Fibrous joints

• Sutures

• Syndesmosis

• Gomphosis

• Cartilaginous joints

• Primary cartilaginous joints or synchondrosis

• Secondary cartilaginous joints or symphysis

• Synovial joints

• Ball-and-socket or spheroidal joints

• Sellar or saddle joints

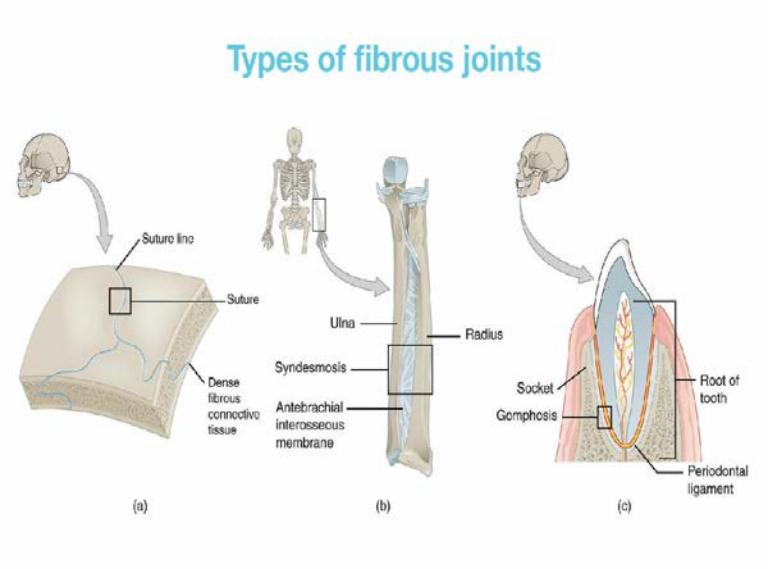
• Condylar or bicondylar joints

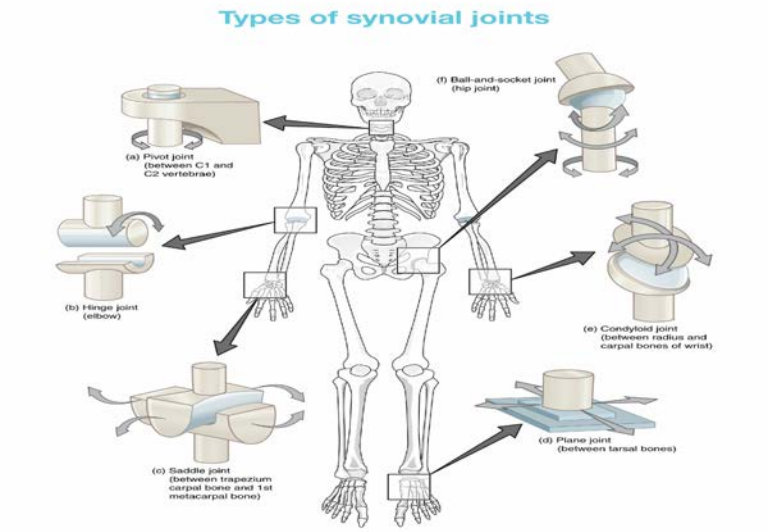
• Ellipsoid joints

• Hinge joints

• Pivot or trochoid joints

• Plane joints





Solution to Question 22:

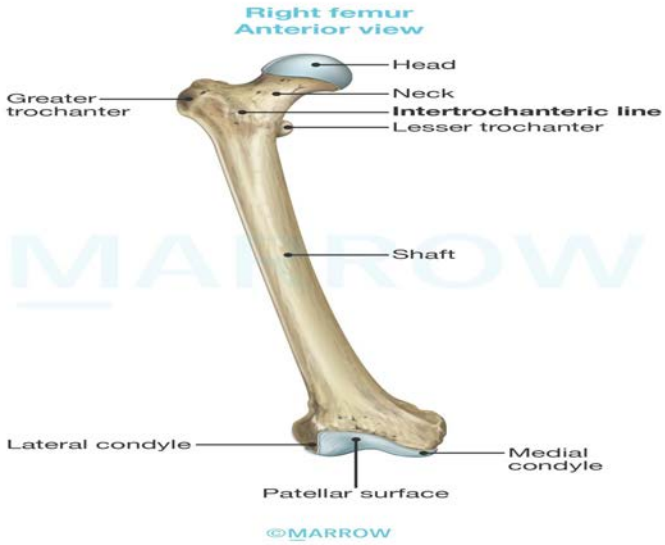
The image shows the posterior surface of the femur, and the structure marked is gluteal tuberosity, to which the gluteus maximus muscle is attached. It causes extension and lateral rotation at the hip joint.

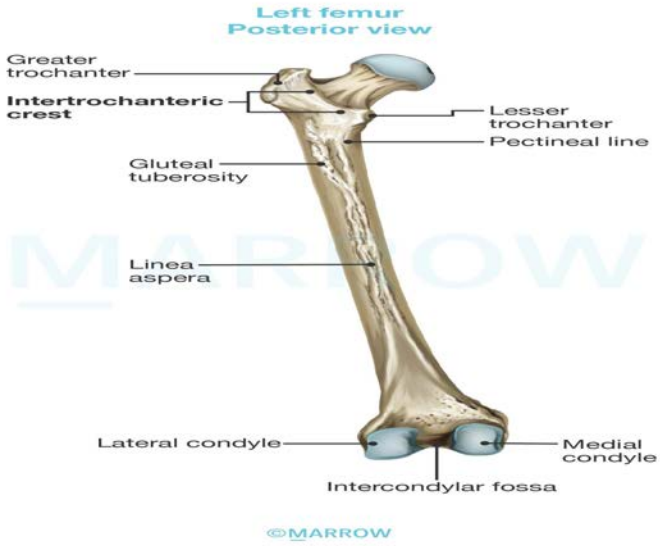
The femur can be divided into:

• The proximal femur - Consists of the head, neck, greater and lesser trochanters. The intertrochanteric line is present on the anterior surface at the junction of the neck and shaft of the femur while the intertrochanteric crest is present on the posterior surface.

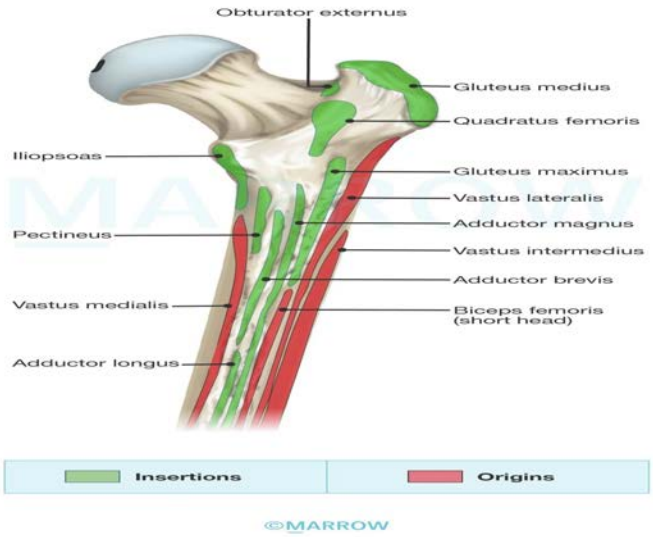
• The shaft of the femur - Consists of linea aspera (bony crest present on the posterior surface), gluteal tuberosity, and pectineal line

• The distal femur - Consists of the medial condyle, lateral condyle, intercondylar fossa, and patellar surface





The image below shows attachments of various muscles over the posterior surface of the right femur.



Gluteus maximus muscle:

Origin:

• Posterior aspect of the dorsal ilium, posterior to the posterior gluteal line

• Posterior superior iliac spine

• Posterior aspect of sacrum and coccyx

• Sacrotuberous ligament.

Insertion - It is inserted mainly in fascia lata at the iliotibial band and also into the gluteal tuberosity on the posterior femoral surface.

Action:

• Major extensor of the hip joint

• Lateral rotation of the hip joint

• Active in powerful abduction of the thigh

Arterial Supply - Inferior and superior gluteal arteries and the first perforating branch of the profunda femoris artery.

Nerve Supply- Inferior gluteal nerve (L5, S1 and S2).

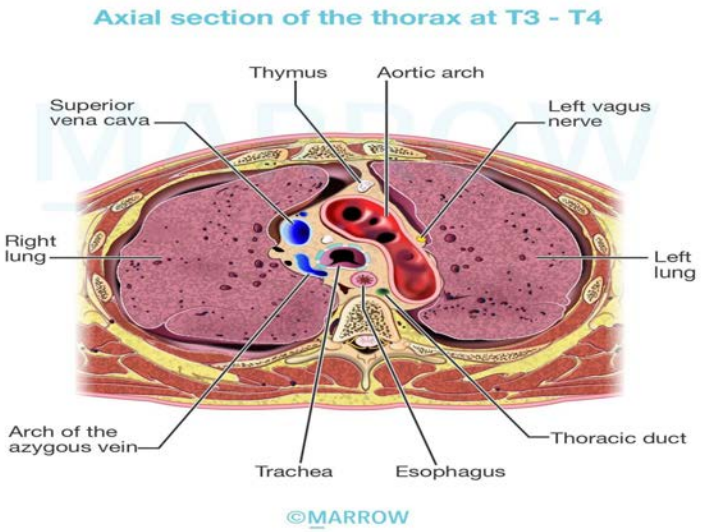
Solution to Question 23:

The cross-section shown in the image is at the level of T3-T4.

The cross-section shows a large vascular opening of the arch of the aorta, along with three small openings corresponding to the brachiocephalic trunk, left common carotid artery and left subclavian artery. This suggests that the section was taken at the level between T3 and T4.

Options A, B: In cross-sections at the levels of T1-T2 and T2-T3, only the small vascular openings of the branches arising from the arch of aorta would be visible.

Option D: In cross-section at the level of T4-T5, where, the arch of the aorta begins and ends, bifurcation of the pulmonary trunk is visible.



Solution to Question 24:

The inability to abduct the arm is most likely due to a lesion of the C5 root.

The deltoid muscle is the main muscle involved in the abduction of the arm. It is innervated by the C5 root of the axillary nerve. So, a lesion involving the C5 causes inability to abduct the arm.

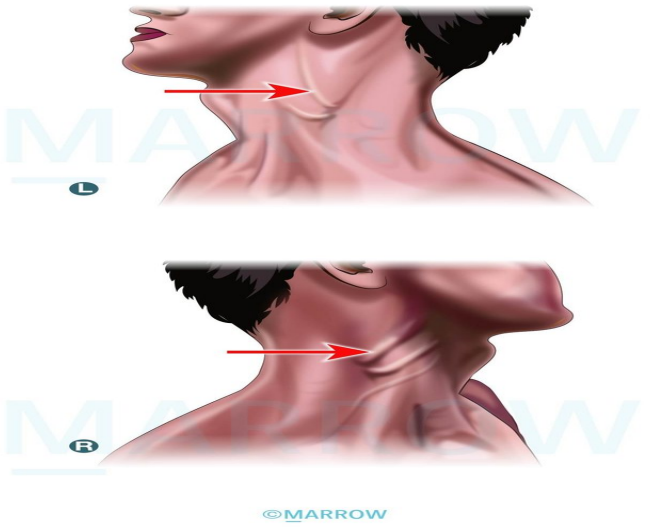
The table below shows the movements and muscles tested to determine the location of the lesion in the upper limb.

Arm movement	Muscle	Root	Nerve
Shoulder abduction	Deltoid	C5	Axillary
Elbow extension	Triceps	C7	Radial
Elbow flexion	BicepsBrachioradialis	C5/6 C6	MusculocutaneousRadial
Radial wrist extensor	Extensor carpi radialis longus	C6	Radial
Finger extensors	Extensor digitorum	C7	Posterior interosseus
Finger flexors	Flexor pollicis longus and flexor digitorum profundus, index Flexor digitorum profundus, ring and little	C8C8	Anterior interosseousUlnar
Finger abduction	First dorsal interosseusAbductor pollicis brevis	T1T1	UlnarMedian

Anatomy NEET 2018

Question 1:

Identify the thickened nerve marked in the arrow in the image shown below:



a) Great auricular nerve

b) Lesser occipital nerve

c) Facial nerve

d) Auriculotemporal nerve

Question 2:

Broca's area is situated in the _____.

a) Inferior frontal gyrus

b) Superior temporal gyrus

c) Angular gyrus

d) Postcentral gyrus

Question 3:

Which of the following cranial nerve nuclei is not a part of the special visceral afferent (SVA) column?

a) Facial nerve

b) Trochlear nerve

c) Vagus nerve

d) Glossopharyngeal nerve

Question 4:

The joint between the attachment of the 8th and 9th rib to the 7th rib is a:

a) Fibrocartilaginous joint

b) Symphyseal joint

c) Synovial joint

d) Fibrous joint

Question 5:

Which is the last fontanelle to close?

a) Anterior

b) Posterior

c) Occipital

d) Mastoid

Question 6:

Which among the following is incorrect regarding Sibsons's fascia?

a) Attached to the inner border of 2nd rib

b) Covers apical part of lung

c) Part of scalenus minimus muscle

d) Vessels pass above the fascia

Question 7:

The structure not passing through the aortic opening of the diaphragm is:

a) Aorta

b) Azygous vein

c) Thoracic duct

d) Vagal trunk

Question 8:

The hard palate contains _____

a) Keratinised epithelium, submucosa, minor salivary glands

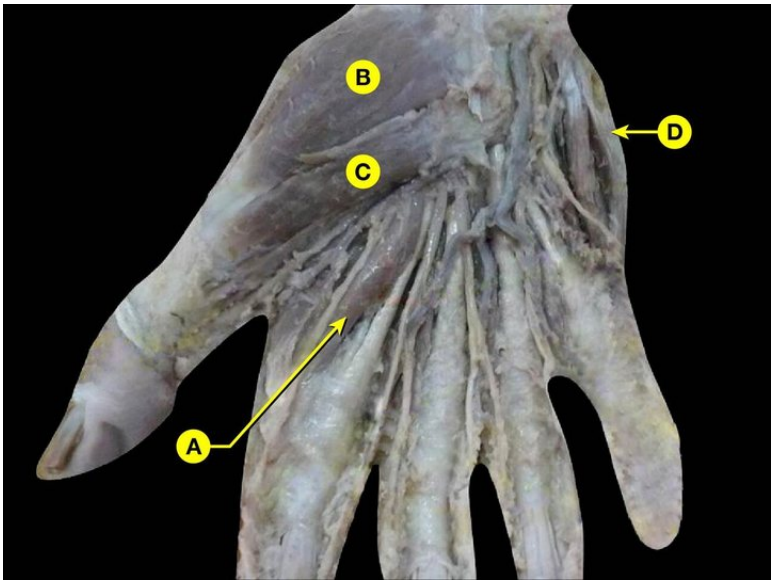
b) Keratinised epithelium, absent submucosa, no salivary glands

c) Non-keratinised epithelium, submucosa, minor salivary glands

d) Non-keratinised epithelium , absent submucosa, minor salivary glands

Question 9:

What is the function of the muscle marked as A in the image below, at the metacarpophalangeal joint?



a) Flexion

b) Extension

c) Adduction

d) Abduction

Question 10:

Which among the following is a tensor of vocal cords?

a) Cricothyroid

b) Lateral cricoarytenoid

c) Thyroarytenoids

d) Posterior cricoarytenoids

Question 11:

The nerve of the second branchial arch is:

a) Glossopharyngeal nerve

b) Trigeminal nerve

c) Facial nerve

d) Vagal nerve

Question 12:

Which of the following statements is true about the iliopubic tract?

a) It is a thickening of the lumbar fascia

b) It lies anterior to the Poupart's ligament

c) It inserts into the pubic tubercle in front of the conjoint tendon

d) Its fibers fan out with fascia iliaca laterally

Question 13:

Ureteric bud develops from:

a) Mesonephric duct

b) Metanephros

c) Pronephros

d) Genital sinus

Question 14:

The heart starts to beat in the _____week of development.

a) 2nd week

b) 4th week

c) 6th week

d) 10th week

Answer Key

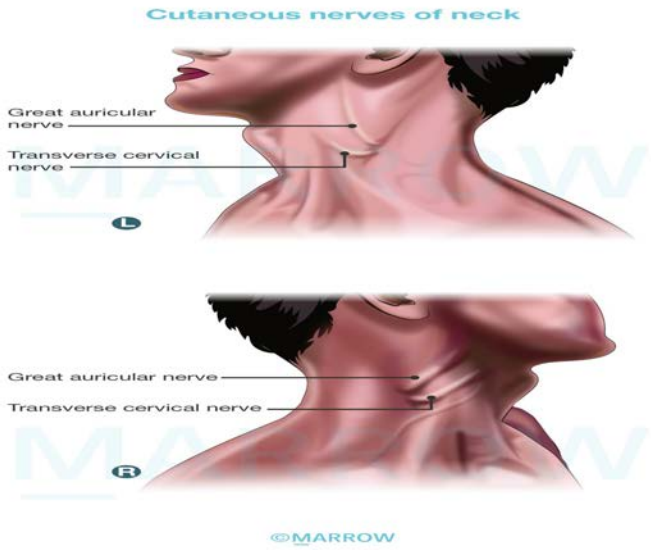
Question No.	Correct Option
1	a
2	a
3	b
4	c
5	a
6	a
7	d
8	a
9	a
10	a
11	c
12	d
13	a
14	b

Detailed Explanations

Solution to Question 1:

The thickened nerve marked with the arrow in the above image is the great auricular nerve and the thickened nerve visible below the great auricular nerve is the transverse cervical nerve.

Nerve thickening in this case is likely to be due to leprosy.



Great auricular nerve:

It is the largest ascending branch of cervical plexus and arises from the second and the third cervical spinal nerves.

It winds over the posterior border of the sternocleidomastoid muscle and ascends upwards. On reaching the parotid gland it divides into the anterior and posterior branches:

• Anterior branch - supplies the facial skin over the parotid gland and joins the facial nerve in the gland.

• Posterior branch - supplies the skin over the mastoid process, posteroinferior part of the auricle, lobule, and concha.

Clinical considerations:

• Leprosy - Nerve thickening is present. The nerve is palpable over the upper part of the sternocleidomastoid muscle. (as seen in the above image)

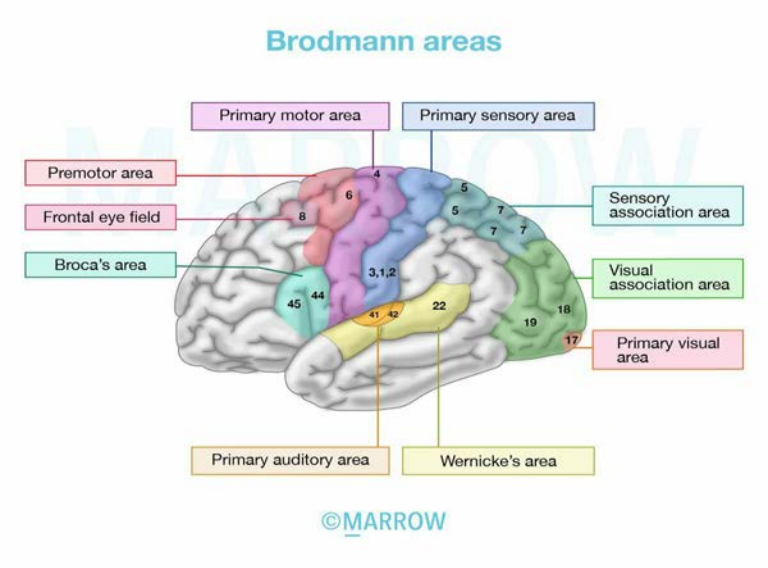
• Frey's syndrome - An aberrant connection between the auriculotemporal nerve and great auricular nerve causes gustatory sweating.

Solution to Question 2:

Broca’s area is situated in the inferior frontal gyrus.

Broca’s motor speech area (44,45) is located in the inferior frontal gyrus.

Wernicke’s area (22) is located in the superior temporal gyrus.

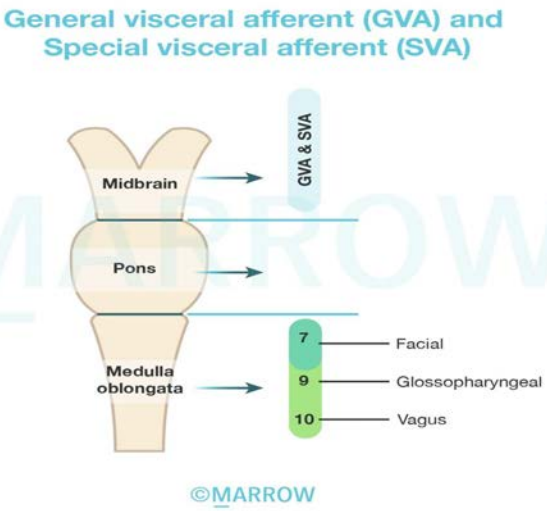


Solution to Question 3:

The trochlear nerve nucleus is a part of the general somatic efferent (GSE) column, not the special visceral afferent column.

The trochlear nerve is a motor nerve that innervates superior oblique muscle in the orbit.

The neurons of the general somatic efferent (GSE) column innervate the extrinsic ocular muscles and muscles of the tongue (III, IV, VI, and XII cranial nerves).



Solution to Question 4:

The interchondral joint between the attachment of the 8th and 9th rib with the 7th rib is a synovial joint.

Joints in the thoracic cavity are of the following types:

• Synarthrosis - structures are connected by a fibrous band of tissue. E.g, 1st sternocostal joint

• Synchondrosis - primary cartilaginous joints. E.g., costochondral joints

• Symphysis - secondary cartilaginous joints. E.g. manubriosternal and xiphisternal joints

• Synovial joints - the presence of these help the thoracic cavity expand during inspiration. E.g.:

• Interchondral joint

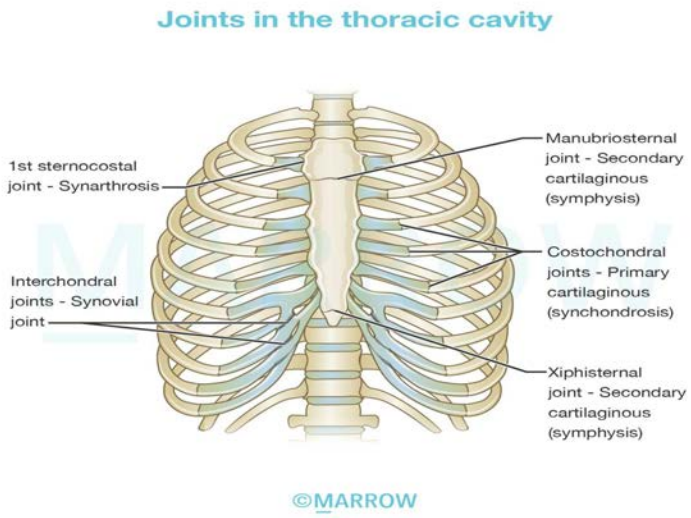
• Sternocostal joint

• Costovertebral joint

• Costotransverse joint

Note:

The interchondral joint between the 9th and 10th cartilages is never synovial and sometimes absent.



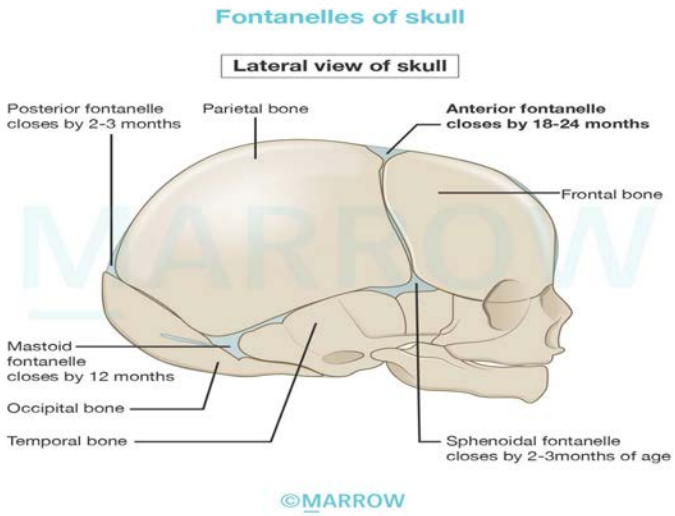
Solution to Question 5:

The anterior fontanelle is the last fontanelle to close. It closes at around 18-24 months of age.

Fontanelles of the skull:

Fontanelle	Location	Closes at
Anterior	Between frontal and parietal bonesJunction marked by br egma	18-24 months

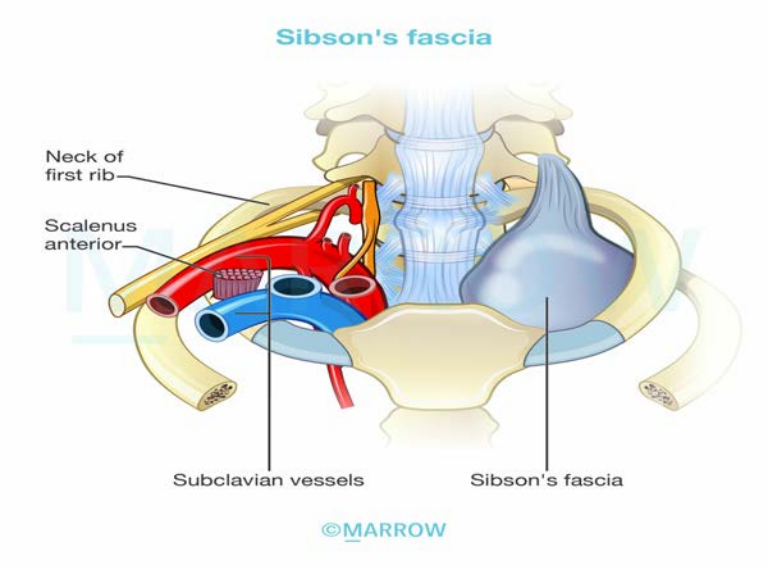
Fontanelle	Location	Closes at
Posterior	Sagittal and lambdoid sutures	2-3 months
Sphenoid	Pterion	2-3 months
Mastoid/Posterolateral	Intersection of temporal, parietal, and occipital bones.	6-18 months (average 12 months)



Solution to Question 6:

Sibson’s fascia is attached to the inner border of the 1st rib, not the 2nd rib.

Sibson's fascia (suprapleural membrane) serves as a plane of separation between the lower neck and the thorax and covers the apical part of the lung. It is attached to the inner border of the 1st rib and posteriorly to the anterior border of the transverse process of the C7 vertebra. It is strengthened by a few spreading muscular fibers derived from the scalene muscles. The subclavian vessels lie on top of it.



Solution to Question 7:

The vagal trunk does not pass through the aortic opening of the diaphragm.

It passes through the esophageal opening at the level of T10 vertebra.

Solution to Question 8:

The hard palate contains keratinised stratified squamous epithelium, has a submucosa, and contains minor salivary gland. This keratinised stratified squamous epithelium has regional variations and may be orthokeratinised or parakeratinised(found in hard palate and gingiva).

The bony structure of the hard palate is covered by a firmly attached mucosa in the central part. In the lateral parts, the hard palate also has a submucosal layer containing blood vessels. There are minor mucous type salivary glands in the submucosa in the posterior part of the hard palate.

(Note: In the orthokeratinized epithelium the cell nuclei disappear in the keratinized layer, whereas in the parakeratinized epithelium flattened, highly condensed nuclei remain in the cell cytoplasm of the keratinized layer until exfoliation)

Solution to Question 9:

The muscle marked 'A' is lumbricals and they cause flexion at the metacarpophalangeal joints.

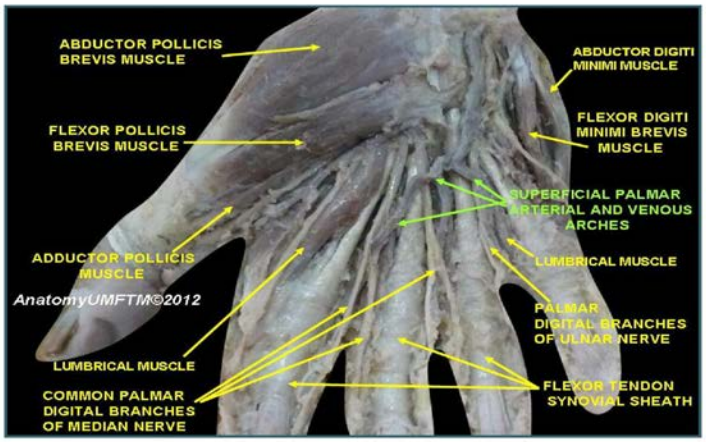
Lumbricals are intrinsic muscles of the hand that flex the metacarpophalangeal joints (MCP) and extend the interphalangeal joints (PIP & DIP).

They originate from flexor digitorum profundus.

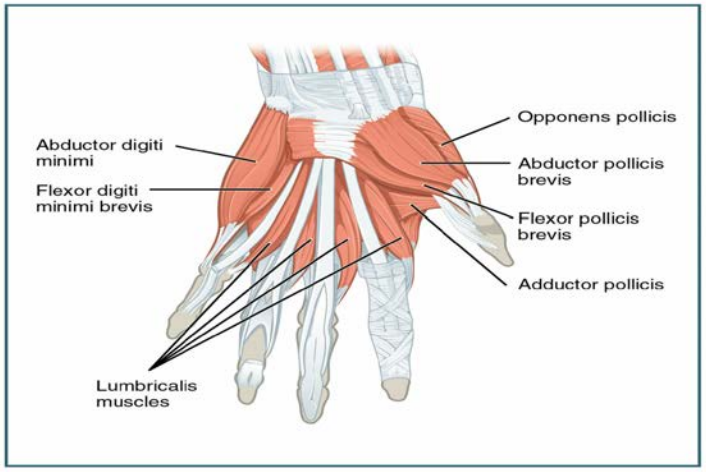
• The lateral two are unipennate, supplied by the median nerve.

• The medial two are bipinnate, supplied by the ulnar nerve.

Superficial muscles of the hand



Superficial muscles of the hand (palmar view)



Solution to Question 10:

Cricothyroid is a tensor of vocal cords.

Solution to Question 11:

The facial nerve is the nerve of the 2nd pharyngeal arch.

Each pharyngeal arch is characterized by its own muscular components. The muscular components of each arch have their own cranial nerve. Wherever the muscle cells migrate, they carry their nerve component with them.

The neurons of the 5th, 7th, 9th, and 10th cranial sensory ganglia that supply the pharyngeal arch structures are derived from ectodermal placodes (epipharyngeal placodes) and from the neural crest cells.

Solution to Question 12:

The fibers of the iliopubic tract fan out with fascia iliaca laterally.

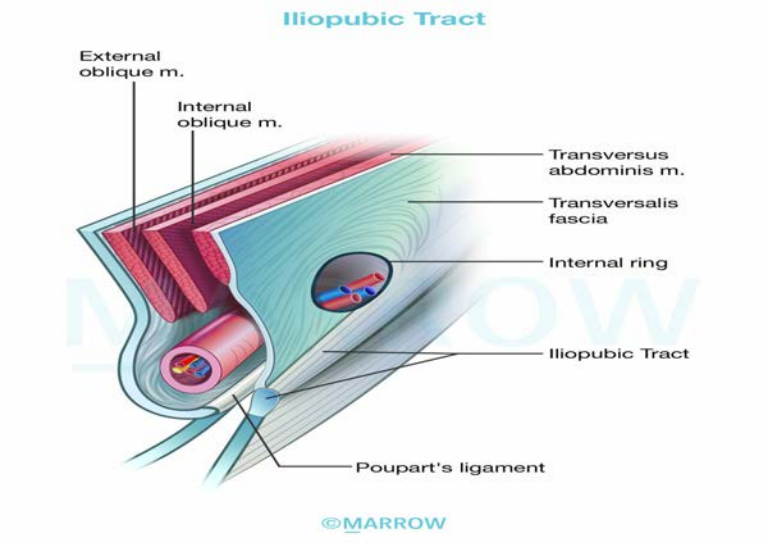
The iliopubic tract is a thickening of the transversalis fascia lying immediately posterior to the inguinal (Poupart's) ligament. It extends from the anterior superior iliac spine (ASIS) superolaterally and arches across the front of the femoral sheath.

Attachments:

• Medially, its fibres insert by a broad attachment into the pubic tubercle and pectineal line, behind the conjoint tendon.

• Laterally, its fibres fan out within the fascia transversalis and fascia iliaca without bony attachment to the iliac spines.

Clinical note: It is considered as an important landmark in laparoscopic hernia surgeries.



Solution to Question 13:

Ureteric bud develops from Mesonephric duct.

• Intermediate mesoderm is a type of mesoderm that is located between the paraxial mesoderm and lateral plate.

• It develops into a part of the urogenital system as well as the reproductive system.

• Intermediate mesoderm develops into Genital ridge and Nephrogenic cord.

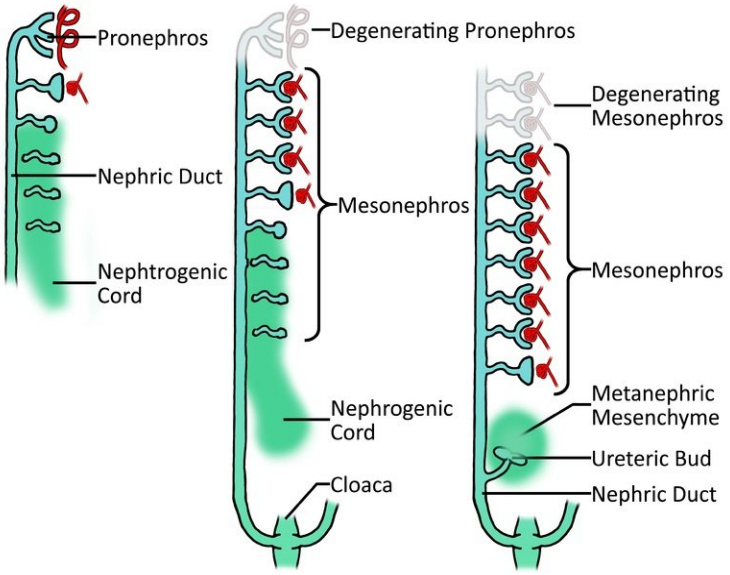
• Nephrogenic cord further develops into Pronephros, Mesonephros and Metanephros.

• Ureteric bud develops from mesonephros which later fuses with Mesonephric duct.

• Metanephros proliferates around the ureteric bud which forms metanephric blastema (definitive kidneys).

Structures arising from metanephric blastema and ureteric bud are as follows -

Metanephric blastema	Ureteric bud
Bowmans capsule	Collecting tubules
Proximal convoluted tubule	Renal papillae
Loop of Henle	Calyces
Distal convoluted tubule	Renal pelvis
	Ureter



Solution to Question 14:

The heart starts to beat in the 4th week of development.

Anatomy NEET 2019

Question 1:

The movements at the _____ joint permit a person to look to the right and left.

a) Atlanto-occipital

b) Atlanto-axial

c) C2-C3

d) C3-C4

Question 2:

All of the following are true about the right coronary artery except _____

a) It's diameter is less than left coronary artery

b) It arises from the anterior aortic sinus

c) It gives rise to circumflex coronary branch

d) Right conal artery is it's first branch

Question 3:

What is the basis for the formation of omphalocele?

a) Excessive length of the intestine

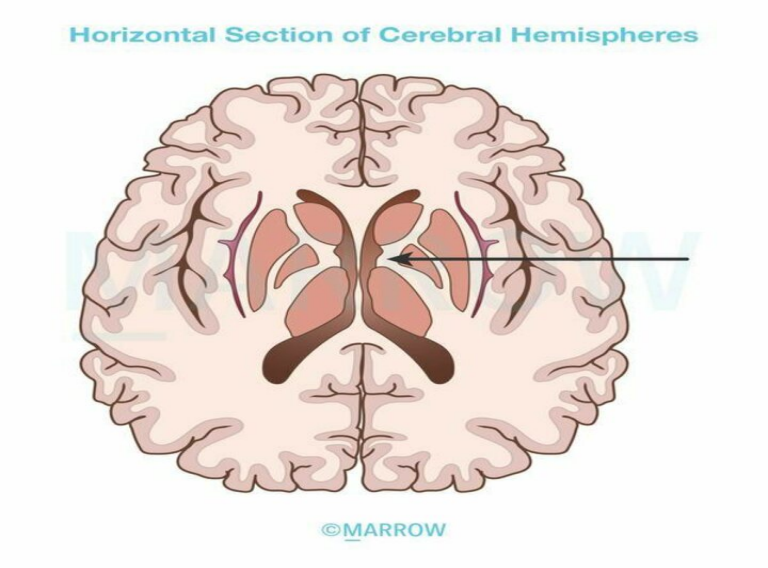
b) Physiological hernia failing to go back

c) Herniation of liver

d) Herniation of umbilicus

Question 4:

Which fibre is marked by the arrow in the image given below?



a) Short association

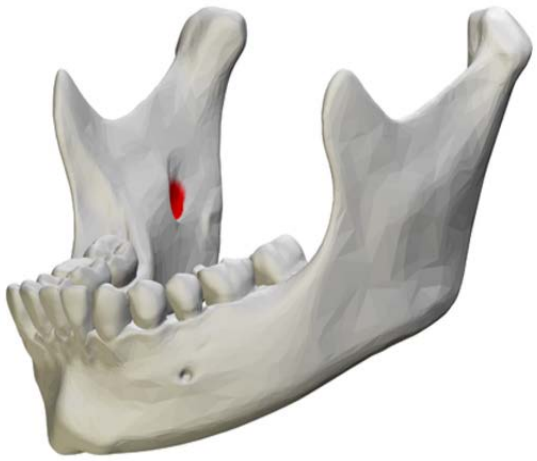
b) Long association

c) Projection

d) Commissural

Question 5:

Which nerve passes through the foramen marked in the image below?



a) Lingual nerve

b) Mandibular nerve

c) Chorda tympani nerve

d) Inferior alveolar nerve

Question 6:

Boundaries of Calot triangle are formed by all except:

a) Common hepatic duct

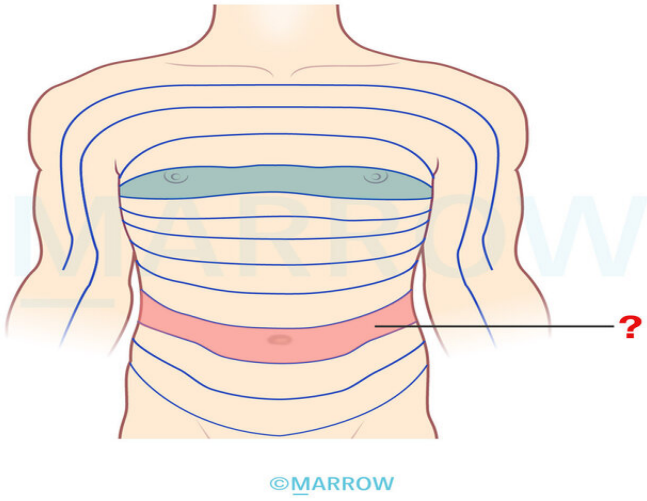
b) Cystic duct

c) Cystic artery

d) Gall bladder

Question 7:

Area marked in the given image is supplied by dermatome number?



a) T8

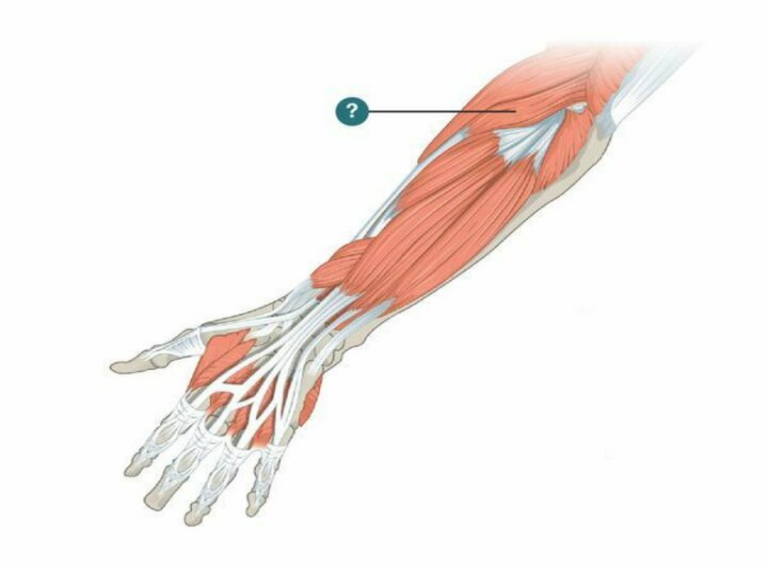
b) T9

c) T10

d) T11

Question 8:

The arrow in the image denotes which of the following muscles?



a) Extensor carpi radialis longus

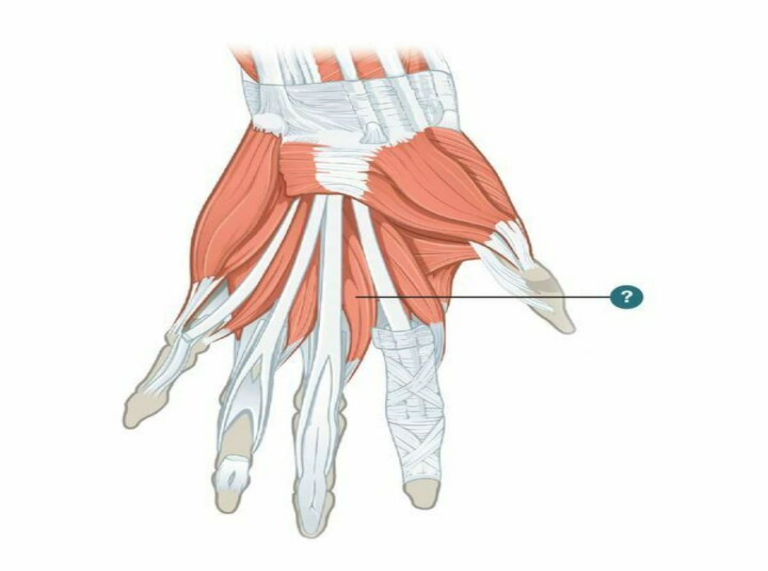
b) Brachioradialis

c) Supinator

d) Flexor carpi radialis brevis

Question 9:

What is the nerve supply of the structure marked in the image below?



a) Posterior interosseus nerve

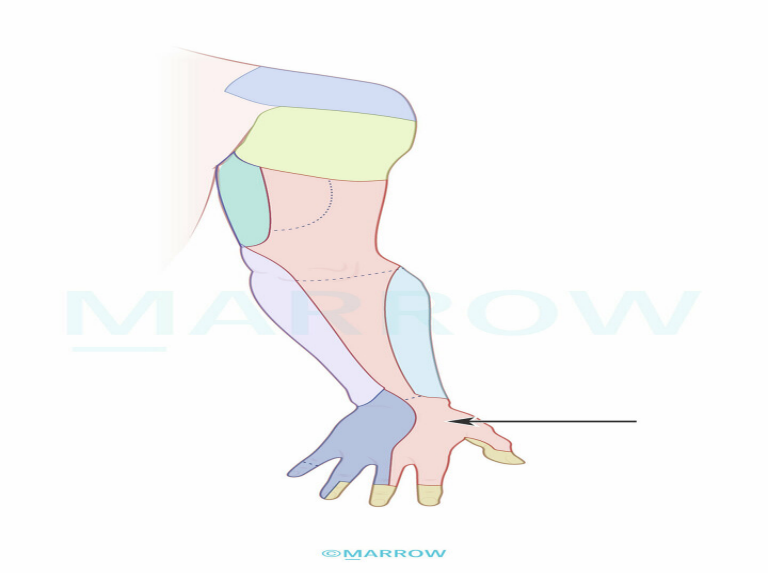
b) Median nerve

c) Anterior interosseus nerve

d) Ulnar nerve

Question 10:

Nerve supply of the area marked by arrow in the image is:



a) Radial nerve

b) Posterior interosseus nerve

c) Median nerve

d) Ulnar nerve

Question 11:

Cholecysto-vena caval line separates which of the following?

a) Gallbladder and inferior vena cava

b) Porta hepatis and inferior vena cava

c) Caudate lobe and quadrangular lobe

d) Right and left lobe of liver

Question 12:

Which of the following is false about skin?

a) Dermis is derived from ectoderm

b) Skin accounts for 15% of total body weight

c) Epidermis is derived from ectoderm

d) Dermis is made up of type 1 and type 3 collagen

Question 13:

All of the following structures are derived from the aponeurosis of the external oblique muscle except:

a) Pectineal ligament

b) Inguinal ligament

c) Lacunar ligament

d) Linea semilunaris

Question 14:

Which of the following lobes of the prostate forms the uvula vesicae?

a) Anterior

b) Posterior

c) Median

d) Lateral

Question 15:

Foot drop is caused by damage to:

a) Common peroneal nerve

b) Femoral nerve

c) Tibial nerve

d) Sciatic nerve

Question 16:

Which of the following is true regarding De Quervain's tenosynovitis?

a) Fingers are held in mild extension

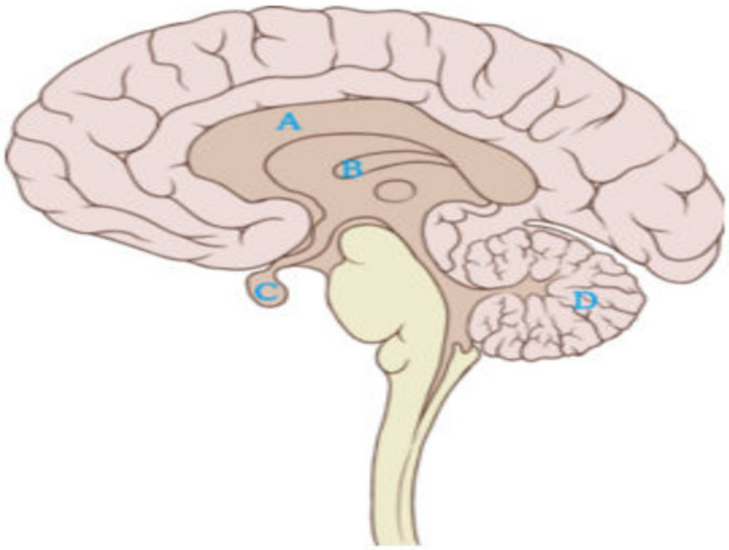
b) It affects APL and EPB

c) Most common involvement is index finger

d) Treatment is surgery

Question 17:

Identify the structure marked B in the image given below :



a) Pineal gland

b) Falx cerebri

c) Fornix

d) Pituitary gland

Question 18:

1st pharyngeal arch gives rise to all except:

a) Medial pterygoids

b) Levator veli palatini

c) Lateral pterygoids

d) Tensor veli palatini

Answer Key

Question No.	Correct Option
1	b
2	c
3	b
4	c
5	d
6	d
7	c
8	a
9	b
10	a
11	d
12	a
13	d
14	c
15	a
16	b
17	c
18	b

Detailed Explanations

Solution to Question 1:

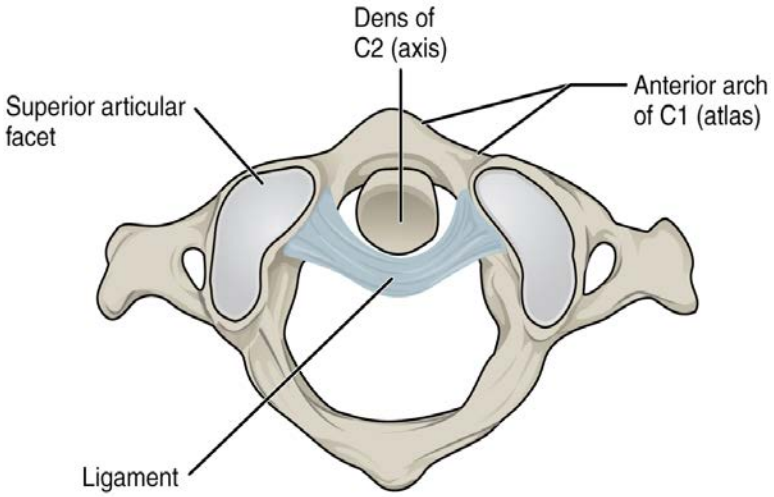
The movements at the atlanto-axial joint allow a person to look left and right.

The atlanto-axial joints include 3 synovial joints:

• Median atlanto-axial joint- The central pivot joint between the dens of the axis and a ring formed by the anterior arch and transverse atlantal ligament

• Lateral atlanto-axial joints- Plain synovial joints between lateral masses of atlas and upper facets of the body of axis

Movements at the atlanto-axial joint almost exclusively is rotation around the axis, which help side-to-side rotation of the head. The normal range of atlanto-axial rotation is about 40°.



Superior view of atlas

Solution to Question 2:

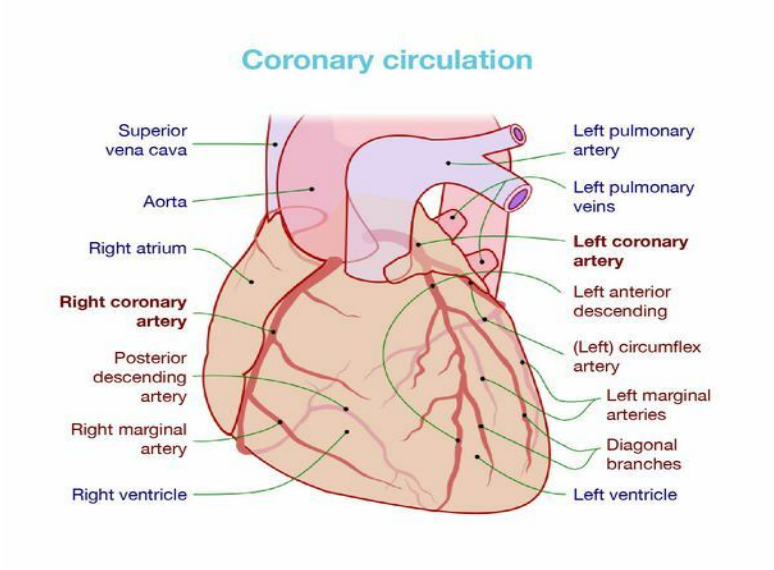
The right coronary artery does not give rise to the circumflex coronary artery.

The right coronary artery arises from the anterior aortic sinus (right coronary sinus) of the ascending aorta. It passes anteriorly and descends vertically in the coronary sulcus between the right atrium and the right ventricle. On reaching the inferior margin, it turns posteriorly and continues in the sulcus onto the diaphragmatic surface and the base of the heart.

The diameter of the right coronary artery is less than that of the left coronary artery.

The right conal artery is, usually the first branch of the right coronary artery.

The circumflex coronary artery is a branch of the left coronary artery and is the exclusive supplier to the right bundle branch.



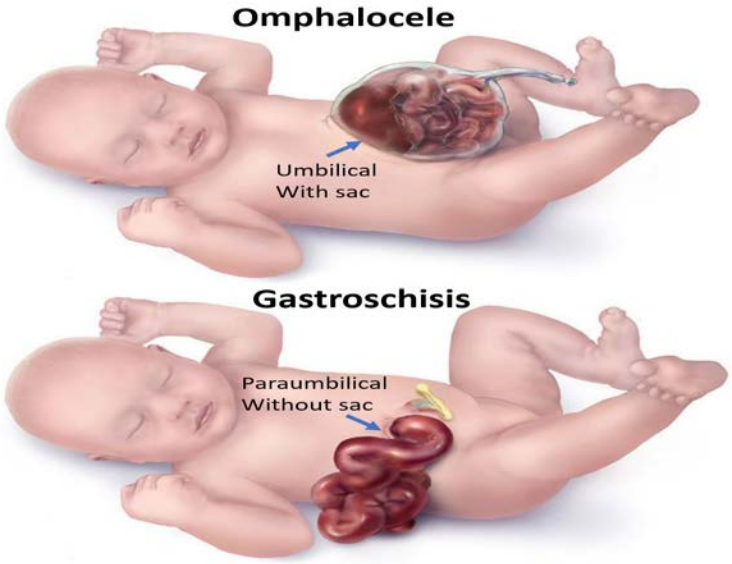
Solution to Question 3:

Omphalocele is protrusion of abdominal contents through the umbilical ring. It is due to failure of physiological hernia to reduce into the abdominal cavity, which results in non-closure of the umbilical ring. .

An omphalocele may contain stomach, liver, and intestines. And these contents are enclosed in a sac.

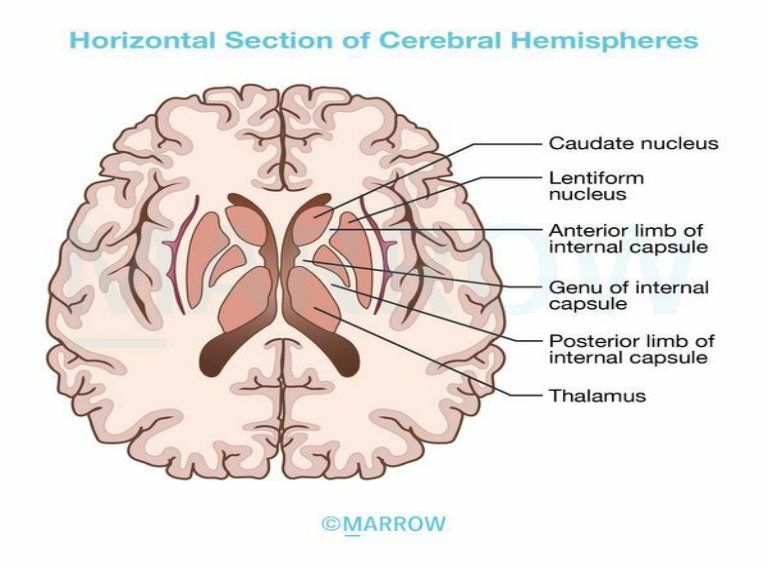
Omphalocele is usually associated with other congenital anomalies (e.g., trisomy 13, trisomy 18, or Beckwith-Wiedemann syndrome) and with increased levels of α-fetoprotein.

Note: In gastroschisis, there is an absence of a membranous sac and is paraumbilical.



Solution to Question 4:

The marked structure is the internal capsule, which is a form of projection fiber.



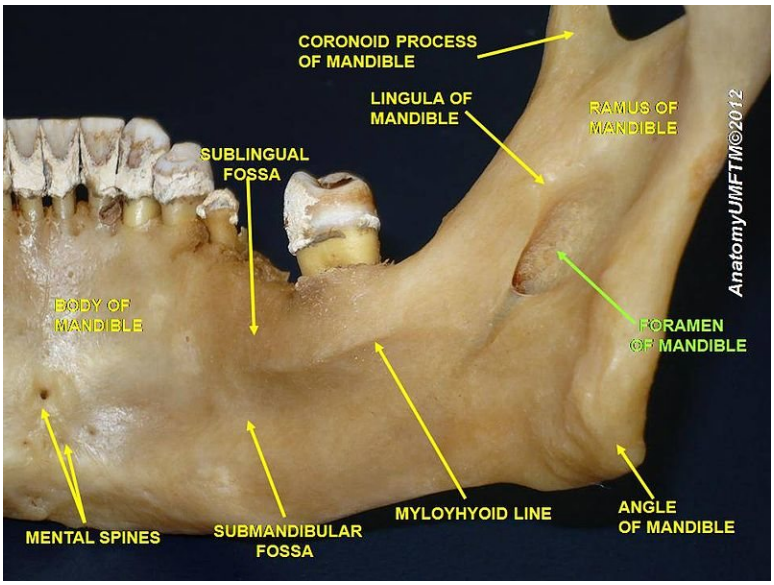
Solution to Question 5:

The marked structure is mandibular foramen and inferior alveolar nerve passes through it.

The inferior alveolar nerve (IAN), a branch of the mandibular nerve (CN V3), it descends behind the lateral pterygoid, at the lower border of the muscle, the nerve passes between the sphenomandibular ligament and the mandibular ramus and enters the mandibular canal via the mandibular foramen

The mandibular foramen is located above the mandibular angle, the opening through which the IAN and the vessels of the mandible pass.

The IAN continues its course through the mandibular canal and then branches off to supply the lower teeth, gums, and lower lip.



Solution to Question 6:

The gall bladder does not form a boundary of the Calot's triangle.

Calot's triangle is bounded by 3C's:

• Medially – Common hepatic duct

• Inferiorly – Cystic duct

• Superior – Cystic artery

Solution to Question 7:

The marked dermatome which includes the umbilicus is supplied by T10.

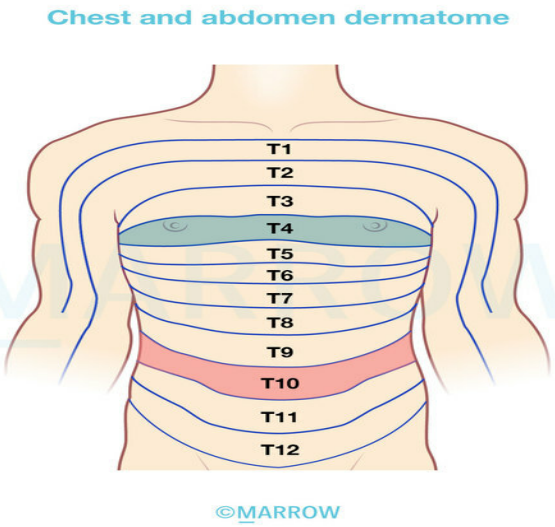
The dermatomal distribution of the abdominal region is as follows:

• T7, T8, T9 - supplies skin from the xiphoid process to just above the umbilicus.

• T10 - supplies skin around the umbilicus.

• T11, T12 - supplies skin below the umbilicus upto the suprapubic region.

• L1 - supplies skin around the genitalia and upper medial thigh.

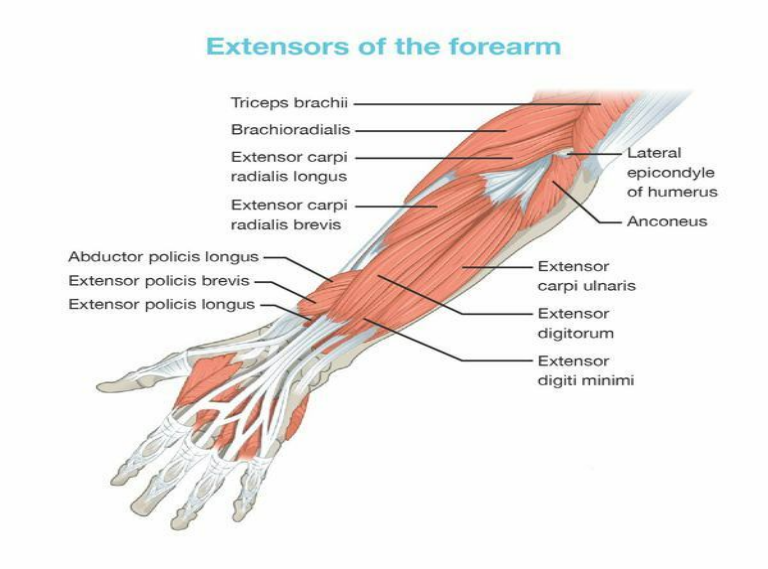


Solution to Question 8:

The arrow shows extensor carpi radialis longus.

It originates from the distal third of the lateral supracondylar ridge of the humerus and inserts at the second metacarpal (radial side). It is innervated by the radial nerve, C6, and C7.

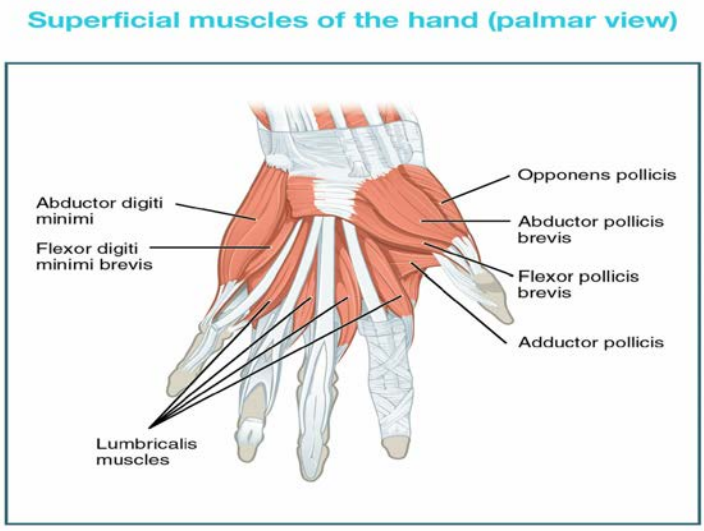
The vascular supply is by radial recurrent artery and it is responsible for the extension and abduction of the wrist joint.



Solution to Question 9:

The marked structure is second lumbrical which is supplied by the median nerve.

The lateral two lumbricals are supplied by the median nerve and the medial two are supplied by the ulnar nerve. Function of these muscles is flexion at the metacarpophalangeal joints and extension at both the interphalangeal joints.



Solution to Question 10:

The area marked in the image is supplied by radial nerve.

Solution to Question 11:

Cholecysto-vena caval line (Cantlie line) separates right and left lobe of the liver.

Cantlie line is an imaginary line that that divides the liver into 2 planes. It extends from the midpoint of the gallbladder fossa at the inferior margin of the liver back to the midpoint of the inferior vena cava (IVC) and contains the middle hepatic vein.

Solution to Question 12:

Dermis is derived from mesoderm and epidermis is derived from ectoderm.

Solution to Question 13:

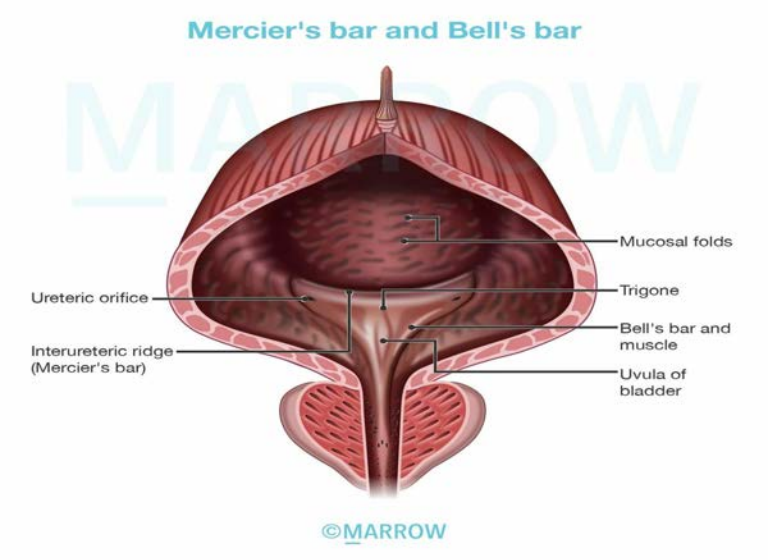
Linea semilunaris is derived from the aponeurosis of the internal oblique muscle.

Pectineal ligament, inguinal ligament and lacunar ligament are derived from the external oblique aponeurosis.

Solution to Question 14:

The median lobe of the prostate forms the uvula vesicae.

Uvula vesicae is an elevation in the mucous membrane of the urinary bladder, behind the internal urethral orifice. It is often enlarged in benign prostatic hypertrophy.



Solution to Question 15:

Foot drop is caused by damage to the common peroneal nerve.

The common peroneal nerve is a component of the sciatic nerve. In the posterior thigh, it supplies the short head of the biceps femoris. It curves around the neck of the fibula deep to peroneus longus and divides into superficial and deep peroneal nerves.

• The superficial peroneal nerve innervates peroneus longus and peroneus brevis which are the evertors of the foot and to the skin over the dorsal area of the foot except for the first webspace and lateral side of the little toe.

• The deep peroneal nerve innervates all muscles of the anterior compartment which are the dorsiflexors of the foot, extensor digitorum brevis, first two dorsal interossei muscles, and skin between great and second toes.

Hence, injury to the common peroneal nerve will lead to:

• Weakness of dorsiflexion of foot or foot drop

• Loss of eversion

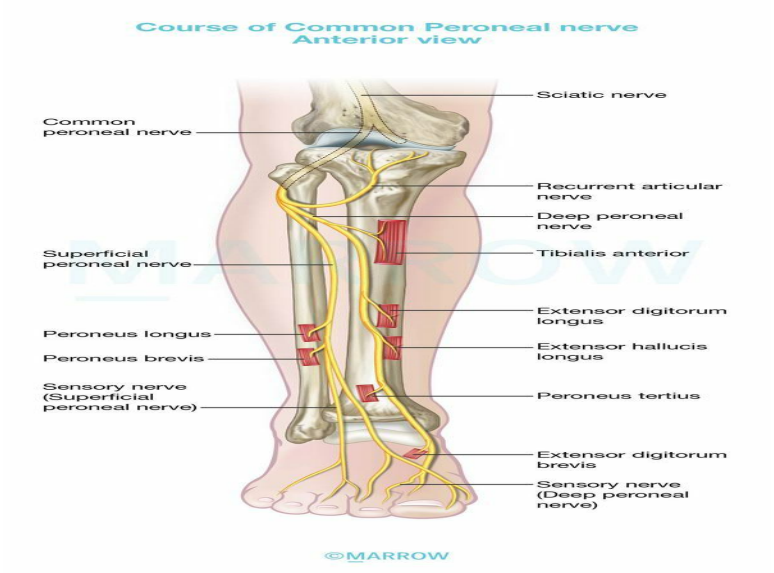
• Loss of extension of toes

• Sensory loss

• Anterior and lateral side of the leg

• Dorsum of the foot including the medial side of the great toe

Th image given below shows the course of common peroneal nerve.



Solution to Question 16:

De Quervain's disease is a stenosing tenosynovitis of the extensor tendons of the first dorsal compartment, namely extensor pollicis brevis (EPB) and abductor pollicis longus (APL).

It is prominent among females, especially pregnant women. Most commonly thumb is involved.

Finkelstein's test: On grasping the patient's thumb and quickly abducting the hand ulnar ward, the pain over the radial styloid tip is excruciating. It's the most pathognomonic objective sign but is also seen in other conditions like radial nerve entrapment and arthritis.

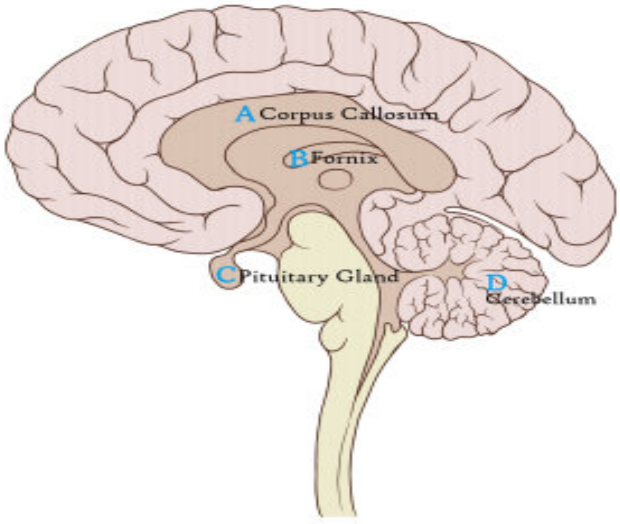
Treatment:

• Majority of the patients are treated medically

• Only few require the release of the 1st dorsal compartment which houses the APL and EPB tendons.

Solution to Question 17:

The image given shows a midsagittal section of the brain. The structure marked B is the Fornix.



Solution to Question 18:

Levator veli palatini is not derived from first pharyngeal arch.

All soft palate muscles including levator veli palatini are derived from the 4th pharyngeal arch and are supplied by vagal plexus.

First pharyngeal arch gives rise to:

• Muscles of mastication (temporalis, masseter, lateral and medial pterygoids)

• Mylohyoid

• Anterior belly of digastric

- Tensor tympani
- Tensor veli palatini and
- Anterior 2⁄3 of tongue.

Anatomy NEET 2020

Question 1:

Which of the following forms the lateral boundary of the anatomical snuff box?

a) Extensor pollicis brevis and abductor pollicis longus

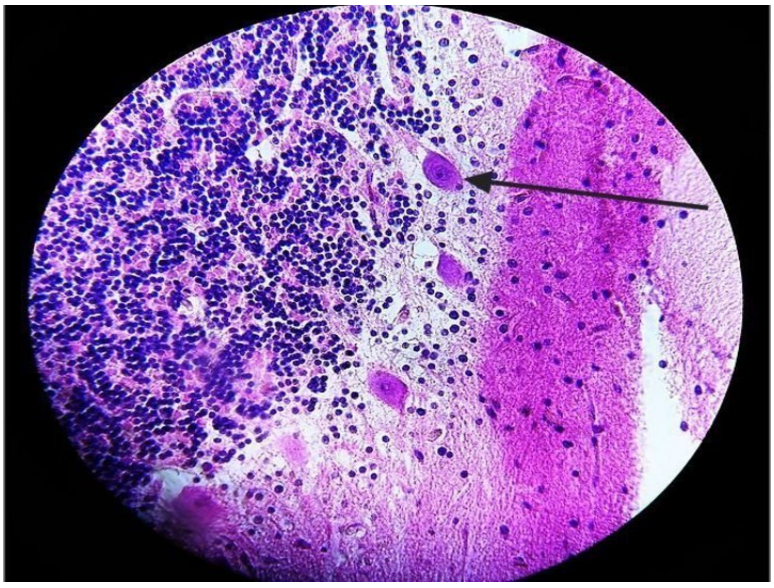
b) Extensor pollicis longus and abductor pollicis brevis

c) Extensor pollicis longus and extensor pollicis brevis

d) Abductor pollicis longus and abductor pollicis brevis

Question 2:

Identify the cell marked in the histological image of the cerebellum shown below :



a) Purkinje cells

b) Basket cells

c) Golgi cells

d) Granule cell

Question 3:

Which of the following is not used for the identification of the facial nerve trunk?

a) Retrograde dissection from distal branch

b) Tragal pointer

c) Inferior belly of omohyoid muscle

d) Posterior belly of digastric

Question 4:

The false statement about fetal circulation is:

a) Anatomical closure of foramen ovale is by 3 to 5 days

b) Anatomical closure of ductus venosus is by 3 to 7 days

c) Right umbilical vein is absent

d) Anatomical closure of ductus arteriosus is by 2 to 3 weeks

Question 5:

A tumor of the uncinate process of the pancreas affects which of the following vessels?

a) Superior mesenteric artery

b) Portal vein

c) Common hepatic artery

d) Inferior mesenteric artery

Question 6:

A patient presented with clinical features of ataxia and incoordination. This is due to thrombosis of which artery?

a) Posterior cerebral

b) Middle cerebral

c) Internal carotid

d) Superior cerebellar

Question 7:

Which of the following structures prevents the upward extension of thyroid swelling through its attachment to the thyroid cartilage?

a) Pretracheal fascia

b) Sternothyroid

c) Thyrohyoid membrane

d) Ligament of berry

Question 8:

A patient presented with the extension of MCP joint and flexion of IP joints. Which muscle is affected?

a) Extensor digitorum

b) Interossei and lumbricals

c) Abductor pollicis

d) Abductor pollicis brevis

Question 9:

Meiosis occurs in:

a) Adrenal

b) Adult ovary

c) Prepubertal testis

d) Hypothalamus

Question 10:

The long left recurrent laryngeal nerve is due to the persistence of which arch artery?

a) 3rd arch

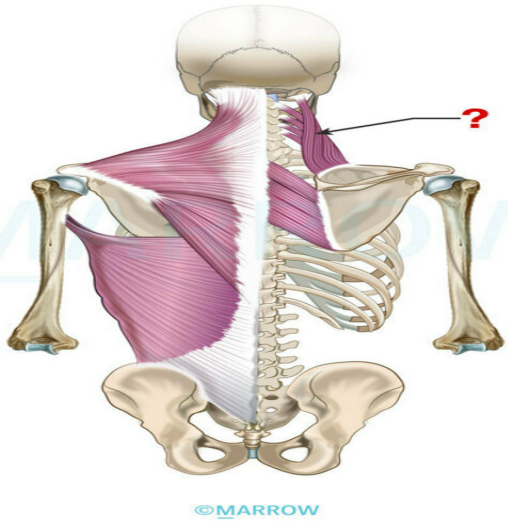
b) 4th arch

c) 5th arch

d) 6th arch

Question 11:

The muscle marked by the arrow in the image below is innervated by the_____.



a) Dorsal scapular nerve

b) Suprascapular nerve

c) From the dorsal rami of C1

d) Subscapular nerve

Question 12:

A patient presented with weakness of the right side of the face with the loss of pain and temperature. Pain and temperature sensation of the left leg is also lost. The lesion is most likely located at?

a) Medial medulla

b) Lateral pons

c) Medial pons

d) Lateral medulla

Question 13:

Ligation of common hepatic artery will impair blood supply in:

a) Right gastric and right gastroepiploic artery

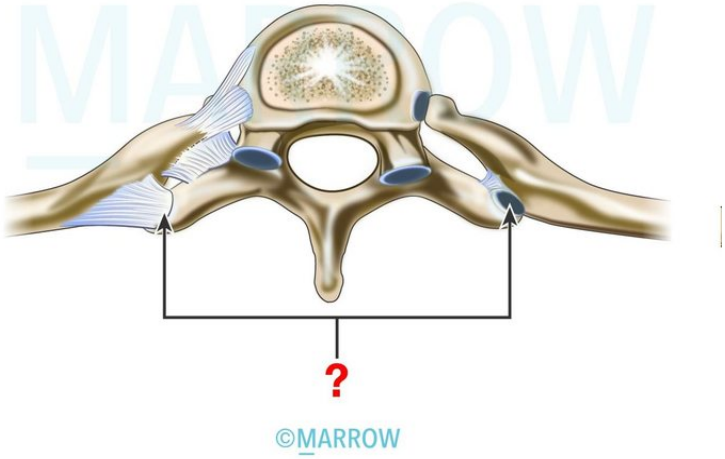
b) Right gastric and left gastric artery

c) Right gastroepiploic and short gastric vessels

d) Right gastric and short gastric vessels

Question 14:

The type of joint marked in the image below is _____:



a) Syndesmosis

b) Synarthrosis

c) Synchondrosis

d) Synovial

Question 15:

Identify the sign shown in the image below:

a) Popeye sign

b) Hill-Sachs sign

c) Griesinger sign

d) Rising sun sign

Question 16:

A patient presented with an enlarged inguinal lymph node. The most likely primary cause is

a) Testicular cancer

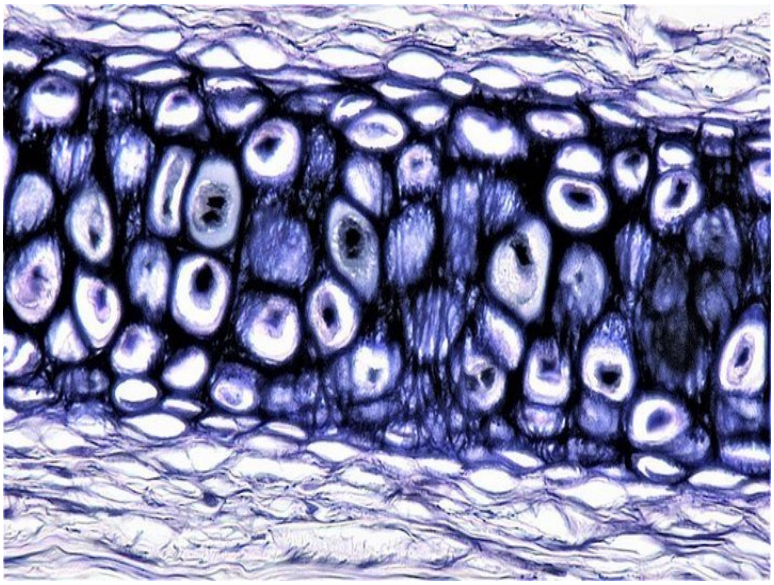
b) Anal cancer

c) Sigmoid colon cancer

d) Prostate cancer

Question 17:

Identify the type of cartilage shown in the image below:



a) Hyaline cartilage

b) Elastic cartilage

c) Articular cartilage

d) Fibrocartilage

Answer Key

Question No.	Correct Option
1	a
2	a
3	c
4	a
5	a
6	d
7	b
8	b
9	b
10	d
11	a
12	b
13	a
14	d

15	a
16	b
17	b

Detailed Explanations

Solution to Question 1:

The lateral boundary of the anatomical snuff box is formed by extensor pollicis brevis and abductor pollicis longus.

Boundaries of the anatomical snuffbox:

• Lateral wall:

• Abductor pollicis longus (APL)

• Extensor pollicis brevis (EPB)

• Medial wall:

• Extensor pollicis longus (EPL)

• Roof:

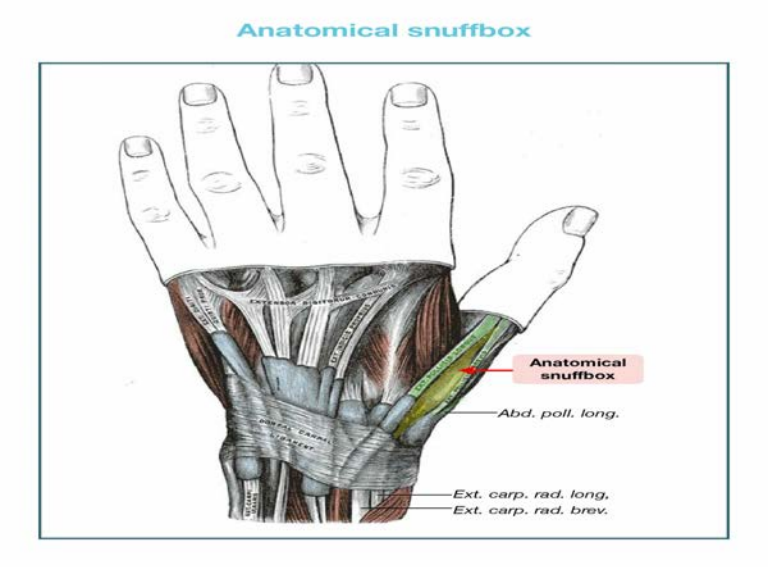
• Cephalic vein

• Superficial branch of the radial nerve

• Floor:

• Radial styloid, scaphoid, trapezium, and 1st metacarpal

Only content: Radial artery



Solution to Question 2:

The cells marked in the above histological image are Purkinje cells.

Characteristics of Purkinje cells:

• Purkinje cells are the flask-shaped cells present in the Purkinje cell layer of the cerebellum.

• The cells are evenly spaced and are arranged in a single layer.

• A dendrite arises from the neck of each flask-shaped cell, which passes upward to enter the molecular layer, which then branches extensively to form a dendritic tree.

• The axon of each cell passes downwards, crosses the granular cell layer to enter the white matter.

• Axons of Purkinje cells are the only efferents of the cerebellar cortex.

• The initial segment of the axon receives synaptic contacts from basket cell axons.

• The main axon terminates in one of the cerebellar or vestibular nuclei.

• Purkinje cells are inhibitory and use GABA as their neurotransmitter.

Pathological significance:

• Negri bodies in rabies, are usually found as eosinophilic, cytoplasmic inclusions in the neurons of the hippocampus and Purkinje cells.

• Loss of Purkinje cells and granule cells is seen in ataxia-telangiectasia.

• In patients with subacute cerebellar degeneration, there is the destruction of Purkinje cells. Some patients show circulating PCA1 antibody (antiYo) against Purkinje cells.

• Purkinje cells and neurons in pyramidal cell layers of hippocampus and cerebral cortex are the most sensitive neurons to hypoxia, and are likely to be damaged in cases of global cerebral ischemia.

Solution to Question 3:

The inferior belly of the omohyoid muscle is not used as an anatomical landmark for the identification of the facial nerve trunk.

There are two methods for localization of the facial nerve trunk:

1. Anterograde method: The facial nerve trunk is identified based on the anatomical landmarks after it exits from the stylomastoid foramen. This includes:

• Tragal pointer/Conley's pointer - It is the inferior portion of the cartilaginous canal. The facial nerve trunk lies 1 cm deep and inferior to its tip.

• Posterior belly of digastric - The facial nerve lies superior to the upper border of the muscle.

• Squamotympanic fissure - It is a fissure in the temporal bone, which runs from TMJ to the tympanic cavity. The facial nerve runs through this fissure.

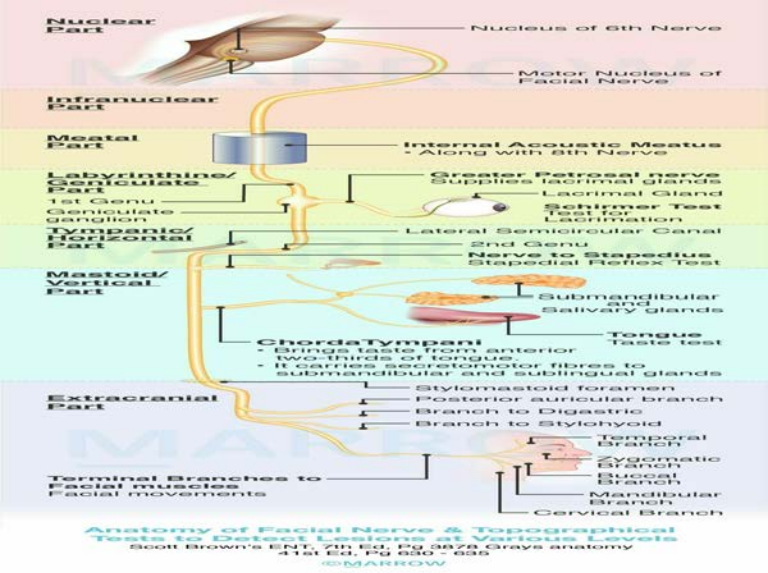
• Styloid process - The facial nerve lies superficial to it.

• Mastoid process - Upon drilling it, the nerve is identified proximally.

2. Retrograde method: The main branches of the facial nerve trunk are identified and are then traced proximally until the main tunk is identified. Some branches used for tracing the facial nerve trunk include:

• Buccal branch - It lies in relation to the parotid gland.

• Marginal mandibular branch - It lies in relation to the facial vessels.



Solution to Question 4:

The anatomical closure of the foramen ovale takes 1 month to a year.

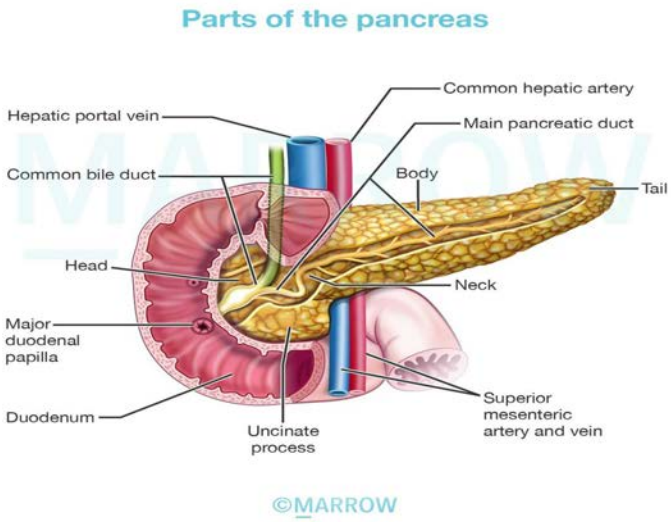
Given below are the fetal circulatory adjustments after birth:

	Functional closure	Anatomical closu re
Ductus venosus	After removal of the placenta	7 days
Foramen ovale	At birth - after breathing is in itiated	Months to years
Ductus arterios us	10–15 hours	10–21 days

Solution to Question 5:

A tumor of the uncinate process of pancreas affects the superior mesenteric artery.

The superior mesenteric artery arises from the abdominal aorta. It lies first behind the body of the pancreas and then in front of the uncinate process.



Relations of the other parts of pancreas:

Head of pancreas:

• Anterior:

• 1st part of the duodenum

• Origin of the transverse mesocolon

• Posterior:

• Right renal vein

• Right renal artery

• Inferior vena cava

• Common bile duct (which is embedded in the head)

• Right crus of the diaphragm

• Termination of the right gonadal vein

Neck of the pancreas:

• Anterior:

• Lesser sac

• pylorus

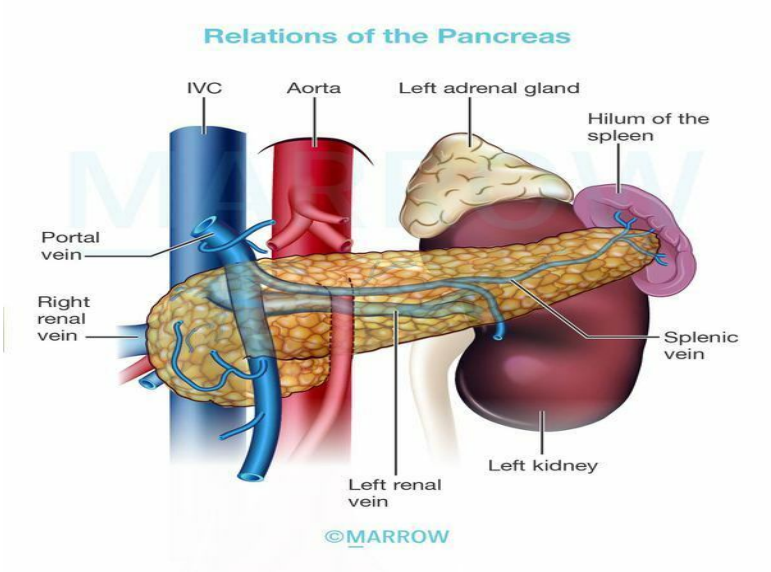
• The anterior superior pancreaticoduodenal branch of the gastroduodenal artery

• Posterior:

• Portal vein

• Superior mesenteric vein

• Inferior mesenteric vein (in 1/3rd individuals)



Solution to Question 6:

Thrombosis of the superior cerebellar artery causes cerebellar lesion which presents with ataxia and incoordination.

Blood supply of cerebellum:

- Superior cerebellar artery
- Posterior inferior cerebellar artery
- Anterior inferior cerebellar artery

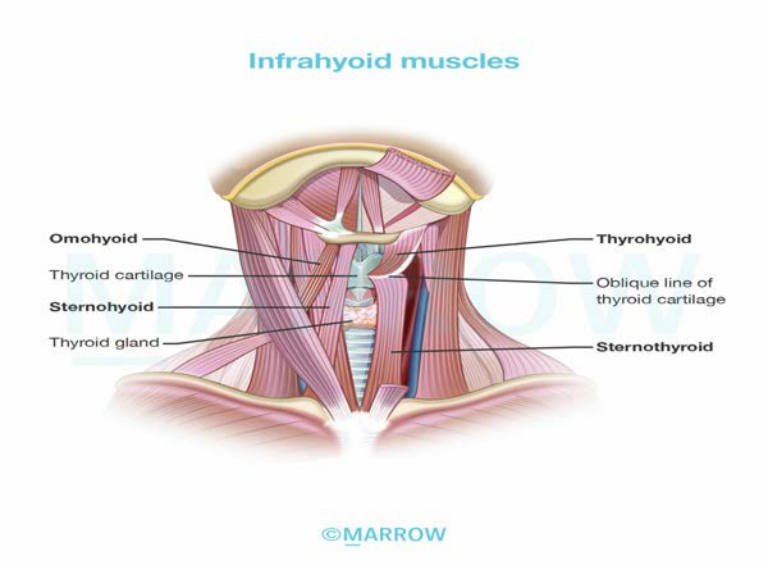
Solution to Question 7:

Sternothyroid and sternohyoid prevent the upward extension of the thyroid swelling through its attachment to the thyroid cartilage.

Pretracheal fascia encloses the thyroid gland and is attached to the larynx. This attachment is responsible for the movement of the enlarged thyroid gland on deglutition.

The thyrohyoid membrane is a fibro-elastic ligament, which arises from the superior margin of the thyroid cartilage, and gets attached to the hyoid bone. It facilitates the upward movement of the larynx during swallowing.

The ligament of Berry, also called the suspensory ligament extends from the cricoid cartilage to the thyroid. Its attachment prevents the thyroid gland from sinking down into the mediastinum.



Solution to Question 8:

The lumbricals and interossei muscles are affected.

The lumbricals and interossei muscles through their attachments to the dorsal digital expansions, cause:

• Flexion of the metacarpophalangeal (MCP) joints

• Extension of the interphalangeal (IP) joints

In cases of ulnar nerve injury, these muscles may get atrophied leading to the extension of MCP joints and flexion of IP joints.

Note: The ulnar nerve innervates all the intrinsic muscles of the hand, except for

• First and second lumbrical

• Abductor pollicis brevis

• Opponens pollicis

• Part of flexor pollicis brevis

Solution to Question 9:

Meiosis occurs in the adult ovary.

Meiosis takes place only in germ cells and results in the formation of haploid gametes. Meiosis requires two cell divisions, meiosis I and meiosis II, to reduce the number of chromosomes to the haploid number of 23.

Option C: Spermatogenesis begins at puberty. Primordial germ cells (PGCs) remain dormant in the testis until puberty. At puberty, PGCs differentiate into spermatogonial stem cells. These

spermatogonial stem cells then give rise to spermatogonia which marks the beginning of spermatogenesis.

Options A and D: These are somatic cells that only undergo mitosis and not meiosis.

Solution to Question 10:

The long left recurrent laryngeal nerve is due to the persistence of the left 6th arch artery.

During the development, the laryngeal nerves initially arise below the 6th arch artery and cross here to innervate the intrinsic muscles of the larynx. As the larynx moves cranially relative to the aortic arch arteries, the recurrent laryngeal nerves on the right and left sides are caught under the 6th arch arteries.

On the right side, the distal 6th arch artery disappears. Since there is no 5th arch artery, the right recurrent laryngeal nerve is caught under the 4th arch artery which becomes the future right subclavian artery.

On the left side, the 6th arch artery persists, which develops into ductus arteriosus, which later forms ligamentum arteriosum. Due to the persistence of the 6th arch artery, the left recurrent laryngeal nerve is caught under it and therefore, has a relatively long course.

Solution to Question 11:

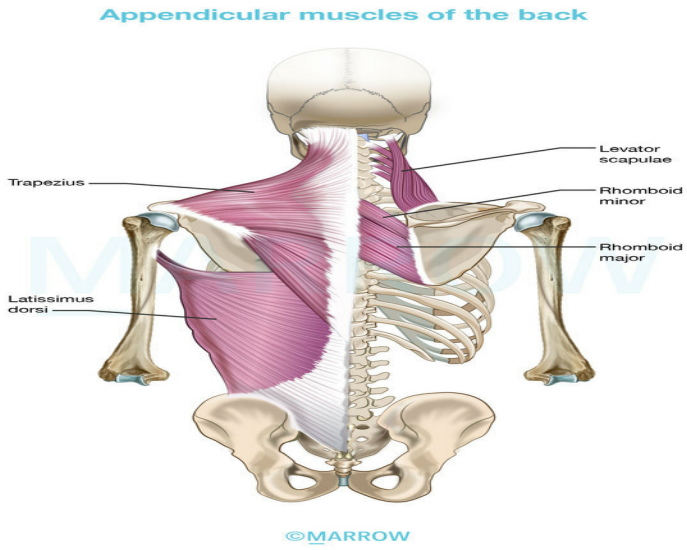
The muscle marked in the above image is levator scapulae, which is innervated by the dorsal scapular nerve.

The appendicular group of back muscles and their innervations include:

Option B: The suprascapular nerve innervates the supraspinatus and infraspinatus muscles.

Option D: The subscapular nerves supply the teres major and subscapularis muscles.

Muscle	Nerve Supply
Trapezius	Accessory nerve
Latissimus dorsi	Thoracodorsal nerve
Levator scapulae	Dorsal scapular nerve
Rhomboid major and minor	Dorsal scapular nerve



Solution to Question 12:

The above clinical scenario is suggestive of lateral pontine syndrome which occurs due to a lesion located at lateral pons.

Lateral pontine syndrome occurs due to the involvement of the anterior inferior cerebellar artery.

• Ipsilateral manifestations include:

• CN VII: Facial paralysis

• CN V: loss of pain and temperature sensation over the face.

• Vestibular nerve or nucleus: Horizontal and vertical nystagmus, vertigo, nausea, vomiting, oscillopsia.

• Auditory nerve or cochlear nucleus: Deafness, tinnitus.

• Middle cerebellar peduncle: Ataxia of limb and gait.

• Contralateral manifestations include:

• Spinothalamic tract: Loss of pain and temperature sensation over the body.

Medial pontine syndrome occurs due to the involvement of the paramedian branch of the basilar artery.

• Ipsilateral manifestation

• CN VI: Diplopia(lateral rectus muscle paralysis - the affected eye looks downwards and inwards)

• Vestibular nucleus: Nystagmus.

• Middle cerebellar peduncle: Ataxia of limb and gait.

• Contralateral manifestation

• Corticobulbar and corticospinal tract: Paralysis of face, arm, and leg.

• Medial lemniscus: loss of touch and proprioception from the body.

Solution to Question 13:

Ligation of the common hepatic artery will cause impairment in the blood supply through its branches i.e right gastric artery and right gastroepiploic artery.

Blood supply of the stomach:

The arterial supply of the stomach is contributed exclusively by the branches of the celiac trunk. They are:

• Left gastric artery - Supplies the lesser curvature of the stomach

• Splenic artery- This further divides into:

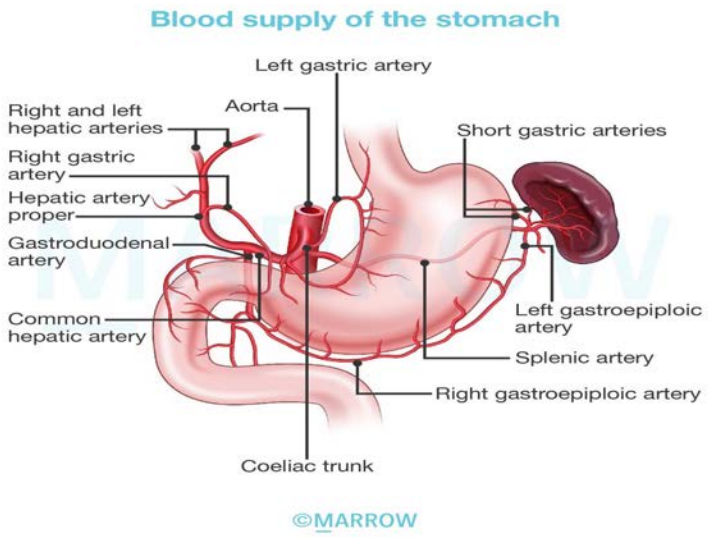
• Short gastric arteries- Supplies the fundus of the stomach

• Left gastroepiploic artery- Supplies the greater curvature of the stomach

• Common hepatic artery, which gives the following branches

• Right gastric artery- Supplies the lesser curvature of the stomach

• Gastroduodenal artery- Right gastroepiploic artery arises from this and supplies the greater curvature of the stomach.



Solution to Question 14:

The joint marked in the above image is the costotransverse joint, which is a synovial type of joint.

The various types of joints in the thoracic wall include:

Sternocostal joints: These are the joints between the costal cartilages of the first seven ribs and the sternum.

• The joint between the 1st costal cartilage and manubrium is a fibrocartilaginous joint (synarthrosis).

• The joints between the 2nd to 7th costal cartilages and the sternum are synovial joints.

The interchondral joint between the costal cartilages of the 9th and 10th ribs is never synovial and is usually absent.

Type of Joint	Examples
Synovial joint	Costovertebral jointCostotransverse jointInterchondral joints
Primary cartilaginous joint/Synchondrosis	Costochondral joint
Secondary cartilaginous/Symphyses joint	Manubriosternal and xiphisternal joints

Solution to Question 15:

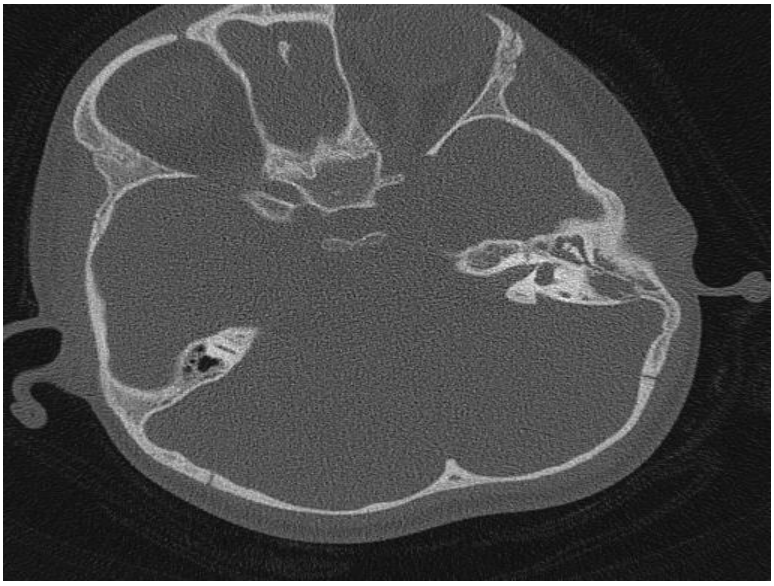
The sign shown in the above image is the popeye sign, which occurs due to the rupture of the tendon of the long head of the biceps brachii.

On flexing the elbow, the characteristic deformity appears due to the bulging of the muscle belly caused by the contraction of the unrestrained muscles.

Option B: Hill-Sachs sign refers to a defect in the postero-lateral surface of the humeral head due to repeated impact against anterior glenoid rim. It is a common complication of Anterior shoulder dislocation.

Option C: Griesinger sign refers to oedema of the postauricular soft tissues overlying the mastoid process as a result of thrombosis of the mastoid emissary vein. It is a complication of acute

mastoiditis.



Option D: Rising sun sign , also known as Schwartze sign, is the otoscopic sign of active otospongiosis characterised by reddish discolouration of the cochlear promontory.

Solution to Question 16:

The most likely primary cause of an enlarged inguinal lymph node is anal cancer.

Lymphatics from the anal canal distal to the dentate line (anal margin) drains into the inguinal lymph nodes. Hence, anal cancer arising distal to dentate line can cause enlarged inguinal lymph nodes. Lymphatics proximal to the dentate line (anal canal) drains into internal iliac lymph nodes through superior rectal lymphatics.

Option A: In testicular cancer, lymphatic spread occurs to the paraaortic lymph nodes.

Option C: In sigmoid colon cancer, lymphatic spread occurs to the regional lymph node and then to the central lymph node.

Option D: In prostate cancer, lymphatic spread occurs to the:

• Lymph nodes beside the internal iliac vein and in the hollow of the sacrum

• External iliac lymph nodes.

Solution to Question 17:

The above image shows an elastic cartilage.

The elastic cartilage, like the hyaline cartilage, contains individual or small groups of chondrocytes that are surrounded by type II collagen fibrils. However, it differs from hyaline cartilage in that, much of the interterritorial matrix consists of fine yellow elastic

fibres containing elastin protein.

On microscopy, elastic cartilage consists of:

• Chondrocytes within lacunae

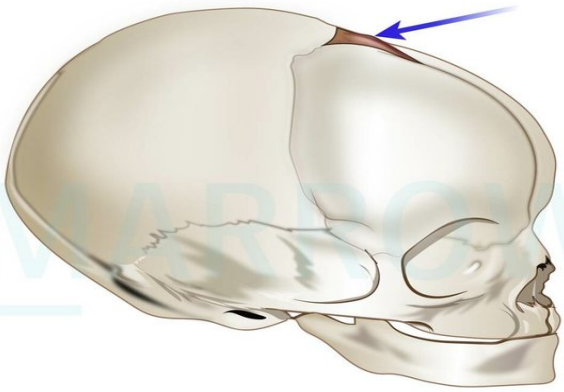
• Elastic fibres in the matrix

• Perichondrium with outer fibrous layer and the inner cellular layer

Anatomy INI-CET 2021

Question 1:

A 6-month-old boy was brought to the casualty with seizures. The pediatrician tries to do CSF sampling. What are the structures punctured by the pediatrician while piercing through the marked structure?



a) Scalp, dura, arachnoid

b) Scalp, epicranium, endocranium and dura

c) Scalp, synchondral membrane, dura, arachnoid

d) Pericranium, dura, arachnoid

Question 2:

A 12-year-old presented with fever and difficulty swallowing. He had swelling in the marked region and was advised to undergo surgery. Post-surgery the gauze continued to soak with blood. Which of the following vessels must have been injured?

a) Tonsillar branch of facial artery

b) Ascending pharyngeal artery

c) Paratonsillar vein

d) Retromandibular vein

Question 3:

At which level does the nerve supply for the marked structure arise?

a) Red nucleus

b) Sub thalamic nuclei

c) Decussation of pyramidal tract

d) Olivary nucleus

Question 4:

Which of the following are branches of the anterior division of the internal iliac artery?

a) 1, 2, 3, 5

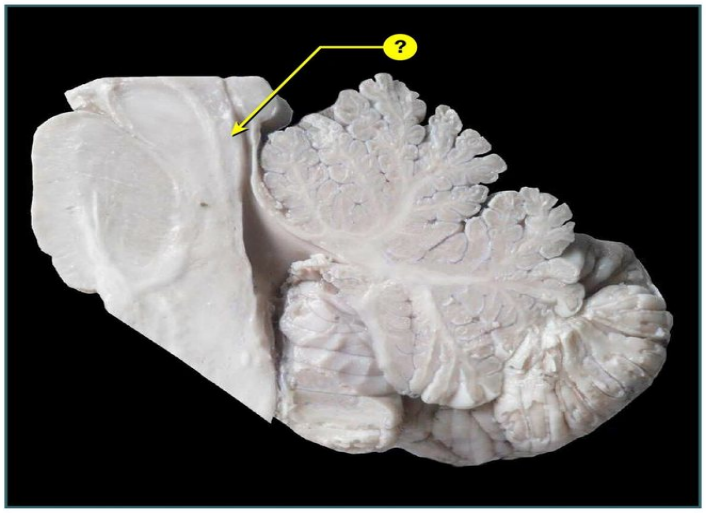
b) 2, 3, 4, 6

c) 2, 3, 4, 5, 6

d) 1, 4, 5, 6

Question 5:

Fibers from the marked structure terminate at which of the following?



a) Fastigial nucleus

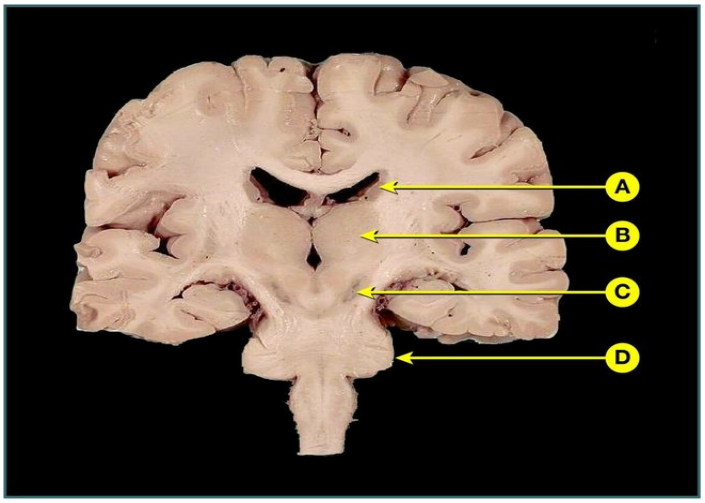
b) Inferior olivary nucleus

c) Red nucleus

d) Subthalamus

Question 6:

A woman with right-sided loss of sensations of both the upper and lower limb complains of shooting pain from her fingers to the right shoulder and a burning sensation when touching cold water. Motor functions are normal. Which of the following structures is likely to be involved?



a) A

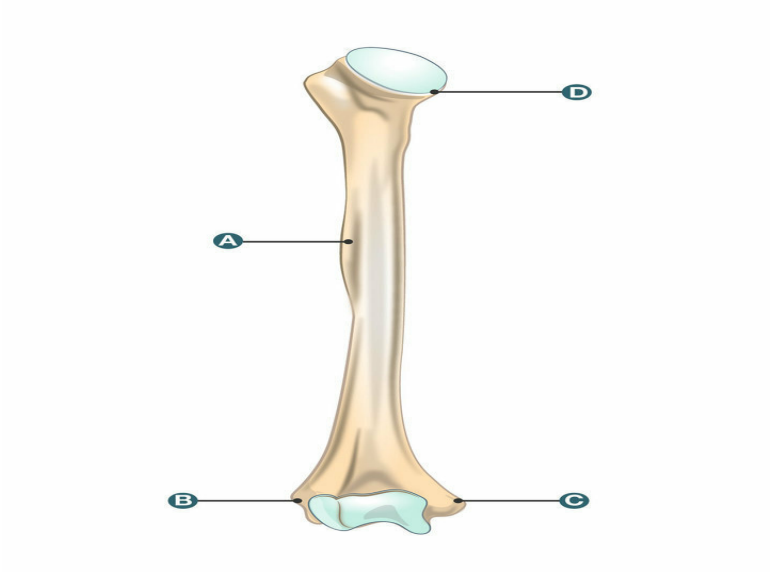
b) B

c) C

d) D

Question 7:

A 25-year-old male presented with symptoms of inability to flex the distal interphalangeal joint of the 4th and 5th digits. He was also not able to hold a piece of paper between his fingers. What is the likely site of injury?



a) A

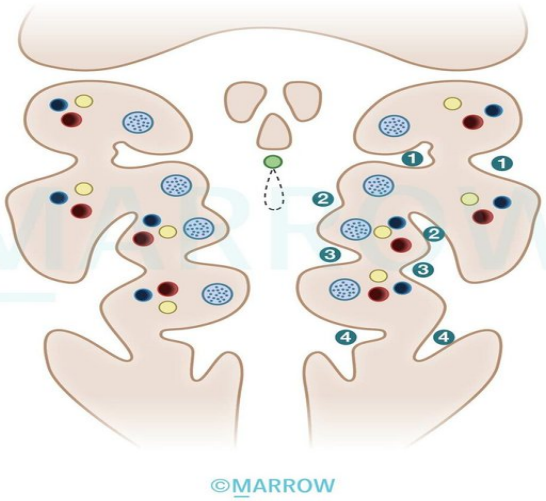
b) B

c) C

d) D

Question 8:

A young child with absent thymus is brought to the OPD with features of hypoparathyroidism and tetany. Which of the following marked area in the picture is defective in this condition?



a) 1

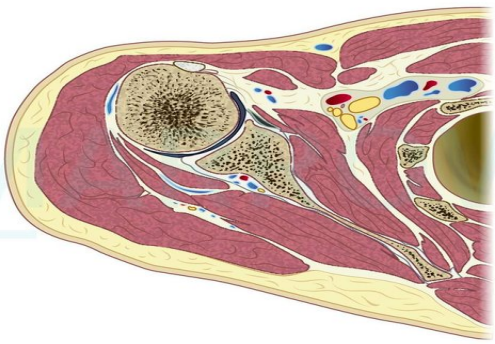
b) 2

c) 3

d) 4

Question 9:

A patient who has taken the first COVID vaccine comes for the second dose. An astute nurse noticed that the shoulder was flabby, flat, and was asymmetrical. There was an associated loss of contour of the shoulder joint. Injury to which of the structures might have resulted and was avoidable?



a) Rotator cuff

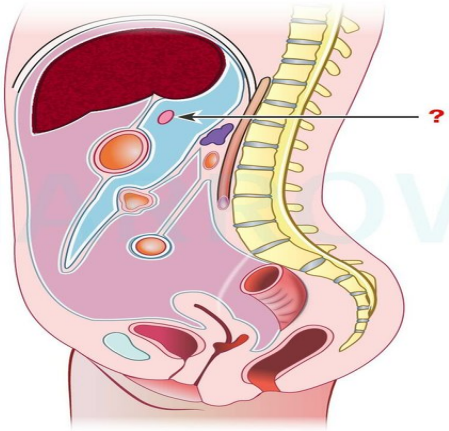
b) Posterior circumflex artery

c) Lateral cutaneous nerve of arm

d) Axillary nerve

Question 10:

The Para-sagittal section of the abdomen is given below. What is the superior border of the marked structure?



a) Caudate lobe of liver

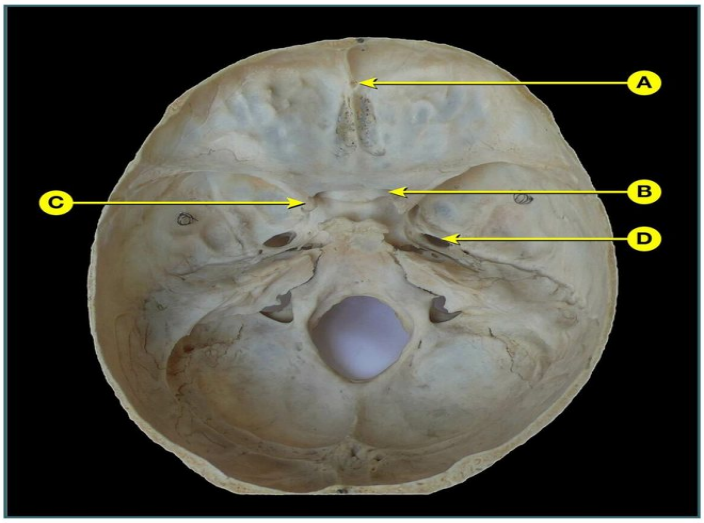
b) Duodenum

c) Lesser omentum

d) Inferior vena cava

Question 11:

Through which of the following marked sites does SARS-COVID 19 spread to the brain?



a) D

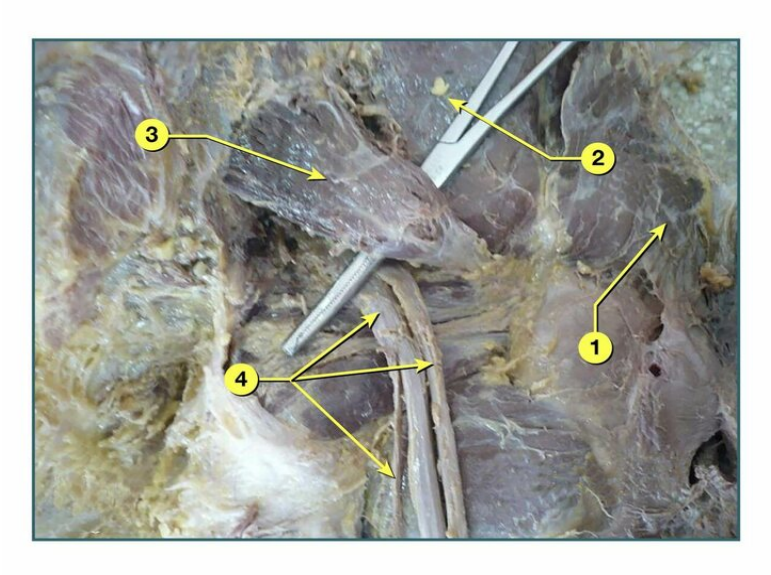
b) C

c) B

d) A

Question 12:

A boy with a history of a fall from a tree presents with a lurching gait and dragging of his feet. Which of the following structures are involved?



a) 1

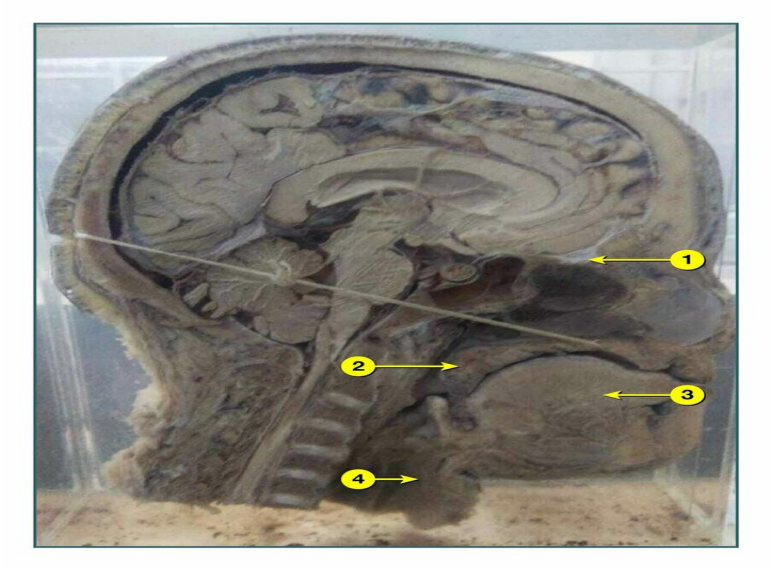
b) 2

c) 3

d) 4

Question 13:

A patient after a road traffic accident presents to the emergency room with difficulty in swallowing and slurred speech. Investigations reveal fractures in the occipitotemporal region. Which of the following areas should be tested in order to find the nerve which is involved?



a) 1

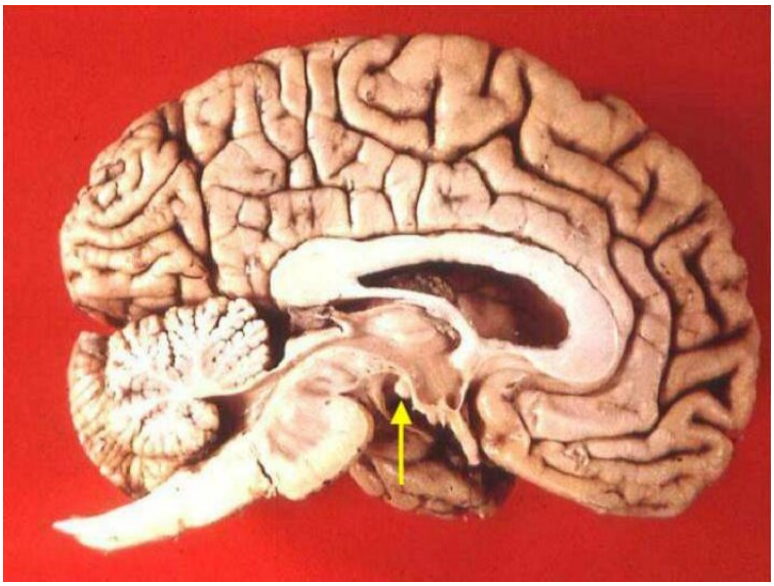
b) 2

c) 3

d) 4

Question 14:

Fibers from the marked structure end in which of the following areas of the thalamus?



a) Posterior nucleus

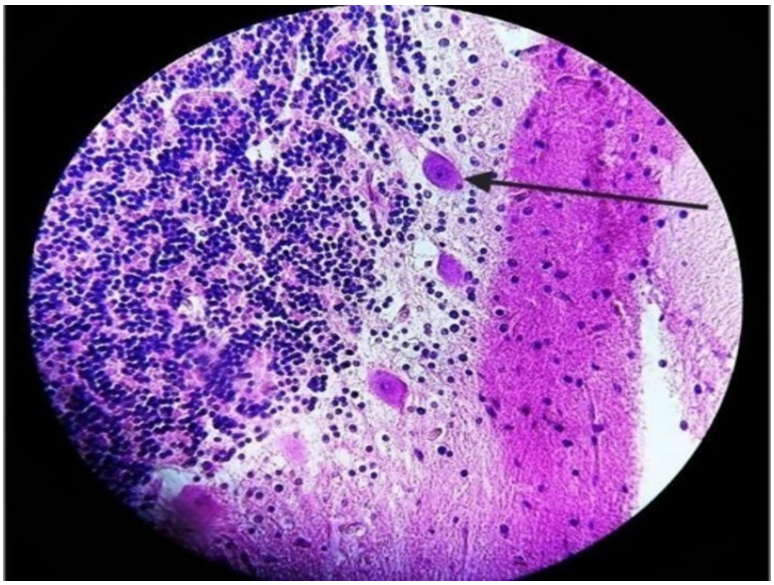
b) Reticular nucleus

c) Anterior nucleus

d) Ventral Lateral nucleus

Question 15:

The cell marked in the below slide is inhibitory to



a) Deep nuclei of cerebellum

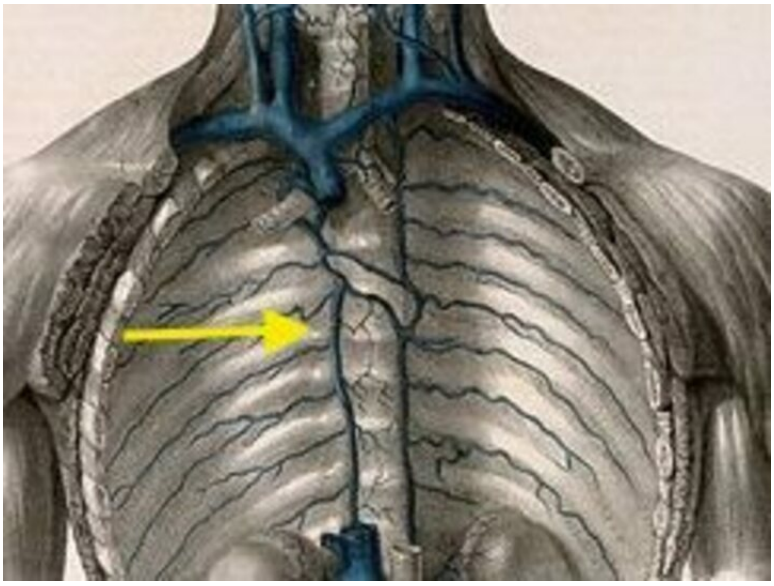
b) Vestibular nuclei

c) Inferior olivary nucleus

d) Basal ganglia

Question 16:

The marked structure develops from which of the following structures?



a) Common cardinal vein

b) Anterior cardinal vein

c) Supracardinal vein

d) Subcardinal vein

Question 17:

Inferior thyroid artery supplies which of the following structures?

a) 1, 2, 3, and 4

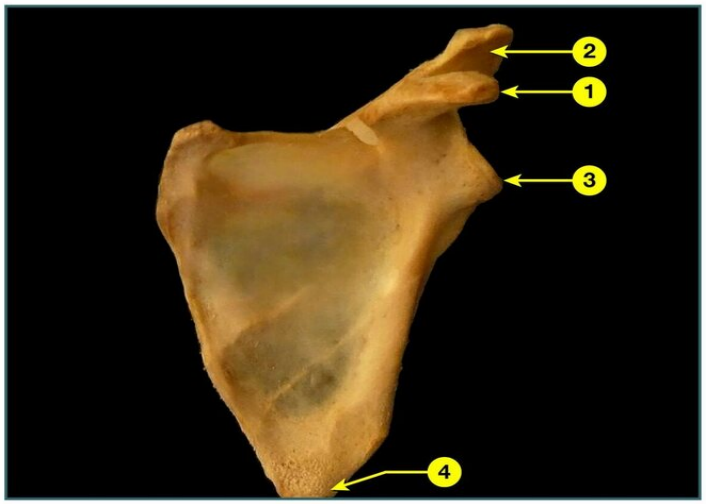
b) 1, 2, and 3 only

c) 1 and 2 only

d) 1, 2 and 4 only

Question 18:

Which part of this bone is palpable in the infraclavicular fossa?



a) 1

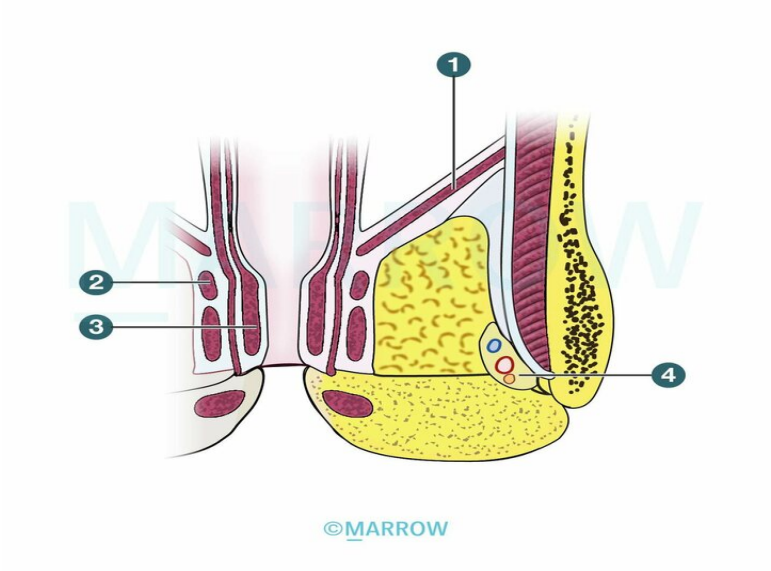
b) 2

c) 3

d) 4

Question 19:

Identify the pelvic diaphragm in the picture given below.



a) 1

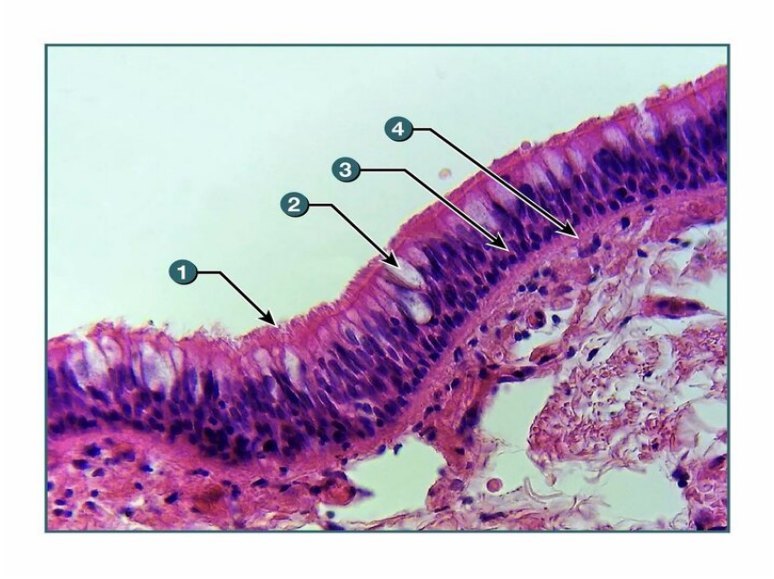
b) 2

c) 3

d) 4

Question 20:

Identify the incorrect match.



a) 1- Cilia

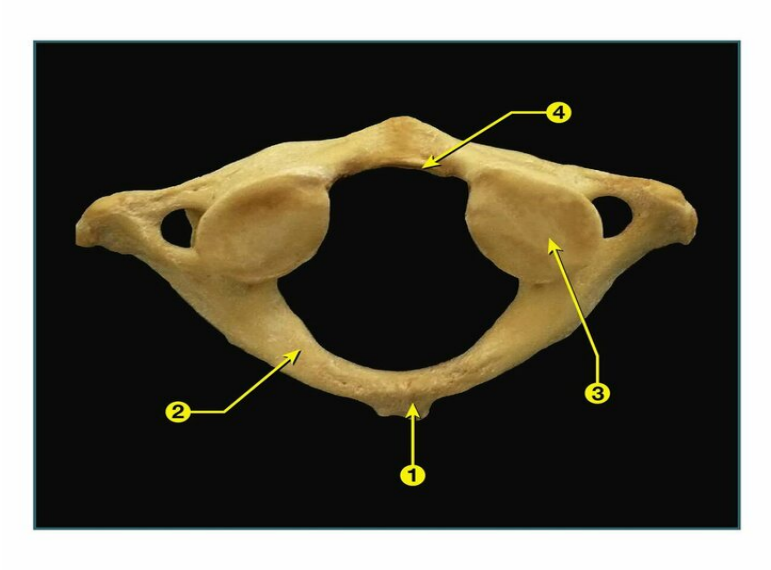
b) 4- Lamina propria

c) 2- Goblet cells

d) 3- Nuclei of epithelial cell

Question 21:

Third part of vertebral artery is related to which of the following ?



a) 4

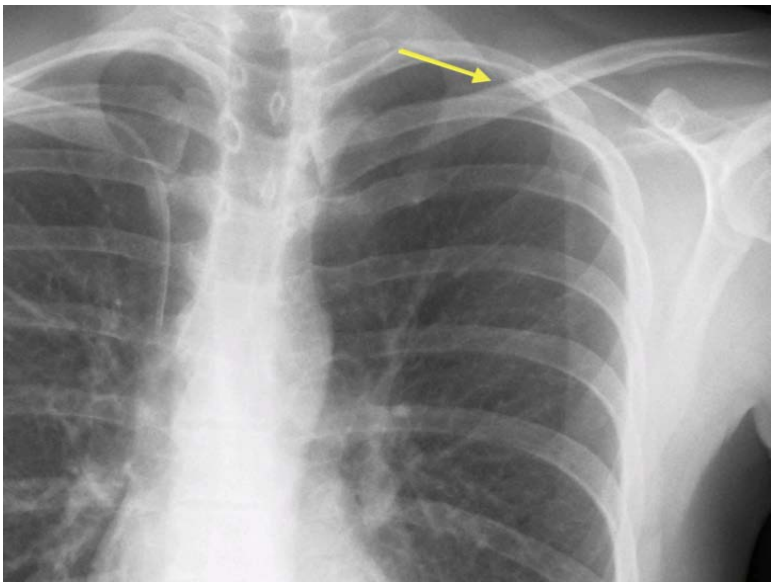
b) 3

c) 2

d) 1

Question 22:

What is the most common complication of the central line insertion below the marked bone?



a) Arterial puncture

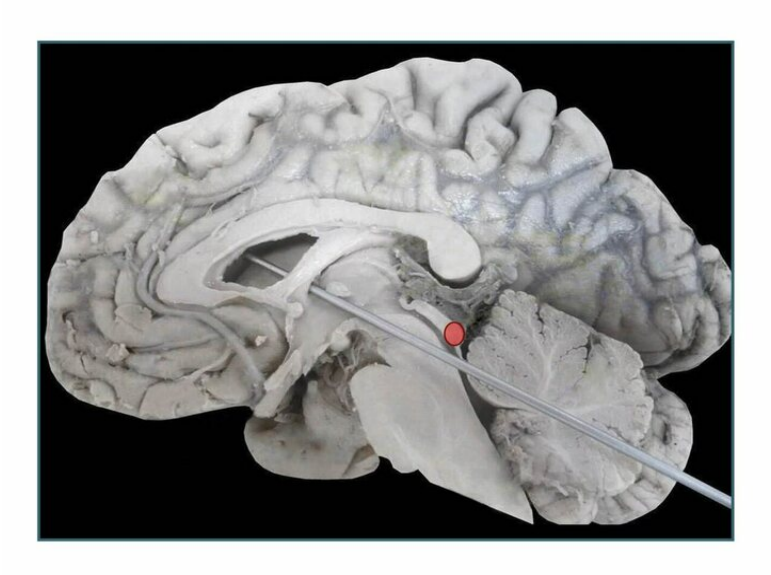
b) Thrombophlebitis

c) Empyema

d) Chylothorax

Question 23:

Identify the cranial nerve passing through the given structure



a) III

b) V

c) IV

d) VI

Answer Key

Question No.	Correct Option
1	a

Detailed Explanations

Solution to Question 1:

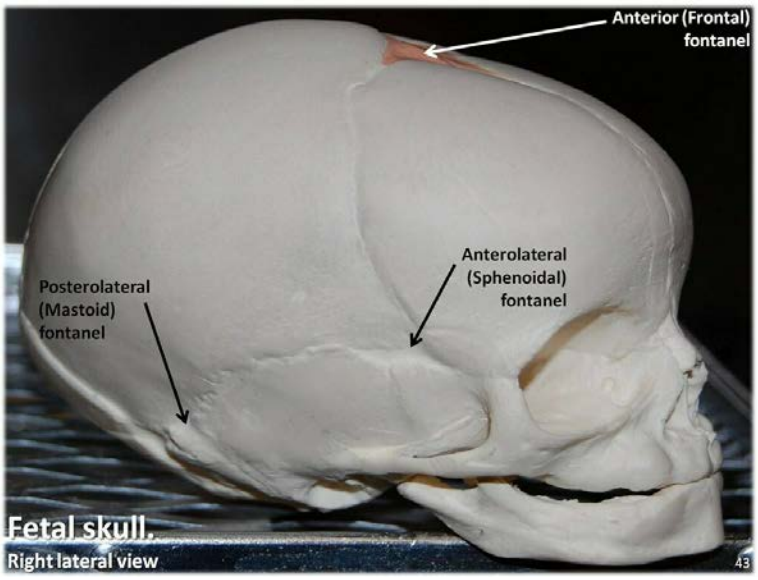
The given image shows the skull of an infant and the arrow points towards the anterior fontanelle. The procedure of collecting CSF from the anterior fontanelle is called ventricular tapping. The various structures pierced are the scalp, dura, and arachnoid.

Fontanelle tap/ Percutaneous ventricular puncture:

A fontanelle tap or percutaneous ventricular puncture is performed in infants without access to a VP shunt, who require urgent ventricular decompression and have an open anterior fontanelle. The infants' open fontanelle is directly punctured with a butterfly needle to enter the lateral ventricle to collect CSF samples or release the pressure or place a drain/catheter.

A 25-gauge butterfly needle is inserted through the anterolateral aspect of the anterior fontanelle (away from the midline, avoiding the superior sagittal sinus).

The image below shows the various fontanelles.



The scalp is a soft tissue that covers the calvaria of the skull. It consists of five layers (Mnemonic: SCALP). Below the scalp and the calvaria lie the meningeal layers, namely, pachymeninges [arachnoid + dura mater (P-AD)] and leptomeninges [arachnoid + pia mater (L-AP)]. One must reach the subarachnoid space below the arachnoid layer to collect or tap CSF. So, the layers pierced in the order are as follows:

• Skin

• Connective tissue (superficial fascia) with blood vessels and nerves

• Aponeurosis (galea aponeurotica) with occipitofrontalis muscle

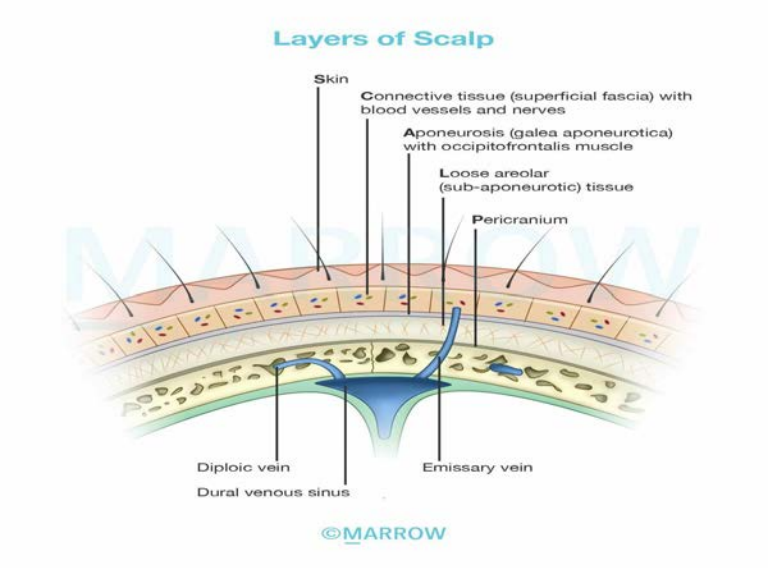
• Loose areolar (subaponeurotic) tissue

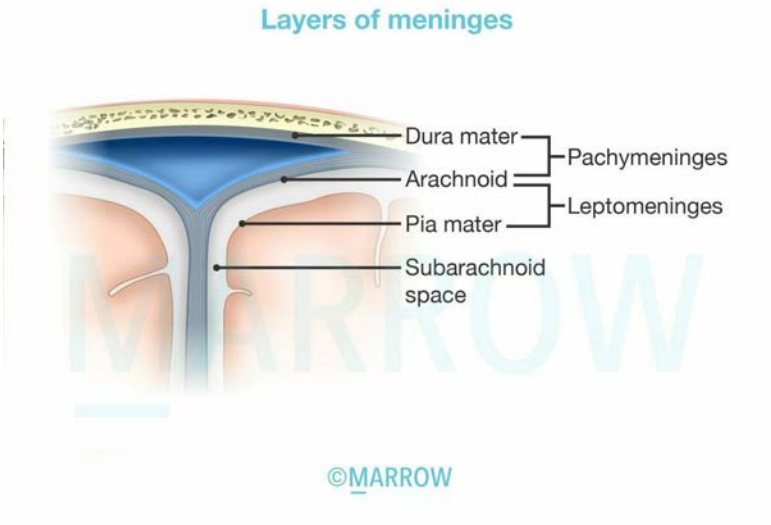
• Pericranium

• Dura mater

• Arachnoid membrane

The given images show the various layers that are pierced.





Solution to Question 2:

The given image is a cadaveric specimen with the arrow pointing towards, the tonsillar fossa, and the given clinical vignette is suggestive of tonsillitis. Post tonsillectomy hemorrhage is commonly venous in origin, from the paratonsillar/ external palatine vein.

Torrential hemorrhage can be due to injury to an aberrantly large or aberrantly placed tonsillar arterial branch of the facial artery.

Blood supply of the tonsils:

Arterial supply:

• The tonsillar branch of the facial artery is the main supply.

• Ascending palatine branch of the facial artery.

• Ascending pharyngeal branch of the external carotid artery.

• Dorsal lingual branches of the lingual artery.

• Descending palatine branches of the maxillary artery.

Venous supply:

• Veins from the tonsils drain into paratonsillar vein which joins the common facial vein and pharyngeal venous plexus.

Types of Hemorrhage seen during/post tonsillectomy:

• Primary hemorrhage:

• Occurs during surgery due to injury to blood vessels.

• Can be controlled by pressure, ligation, or electrocoagulation of the bleeding vessels.

• Reactionary hemorrhage:

• It occurs within 24 hours of surgery.

• It may be due to dislodgement of the clot, slippage of ligature, or return of blood pressure to normal.

• It is managed by removal of clot and application of pressure or vasoconstrictor.

• If not controlled the patient is anesthetized and hemorrhage is managed by re-exploration.

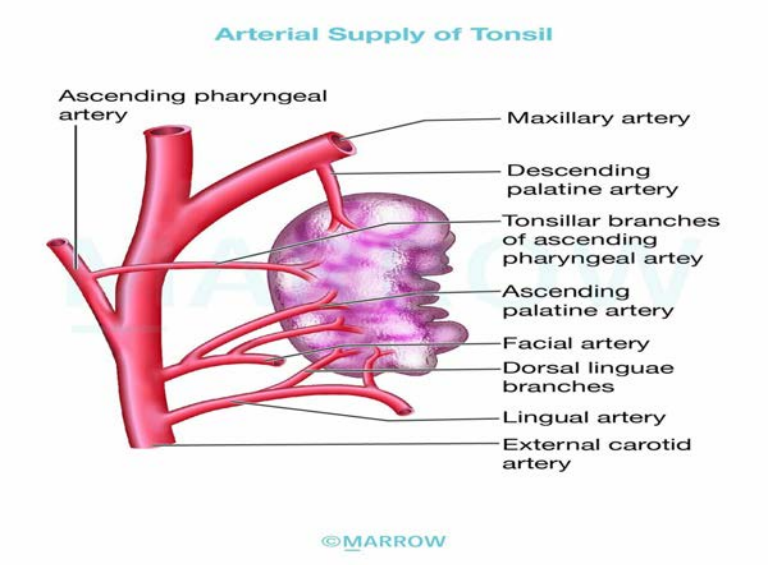
• Secondary hemorrhage:

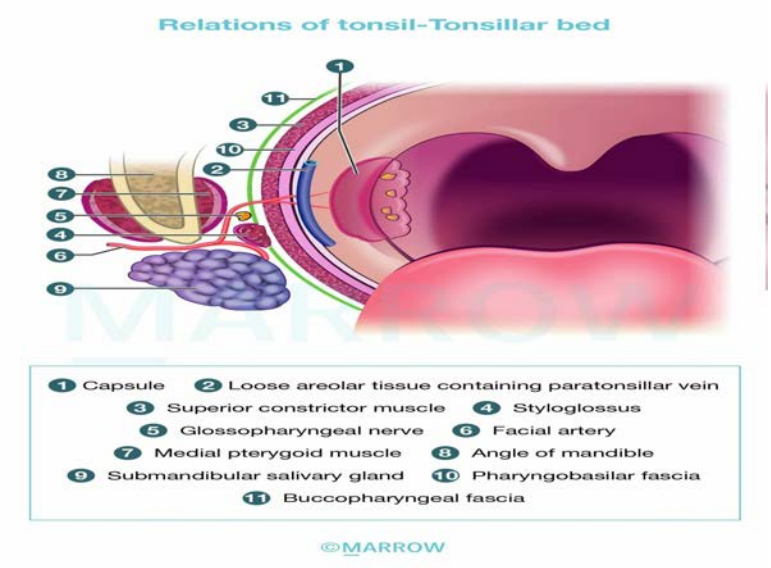
• It occurs between 24 hours to 10 days (most common between 5th to 8th postoperative days).

• It is due to sepsis and premature separation of the membrane.

• The patient is started on IV antibiotics and if not controlled, general anesthesia is given and the bleeding vessel is electrocoagulated or ligated.

The images below summarize the blood supply to the tonsils and the relations of the tonsillar bed respectively.





Solution to Question 3:

The muscle marked in the given CT image is that of the medial rectus. The medial rectus is supplied by the oculomotor nerve, the nucleus of which is situated at the level of the superior colliculus close to the red nucleus.

The nuclear complex from which the oculomotor nerve arises consists of:

• Several groups of large motor neurons are collectively called the oculomotor nucleus. The motor neuron groups of the oculomotor nucleus innervate, in dorsoventral order, the ipsilateral inferior rectus, inferior oblique, and medial rectus. A medially placed column of cells innervates the contralateral superior rectus.

• Smaller preganglionic parasympathetic neurons called the Edinger–Westphal preganglionic nucleus

Red Nucleus/ Nucleus Ruber

It is a rounded mass of grey matter located dorsomedial to the substantial nigra. It has a reddish hue in fresh specimens due to its extensive vascularity and the presence of ferric iron pigments in multipolar neurons.

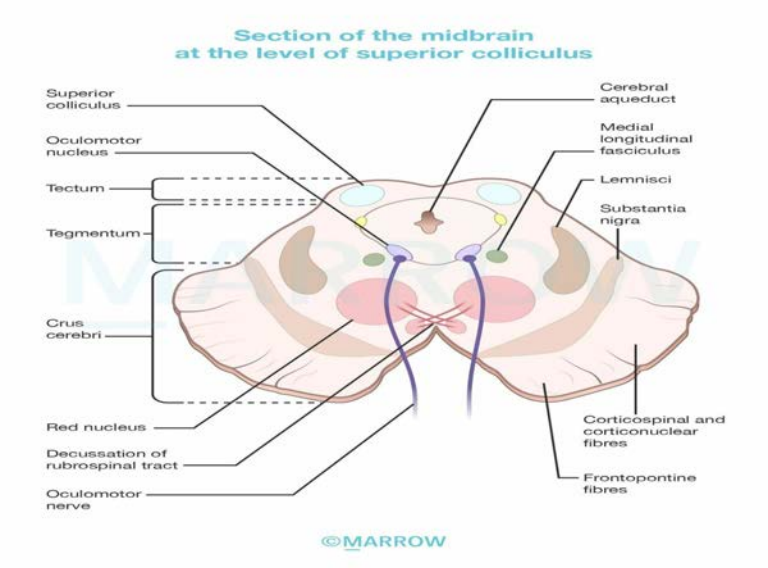
Clinical correlate:

Injury to the red nucleus can cause Benedikt's syndrome characterized by ipsilateral oculomotor nerve palsy and contralateral tremors, chorea, and athetosis.

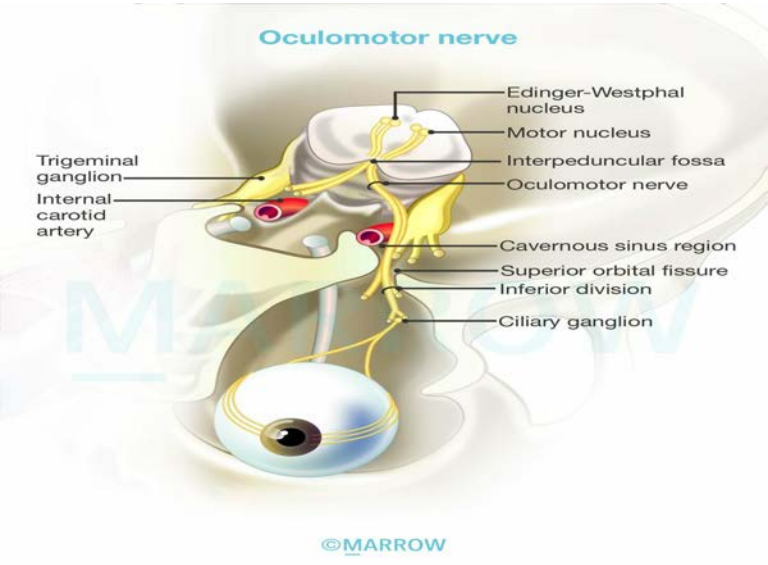
The given image shows the midbrain section at the level of superior colliculus. We can appreciate the two nuclei being close to each other.

Afferent connections	Efferent connections
The cerebral cortex by the co rticospinal fibers	The spinal cord by the rubros pinal tract

Afferent connections	Efferent connections
The cerebellum through the s uperior cerebellar peduncle	The reticular formation throu gh the rubroreticular tract
The lentiform nucleus, hypot halamic and subthalamic nuc lei, substantial nigra, and spi nal cord.	The substantia nigra and the thalamus



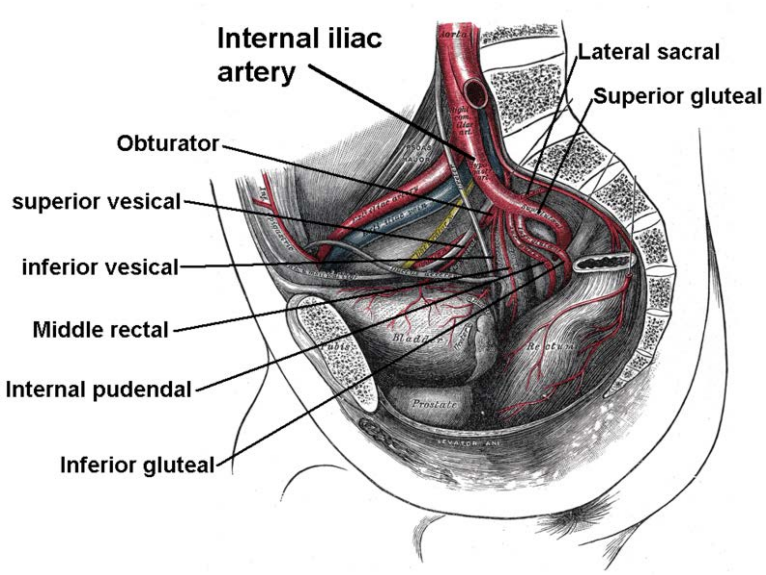
The image attached below summarizes the course of the oculomotor nerve.



Solution to Question 4:

The branches from the anterior division include 2, 3, 4, 5, 6.

The internal iliac artery is the major artery of the pelvis. At the superior border of the greater sciatic foramen in the pelvis, it divides into anterior and posterior trunks.

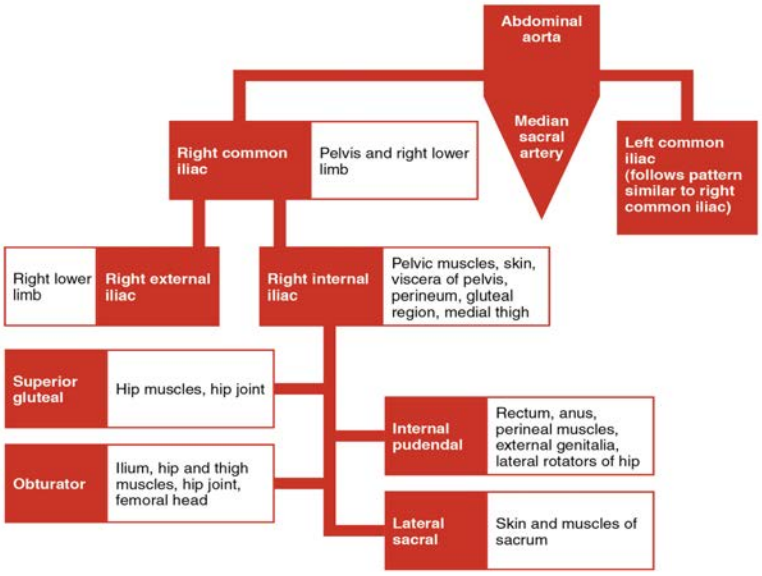


Branches of the anterior trunk of the internal iliac artery:

- Obturator artery
- Superior vesical artery
- Inferior vesical artery
- Inferior gluteal artery
- Middle rectal artery
- Vaginal artery (in females)
- Uterine artery (in females)
- Internal pudendal artery

Branches of the posterior trunk of the internal iliac artery:

- Iliolumbar artery
- Lateral sacral arteries
- Superior gluteal artery

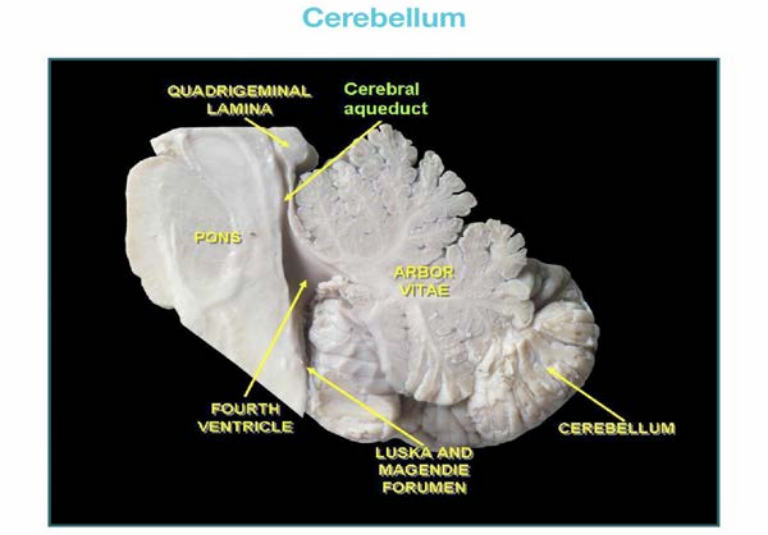


Solution to Question 5:

The peduncle highlighted in the image is the superior cerebellar peduncle. The superior cerebellar peduncle includes fibers from deep cerebellar nuclei that project to the brainstem, red nucleus, and thalamus. It also contains the ventral spinocerebellar tract fibers.

The superior cerebellar peduncle contains all the efferent fibers from the dentate, emboliform, and the globose nuclei, and a small fascicle from the fastigial nucleus. Its fibers decussate in the caudal mesencephalon and are destined to synapse in the contralateral red nucleus and thalamus. The middle cerebellar peduncle contains only afferent fibers from the contralateral pontine nuclei. The inferior cerebellar peduncle is a mixture of afferent fibers from the brainstem and spinal cord and efferent fibers to the vestibular nuclei.

The image below summarizes the various tracts in the cerebellar unit.



The cerebellum consists of two hemispheres (right and left) joined by a median vermis. It is divided into three lobes:-

• Anterior lobe - lies superiorly above the primary fissure

• Middle lobe - lies inferiorly below the primary fissure. It is the largest lobe. It is also called the posterior lobe.

• Flocculonodular lobe - lies posterior to the uvulonodular fissure

It has two surfaces - superior and inferior separated by a horizontal fissure. It is connected to the other parts of the central nervous system via three peduncles

• Superior cerebellar peduncle -connecting to the midbrain

• Middle cerebellar peduncle - connecting to the pons

• Inferior cerebellar peduncle - connecting to the medulla oblongata

Solution to Question 6:

The given clinical stem of a hemi-sensory loss and severe excruciating pain of the affected areas is suggestive of thalamic pain syndrome also known as Dejerine Roussy syndrome. Hence, thalamus marked as B is most likely to be involved.

Occlusion of these thalamic and thalamogeniculate branches results in the thalamic pain syndrome. It is characterized by C/L hemisensory loss which starts as numbness and progresses to cause severe burning pain in the affected regions. As the thalamus is the site for the relay of sensory information between the periphery and cortex, a lesion in the thalamus causes a miscommunication between the afferent pathway and cortex of the brain. Pain occurs during the recovery from the thalamic infarct. This pain responds poorly to analgesics. Anticonvulsants such as carbamazepine or gabapentin or tricyclic antidepressants may be beneficial.

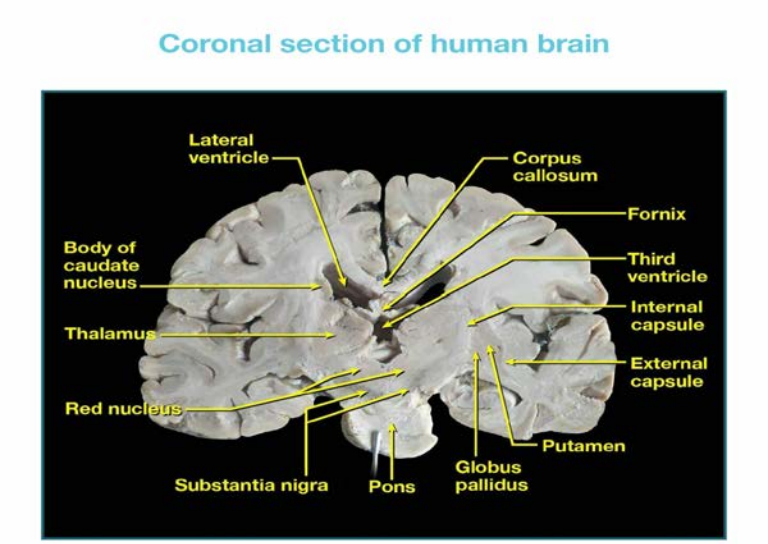
Other markings:

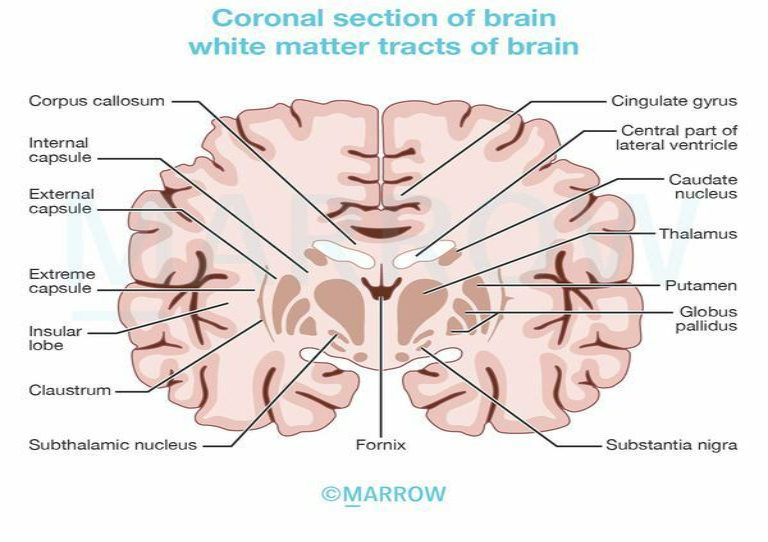
A: Caudate nucleus

C: Substantia nigra

D: Pons

The image below shows the coronal section of the brain with different parts of the basal ganglia:





Solution to Question 7:

The given clinical situation with a positive card test and an inability to flex the distal interphalangeal joint of the 4th and 5th digits, suggests an ulnar nerve injury. The most likely site of injury would thus be medial epicondyle: site C

Injury at the medial epicondyle damages the ulnar nerve, leading to paralysis of flexor carpi ulnaris (loss of ulnar deviation) and medial half of flexor digitorum profundus (loss of distal interphalangeal joint flexion). It leads to hypothenar paralysis (lead to atrophy) and sensory loss. Also, flexor digitorum superficialis (supplied by median nerve) and extensor digitorum (supplied by the radial nerve) are still functional. Hence complete paralysis of the 3rd and 4th digits is not seen. The positive card test is due to the weakness of palmar interossei leading to loss of adduction.

Ulnar nerve branches and supply:

Superficial branch supplies palmaris brevis, skin on the palmar surface of medial 1½ fingers. The deep branch runs within the concavity of deep palmar arch and supplies all intrinsic muscles of the hand (except first 2 lumbricals and thenar muscles).

Injury to the Ulnar nerve:

Other tests seen in ulnar nerve lesions are as follows:

• Claw hand deformity

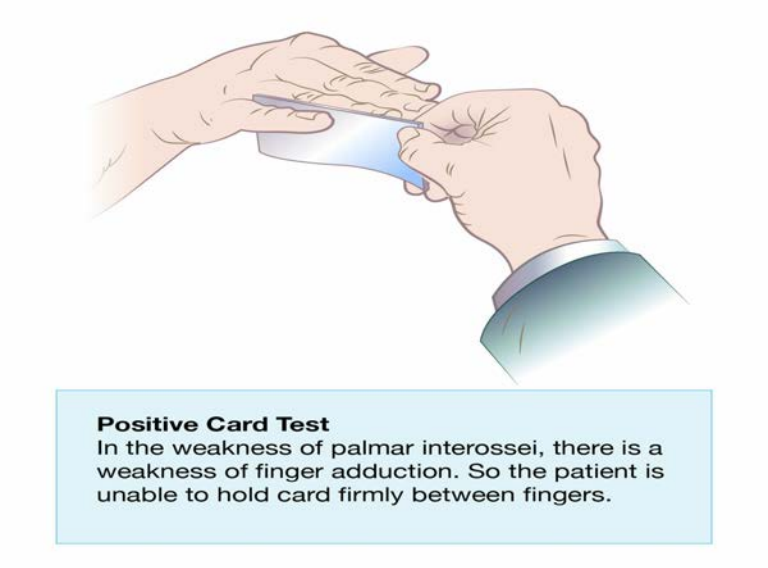
• Froment's sign positive

• Wartenberg sign

• Palmaris brevis sign

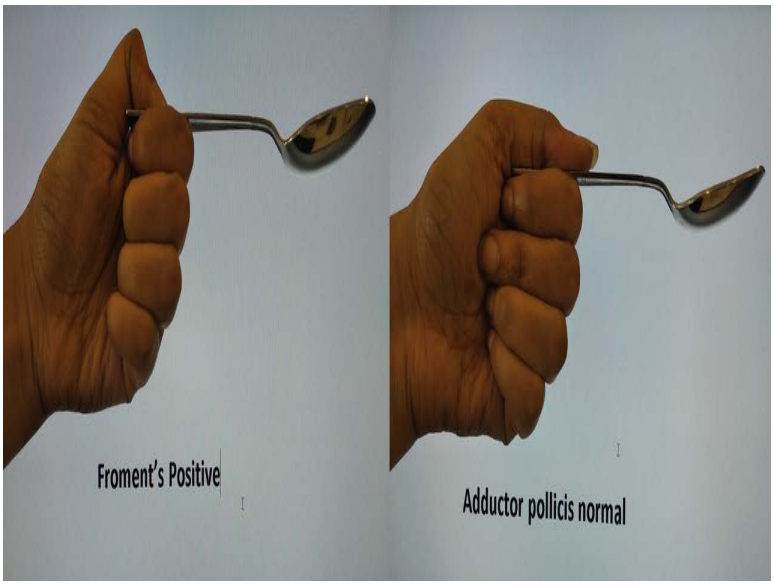
	High lesion(Elbow)	Low lesion(Wrist)
Site of injury	Fracture/dislocation of theme dial epicondyleCubital tunnel syndromeCompression betw een the two heads of FCUTar dy ulnar nerve palsy (Valgus deformity)	Wrist laceration/ slashingGuy on's canalsyndrome
Motor loss	Claw-handdeformityHypothe nar & interosseous wastingLo ss of:• Abduction & adduction of fingers(Card test- Positive) • Adduction of thumb(Frome nt sign-Positive)• Flexion of MCP jointsWeakness of wrist flexion (radial deviation)	Claw-handdeformity(more pr onounced)Hypothenar & inte rosseous wastingLoss of:• Ab duction & adduction of finger s(Card test- Positive)• Adduct ion of thumb(Froment sign-P ositive)
Sensory loss	Over palmar & dorsal aspect of themedial thirdof thehand Over palmar & dorsal aspect of themedial 11/2fingers	No sensory lossover palmar & dorsal aspect of the medial third of the handOver palmar & dorsal aspect of themedial 11/2fingers

The image below shows a positive card test.



Positive Card Test
In the weakness of palmar interossei, there is a weakness of finger adduction. So the patient is unable to hold card firmly between fingers.

Wartenberg's sign: (Weakness of palmar interossei), Sensory loss Palmar and dorsal surface of the medial third of hand and medial 1 and a half fingers.



Other options:

• Option A: Radial groove - Radial nerve

• Option D: Neck of humerus - Axillary nerve

• Option B: Lateral epicondyle – May lead to tardy ulnar nerve palsy after fracture but the incidence is less.

Solution to Question 8:

The image shows pharyngeal pouches and based on the clinical history, the patient most likely has DiGeorge syndrome(thymic and parathyroid defects). It may be caused by defective development of the third and fourth pharyngeal pouch. In the given stem, it is clearly mentioned that the thymus is absent. Thus, the better of the two options is 3.

DiGeorge syndrome is a complex embryopathy that is caused by hemizygous interstitial deletion of chromosome 22, leading to multiple developmental defects, including conotruncal defects, hypoparathyroidism, and dysmorphic syndrome. Microdeletion at chromosome 22q11 can lead to variable presentations including

• Cleft palate

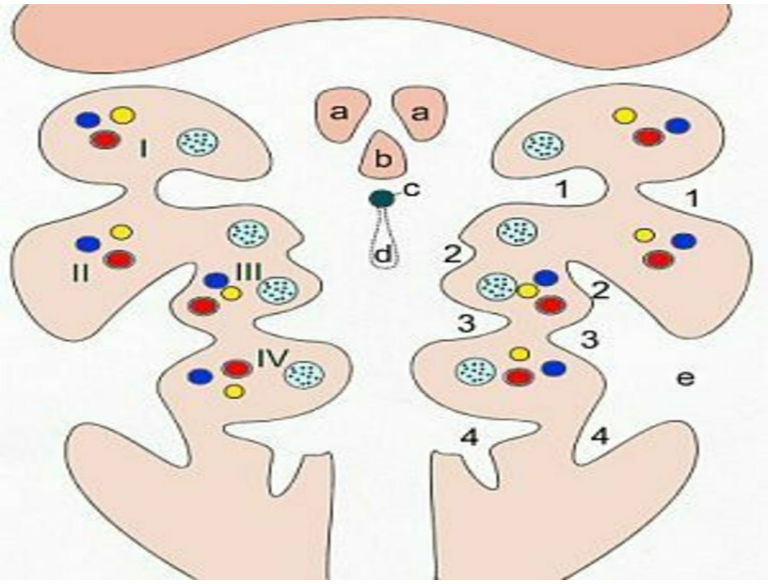
• Abnormal facies

• Thymic aplasia leading to T-cell deficiency

• Cardiac defects

• Hypocalcemia 2° to parathyroid aplasia. (Mnemonic: CATCH-22)

Velocardiofacial syndrome - palate, facial, and cardiac defects.



In the diagram, I-IV are the branchial arches, 1-4 are pharyngeal pouches (inside), and/or pharyngeal grooves (outside)

• Tuberculum lateral

• Tuberculum impar

• Foramen cecum

• Ductus thyroglossus

• Sinus cervicalis

• First pharyngeal pouch, middle ear cavity, and epithelial lining of the auditory tube.

• Second pharyngeal pouch, palatine tonsils

• Points towards third pharyngeal pouch which gives rise to inferior parathyroid gland and thymus.

• Fourth pharyngeal pouch, Superior parathyroid gland, and ultimobranchial body.

Solution to Question 9:

The given clinical vignette is suggestive of injury to axillary nerve which leads to deltoid muscle palsy.

The axillary nerve supplies the deltoid muscle. Iatrogenic injuries of the axillary nerve can occur due to incorrectly administered IM injection or while performing transaxillary operations on the shoulder with lateral deltoid-splitting incisions. But, note that this nerve is commonly injured during shoulder dislocation (most commonly anterior type) or fractures of the humeral neck as both the nerve and the posterior circumflex vessels (Option-B) pass horizontally and posterior to the neck of the humerus.

Injury to the axillary nerve can lead to:

• Weakness of abduction and lateral rotation of the arm

• Retropulsion (extension of the shoulder with the arm abducted to 90 degrees) is impossible.

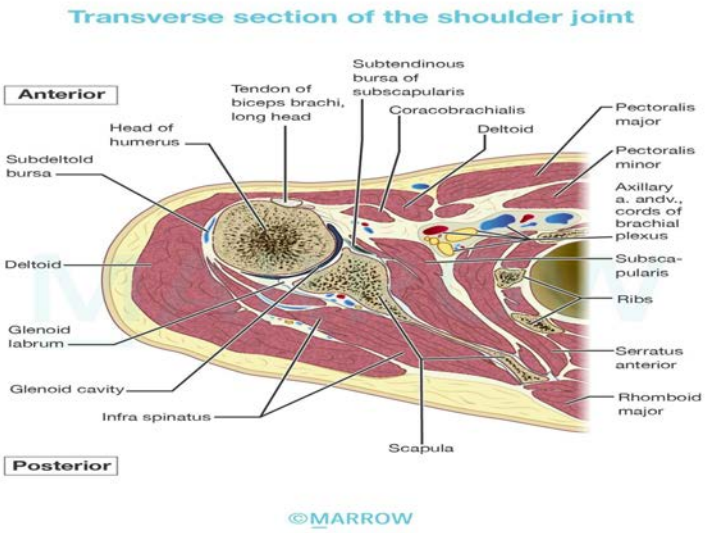
• Atrophy of the Deltoid muscle leading to the loss of muscle contours of the shoulder

• Loss of sensation in the Regimental badge area

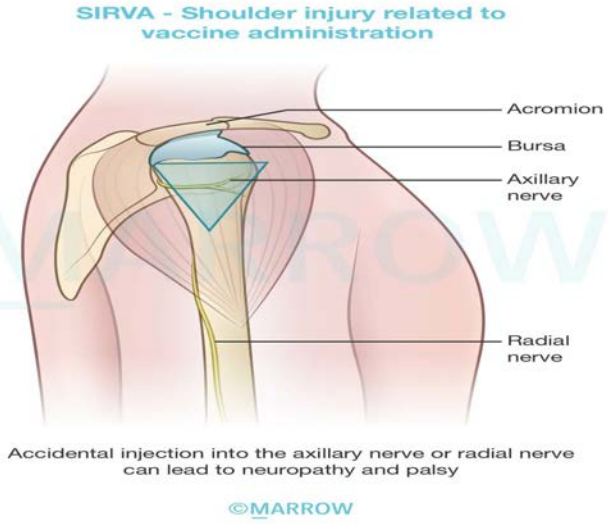
Note:

Upper (superior) lateral cutaneous nerve of the arm (Option-C) that innervates the skin over the lower deltoid (regimental badge area). Thus, this is not the best of the given four options.

The images below show the Seargent/regimental badge sign and the various anatomical structures that can be appreciated in the transverse section of the shoulder joint respectively.



Vaccine administration in the deltoid can sometimes injure the axillary and the radial nerve.

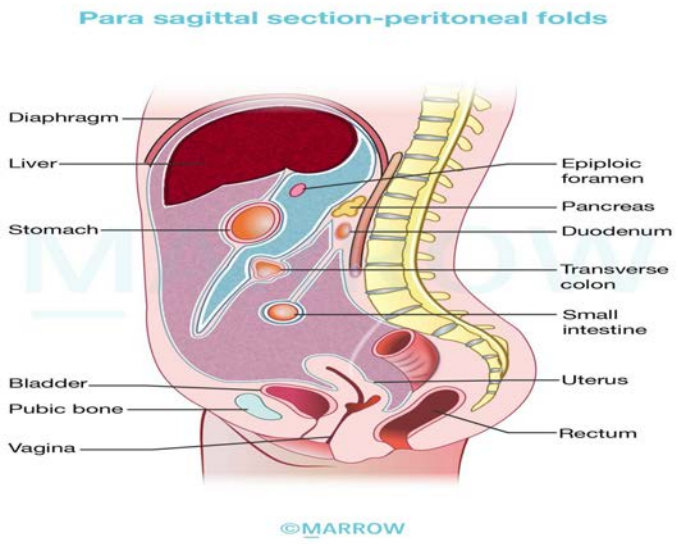


Solution to Question 10:

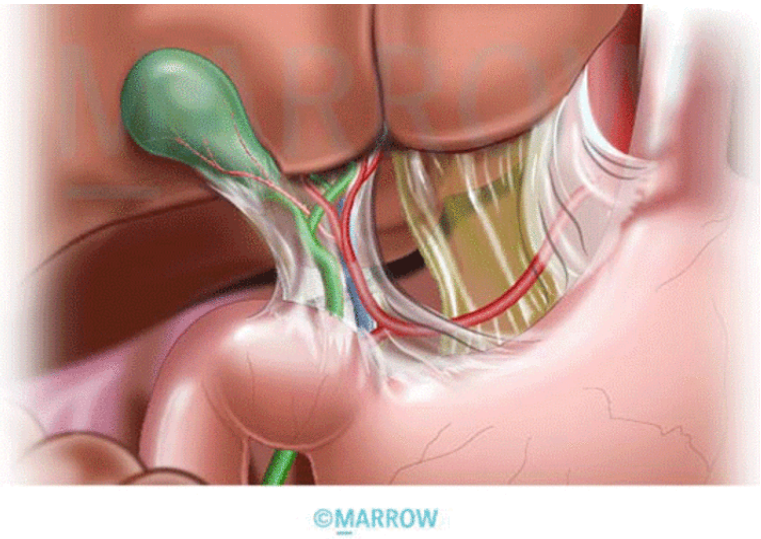
The structure marked in the given image is epiploic foramen. The superior border of the epiploic foramen (foramen of Winslow) is formed by the caudate lobe of the liver.

Epiploic foramen is a vertical slit of about 3 cm behind the free right border of the lesser omentum. It connects the lesser sac to the greater sac. The pearl summarizes the various relations of the foramen.

The image attached shows the various peritoneal reflections.



Clinical note: Pringle maneuver (as shown below) is a technique where the free margin of the lesser omentum is compressed to obtain rapid control of the hepatic artery and portal vein in liver trauma and surgery.

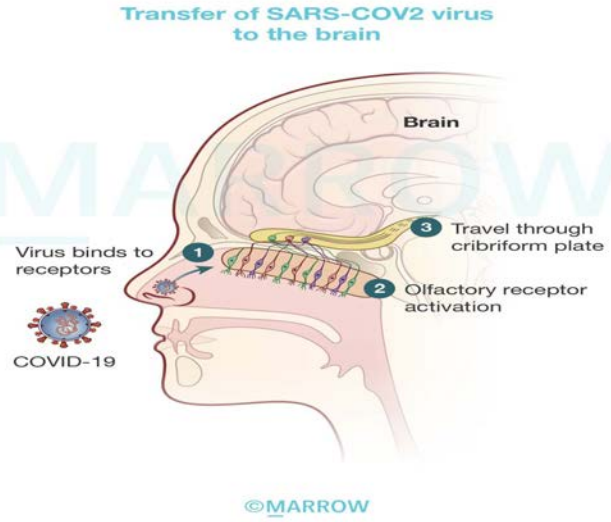


Solution to Question 11:

The given image shows various skull foramina's. Infection through the cribriform plate and olfactory bulb (A) and dissemination through trans-synaptic transfer are some of the mechanisms proposed for the SARS-COV2 virus to reach the brain.

Encephalitis, demyelination, neuropathy, and stroke are the neurological sequelae to severe COVID-19 infection. The neurological invasion of the virus on the medullary cardiorespiratory center can lead to refractory respiratory failure in patients infected with COVID-19.

The pathogenesis implicated is explained in the image attached below.



Solution to Question 12:

The structure involved in causing lurching gait in the child is gluteus medius (marked as 2).

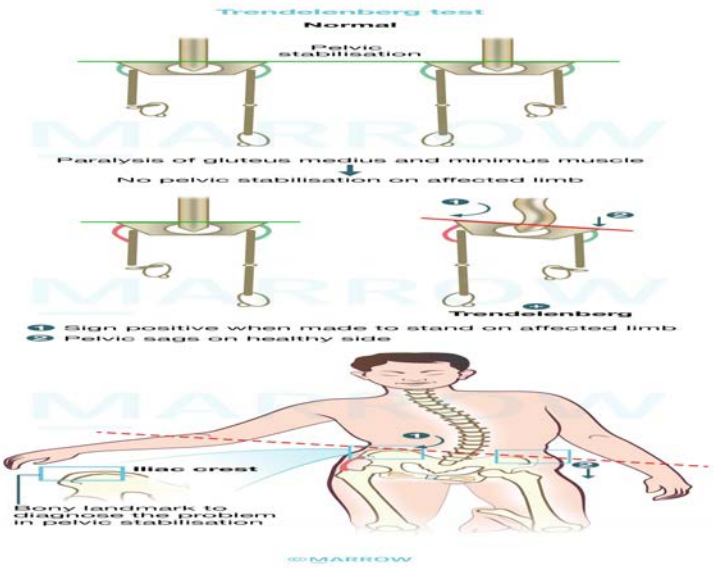
The gluteus medius originates from the outer surface of the ilium between the anterior and posterior gluteal lines. Insertion of the muscle is at the lateral surface of the greater trochanter. It is supplied by the superior gluteal nerve.

Gluteus medius and minimus are powerful abductors of the hip joint. Mechanism of actions of gluteus medius and minimus:

• When the leg on one side is lifted off the ground, the gluteus medius and minimus muscles, on the opposite supported side, exert traction on the hip bone by acting from the femur. This action results in a slight raising of the pelvis on the unsupported side, which helps maintain the trunk in the upright position.

• The actions of these muscles are affected when there is an injury to the superior gluteal nerve, neck of the femur, or loss of normal angulation of the shaft of the femur. This occurs in conditions like paralysis of the glutei, developmental dysplasia of the hip, etc.

• When the gluteus medius and minimus are paralyzed, the pelvis sinks down on the unsupported (normal) side, when the patient tries to stand on the affected limb. This leads to a positive Trendelenburg's sign with a characteristic lurching gait - the patient lurches towards the affected side with contralateral pelvis drop.

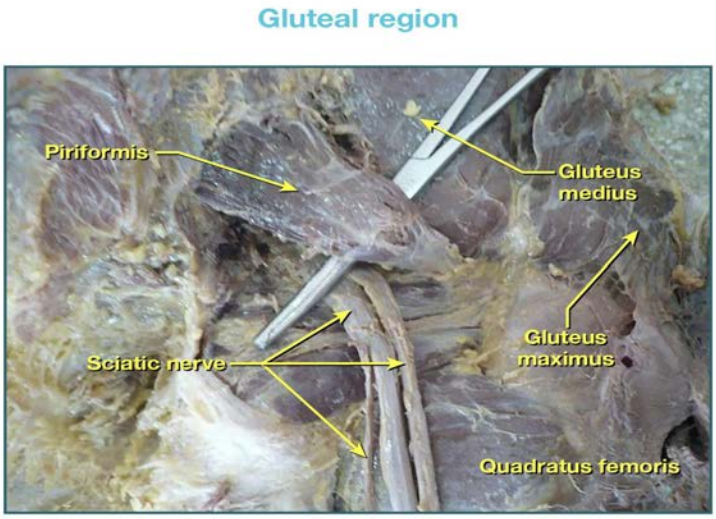


Other options

1 - Gluteus maximus - involved in the extension of flexed thigh, abduction (only upper fibres), and lateral rotation at the hip joint. Insertion is at the iliotibial tract.

3 - Piriformis - involved in lateral rotation and assists abduction at the hip joint. It is inserted into the medial side of greater trochanter of the femur. Entrapment of the sciatic nerve in the piriformis can lead to piriformis syndrome.

4 - Sciatic nerve - The nerve passes over the obturator internus, gemellus superior, gemellus inferior and quadratus femoris. It supplies knee flexors and muscles below the knee. Paralysis of this nerve results in flail foot and severe difficulty in walking.



Solution to Question 13:

The given clinical scenario is suggestive of the involvement of 9th and 10th cranial nerves due to occipitotemporal fracture and they are examined by testing the uvula which is marked as 2 in the given image.

The jugular foramen is located between the lower border of the petrous part of the temporal bone and the condylar part of the occipital bone. As the investigations reveal fractures in the occipitotemporal region, along with the history of difficulty in swallowing and slurred speech, are suggestive of injury to the glossopharyngeal and vagus nerve passing through the jugular foramen.

Unilateral lesions of IX and X cranial nerves are commonly caused by skull-base fractures, strokes, or tumors.

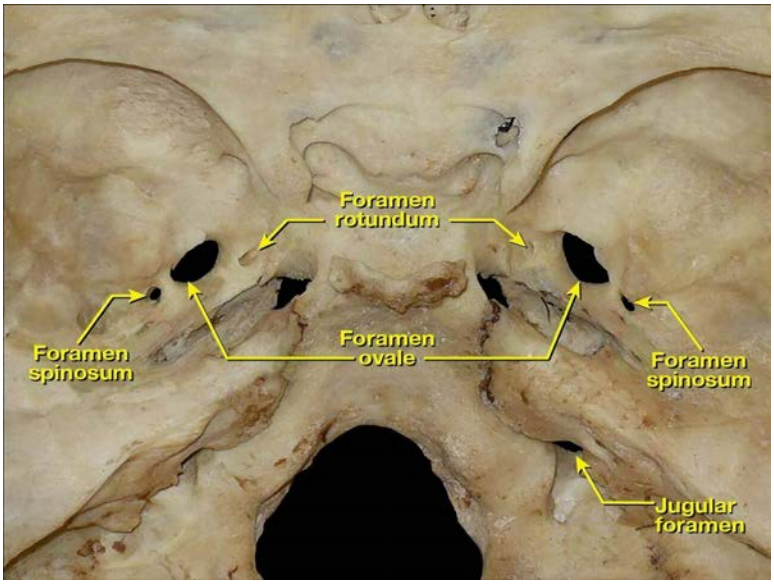
Glossopharyngeal and Vagus nerve examination include:

• Observing the position and symmetry of the palate and uvula(marked as 2 in the given image) at rest and with phonation (“aah”).

• The pharyngeal (“gag”) reflex is evaluated by stimulating the posterior pharyngeal wall on each side with a sterile, blunt object (e.g., tongue blade)

Patients with a proximal unilateral lesion of the vagus nerve complain of dysphagia. There will be a weakness of the soft palate muscles on the affected side. Attempts to voluntarily elevate the soft palate, like by asking the patient to say “aah” will reveal a weakness in elevation of the palate on the affected side. Along with this, there will be deviation of the uvula to the normal side, due to the unopposed action of palatal muscles on that side.

The below image shows the base of the skull and its foramina:



Solution to Question 14:

The structure marked in the above image is mamillary body and the fibers from the mamillary body end in the anterior nucleus of the thalamus.

The mammillary bodies are two small hemispherical, pea-sized eminences, lying side by side, forming the floor of the third ventricle. The fibres from medial mammillary nucleus project to the

anterior nucleus of the thalamus.

The anterior thalamic nuclei have 3 subdivisions—anteroventral nucleus, anteromedial nucleus, and anterodorsal nucleus.

• Major input: Mamillothalamic tract from the mammillary nuclei of the hypothalamus.

• Major cortical output: Anterior limbic area, cingulate, and the parahippocampal gyrus

• Major function:

• Regulation of alertness and attention

• Acquisition of memory

Solution to Question 15:

The structure marked in the image is a flask-shaped neuron in the cerebellar cortex, which is a Purkinje cell. It is inhibitory to deep cerebellar nuclei.

Purkinje cells are the flask-shaped cells present in the Purkinje cell layer of the cerebellum. They are evenly spaced and arranged in a single layer between molecular and granular cell layers. The dendrite from each cell passes upward to enter the molecular layer and the axon of each cell passes downwards, crosses the granular cell layer, and terminates on the deep cerebellar nuclei. They are inhibitory and use GABA as their neurotransmitter.

Axons of Purkinje cells are the only efferents of the cerebellar cortex. They receive excitatory input from the climbing fibers from the inferior olivary nucleus and mossy fibers.

Pathological significance of Purkinje cells:

• Negri bodies in rabies are usually found as eosinophilic, cytoplasmic inclusions in the neurons of the hippocampus and Purkinje cells of the cerebellum.

• In paraneoplastic cerebellar degeneration, there is the destruction of Purkinje cells due to antibodies directed against them.

• Purkinje cells and neurons in pyramidal cell layers of the hippocampus and cerebral cortex are the most sensitive neurons to hypoxia and are likely to be damaged in cases of global cerebral ischemia.

Solution to Question 16:

The structure marked in the given image is the azygos vein, which develops from the supracardinal vein.

The azygos system of veins forms a connecting channel between the superior and inferior venae cavae. It occupies the upper part of the posterior abdominal wall and the posterior mediastinum. It also connects the portal, caval system, and vertebral venous systems.It drains the thoracic wall and the upper lumbar region.

Development: The azygos venous system arises from the supra cardinal veins embryologically. The right supra cardinal vein becomes the azygos vein, while the left supra cardinal vein becomes

the hemiazygos vein.

• The 4th to 11th right intercostal veins empty into the right supracardinal vein, which together with a portion of the posterior cardinal vein forms the azygos vein.

• On the left, the 4th to 7th intercostal veins enter into the left supracardinal vein, and the left supracardinal vein, then known as the hemiazygos vein, which also empties into the azygos vein.

Other options: Cardinal veins form the main venous drainage system of the embryo. It consists of,

• Anterior cardinal veins, which drain the cephalic part of the embryo, and

• Posterior cardinal veins, which drain the rest of the embryo.

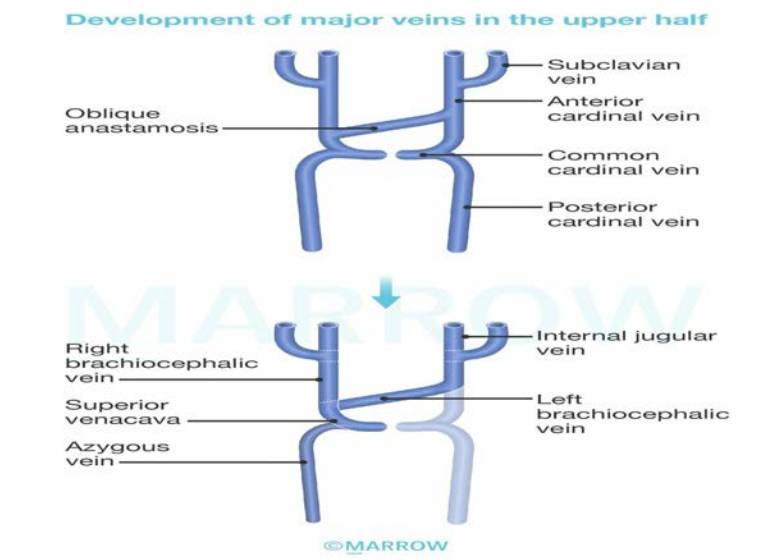
During the fifth to the seventh weeks, a number of additional veins are formed. It includes,

• Subcardinal veins, which mainly drain the kidneys;

• Sacrocardinal veins, which drain the lower extremities;

• Supracardinal veins, which drain the body wall by way of the intercostal veins.

Below image shows cardinal veins development.



Solution to Question 17:

All the given 4 structures are supplied by the Inferior thyroid artery.

Inferior thyroid artery is a branch of the thyrocervical trunk, which in turn, is a branch of the first part of the subclavian artery. The inferior thyroid artery loops upwards anterior to the medial border of the scalenus anterior, turns medially just below the sixth cervical transverse process, and then descends on longus colli to the lower border of the thyroid gland.

Branches:

• Pharyngeal branches: These supply the lower part of the pharynx.

• Tracheal branches supply the trachea and anastomose with the bronchial arteries;

• Oesophageal branches supply the oesophagus and anastomose with the oesophageal branches of the thoracic aorta; and

• Inferior and ascending glandular branches supply the posterior and inferior regions of the thyroid gland, and anastomose with the contralateral inferior and ipsilateral superior thyroid arteries.

• The ascending branch also supplies the parathyroid glands.

• Ascending cervical artery

• Inferior laryngeal

• Muscular branches

Note: Thymic branches originating from the internal thoracic, inferior thyroid artery, and sometimes superior thyroid arteries supply the thymus and the surrounding mediastinal connective tissue.

Solution to Question 18:

The part of the scapula marked as 1 is the coracoid process and it is palpable in the infraclavicular fossa. The tip of the coracoid process lies approximately 2.5 cm below the clavicle, immediately lateral to the infraclavicular fossa (deltopectoral triangle). Hence, the coracoid process can be palpated below the clavicle.

The coracoid process arises from the upper border of the neck of the scapula and it projects forwards and slightly laterally. Attachments at the coracoid process include

• The conoid portion of the coracoclavicular ligament

• Pectoralis minor

• Medial end of coraco-acromial ligament

• Coracohumeral ligament

• Glenocorocoid ligament

• Coracobrachialis muscle

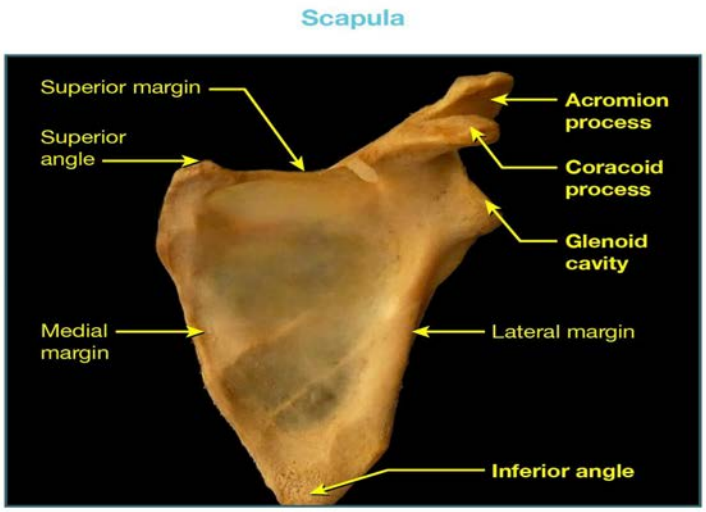
Other options

Option B - Acromian process continues from the spine of the scapula. The acromion is subcutaneous over its dorsal surface, The attachments at the acromion are the coracoacromial ligament, the articular capsule of the acromioclavicular joint, and horizontal fibers of the trapezius.

Option C - The glenoid fossa is present at the lateral angle of the scapula. It is articular with the humerus to form the shoulder joint.

Option D - The inferior angle lies over the seventh rib. Dorsally, it is related to latissimus dorsi. The angle is visible when the arm is raised over the head.

Parts of the scapula are given in the image below.



Solution to Question 19:

The structure marked "1" is the levator ani muscle which is part of the pelvic diaphragm.

Other structures marked in the above image are

2: External anal sphincter

3: Internal anal sphincter

4: Pudendal canal

Pelvic diaphragm

The muscular part of the pelvic floor is the pelvic diaphragm. It is attached to the pelvic wall on either side between the greater and lesser sciatic foramen. Levator ani and coccygeus muscles form the pelvic diaphragm and delineate the lower limit of the true pelvis.

Levator ani is formed by pubococcygeus, iliococcygeus, and puborectalis. The muscles blend together posterior to the vagina in women and around the anus in both sexes. Posterior to the anal aperture, the form the anococcygeal body attaches to the coccyx. Urogenital hiatus is present anteriorly separating the muscles. This allows the urethra and vagina to pass through. Levator ani reinforces the external anal sphincter. In women, it functions as the vaginal sphincter.

The coccygeus muscles, one on each side are triangular in shape and form the posterior part of the pelvic diaphragm. The apices are attached to the tips of ischial spines. The bases are attached to the coccyx and sacrum.

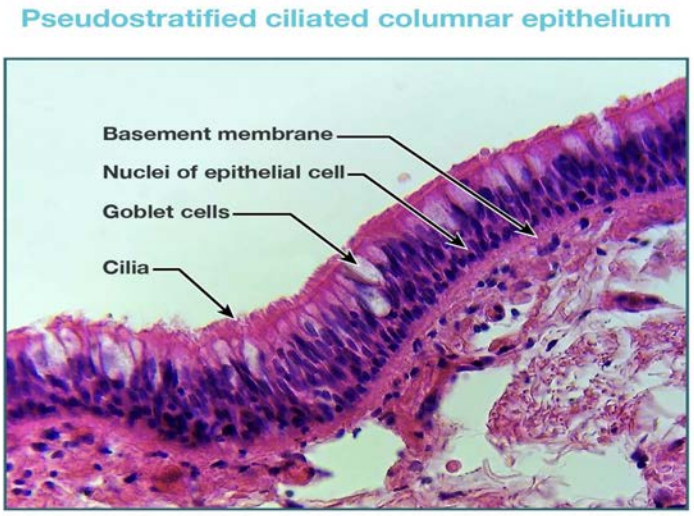
Solution to Question 20:

Among the given options, Option B represents an incorrect match, as the structure labeled as 4 is showing the basement membrane and not lamina propria.

The given image is of pseudostratified ciliated columnar epithelium, as it shows irregular cells, which are attached to the basement membrane(marked as 4 in the image). It appears to be multi-layered. However, there is actually only one layer of cells. The multi-layered appearance is due to the fact that the nuclei of epithelial cell(marked as 3 in the image) lie at different levels.

The epithelium shows hair-like projections called cilia (marked as 1 in the image) and goblet cells (marked as 2 in the image). Goblet cells secrete mucous which helps to trap dust entering the passages. The cilia are capable of movement and help in the clearance of mucous.

Example include epithelium lining the trachea and in large bronchi.



Solution to Question 21:

The third part of the vertebral artery (V3) is related to the area marked 2, which is the posterior arch of the first cervical vertebra or the atlas.

The given image shows the first cervical vertebra - atlas.

• The area marked 1 is the posterior tubercle.

• The area marked 2 is the posterior arch. The superior surface bears a groove for the of vertebral artery and venous plexus immediately behind.

• The area marked 3 is the superior articular facet.

• The area marked 4 is the posterior surface of the anterior arch. It gives attachment to the apex of dens from the second cervical vertebra.

The vertebral artery arises from the first part of the subclavian artery. It passes through the foramina of transverse processes of C6 to C1 cervical vertebrae and enters the cranium through the foramen magnum. The vertebral arteries of both sides join to form the basilar artery. In its course, it is divided into four parts:

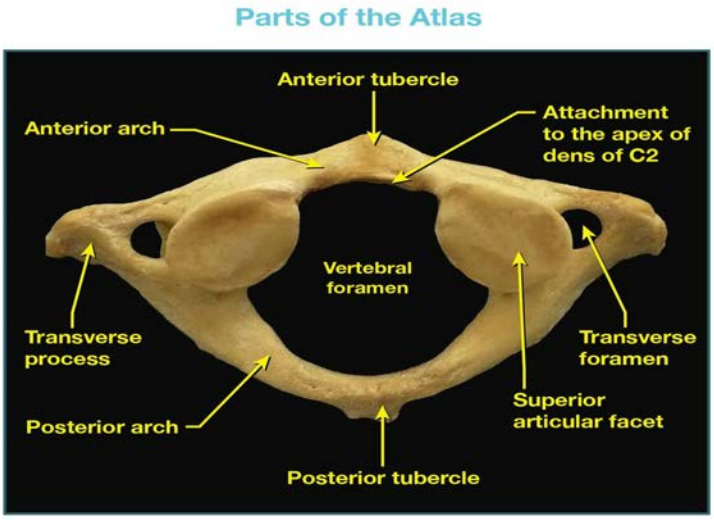
The first part, V1, begins at its origin from the subclavian artery and ends at its entry into the transverse process of the C6 cervical vertebra. This part is crossed by the inferior thyroid artery on

both sides, and thoracic duct on the left side, and the right lymphatic duct on the right side.

The second part, V2 is that part of the artery ascending through the foramina in the transverse process of the cervical vertebrae.

The third part, V3 is curved backward behind the atlas. In this position, it lies in a groove on the posterior arch of the atlas. This part of the artery lies in the suboccipital triangle.

The fourth part, V4 pierces the dura and arachnoid mater and unites with the contralateral vertebral artery to form the midline basilar artery at the lower border of pons.



Solution to Question 22:

The bone marked in the above image is the left clavicle. The most common complication of a central line insertion below this bone is an arterial puncture.

Complications of central vein catheterization are

• Arterial puncture- this is the most common complication.

• Cardiac tamponade is the most important life-threatening complication. It occurs as a result of puncture of intrapericardial superior vena cava, right atrium, or right ventricle.

• Pneumothorax- injury to the underlying pleura may lead to pneumothorax. This is more common in subclavian vein catheterization.

• Chylothorax can occur particularly in left subclavian vein catheterisation. But it is not the most common.

• Injury to the associated nerves like brachial plexus, stellate ganglion, phrenic nerve, or vocal cords.

• Thromboembolism leading to venous thrombosis, pulmonary embolism is more common with femoral veins.

• Infections

Central venous catheterization is the insertion of the catheter into a large central vein. The veins preferred largely depend on the underlying disease in the patient, the clinical setting, and the expertise of the doctor.

The internal jugular vein is preferred when the patient has:

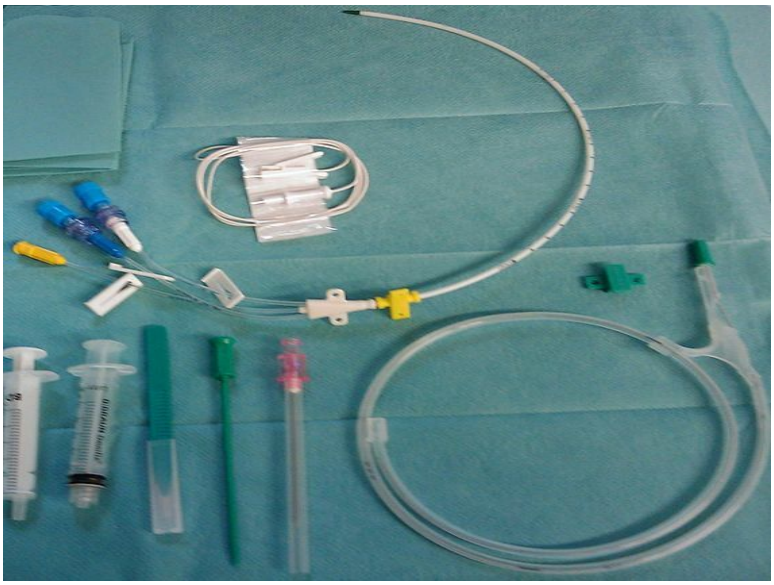
• Bleeding diathesis- Bleeding from this vein can be easily detected and can be controlled with pressure.

• Pneumothorax- The lesser risk of injury to the lung

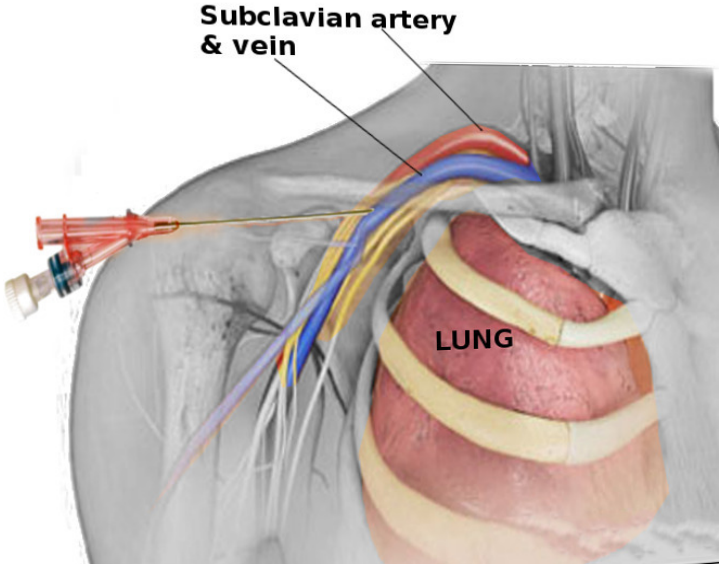
• Needs cardiac pacing- right internal jugular vein is used.

Femoral or subclavian veins can be used in patients when the neck is immobilized using a cervical collar.

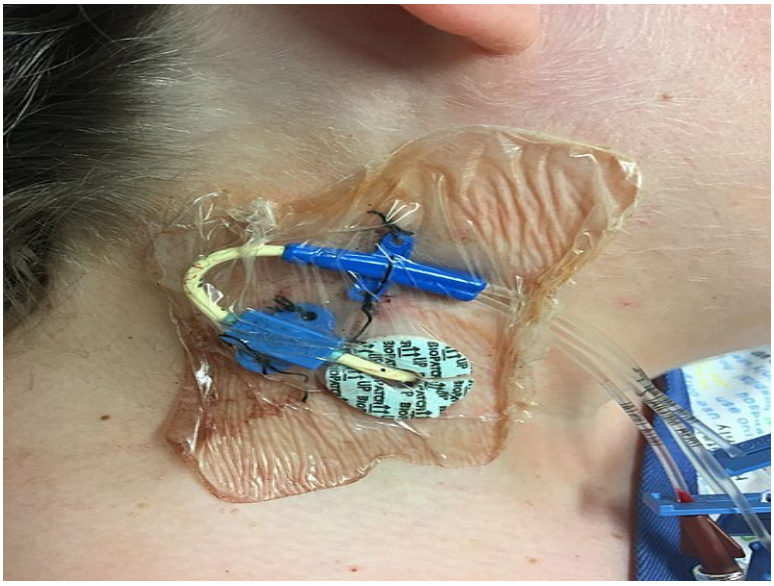
The below image shows central vein catheter



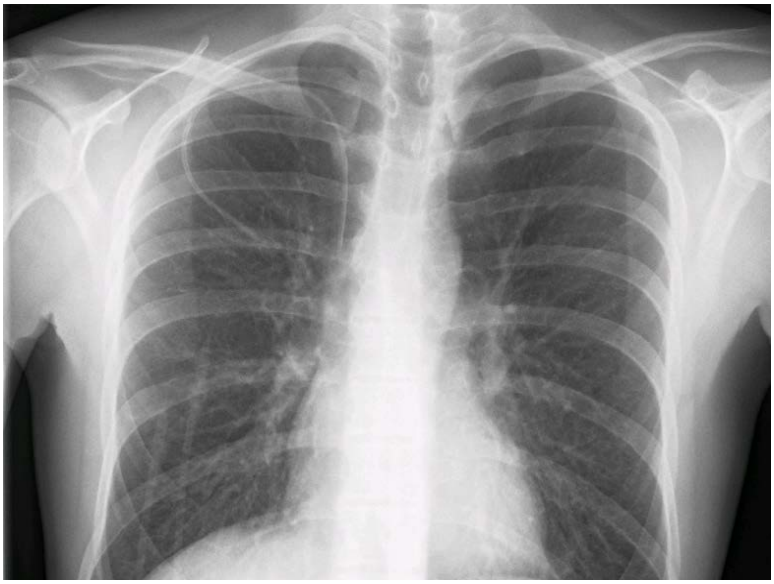
The below image shows subclavian vein catheterization.



The below image shows catheterisation into jugular vein



Below image shows radiograph of subclavian vein catherisation



Solution to Question 23:

In the given image, the dorsal aspect of the brainstem is marked and the cranial nerve that is passing there is the trochlear nerve (CN IV).

The trochlear nerve is the fourth cranial nerve that originates from the trochlear nuclei within the midbrain at the level of the inferior colliculus. It is the only cranial nerve that emerges from the dorsal surface of the brainstem and has the longest intracranial course. It passes on to the lateral surface of the crus of cerebellar peduncle and lateral wall of the cavernous sinus. The nerve then crosses the oculomotor nerve to enter the orbit through the superior orbital fissure to exclusively

supply the contralateral superior oblique muscle.

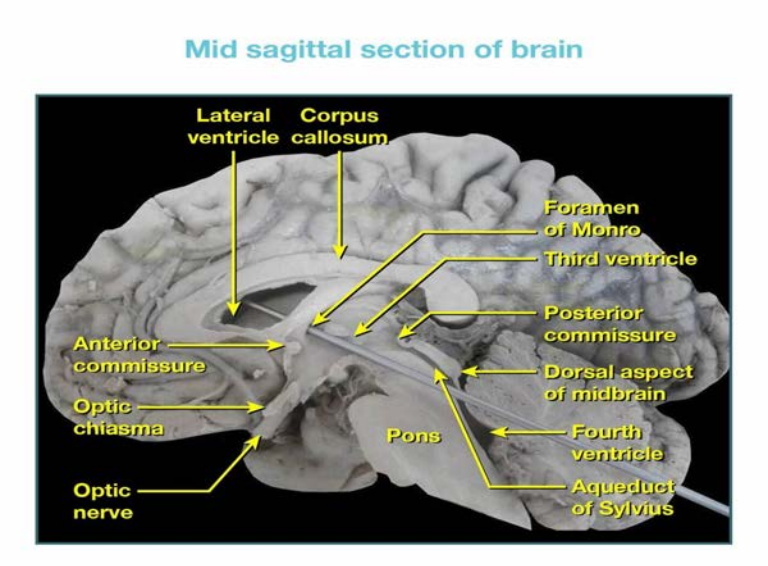
The main actions of superior oblique are

• Depression in adducted position- The muscle elevates the posterior of the eye causing the front of the eye to be depressed. Patients with trochlear nerve palsy have difficulty in looking downwards when eyes are in the adducted position.

• Abduction

• Intortion of the eyeball.

Other options- Oculomotor (CN III), trigeminal (CN V) and abducens (CN VI) nerves exit ventrally from the brainstem.



Anatomy NEET 2021

Question 1:

A patient presented with vision loss. On radiological investigation, an aneurysm causing damage to the optic chiasma was noted. Which of the following arteries is most likely to be the artery that is causing the damage?

a) Anterior communicating artery

b) Anterior choroidal artery

c) Middle cerebral artery

d) Anterior cerebral artery

Question 2:

A 34-year-old man presented with fever and massive splenomegaly. On palpation, the spleen was 15 cm and directed obliquely when measured from the right iliac fossa. Which of the following structures prevent the vertical and downward descent of the spleen?

a) Lienorenal ligament

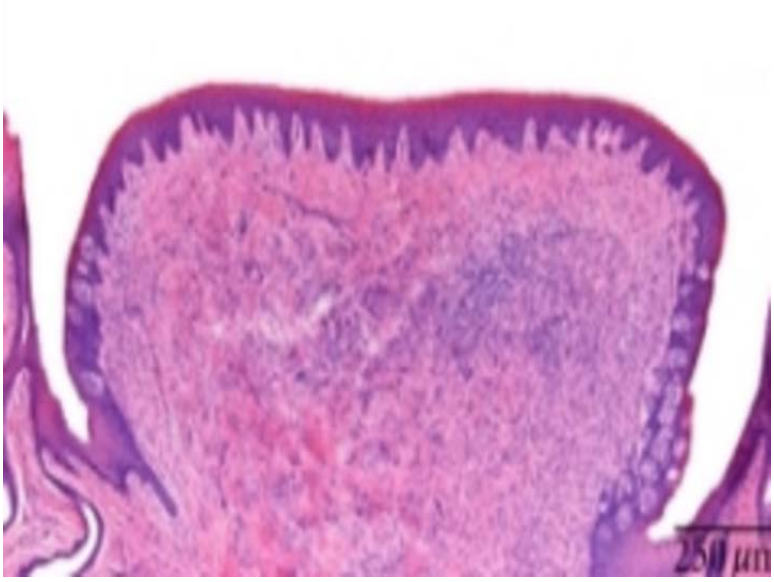
b) Gastrosplenic ligament

c) Phrenicocolic ligament

d) Lienophrenic ligament

Question 3:

Identify the papillae from the given histological section.



a) Fungiform

b) Circumvallate

c) Filiform

d) Foliate

Question 4:

A 7-year-old boy was brought to the hospital with multiple fractures of the humerus secondary to a fall from height. On examination, there is difficulty in flexion of the elbow and supination of the forearm, and associated loss of sensation over the lateral aspect of the forearm. Which is the nerve most likely to be injured?

a) Median nerve

b) Radial nerve

c) Musculocutaneous nerve

d) Ulnar nerve

Question 5:

A patient presented with jaw swelling and weight loss. Suspecting a malignancy, the submandibular gland was resected. Which is the most likely nerve to be damaged during submandibular gland resection?

a) Nerve to mylohyoid

b) Inferior alveolar nerve

c) Lingual nerve

d) Hypoglossal nerve

Question 6:

A patient underwent a coronary bypass graft with the great saphenous vein. The patient now complains of paresthesia and sensory loss over the medial aspect of the leg and foot. Which of the following nerves is most likely to be involved?

a) Superficial peroneal nerve

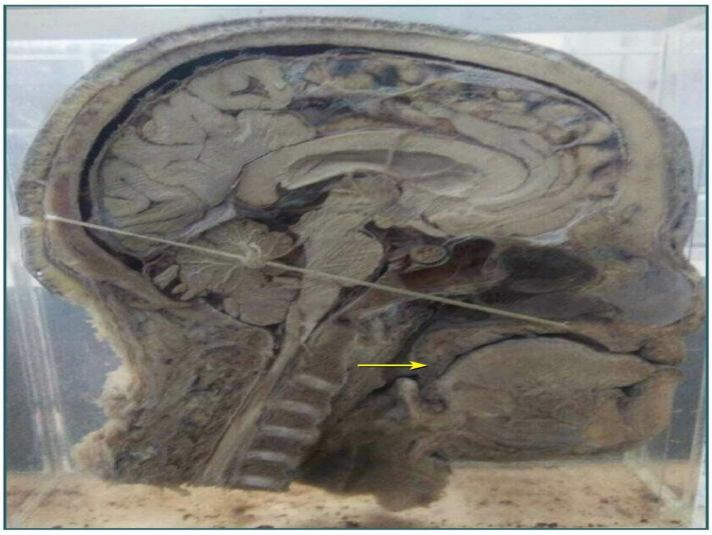
b) Saphenous nerve

c) Femoral nerve

d) Sural nerve

Question 7:

During the clinical examination of the nervous system, which of the following nerves can be tested by touching the highlighted structure?



a) IX

b) X

c) XI

d) XII

Answer Key

Question No.	Correct Option
1	a
2	c
3	b
4	c
5	c
6	b
7	a

Detailed Explanations

Solution to Question 1:

An aneurysm of the anterior communicating artery is most likely to be causing damage to the optic chiasma, leading to vision loss in this patient.

Circle of Willis is a large arterial anastomosis that unites the internal carotid and vertebrobasilar systems. It lies in the subarachnoid space within the basal cisterns that surround the optic chiasma and infundibulum.

Anterior communicating artery aneurysm:

Anterior communicating artery (Acom) links the right and left anterior cerebral arteries and is directed anterior and superior to the optic chiasma. The aneurysm will protrude in the posterior direction and will impinge upon the optic chiasma from above, leading to loss of vision.

Compression of the optic chiasma (central lesion) by an ACom aneurysm, will lead to bitemporal hemianopia i.e, loss of vision in the left/temporal halves of both visual fields. Nasal fibers of each retina cross through the chiasma at this level and hence, these fibers will be compromised.

In the case of a bilateral peripheral lesion of the optic chiasma, binasal hemianopia will be seen.

Other causes of chiasmal lesions are

• Pituitary adenoma (most common)

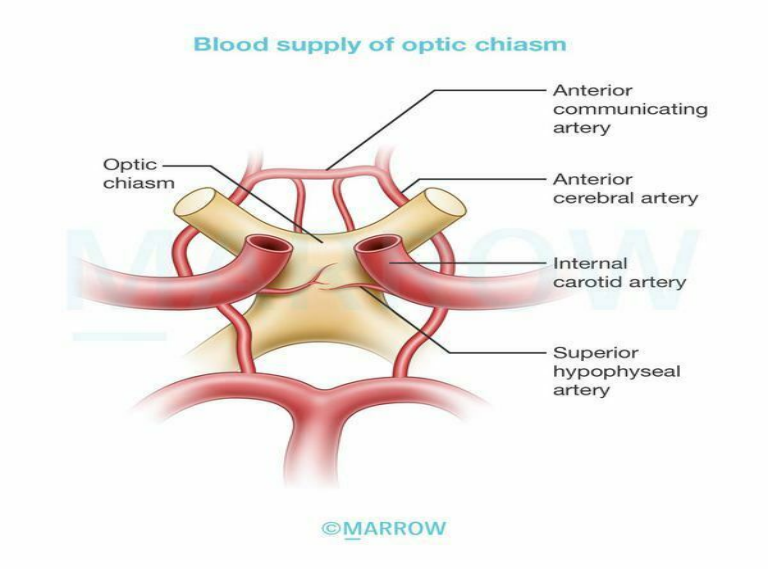
• Craniopharyngioma

• Meningioma

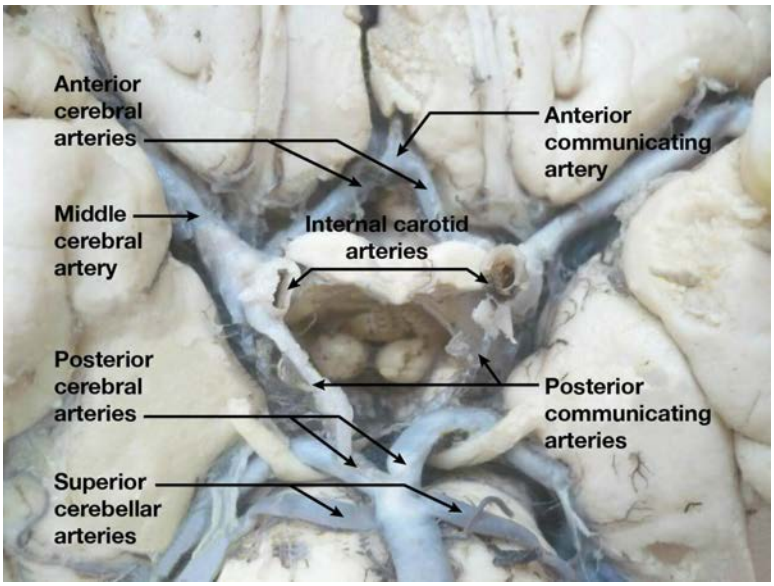
• Glioma

Blood supply of optic chiasma: The left and right anterior cerebral arteries, along with the superior hypophyseal artery (branch of the internal carotid artery) form the blood supply of optic

chiasma.



The given cadaveric image below is of the vascular structures (Circle of Willis) at the base of the brain.



Investigation: Digital subtraction angiogram is the definitive imaging modality for aneurysms arising from the circle of Willis. Other investigations are CT and MRI.

Other options:

Aneurysms of the anterior choroidal artery (option B) and middle cerebral artery (option C) aneurysms will not compress the optic chiasma as they are anatomically not in close proximity to be able to exert pressure on the chiasma and cause loss of vision.

Despite the anatomical proximity of the anterior cerebral artery (option D) to the optic chiasma, anterior communicating artery (Acom) aneurysm is the commonest intracranial aneurysm.

Solution to Question 2:

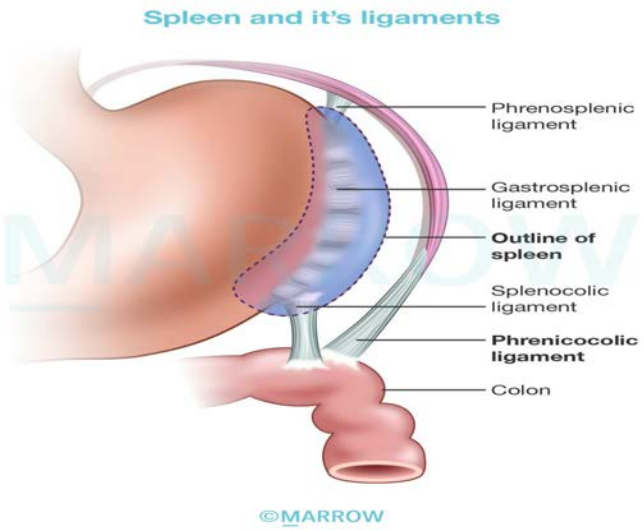
The vertical and downward descent of the spleen is prevented by the phrenicocolic ligament.

The phrenicocolic ligament is not attached to the spleen. It attaches the splenic flexure of the colon to the diaphragm.

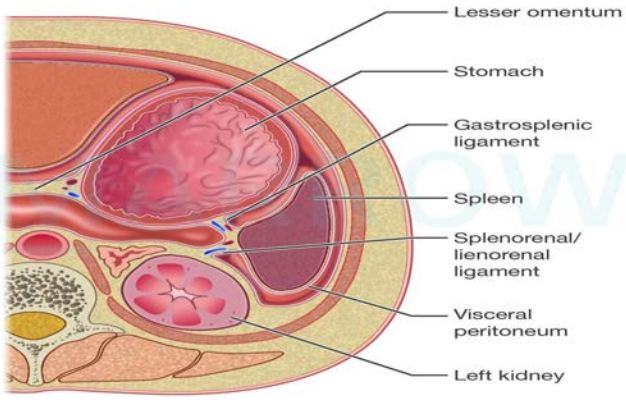
When the spleen gets enlarged, the phrenicocolic ligament along with the splenic flexure of the colon restricts its downward displacement. The enlargement of the spleen occurs towards the right iliac fossa and hence the spleen is directed obliquely.

Splenic ligaments and their attachments:

Splenic ligament	Attachments	Contents
Phrenicocolic ligament	Diaphragm to the splenic flexure of the colon	-
Phrenicosplenic ligament	The undersurface of the diaphragm to the spleen	-
Splenorenal (lienorenal) ligament	Hilum of the spleen to the anterior surface of the left kidney	Tail of pancreasSplenic artery and vein
Gastrosplenic ligament	The greater curvature of the stomach to the upper pole of the spleen	Short gastric vesselsLeft gastroepiploic artery



Cross-sectional view of the spleen and its ligaments



©MARROW

The spleen becomes palpable when it is enlarged 2-3 times more than its normal size. A characteristic splenic notch can be felt in the medial border in an enlarged spleen. Also, fingers cannot be insinuated between the left costal margin and the enlarged spleen.

In the classical method of palpation, the right hand (with fingers pointed towards the left costal margin) is placed on the right iliac fossa. Palpation begins from the right iliac fossa towards the left hypochondrium in an upwards and lateral direction. Between each breath of the patient, the edge of the spleen can be felt.

In the hooking method, the hooked fingers of the right hand are placed under the left costal margin, and with the left hand, pressure is exerted over the posterolateral aspect of the lower thorax. Spleen is felt at the deep inspiratory phase.

Solution to Question 3:

The given histological image is a section of the tongue showing circumvallate papillae, the largest papillae of the tongue.

Circumvallate papillae are large cylindrical structures that are around 8-12 in number, covered by non-keratinized stratified squamous epithelium.

They are arranged in a V-shaped row immediately in front of the sulcus terminalis (not on the sides of the tongue) on the dorsal surface of the tongue. It is narrower at its base than its apex.

Numerous taste buds (around 250 taste buds for each of the 8-12 papillae) are present within the papillary walls and they contain chemosensory cells that synapse with the gustatory nerves. Serous glands of von Ebner empty via the ducts into the base of the sulcus.

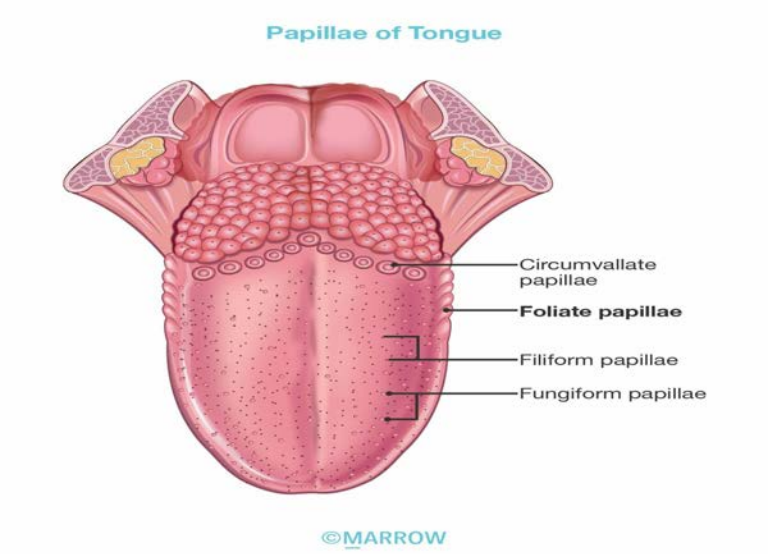
Identification: They can be identified by their characteristic dome-shaped structure lined by stratified squamous epithelium.

Other options:

Option A - Fungiform papillae are large, rounded, and red in color and are mainly present on the lingual margins and also on the dorsal surface of the tongue. They are covered by non-keratinized stratified squamous epithelium. It is supplied by the lingual nerve.

Option C- Filiform papillae are minute cylindrical or conical projections that are mainly present on the dorsal part of the anterior 2/3rd of the tongue. All except filiform papillae contain taste buds. They are covered by keratinized stratified squamous epithelium. It is supplied by the lingual nerve.

Option D - Foliate papillae are red, leaf-like mucosal ridges that are present bilaterally in two zones at the sides of the tongue near the sulcus terminalis. They are covered by non-keratinized stratified squamous epithelium.



Solution to Question 4:

The given clinical vignette in a patient with difficulty in flexion of the elbow and supination of the forearm, with associated loss of sensation over the lateral aspect of the forearm, is suggestive of injury to the musculocutaneous nerve.

Fall from a height on an outstretched hand is one of the main causes of humerus fractures.

Course:

The musculocutaneous nerve (C5, C6, C7) is a branch of the lateral cord of the brachial plexus. It emerges at the lower border of the pectoralis minor and pierces coracobrachialis. It then descends between biceps brachii and brachialis where it supplies a branch to the shaft of the humerus. Then it enters the elbow and continues as the lateral cutaneous nerve of the forearm.

It innervates all the muscles of the anterior compartment of the arm i.e.,

• Biceps brachii - involved in flexion of elbow and supination of the forearm

• Brachialis - involved in the flexion of the elbow

• Coracobrachialis - flexes the arm at the glenohumeral joint

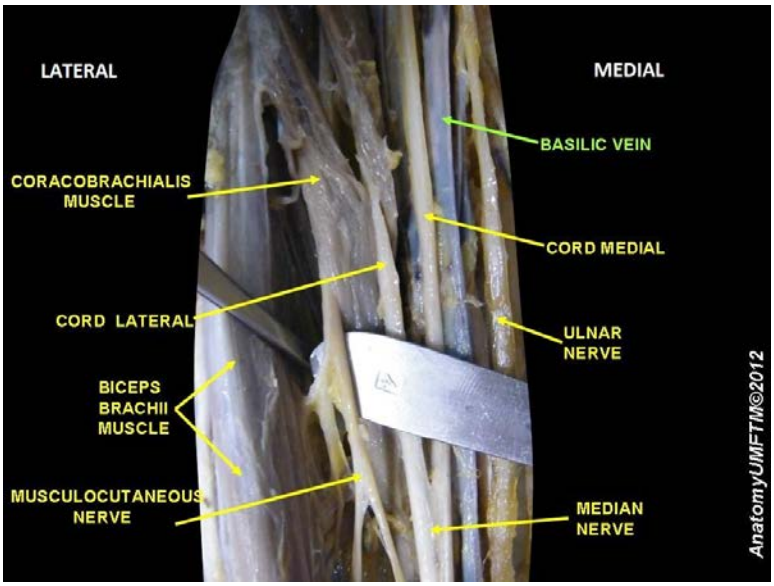
Cutaneous innervation of the lateral aspect of the forearm is by a branch of the musculocutaneous nerve, namely, the lateral cutaneous nerve of the forearm (C5, C6).

Hence, injury to the musculocutaneous nerve results in weakness of supination of forearm (biceps brachii), weakness in flexion of the elbow (biceps brachii, brachialis), and loss of sensation over the lateral aspect of the forearm (lateral cutaneous nerve of the forearm).

Muscles of the anterior compartment of the arm:

The below image shows the anterior compartment of the arm

Muscles	Origin	Insertion	Innervation
Coracobrachialis	Coracoid Process of scapula	The medial side of the midshaft of the humerus	Musculocutaneous nerve
Brachialis	Distal half of anterior aspect of the humerus	Ulnar tuberosity	Musculocutaneous and radial nerve
Biceps Brachii	Short head: Coracoid process Long head: Supraglenoid tubercle	Radial tuberosity	Musculocutaneous nerve



Other options:

Option A:

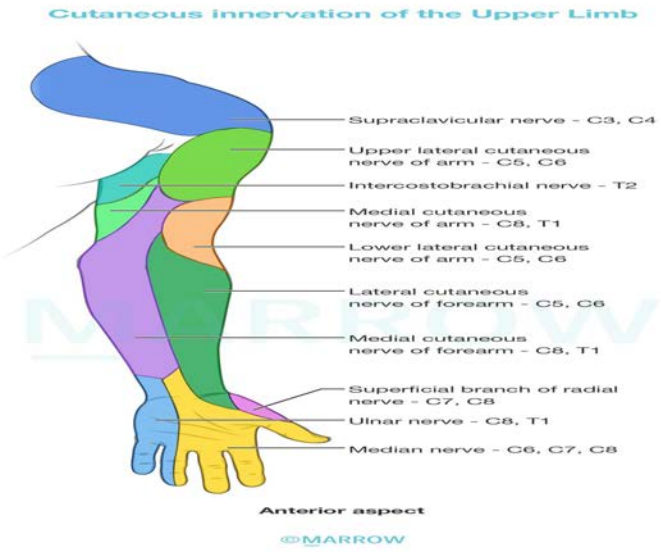
Median nerve injury is characterized by sensory loss over the radial 3 1/2 fingers and loss of thumb abduction. In high lesions, the long flexors of the thumb, index, and middle fingers, the radial wrist flexors, and the forearm pronator muscles are also paralyzed. Wasting of the thenar eminence is seen in long-standing cases.

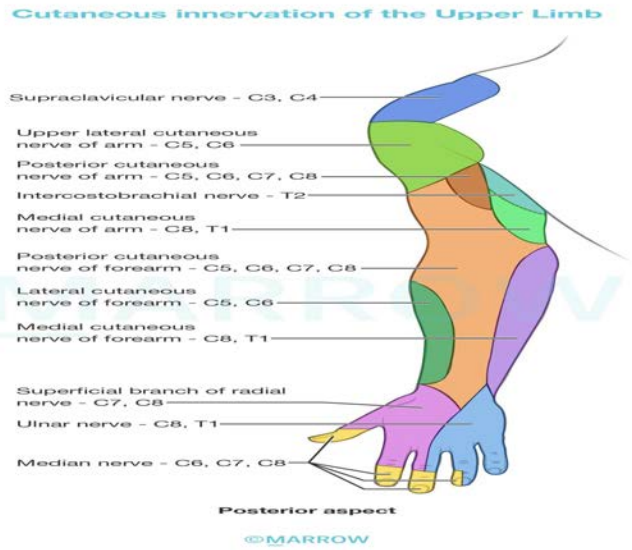
Option B:

Radial nerve injury can present with wrist drop, thumb drop, and finger drop. Extension of the elbow will be spared in lesions below the elbow. The extension of the IP joints is intact due to the action of the intrinsic muscles of the hand. Loss of sensation over the first dorsal web space is observed.

Option D:

Ulnar nerve injury is characterized by ulnar claw hand, wasting of the hypothenar muscles and intrinsic muscles of the hand, and sensory loss over palmar & dorsal aspect of the medial third of the hand and medial 1 1/2 fingers.





Solution to Question 5:

The most likely nerve to be damaged during submandibular gland resection is the lingual nerve.

It loops around the submandibular duct and hence is susceptible to injury during submandibular gland resection.

Course:

The lingual nerve arises from the posterior trunk of the mandibular nerve (V3 branch of the trigeminal nerve). The lingual nerve descends between the tensor veli palatini muscle and the lateral pterygoid muscle, where it is joined by the chorda tympani nerve. It then descends across the medial pterygoid muscle to enter the oral cavity. As the lingual nerve enters the floor of the oral cavity, it lies on the deep portion of the submandibular gland. It then passes into the tongue on the hyoglossus muscle where it is attached to the submandibular ganglion.

The submandibular duct lies between the lingual and hypoglossal nerves, superficial to the hyoglossus muscle. As the duct reaches the anterior border of the hyoglossus, it is crossed by the lingual nerve and lies in close proximity to the nerve. Hence lingual nerve injury is the most common.

Injury:

The lingual nerve is at risk to be injured during submandibular gland resection because dissection of the submandibular duct from the nerve is required. Also, it is connected to the submandibular ganglion which will lead to the nerve being exposed within the operating field.

The manifestations of lingual nerve injury depend on whether the lesion is proximal or distal to where it is joined by the chorda tympani nerve.

• Proximal injury: There is loss of sensation from the anterior two-thirds of the tongue, gingivae, oral mucosa, lower lip, and chin.

• Distal injury: In addition to features of proximal injury, secretion from the salivary glands below the oral fissure and taste from the anterior two-thirds of the tongue is also lost.

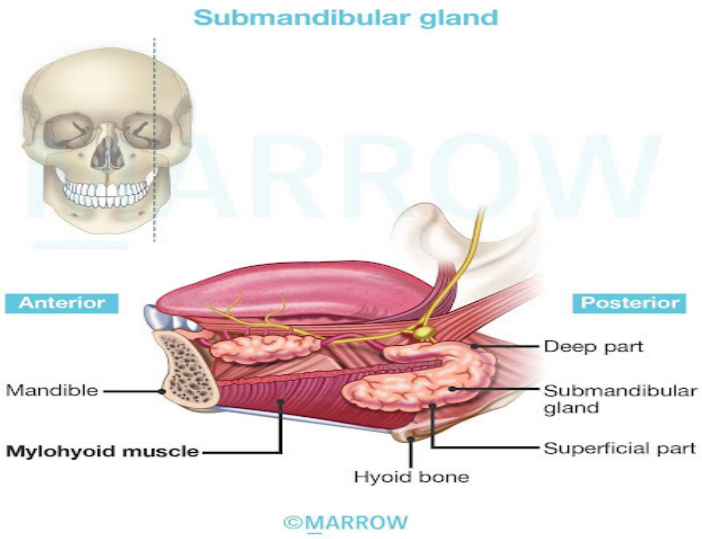
Note:

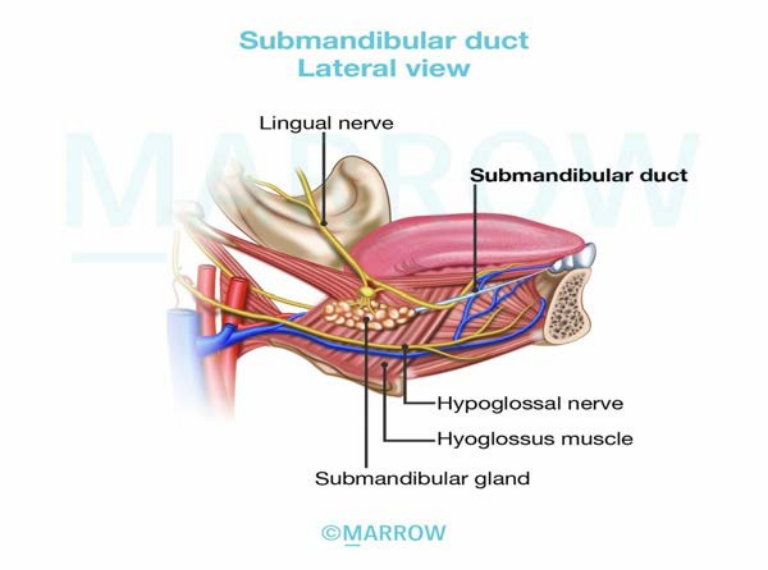
The cranial nerves that are at risk during submandibular gland resection include:

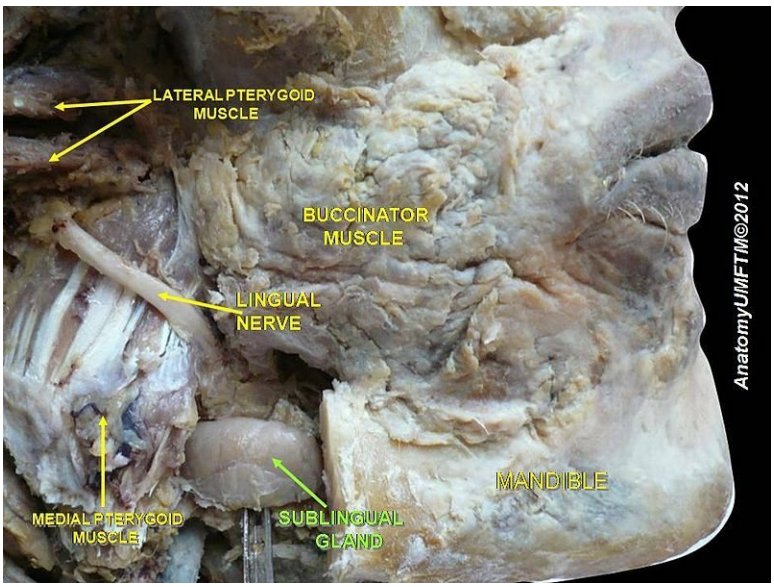
• The marginal mandibular branch of the facial nerve

• Lingual nerve

• Hypoglossal nerve







Other options:

Option A: Nerve to mylohyoid is a branch of the inferior alveolar nerve and lies in the mylohyoid groove inferior to the mandibular foramen, hence the risk of injury is less.

Option B: Inferior alveolar nerve enters the mandibular canal via the mandibular foramen, hence is unlikely to be injured during submandibular gland excision.

Option D: Hypoglossal nerve injury is less common than lingual nerve injury as it only lies below and parallels to the submandibular duct.

Solution to Question 6:

The given clinical vignette in a patient with paresthesia and sensory loss over the medial aspect of the leg and foot is suggestive of injury to the saphenous nerve.

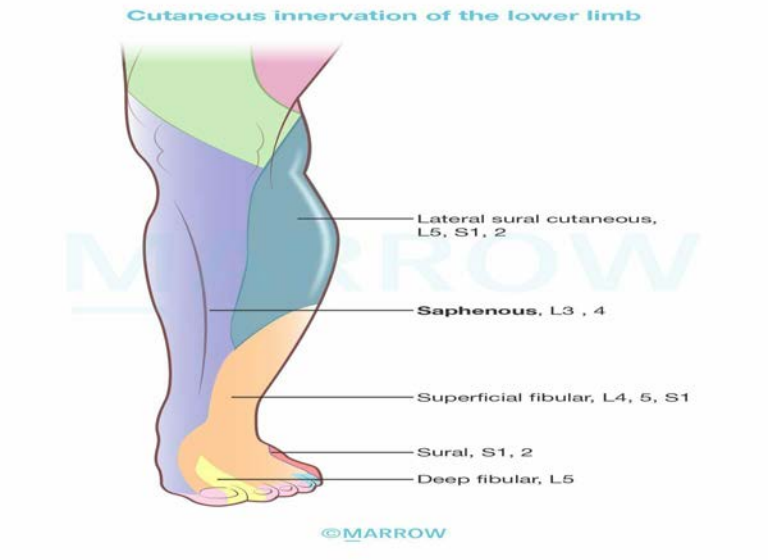
Injury to the saphenous nerve is common following venous cut down for access to the great saphenous vein, in this case for coronary bypass graft.

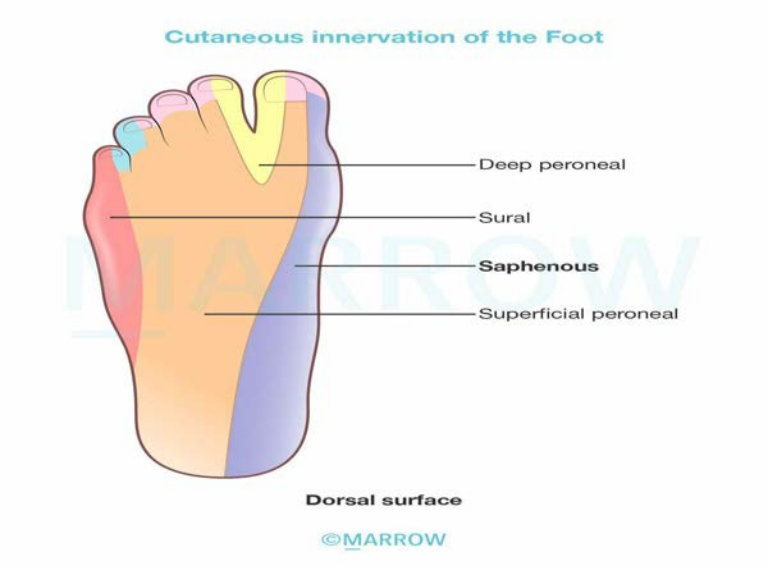
Saphenous nerve:

It is the longest and largest cutaneous branch of the femoral nerve and is the longest nerve in the body. It arises from the posterior division of the femoral nerve. It then enters the adductor canal and exits it by piercing the fascia lata between the gracilis and sartorius and supplies the skin over the patella. The saphenous nerve then descends along the medial border of the tibia along with the great saphenous vein (anterior to the vein) and supplies the skin on the medial side of the knee, leg, and foot as far as up to the first metatarsophalangeal joint.

Saphenous nerve injury:

When the great saphenous vein is being harvested for coronary bypass graft, injury to the saphenous nerve is common as it closely travels with the great saphenous vein. Sensory loss over the medial side of the knee, leg, and foot is observed in saphenous nerve injury.





Other options:

Option A: Superficial peroneal nerve injury causes sensory loss over the lateral aspect of the leg and the dorsum of the foot.

Option C: Femoral nerve gives rise to anterior cutaneous branches, the saphenous nerve, and motor supply to the quadriceps and sartorius. Anterior cutaneous branches supply the skin on the anterior thigh and knee. If the saphenous nerve was not an option in the question, the femoral nerve would have been the next best answer.

Option D: Sural nerve injury causes sensory loss over the posterior and lateral aspects of the distal third of the leg and lateral side of the foot and fifth toe. It is often used as an autologous peripheral nerve graft as it is readily identified and easy to harvest.

Solution to Question 7:

The structure marked in the given sagittal section of the head and neck is the uvula. The sensory supply to the uvula is by the glossopharyngeal nerve and it is tested in this case.

Nerve supply by glossopharyngeal nerve:

• Sensory fibers to the uvula, tympanic cavity, pharyngotympanic tube, tonsils, fauces, nasopharynx, and posterior third of the tongue.

• Motor fibers to the stylopharyngeus muscle

• Parasympathetic secretomotor fibers to the parotid gland

• Gustatory fibers for the postsulcal part of the tongue.

Pharyngeal plexus:

The nerve supply of the pharynx is mainly from the pharyngeal plexus of nerves. It is formed by the pharyngeal branches of the glossopharyngeal nerve and vagus nerve. It also has contributions from the superior cervical ganglion. The vagus nerve provides the motor supply and the glossopharyngeal nerve provides the sensory supply.

Nerve supply by the pharyngeal branch of the vagus nerve:

• All the muscles of the soft palate(except tensor veli palatini - supplied by mandibular division of the trigeminal nerve)

• All the muscles of the pharynx(except stylopharyngeus - supplied by the glossopharyngeal nerve)

Note:

Previously cranial root of the spinal accessory nerve was thought to contribute to the motor functions of the pharyngeal plexus, but recent evidence suggests that it is not a major part of the motor drive to the pharyngeal plexus.

Innervation of the soft palate:

General sensation - It is mostly carried by the lesser palatine nerve which is a branch of maxillary nerve. The sensation from posterior part is carried by the pharyngeal branches of the glossopharyngeal nerve and from the plexus around the tonsil which is formed by the tonsillar branches of the glossopharyngeal and lesser palatine nerves.

Taste sensation - There are taste buds in the oral surface of soft palate and sensation from them is carried by the lesser palatine nerve.

Secretomotor supply - It is by the lesser palatine nerve via postganglionic fibres from the pterygopalatine ganglion.

Motor supply - It is by the pharyngeal branch of the vagus nerve except for tensor veli palatini which is supplied by mandibular division of the trigeminal nerve.

Anatomy INI-CET 2022

Question 1:

Arrange in sequence the structures involved in the direct pathway:

a) 1,2,3,4,5

b) 5,4,2,3,1

c) 5,1,2,3,4

d) 1,3,4,2,5

Question 2:

What is the volume of the prostate in normal adult males?

a) 20cc

b) 50cc

c) 75cc

d) 100cc

Question 3:

Which ligament connects medial cuneiform to the base of the 2nd metatarsal?

a) Chopart

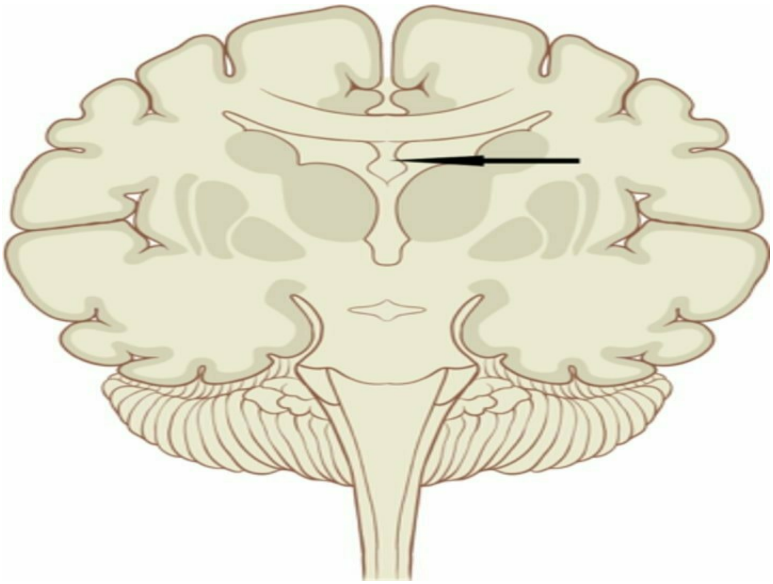
b) Spring

c) Lisfranc

d) Deltoid

Question 4:

Fibres of the given structure originate from ?



a) Amygdala

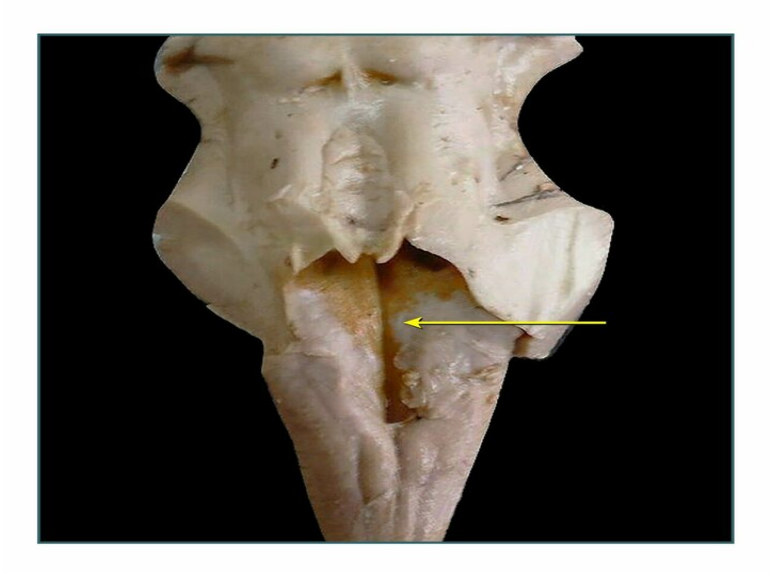
b) Mammillary body

c) Caudate nucleus

d) Hippocampus

Question 5:

Which structure is supplied by the nerve causing this elevation?



a) Lateral rectus

b) Superior oblique

c) Risorius

d) Levator palpebrae superioris

Question 6:

Arrange lung hilar structures from anterior to posterior:

a) 1,2,3,4

b) 2,3,4,1

c) 3,4,1,2

d) 4,3,2,1

Question 7:

Which is not a branch of facial artery in the face?

a) Lateral nasal

b) Mental

c) Superior labial

d) Inferior labial

Question 8:

Which of the following structures passing via jugular foramen has a separate canal?

a) Hypoglossal nerve

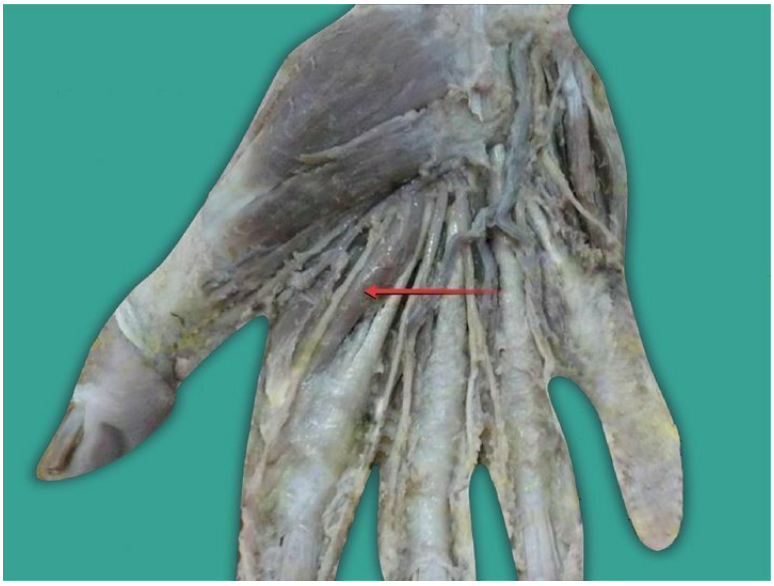
b) Glossopharyngeal nerve

c) Vagus nerve

d) Accessory nerve

Question 9:

What is the nerve supply of the structure marked in the image?



a) Radial nerve

b) Median nerve

c) Ulnar nerve

d) Musculocutaneous nerve

Question 10:

A child lacks thymus and inferior parathyroid glands. Defective development of which of the following structures is likely to be the cause?

a) 1

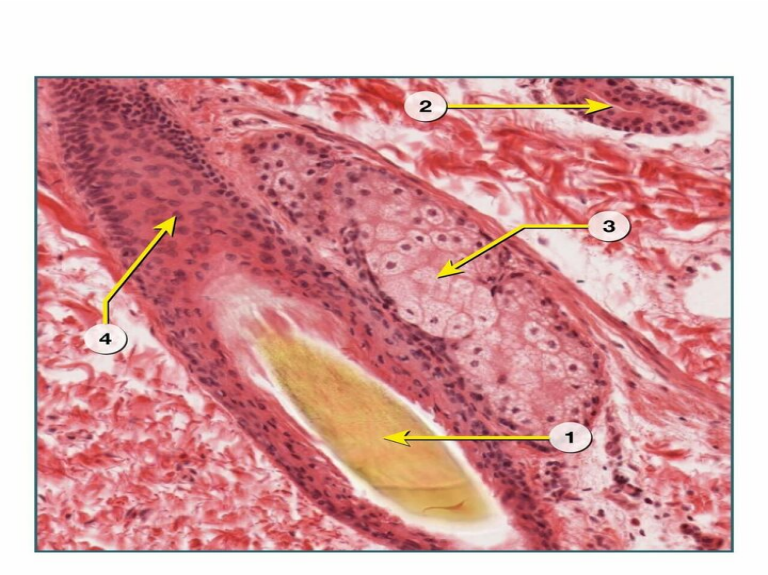
b) 2

c) 3

d) 4

Question 11:

Identify which of the following structure is a merocrine gland:



a) 1

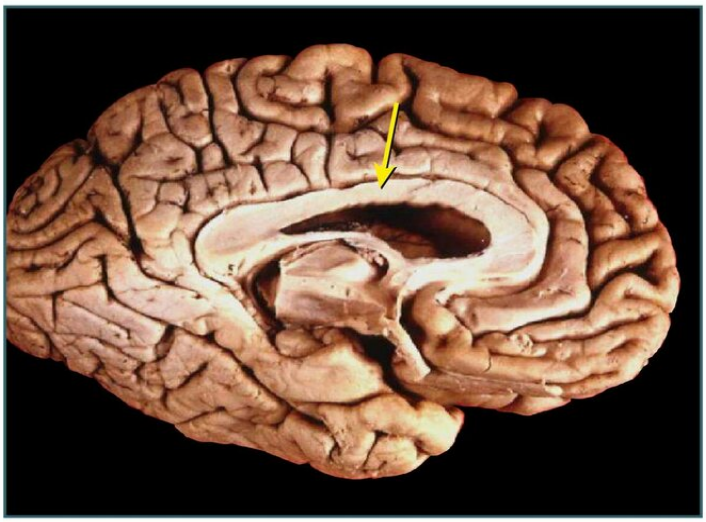
b) 2

c) 3

d) 4

Question 12:

What is the blood supply of the structure marked in the image below?



a) Anterior cerebral artery and middle cerebral artery

b) Anterior cerebral artery and posterior cerebral artery

c) Anterior cerebral artery and anterior communicating artery

d) Middle cerebral artery and posterior cerebral artery

Question 13:

Superior gluteal nerve supplies all of the following structures except:

a) Gluteus medius

b) Gluteus minimus

c) Piriformis

d) Tensor fasciae latae

Question 14:

Arrange the structures of the cubital fossa in sequence from medial to lateral.

a) 1,2,3,4

b) 1,3,4,2

c) 1,4,3,2

d) 4,3,2,1

Question 15:

Arrange the cells according to their positions from the basal layer towards the lumen in the seminiferous tubules.

a) 1,5,4,2,3

b) 1,2,3,4,5

c) 5,4,3,2,1

d) 5,1,2,3,4

Question 16:

Which skull foramen is formed by 3 bones?

a) Foramen lacerum

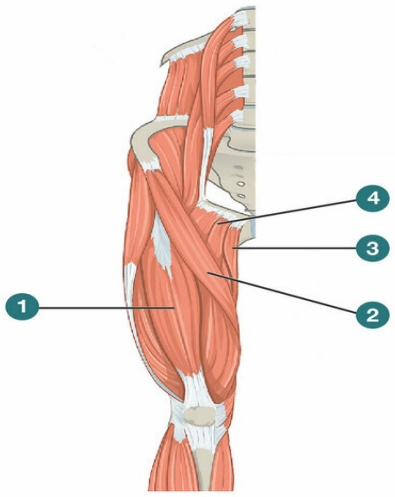
b) Foramen magnum

c) Foramen rotundum

d) Foramen jugulare

Question 17:

Which marked structure causes lateral rotation, flexion, and abduction at the hip joint, along with flexion at the knee joint?



a) 1

b) 2

c) 3

d) 4

Question 18:

Which among the following statements is true regarding the course of the mandibular nerve?

a) 2,3

b) 1,3

c) 3,4

d) 1,4

Question 19:

Identify the incorrectly matched pair(s) of pharyngeal arch and its artery.

a) iv, v

b) iii

c) v

d) ii, iii

Question 20:

The rupture of penile urethra does not cause extravasation of blood into which of the following spaces?

a) Superficial perineal pouch

b) Deep perineal pouch

c) Ischiorectal fossa

d) Skin around the scrotum

Question 21:

Which nerve is blocked when local anesthesia is given below the inguinal ligament during femoral vein catheterization?

a) Femoral nerve

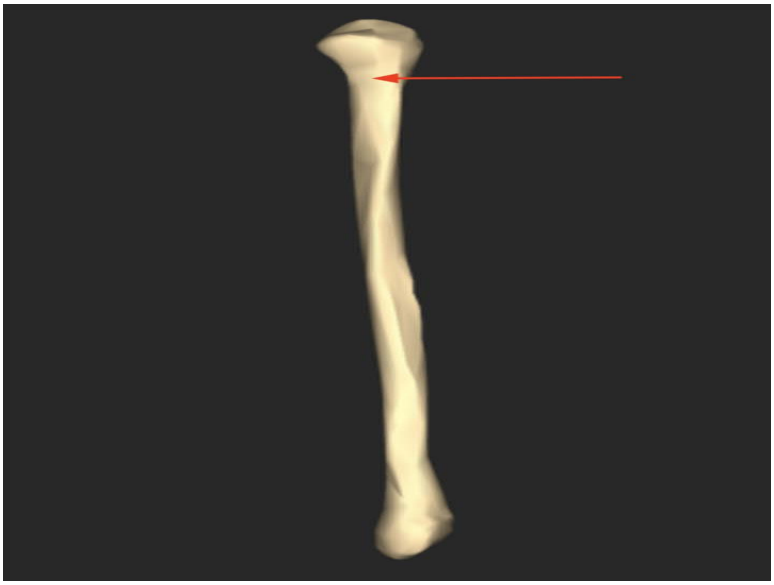
b) Genitofemoral nerve

c) Lateral cutaneous nerve of thigh

d) Ilioinguinal nerve

Question 22:

Identify the nerve passing around the marked structure.



a) Common peroneal nerve

b) Sural nerve

c) Tibial nerve

d) Femoral nerve

Question 23:

Which of the following cells are present in the molecular layer of the cerebellum?

a) 1, 2

b) 1, 3

c) 2, 4

d) 2, 3

Question 24:

Bleeding as shown in the image is due to which of the following vessels?

a) Bridging veins

b) Middle meningeal artery

c) Lenticulostriate artery

d) Vertebral artery

Question 25:

Which of the following statements are true about the internal capsule?

a) 1, 3, 4

b) 2, 3, 4

c) 1, 2, 4

d) 1, 2, 3

Question 26:

Which of the following is not a branch of posterior division of internal iliac artery ?

a) Iliolumbar artery

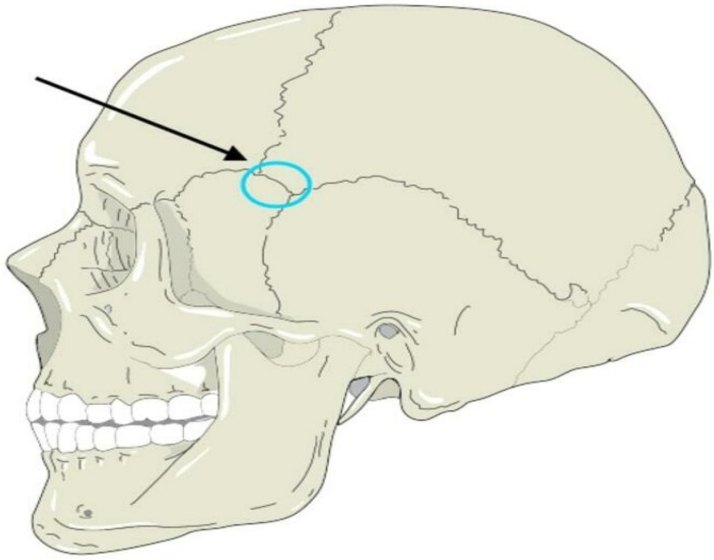
b) Lateral sacral artery

c) Inferior gluteal artery

d) Superior gluteal artery

Question 27:

Identify the incorrect statement regarding the marked structure.



a) It is the meeting point of frontal, parietal, temporal and sphenoid bones.

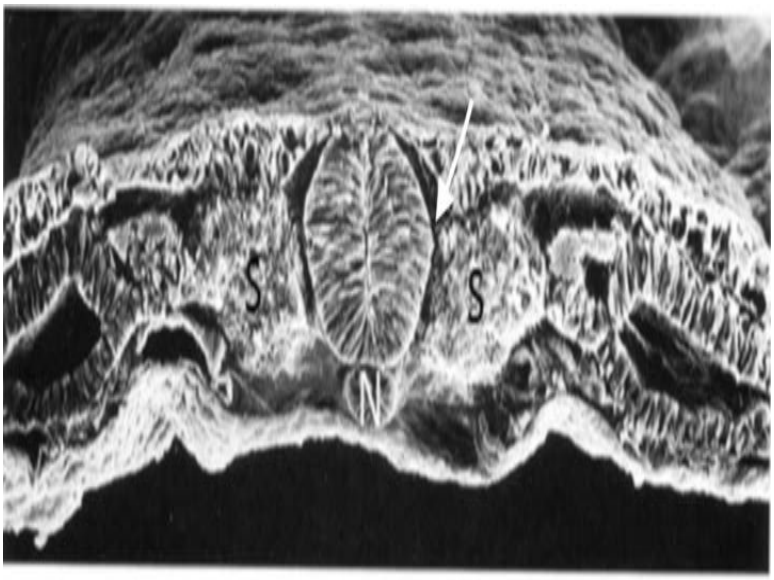
b) Blow to the lateral side of the skull injures the marked structure.

c) Accessory middle meningeal artery lies under this structure.

d) It corresponds to site of anterolateral fontanelle of fetal skull.

Question 28:

What are the derivatives of the marked cells?



a) 1, 3, 5, 6

b) 2, 3, 4, 6

c) 1, 2, 3, 6

d) 1, 2, 3, 4

Question 29:

Which of the following muscles form the pelvic diaphragm?

a) A, B

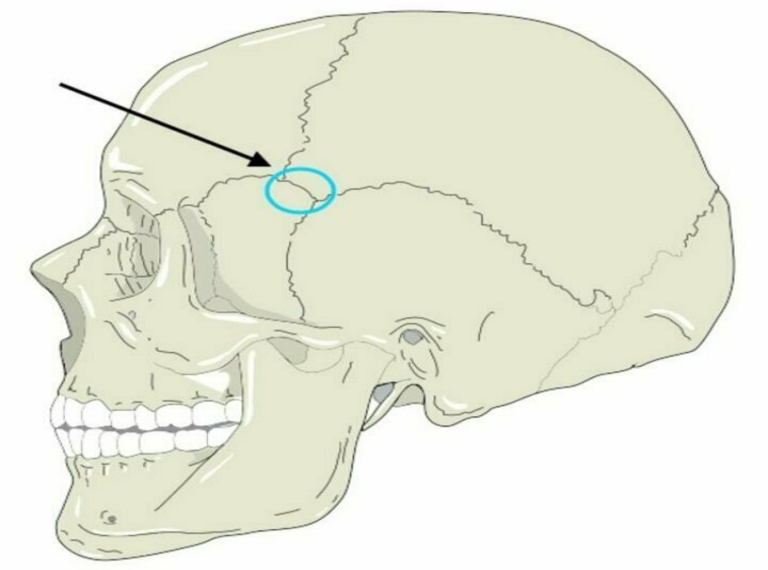
b) A, B, C, D

c) A, B, D

d) A,D

Question 30:

Which of the following arteries passes in close proximity to the area marked by the arrow in the given image?



a) Anterior division of middle cerebral artery

b) Anterior division of the middle meningeal artery

c) Posterior division of middle cerebral artery

d) Stem of middle meningeal artery

Question 31:

Fracture of the jugular canal can present as

a) Loss of taste sensation in anterioir 2/3rd of tongue

b) Loss of taste sensation in posterior 1/3rd of tongue

c) Loss of general sensation in anterior 2/3rd of tongue

d) Loss of motor sensation in anterior 2/3rd of tongue

Question 32:

Injury of the lower brachial plexus leads to Klumpke's paralysis. What is the characteristic clinical finding seen in this lesion?

a) Policeman tip hand

b) Wrist drop

c) Claw hand

d) Horner's syndrome

Question 33:

Identify the liver segment marked in the image below:

a) V

b) IVa

c) VII

d) III

Question 34:

Which of the following lobes of the lung is affected when there is aspiration in supine position?

a) Lingula

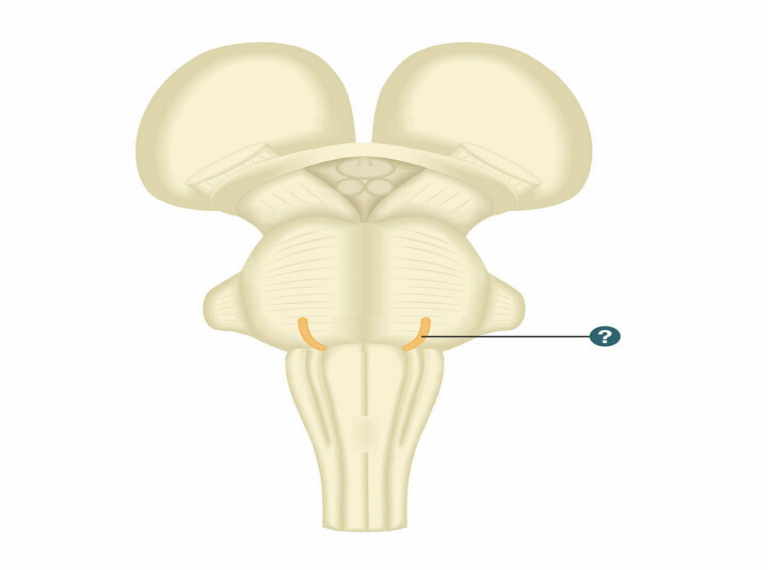
b) Upper part of right inferior lobe

c) Right superior lobe

d) Right middle lobe

Question 35:

Identify the cranial nerve that arises from the marked part.



a) Occulomotor nerve

b) Glossopharyngeal nerve

c) Abducens nerve

d) Facial nerve

Question 36:

Which of the following are a part of the limbic system?

a) 1, 2

b) 1, 3

c) 2, 3

d) 1, 2, 3

Question 37:

A 50-year-old male presented with a positive Trendelenburg test on the right side. Identify the nerve injured.

a) Right inferior gluteal nerve

b) Right superior gluteal nerve

c) Left superior gluteal nerve

d) Left inferior gluteal nerve

Detailed Explanations

Solution to Question 1:

The sequence of structures involved in the direct pathway is cortex > striatum > globus pallidus > substantia nigra > thalamus.

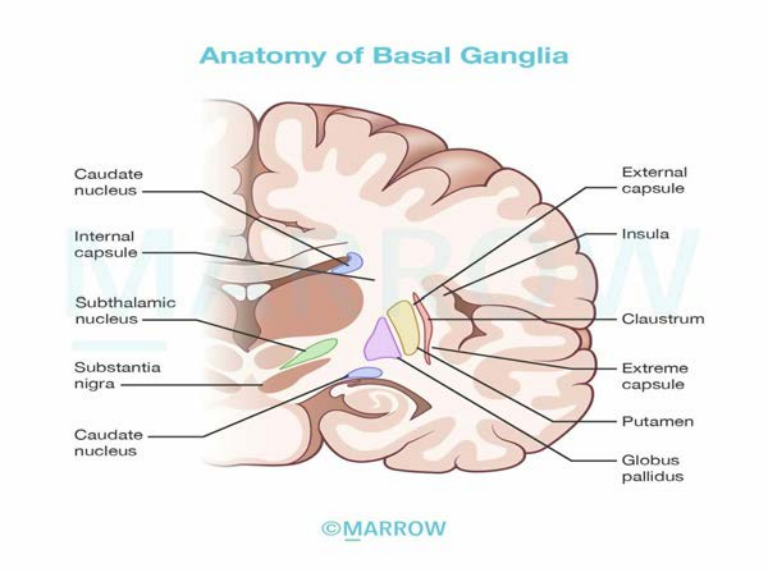
There are five parallel circuits that connect the frontal cortex to the striatum, pallidum, substantia nigra, and thalamus. These circuits have both direct and indirect pathways. The direct pathway stimulates the cortex to produce movement, whereas the indirect pathway inhibit it.

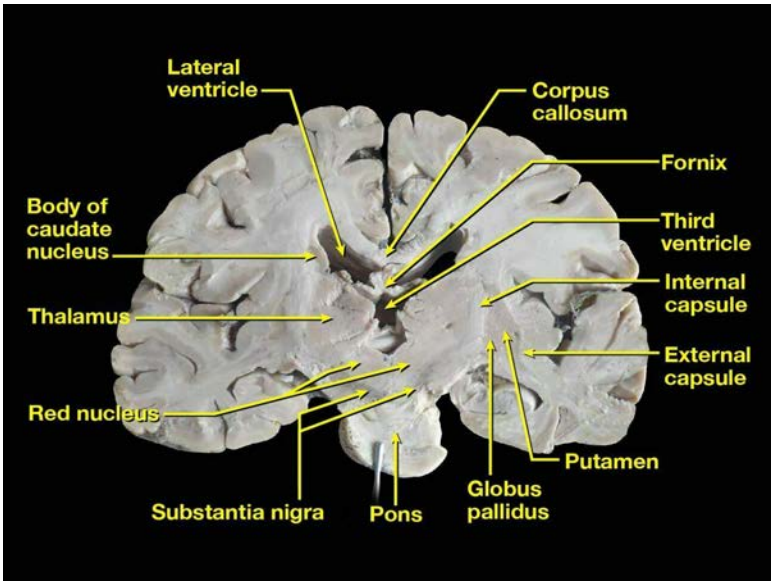
The cerebral cortex projects into the striatum. The striatum is seen projected into the pallidum and substantia nigra pars reticularis. Fibres originate from different striatal cells according to their endings in the external and internal pallidum. In the direct pathway, striatal neurones project directly to the internal pallidum. Whereas some other fibres that arise from the neurons project to the external pallidum. This is called the indirect pathway.

The sequence of structures involved in the indirect pathway is cortex > striatum > globus pallidus externa > subthalamic nucleus > globus pallidus interna and substantia nigra >Thalamus

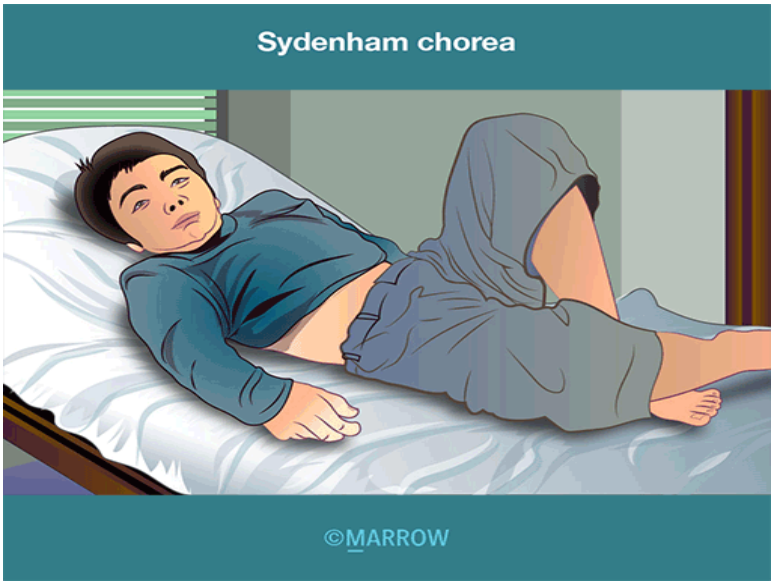
The striatal activity in the direct pathway is mediated by D1 dopamine receptors and in the indirect pathway by D2 dopamine receptors.

Putamen lies lateral and the internal capsule lies medial to the pallidum. It receives fibres from the striatum and subthalamic nuclei. It acts as the main output of the basal ganglia to the thalamus and superior colliculus. The substantia nigra is seen in each cerebral peduncle of the midbrain located deep to the crus cerebri. The levels of dopamine in the substantia nigra and striata are seen reduced in parkinsonism disease.





In parkinsonism disease, due to the death of neurons in substantia nigra activity of the direct pathway is reduced and the indirect pathway is increased. This results in bradykinesia in parkinsonism disease. Whereas in Huntington's disease, the activity of the indirect pathway is affected resulting in choreic involuntary movements.



Solution to Question 2:

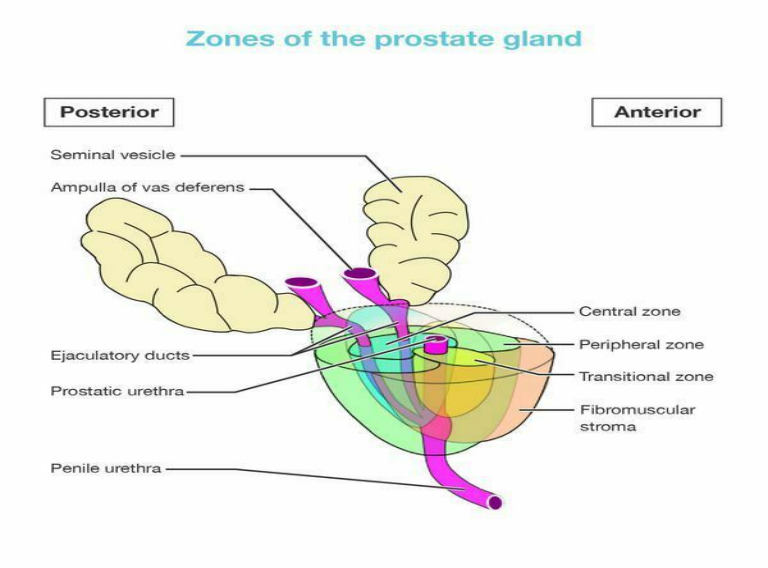
The volume of the prostate in normal adult males is 20cc.

Prostate is an accessory glandular tissue embedded in the fibromuscular stroma. It usually weighs 8 grams in the young adults and its weight ranges from 40-150 grams in men aged >50 years.

The prostate gland is situated in the lesser pelvis and surrounds the prostatic urethra which extends from bladder base to the membranous urethra. Pubic symphysis and pubic arch lie anteriorly to the prostate whereas rectourethralis and rectal ampulla lie posteriorly to it.

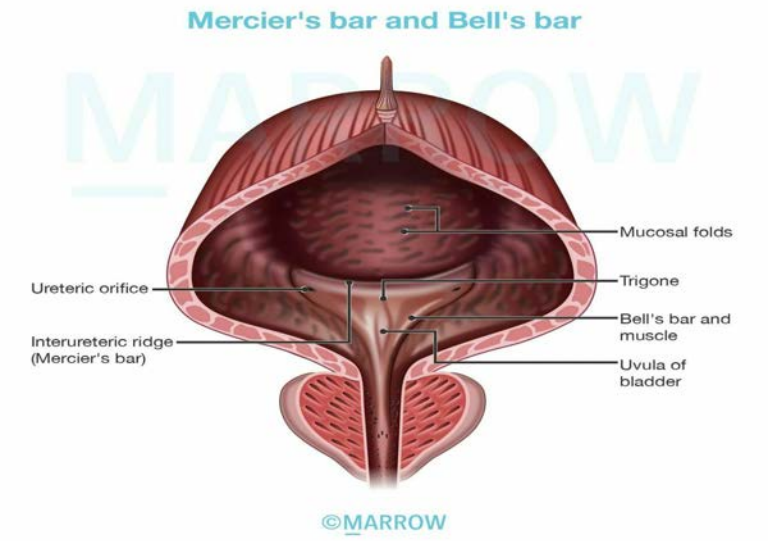
The prostate has three distinct zones as follows:

Zone	Structures enclosed	Clinical significance
Transitional zone	Urethra	Most common site for benign prostatic hyperplasia (BPH)
Central zone	Ejaculatory ducts	Atrophies secondary to BPH
Peripheral zone	Central and transitional zones Pre-prostatic urethra	Most common site for prostatic carcinoma



The prostate is composed of 5 lobes. They are anterior, posterior, two lateral and one medial or middle lobe.

The median lobe of the prostate forms the uvula vesicae. It is an elevation found in the lower part of the bladder trigone. It is the most common site of adenoma.



Microstructure of the prostate gland:

The glandular tissue of the prostate gland is composed of many follicles with frequent internal papillae. The follicular epithelium is either a single-layered or pseudostratified columnar epithelum. These follicles open into canals, which join to form the main ducts. Small eosinophilic colloid amyloid bodies called corpora amylacea are frequently seen within a follicle.

The prostatic ducts open into the prostatic sinus in the prostatic urethra. The ducts of the prostate follicles are lined by bilayered epithelium (basal cuboidal and apical columnar).

The secretions of the prostate are acidic and contain acid phosphatase, amylase, prostate-specific antigen (PSA), fibrin, and zinc.

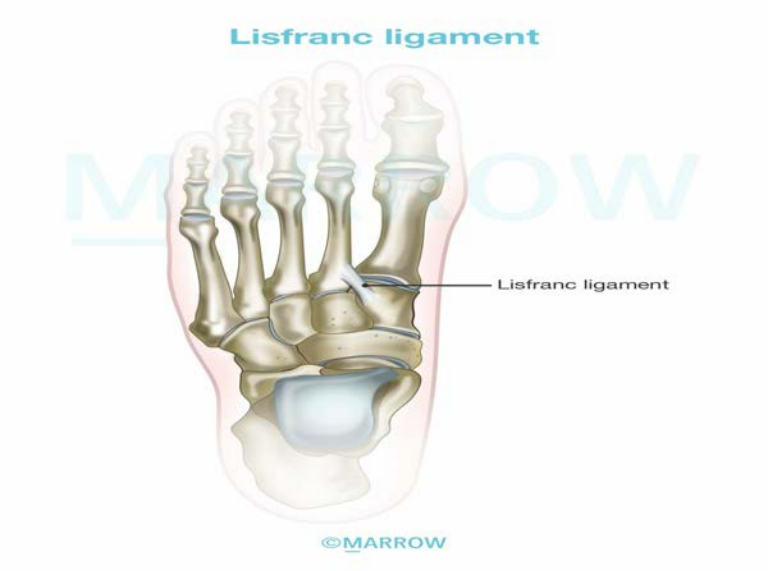
The blood supply to the prostate is by the inferior vesical, internal pudendal and middle rectal arteries. It recieves nerve supply from the inferior hypogastric plexus.

Solution to Question 3:

The Lisfranc ligament connects the medial cuneiform to the base of the 2nd metatarsal.

Lisfranc ligament is a cuneometatarsal interosseous ligament. It is the strongest ligament among the three cuneometatarsal interosseous ligaments. It passes from the lateral surface of the medial cuneiform to the adjacent angle of the second metatarsal bone.

Deformity of this ligament can lead to instability and deformity of the tarsometatarsal joint.

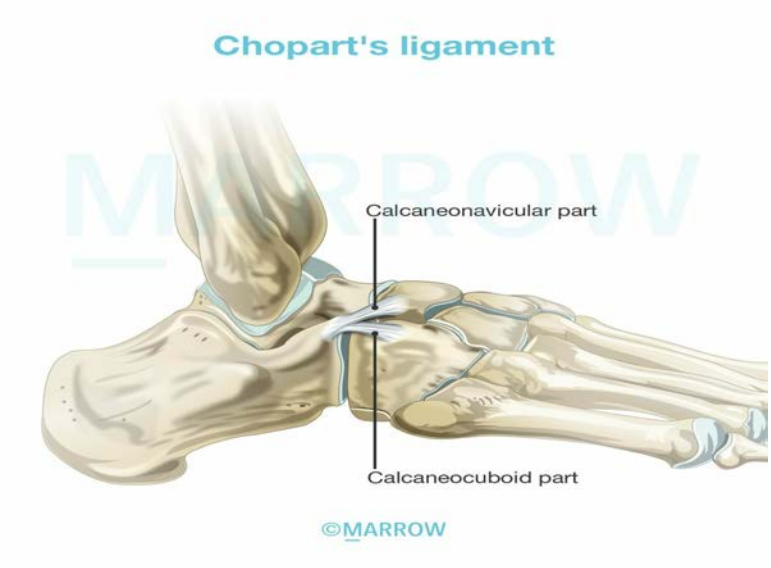


Other options:

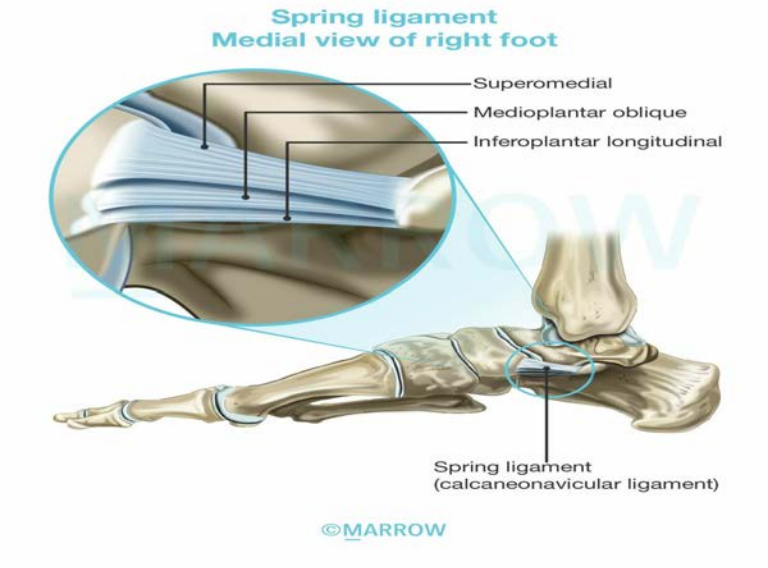
Option A: Chopart's ligament is related to both calcaneocuboid and calcaneonavicular joints. It is a strong Y-shaped band, having a proximal stem and 2 distal limbs.

• The proximal limb is attached by a stem to the anterior part of the upper calcaneal surface.

• The distal limb divides into calcaneocuboid and calcaneonavicular parts.



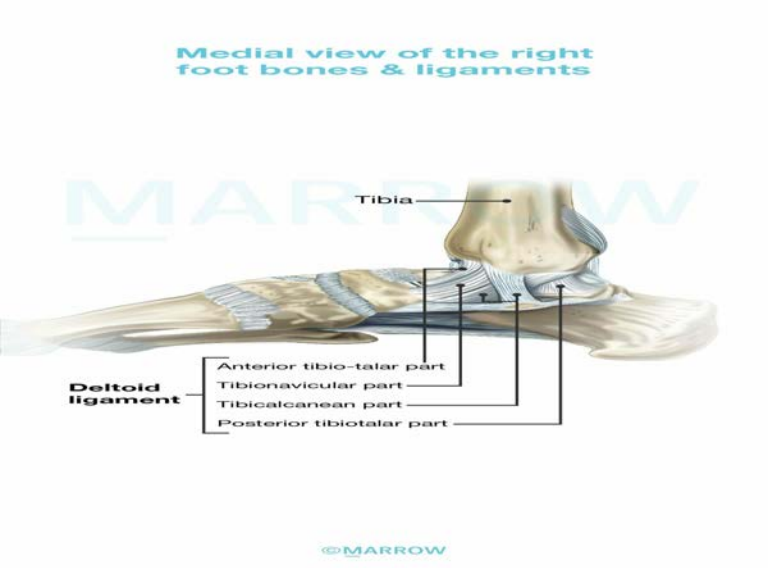
Option B: Spring ligament also known as the plantar calcaneonavicular ligament connects the sustentaculum tali to the navicular. It ties the calcaneus to the navicular and maintains the medial longitudinal arch of the foot. It is made up of the superomedial calcaneonavicular portion and the inferior calcaneonavicular portion.



Option D: Deltoid ligament also called the medial collateral ligament is attached to the apex, anterior and posterior borders of the medial malleolus. It has 2 layers, superficial and deep:

• The superficial layer consists of tibionavicular fibres anteriorly, tibiocalcaneal fibres in the middle, and superficial posterior tibiotalar fibres posteriorly.

• Deep layer consists of anterior tibiotalar fibres, tibiocalcaneal in the middle and deep posterior tibiotalar posteriorly.



Solution to Question 4:

The given structure is the fornix and its fibres arise from the hippocampus.

The fornix is a part of the connecting pathways of the limbic system. It arises from the hippocampus which wraps around the thalamus and ends in the mammillary body. It connects the hippocampus with distal brain sites.

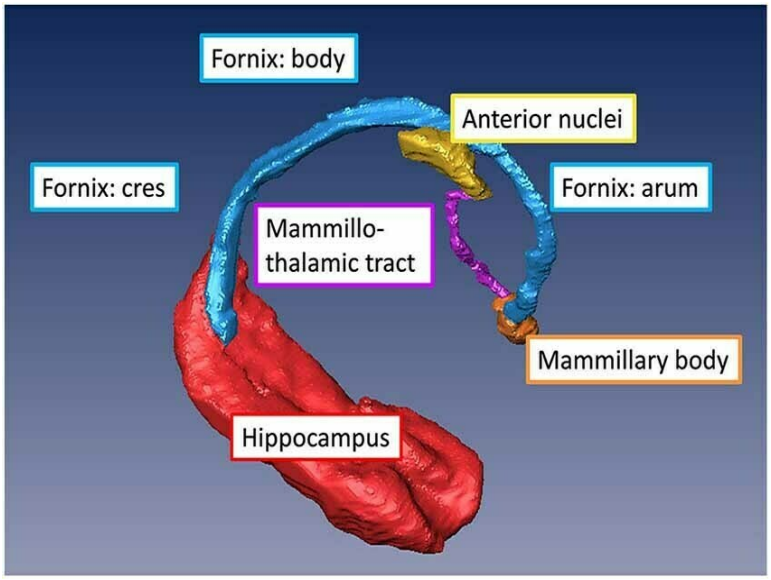
The fornix has two types of fibres:

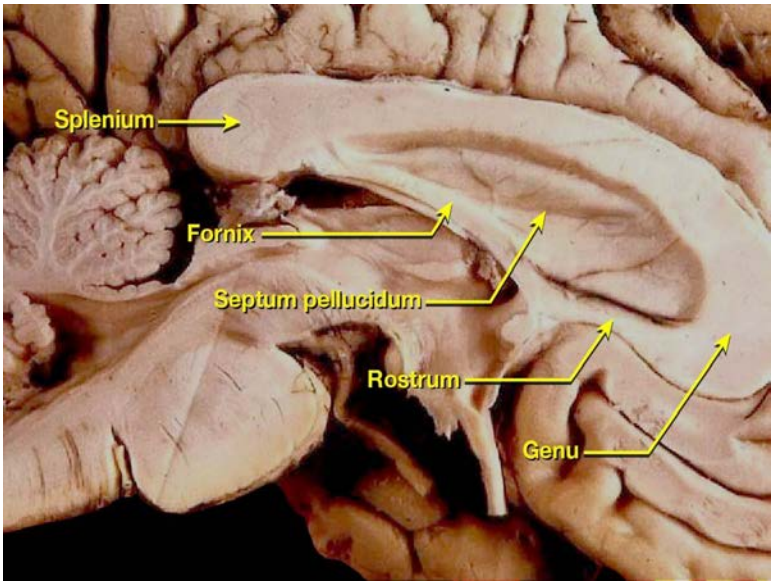
• Association fibres: They connect the various cortical regions within the same hemisphere

• Commissural fibres: They connect the corresponding regions of two hemispheres. It is seen in the hippocampal commissure of the fornix.

The blood supply of fornix is by the anterior communicating artery which arises from the anterior cerebral artery.

The limbic system is a group of structures seen between the cerebral cortex and the hypothalamus. It is involved in emotional and motivation activity, learning, and memory.





Other options:

Option A: Amygdala is a part of the limbic system that consists of lateral, central and basal nuclei. It can Influence the body's response to enviromnental changes. In a fearful situation it can change the heart rate, blood pressure, respiratory rate etc.

Option C: Caudate nucleus is a C-shaped mass of grey matter. It is divided into a head, body, and tail. Degeneration of the caudate nucleus is seen in Huntington's disease.

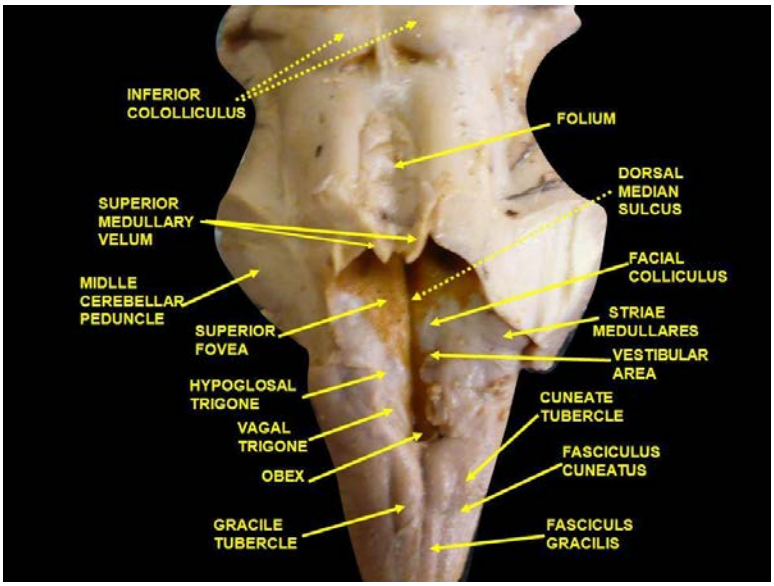
Solution to Question 5:

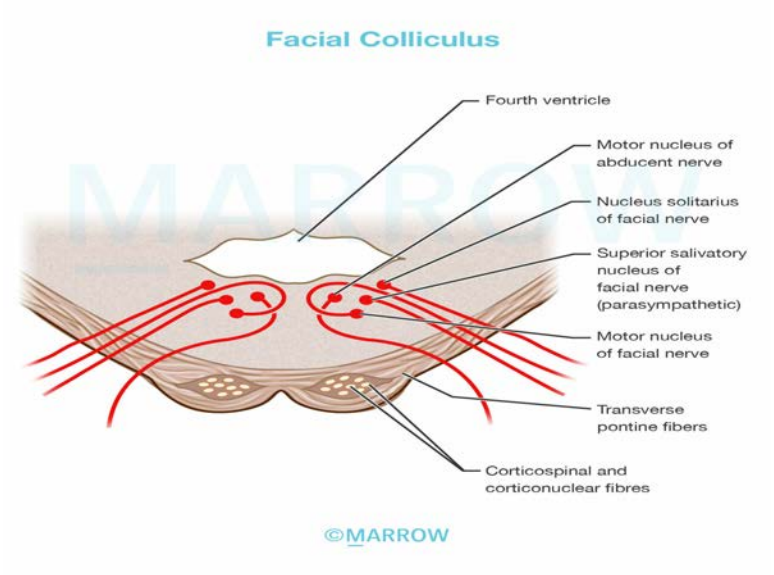
Risorius is supplied by the facial nerve which causes the elevation marked. The image shows the floor of the fourth ventricle and the facial colliculus is marked.

The fourth ventricle is located between the brainstem and the cerebellum. The rhomboid fossa is a diamond-shaped depression seen on the floor of the fourth ventricle. The superior and the inferior part of the floor is triangular in shape. It is divided by a longitudinal median sulcus into two halves. Each half is again divided into the medial and lateral regions.

The facial colliculus is present in the superior part, which presents as a small elevation produced by the root of the facial nerve winding around the nucleus of the abducens nerve. Columns are formed by groups of facial neurones, which innervate individual muscles and give branches of the facial nerve. Dorsal neurones innervate muscles in the scalp and upper face and ventral neurons supply the lower facial musculature.

Risorius falls under the buccolabial muscle group and act as the elevator, retractor and evertor of the upper lip. Some of its peripheral attachments are the zygomatic arch, parotid fascia and fascia over the mastoid process. It is involved in actions like grinning and laughing and is innervated by the buccal branches of the facial nerve.



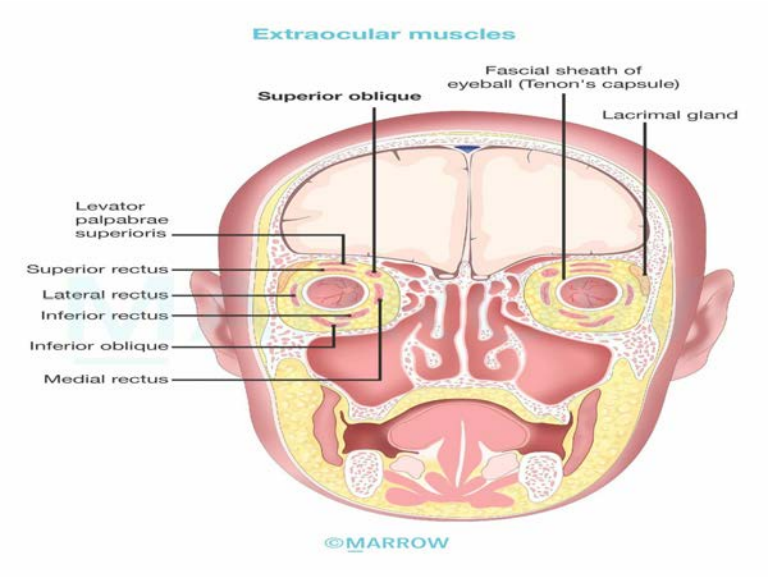


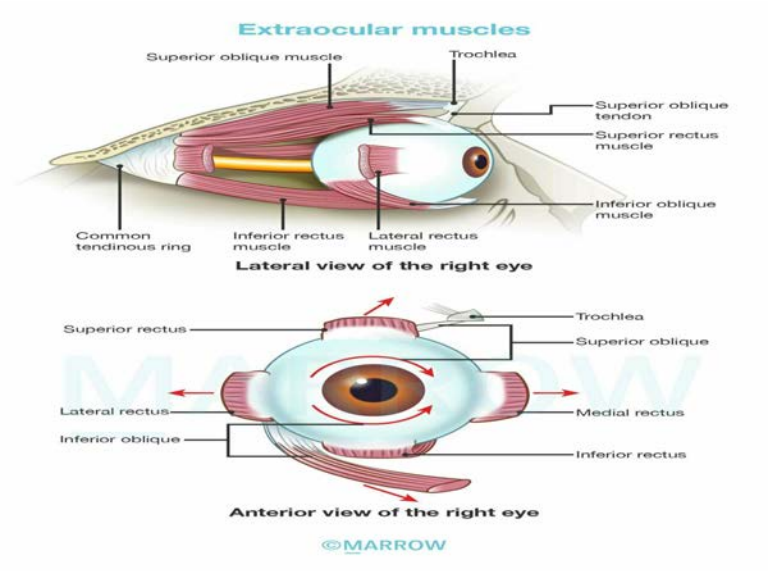
Other options:

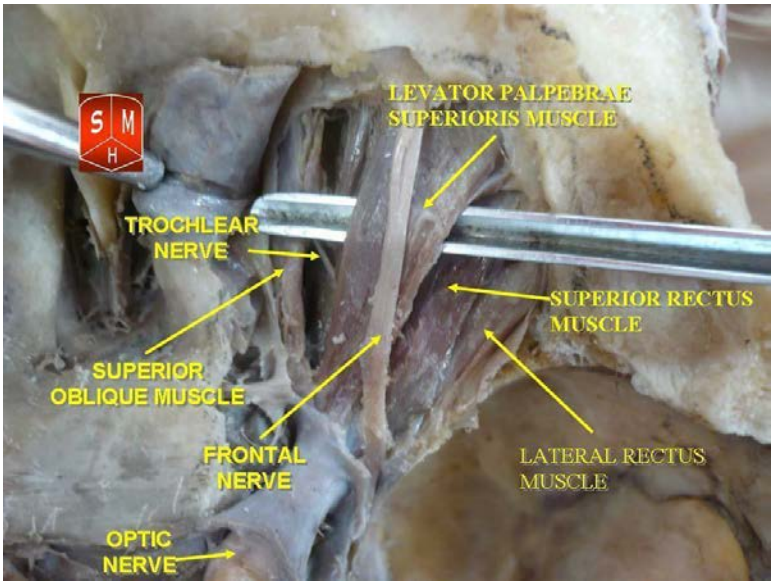
Option A: Lateral rectus is an extraocular muscle that arises from the lateral part of the common tendinous ring. It is innervated by the abducens nerve.

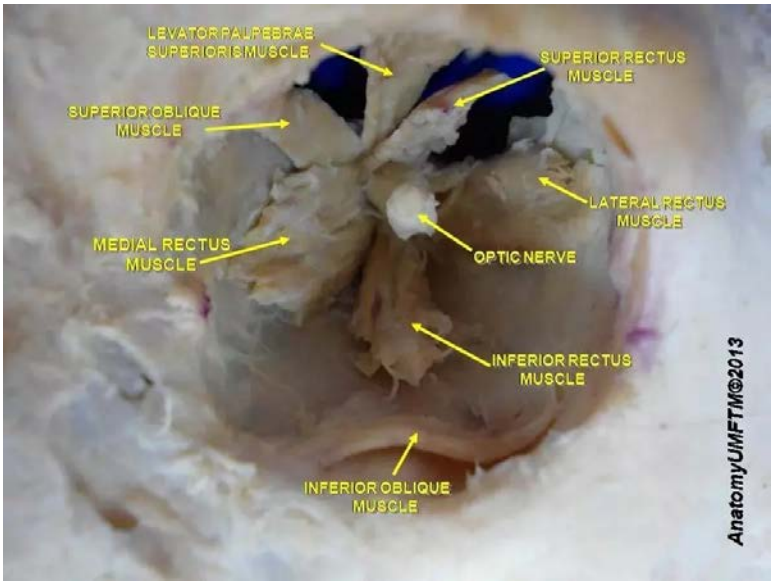
Option B: Superior oblique is an extraocular muscle that arises from the body of the sphenoid. It is innervated by the trochlear nerve.

Option D: Levator palpebrae superiors is an extraocular muscle that arises from the lesser wing of sphenoid. It is innervated by the oculomotor nerve.









Solution to Question 6:

Lung hilar structures are arranged from the anterior to posterior in the order:

- Pulmonary vein
- Pulmonary artery
- Primary bronchus
- Bronchial artery

The medial surface of the lung is connected to the heart and trachea by a group of structures that enter or leave the hilum. It is called the pulmonary root. It is anteriorly related to the phrenic nerve, pericardiacophrenic vessels , and anterior pulmonary plexus. The vagus nerve and posterior pulmonary plexus form the posterior relation and the pulmonary ligament the inferior

relation.

The superior vena cava and right atrium are seen in front of the right root and terminal part of the azygos vein superiorly. The hilar structures are arranged from the superior to inferior as:

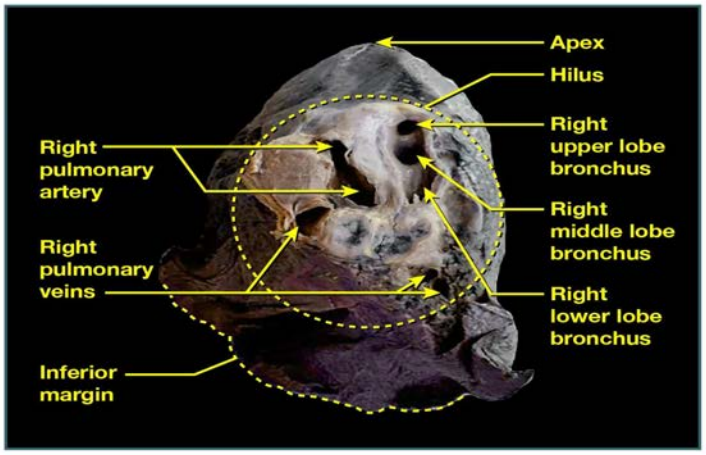
• Superior lobar bronchus

• Pulmonary artery

• Principal bronchus

• Inferior pulmonary vein

Structures related to right lung



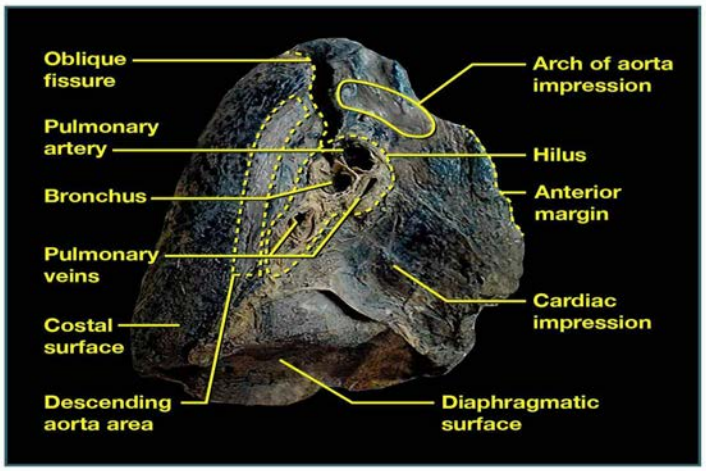
The aortic arch is seen superiorly and descending thoracic aorta posteriorly of the left root. The hilar structures are vertically arranged as:

• Pulmonary artery

• Principal bronchus

• Inferior pulmonary vein

Structures related to Left lung



Solution to Question 7:

Mental is not a branch of the facial artery but the branch of the maxillary artery in the face.

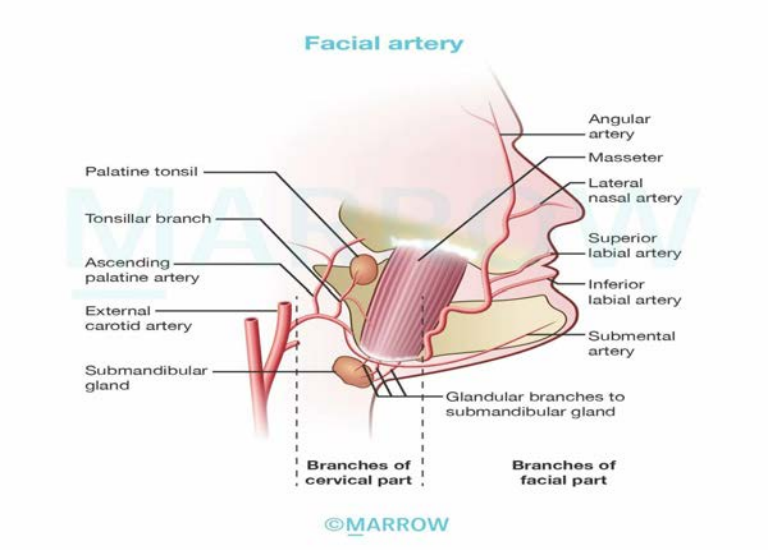
The first part of the maxillary artery gives rise to the mental artery as a terminal branch of the inferior alveolar artery.

The facial artery is a branch of the external carotid artery which arises in the carotid triangle, above the origin of the lingual artery. It runs upwards in the neck and curves around the anteroinferior border of the masseter to enter the face.

The premasseteric artery passes along the anterior border of the masseter and the surrounding tissues are supplied by it. The inferior labial artery mainly supplies the inferior labial glands. It then anastomoses with its controlateral fellow and with the mental branch of the inferior alveolar artery. The superior labial artery supplies the upper lip whereas the lateral nasal artery supplies the dorsum and alae of the nose. Both these arteries anastomose with its controlateral fellow.

The image shows the branches of facial artery:

Branches of facial artery in th e neck	Branches of facial artery in th e face
Ascending palatine artery	Premasseteric artery
Tonsillar branch	Superior and inferior labial a rteries
Submental artery	Lateral nasal artery
Branches to submandibular g land	Angular artery



Solution to Question 8:

The glossopharyngeal nerve passing through the jugular foramen has a separate canal.

The jugular foramen is formed by the occipital bone and the petrous part of the temporal bone. The spinal accessory nerve and vagus nerve also pass through this foramen.

The glossopharyngeal nerve leaves the skull through the anteromedial part of the jugular foramen in a separate dural sheath.

The branches of the nerve are tympanic, carotid, pharyngeal, muscular, tonsillar and lingual branches.

Infection, malignancy and postoperative inflammation of the tonsil and tonsillar fossa will cause referred pain in the ear. This is conducted through the tympanic branch of the glossopharyngeal nerve.

Pharyngeal branches of the glossopharyngeal nerve and vagus nerve form the pharyngeal plexus of nerves. These plexes mainly supply the pharynx. It also has contributions from the superior cervical ganglion.

Nerve supply by the pharyngeal branch of the vagus nerve are:

• All the muscles of the soft palate(except tensor veli palatini - supplied by mandibular division of the trigeminal nerve)

• All the muscles of the pharynx(except stylopharyngeus - supplied by the glossopharyngeal nerve)

Motor fibres to the stylopharyngeus and parasympathetic secretomotor fibres to the parotid gland are also supplied by the glossopharyngeal nerve.

Sensory supply includes uvula, posterior one-third of the tongue, tympanic cavity etc.

The glossopharyngeal nerve is rarely damaged alone. Lesions will result in loss of sensation of the posterior third of the tongue, reduced gag reflex, loss of sensation over the ipsilateral soft palate etc.

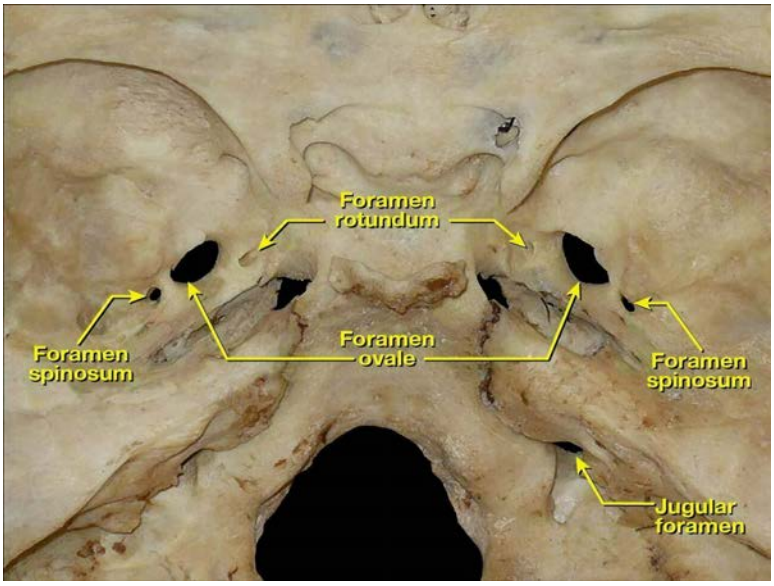
The main functions of IX and X can be tested together by assessing swallowing, phonation/articulation and sensation from the pharynx/larynx.

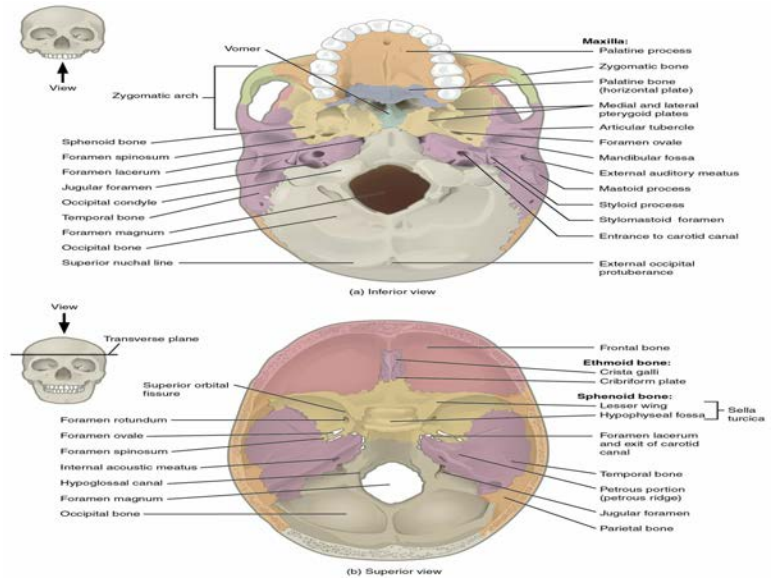
Glossopharyngeal and vagus nerve examinations include:

• Observing the position and symmetry of the palate and uvula at rest and with phonation (“aah”).

• By assessing the strength of the cough

The image below shows the base of the skull and foramina:





Solution to Question 9:

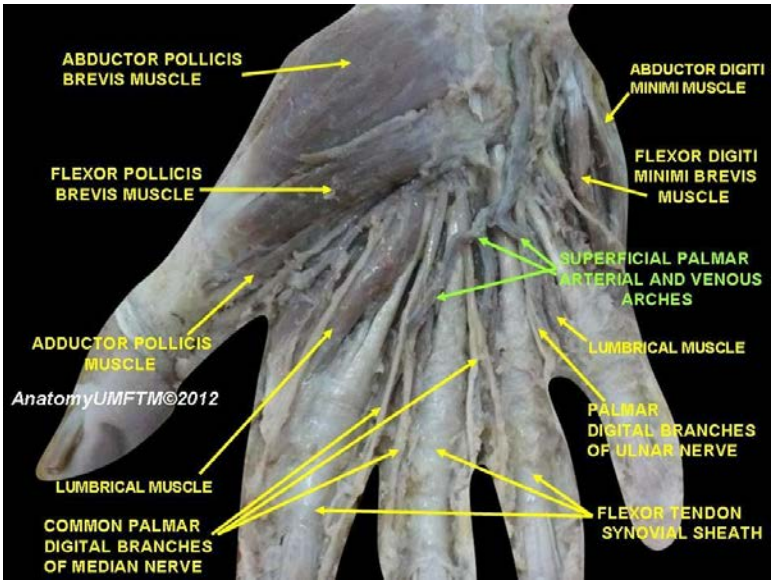
The median nerve supplies the 1st lumbrical which is marked.

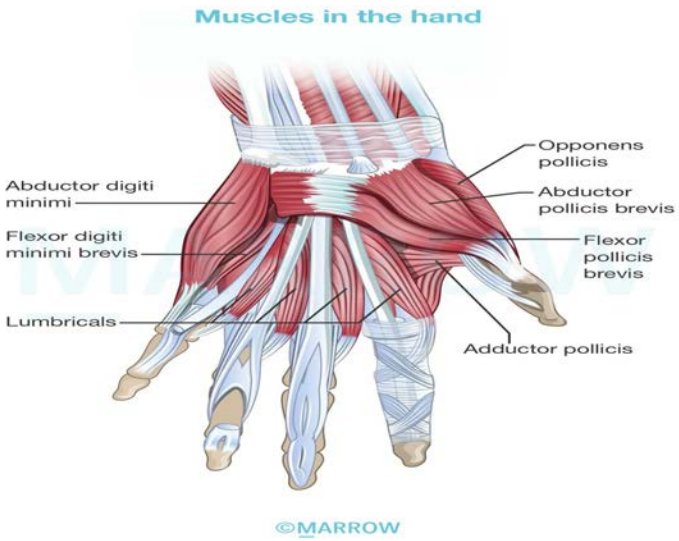
There are four lumbrical muscles. They originate from the tendons of the flexor digitorum profundus. It passes to the radial side of the corresponding fingers and is inserted into the dorsal digital expansion of the extensor digitorum.

The action of lumbricals is flexion at the metacarpophalangeal joint and extension of interphalangeal joints.

Lumbricals can be tested only along with interosseous muscle. The examiner will hold the metacarpophalangeal joint of the index finger in hyperextension. Then the patient is asked to extend the proximal interphalangeal joint against resistance. The test is repeated on other fingers as well.

The median nerve innervates the first and second lumbricals. The deep terminal branch of the ulnar nerve innervates the third and the fourth.





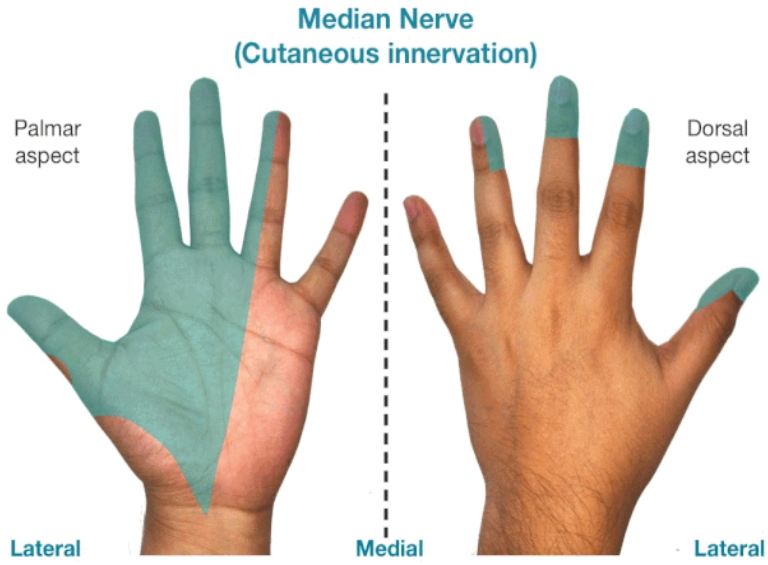
The median nerve is formed by the union of the lateral root (C6, 7) from the lateral cord, and the medial root (C8, T1) from the medial cord.

On the hand, it is seen proximal to the flexor retinaculum and lateral to the tendons of flexor digitorum superficialis. It also lies between the tendons of flexor carpi radialis and palmaris longus.

Its cutaneous supply in hand is as follows:

• Lateral 2/3rd of the palm by superficial cutaneous branch

• Lateral 3½ fingers (palmar aspect and dorsal aspect of nailbeds) by palmar digital nerves



The muscles supplied by the median nerve in the hand are flexor pollicis brevis, abductor pollicis brevis, and opponens pollicis

The median nerve sometimes gets compressed under the fibro-osseous tunnel beneath the flexor retinaculum leading to carpal tunnel syndrome.

Pen test is used to test the median nerve in the hand. It tests the abductor pollicis brevis muscle. The hand must remain flat with the palm facing upwards. A pen is held above the palm and the patient is asked to touch the pen with his thumb.

Solution to Question 10:

The given clinical scenario is suggestive of DiGeorge syndrome. Defective development of the third pharyngeal pouch marked as 3 causes this condition.

A child with DiGeorge syndrome lacks thymus and inferior parathyroid glands due to defective development of the 3rd pharyngeal pouch. The child can also lack superior parathyroid glands, due to defective development of the 4th pharyngeal pouch. It is caused by chromosome 22q deletion and is characterized by the following (Mnemonic: CATCH-22)

• Cleft palate

• Abnormal facies

• Thymic aplasia leading to T-cell deficiency and recurrent infections

• Cardiac defects

• Hypocalcemia, secondary to parathyroid aplasia.

Derivatives of the Pharyngeal Pouches

1st Pouch

• Tympanic cavity (middle ear cavity)

• Auditory tube (eustachian tube)

2nd Pouch

• Palatine tonsils

• Tonsillar fossa

3rd Pouch

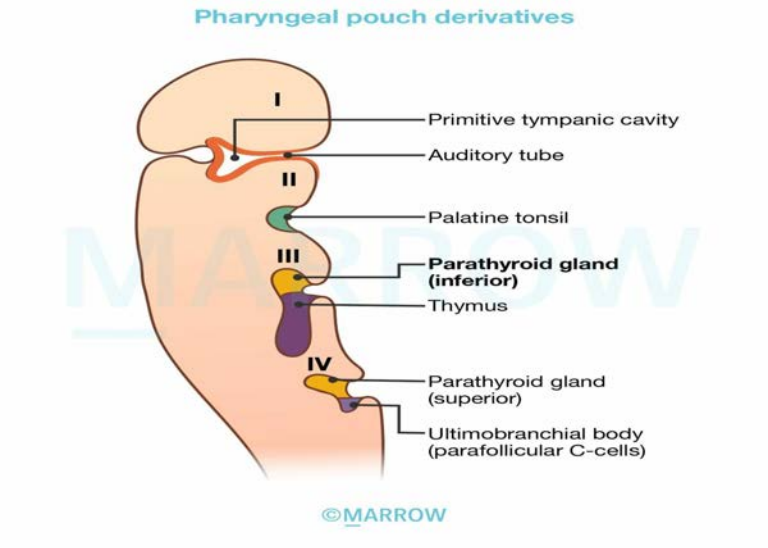
• Inferior parathyroid glands

• Thymus

4th Pouch

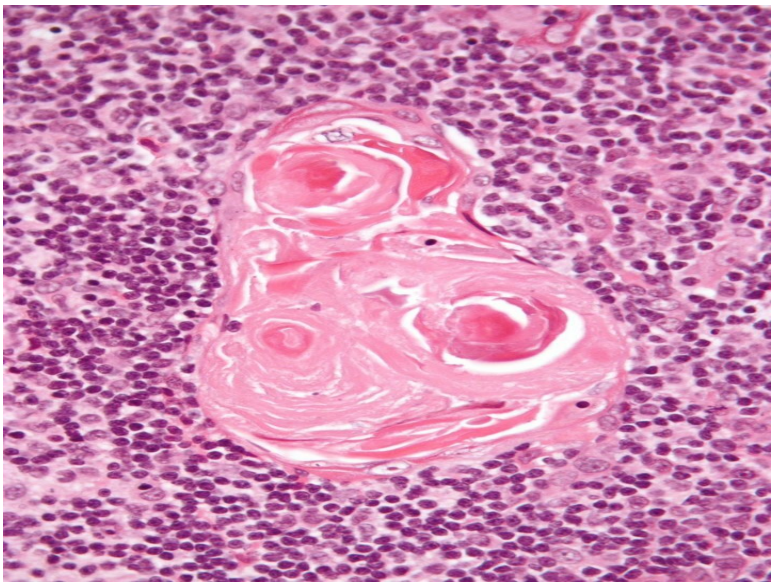
• Superior parathyroid glands

• Ultimobranchial body - gives rise to parafollicular (C) cells of the thyroid gland



The medulla of the thymus has Hassall's corpuscles. They are small rounded structures formed from whorls of medullary epithelial cells with a central partially keratinized core appearing as an eosinophilic-staining mass.

Histological image of Hassall's corpuscles is given below:

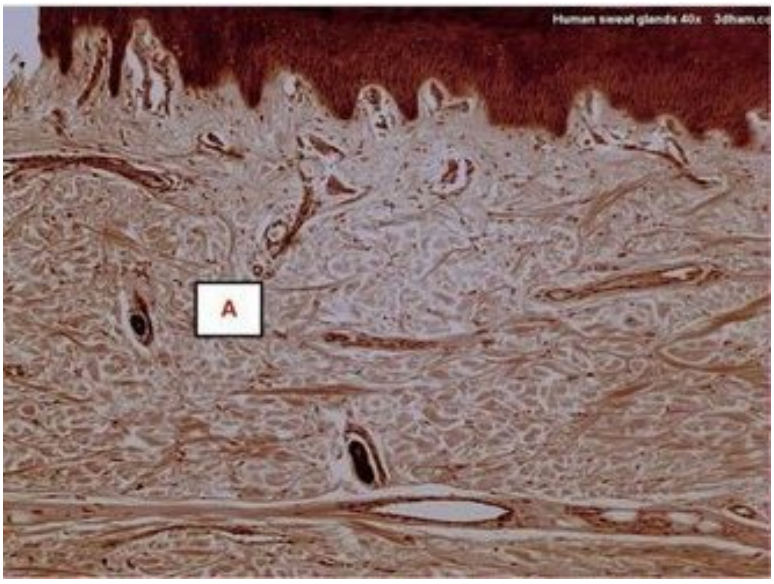


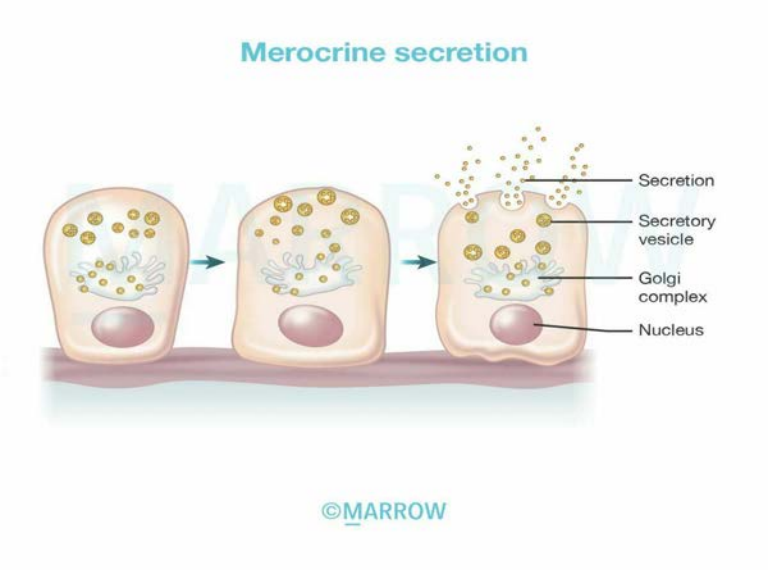
Solution to Question 11:

Sweat gland marked 2 is a merocrine gland.

Eccrine and apocrine are the two types of sweat glands. Secretions of the sweat glands are by exocytosis hence they are also known as merocrine sweat glands.

A histopathological image of the sweat gland is shown below:



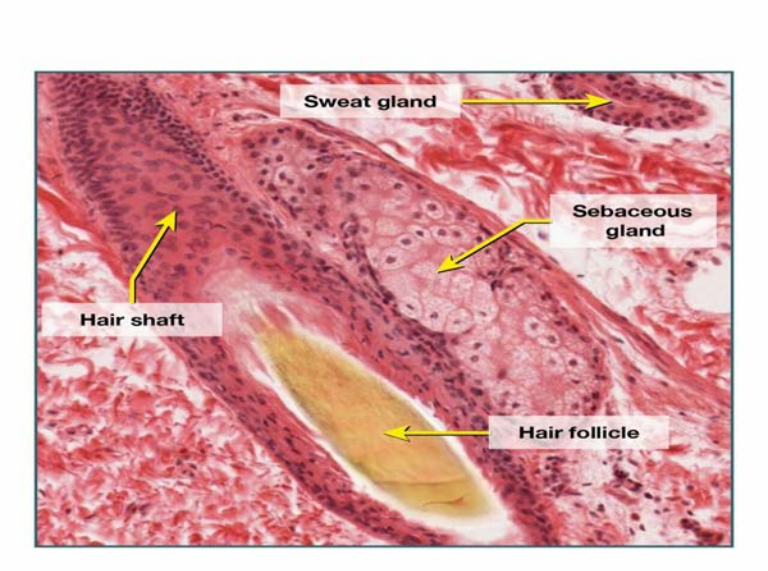


The other structures marked are:

1- Hair follicle

3- Sebaceous gland

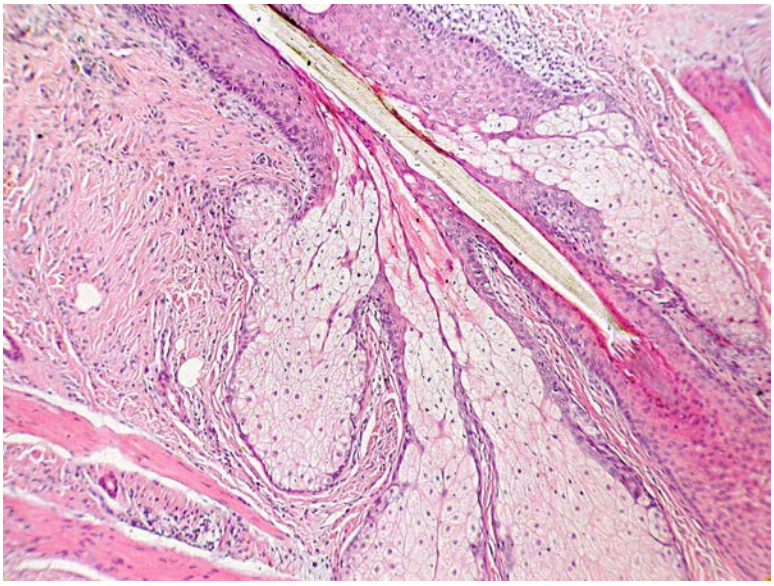
4- Hair shaft

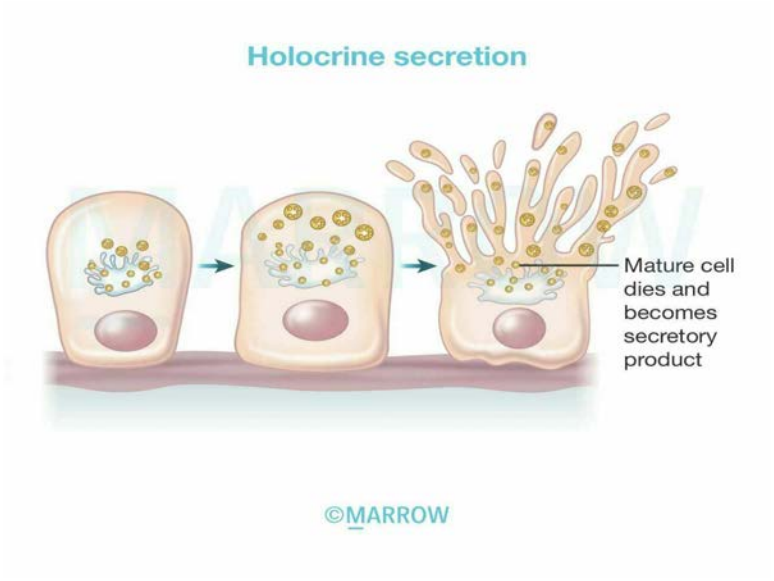


Glands are divided into holocrine, apocrine, and merocrine on the basis of the manner in which their secretions are poured out of the cells.

In holocrine secretions, the secretory cells themselves are disintegrated as part of their terminal differentiation. Afterwhich, the terminally differentiated cells filled with lipid products are released. The sebaceous gland and hair follicles are examples.

A histopathological image of the sebaceous gland is shown below:

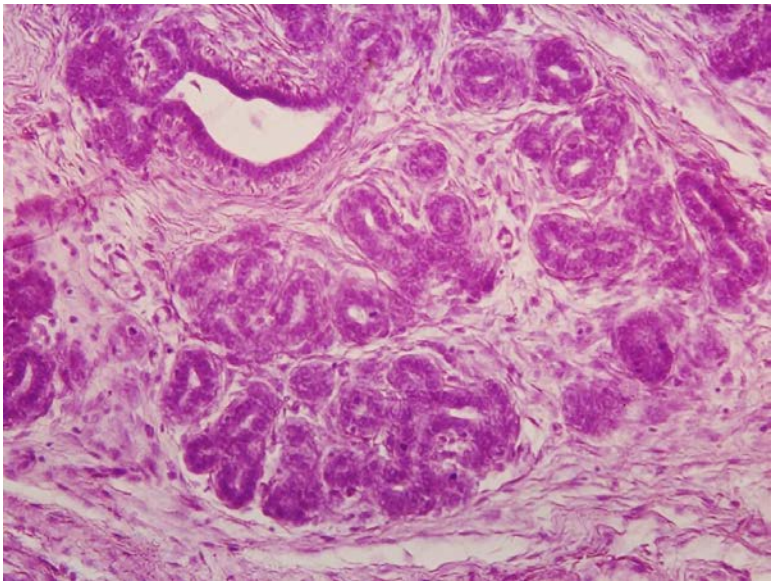


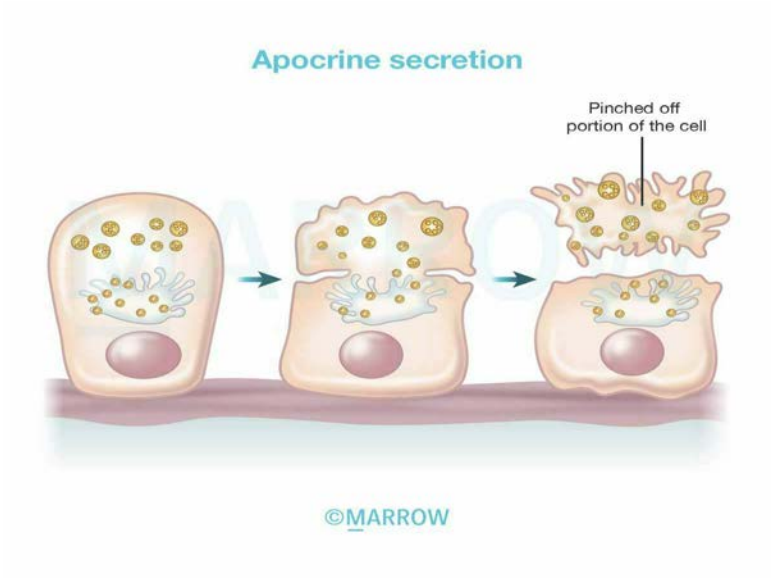


Merocrine uses exocytosis for secretions. Most of the exocrine glands are merocrine.

In apocrine, product-filled areas of cells are released, the mammary gland is an example.

Histopathological image of mammary gland is shown below:



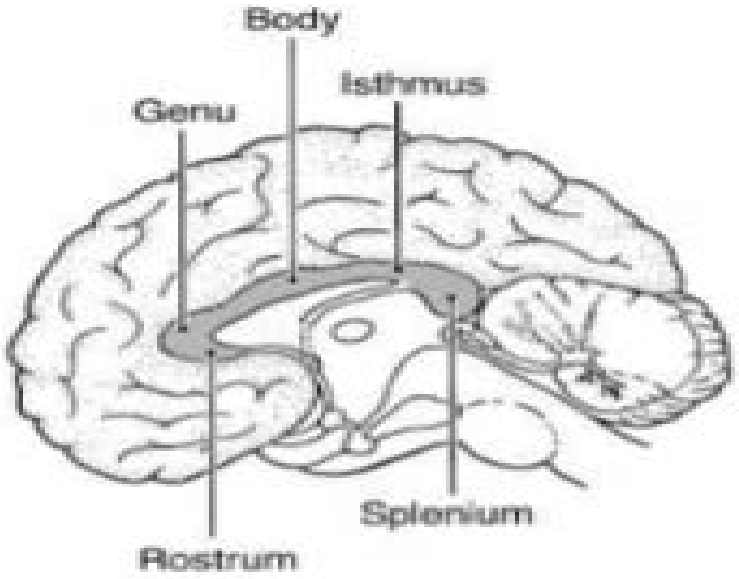


Solution to Question 12:

Blood is supplied by the anterior cerebral artery and anterior communicating artery as the marked structure is the anterior part of the corpus callosum.

Corpus callosum is the largest fibre pathway of the brain. The parts of the corpus callosum are the rostrum, genu, trunk or body, and splenium.

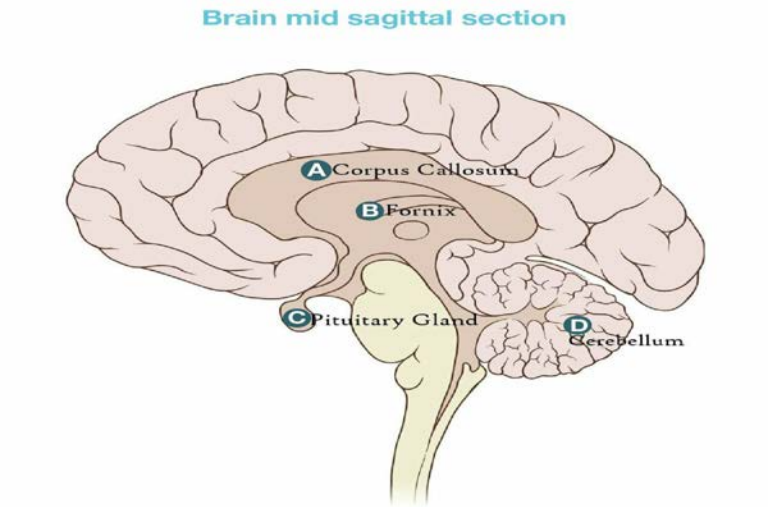
The image below shows the parts of the corpus callosum:



Anterior cerebral artery is a branch of the internal carotid artery. The frontal branch of the anterior cerebral artery supplies the corpus callosum and the central branch which supplies the rostrum.

Central or perforating arteries arises from the circle of willis. They are again divided into the anteromedial, anterolateral, posteromedial and posterolateral groups. The anterior cerebral and anterior communicating artery give rise to anteromedial group which supplies the rostrum of the corpus callosum.

The image below shows the mid sagittal section of the brain:



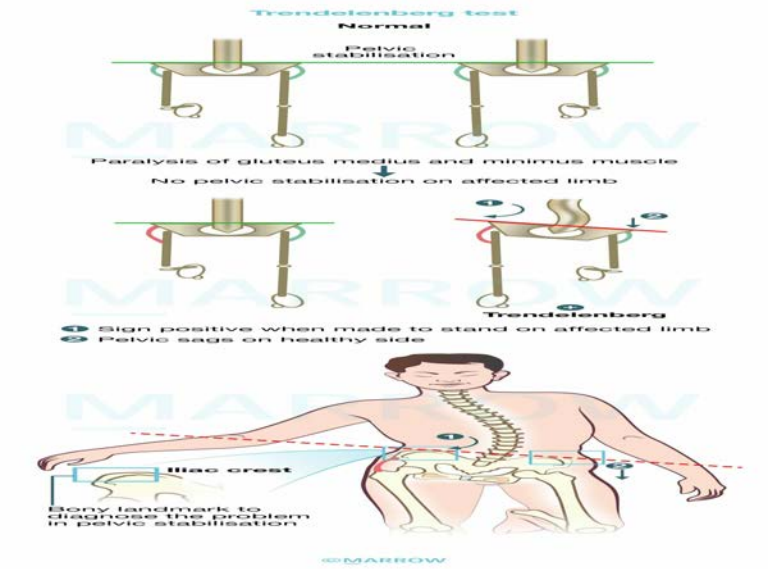
Solution to Question 13:

All of the structures except pyriformis are supplied by the superior gluteal nerve. Pyriformis is supplied by the nerve to the piriformis.

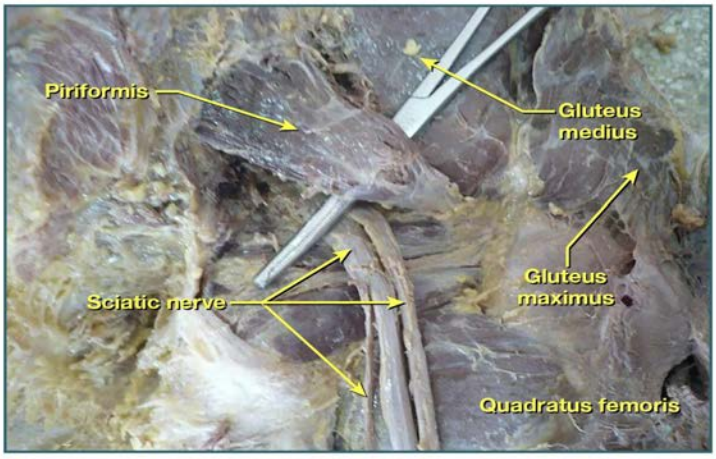
The dorsal branches of the L4, L5, and S1 rami give rise to the superior gluteal nerve. It is accompanied by superior gluteal vessels. This nerve leaves the pelvis via the greater sciatic foramen above piriformis and divides into superior and inferior branches. It supplies gluteus medius, gluteus minimus, and tensor fasciae latae.

The dorsal branches of the S1 and S2 rami give rise to the nerve to the piriformis.

Gluteus medius and gluteus minimus act as the abductors of the hip joint. Stabilizing the pelvis on the femur during walking is done by these muscles. It is demonstrated by asking the subject to stand on one limb. If the ipsilateral abductors are normal, the pelvis remains in a horizontal position. If the ipsilateral abductors are weak, then the pelvis tilts towards the opposite (unsupported) side. This is called positive Trendelenburg's sign.



Gluteal region



Solution to Question 14:

The structures are arranged in the cubital fossa from medial to lateral as follows:

• Median nerve

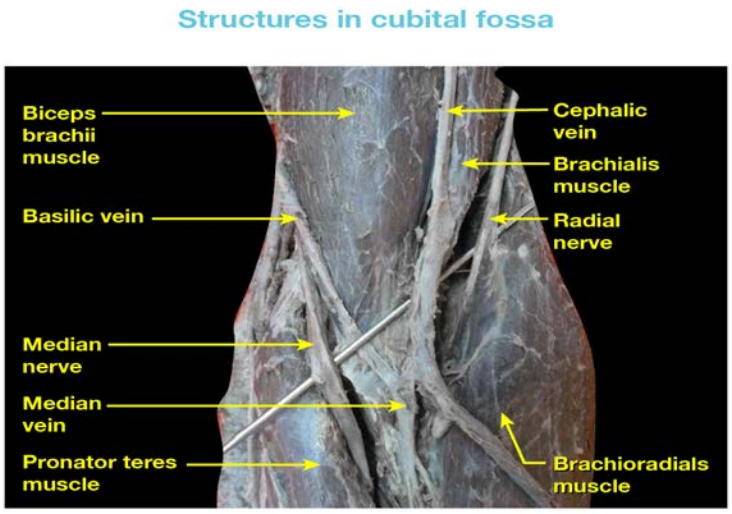
• Brachial artery

• Tendon of biceps brachii

• Radial nerve

The cubital fossa is a triangular depression in the anterior aspect of the upper forearm. It is related to the epicondylar line proximally, lateral border of pronator teres medially, and by the medial surface of brachioradialis laterally.

Its roof is formed by the deep fascia of the forearm. The floor of the fossa is formed by the brachialis and supinator. Veins like basilic, median cubital, and cephalic veins are arranged in the superficial fascia from medial to lateral side.



Solution to Question 15:

From the basal layer towards the lumen in the seminiferous tubules, the cells are arranged in the order of:

• Myoepithelial cells

• Spermatogonia

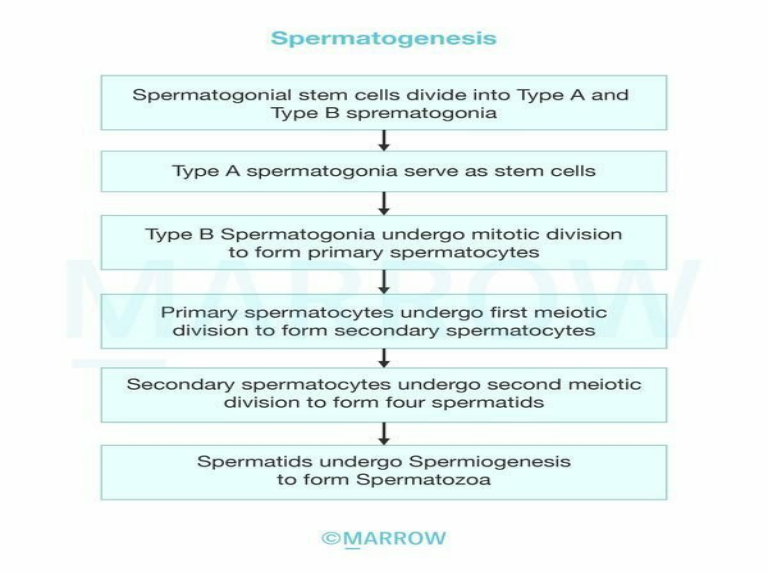
• Primary spermatocyte

• Spermatid

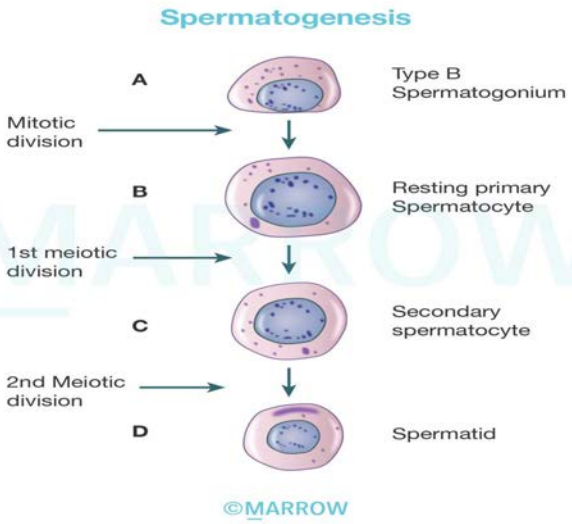
• Spermatozoa

Spermatogenesis is the process in which spermatogonia are transformed into spermatozoa. It begins at puberty. During puberty, the sex cords acquire lumen to become seminiferous tubules.

The primordial germ cells give rise to spermatogonial stem cells. The transformation of spermatogonial stem cells to spermatozoa is given in the flowchart below.



The process by which spermatids are transformed into spermatozoa is called spermiogenesis.



Solution to Question 16:

Foramen lacerum is formed by three bones.

The three bones involved in the formation of foramen lacerum are:

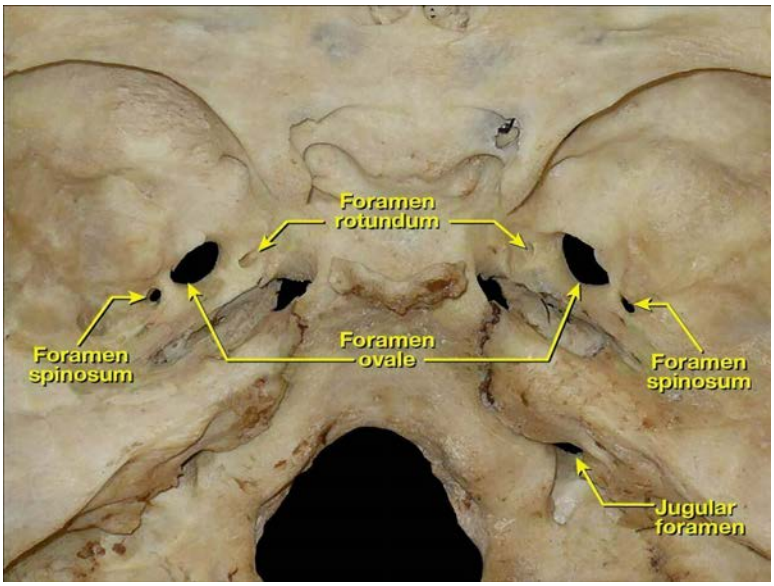
- Petrous part of the temporal bone
- Greater wing of the sphenoid bone
- Basilar part of the occipital bone

The internal carotid artery enters the skull through this foramen. It ascends through the carotid canal and from the upper end of the foramen lacerum.

It is accompanied by venous and sympathetic nerve plexuses. It is also transversed by the meningeal branches of the ascending pharyngeal artery and emissary veins from the cavernous sinus.

On the anterior margin of the foramen lacerum pterygoid canal can be seen which leads to the pterygopalatine fossa. The nerve of the pterygoid canal and accompanying vessels are transmitted by them.

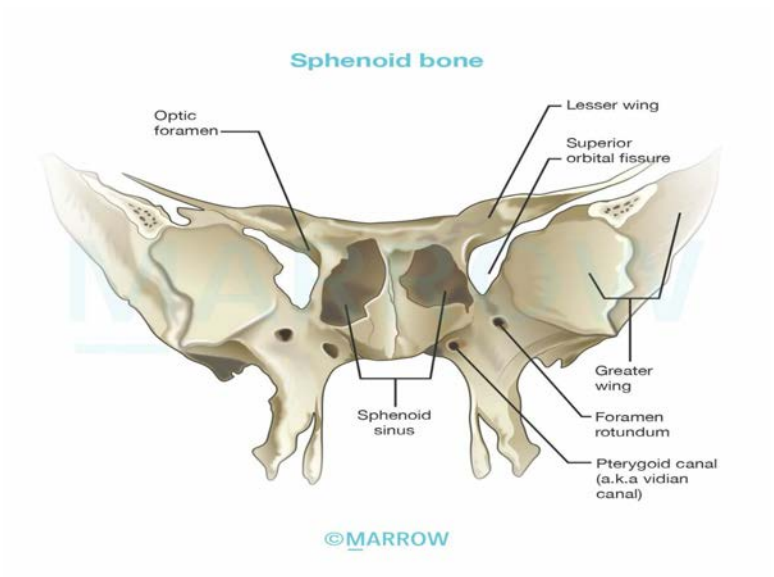
The image below shows the base of the skull and foraminas:



Other options:

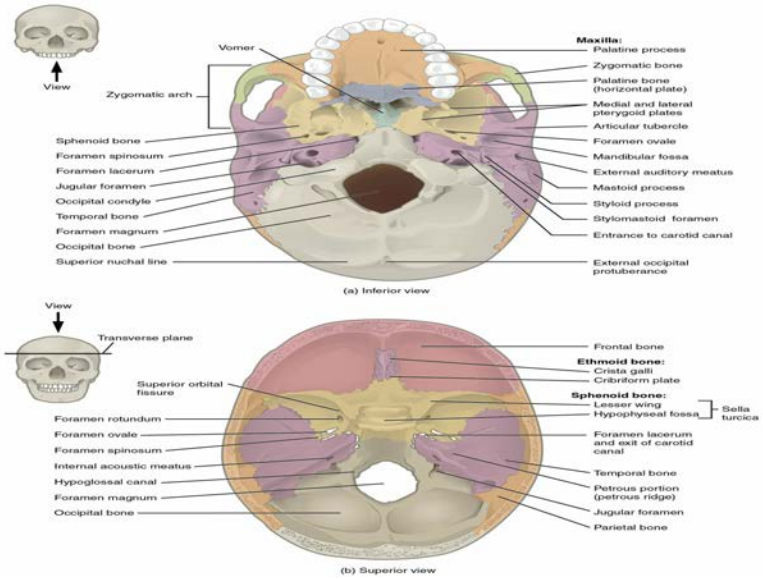
Option B: Foramen magnum is formed by the occipital bone.

Option C: Foramen rotundum is a hole seen in the greater wing of the sphenoid bone.



Option D: Foramen jugulare is formed by the petrous part of the temporal bone and occipital bone.

The image below shows superior and inferior views of the skull base:



Solution to Question 17:

Sartorius is involved in lateral rotation, flexion, and abduction at the hip joint, and flexion at the knee. The structure marked '2' is sartorius.

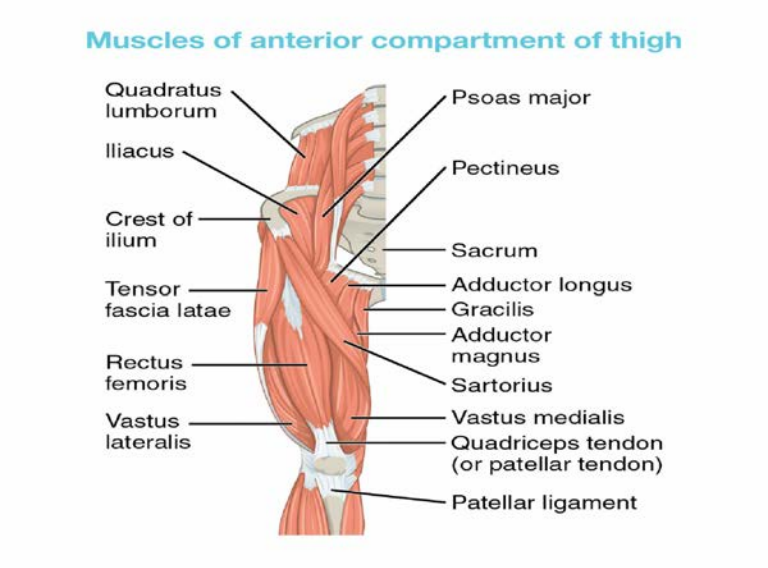
The sartorius muscle is known as the tailor muscle and is also the longest muscle in the body. The word "sartorius" is derived from the Latin word sartor, which translates to tailor, due to the way the individual will position one's leg while working.

Origin: Anterior superior iliac spine and the upper half of the notch below it.

Insertion: Into the superior aspect of the medial surface of the tibial shaft near the tibial tuberosity (joins aponeurosis of gracilis and semitendinosus to form pes anserinus).

Action: Flexion, abduction, and lateral rotation of the thigh; and flexion of the leg.

Innervation: By femoral nerve (L2 and L3)



Other options:

Option A: Rectus femoris is involved in flexion at the hip and extension at the knee.

Option C: Gracilis is involved in adduction at the hip and flexion and medial rotation at the knee.

Option D: Adductor longus is involved in adduction, flexion, and medial rotation at the hip.

Solution to Question 18:

The true statements are 2 and 3.

The lingual nerve is a branch from the posterior division of the mandibular nerve, and it arcs around the submandibular duct.

The buccal branch is a branch from the anterior division of the mandibular nerve, and it emerges from behind the mandibular ramus.

The other statements:

1. The auriculotemporal nerve emerges from behind the temporomandibular joint and is a branch from the posterior division of the mandibular nerve.

4. The ophthalmic nerve arises in the middle cranial fossa and is a division of the trigeminal nerve, along with the maxillary and mandibular nerves.

Solution to Question 19:

All the given pairs of pharyngeal arteries and their arteries are correctly matched except for 'v' (option C).

The 6th pharyngeal arch has its blood supply on the left side from the left pulmonary artery and ductus arteriosus, not from the aorta.

Solution to Question 20:

Rupture of the penile urethra causes extravasation of blood into the superficial perineal pouch, scrotum, penis, and then up to the lower anterior abdominal wall.

The superficial perineal pouch is a compartment of the perineum enclosed by the membranous layer of the perineal fascia that surrounds the scrotum or labia and penis or clitoris.

Anteriorly, the membranous layer of perineal fascia is continuous over the pubic symphysis and pubic bones. It is later continuous with the membranous layer of the anterior abdominal wall. Thus, the fluid that accumulates in the perineal pouch extends to the lower anterior abdomen.

In the lower lateral abdominal wall, the abdominal fascia is attached to the deep fascia of the thigh, inferior to the inguinal ligament. Thus, on trauma at the penile urethra, urine does not extravasate into the anterior thigh.

The superficial perineal pouch is closed posteriorly by attaching the membranous layer of superficial fascia to the posterior margin of the urogenital diaphragm. Thus, commonly there is no extravasation into the deep perineal pouch and the ischiorectal fossa.

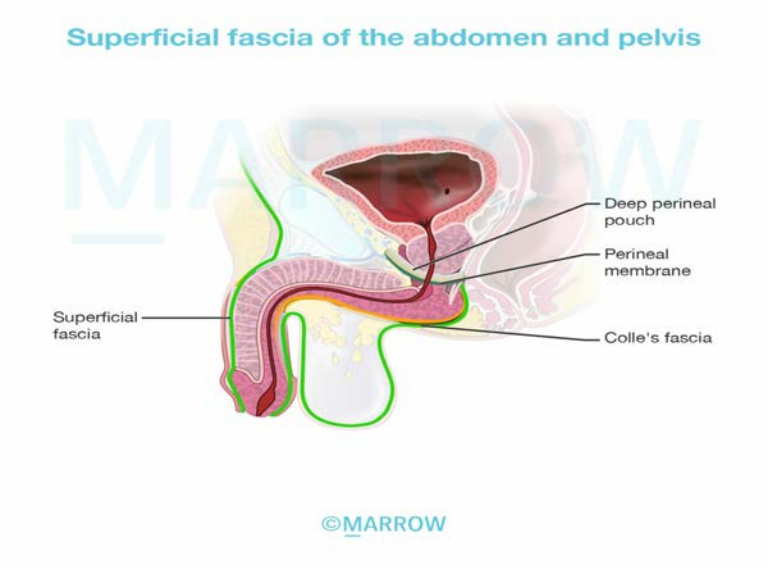
Also, the membranous layer of superficial fascia attaches to the ischiopubic rami and forms the lateral borders of the urogenital triangle. Thus, the urine does not extravasate to the thigh.

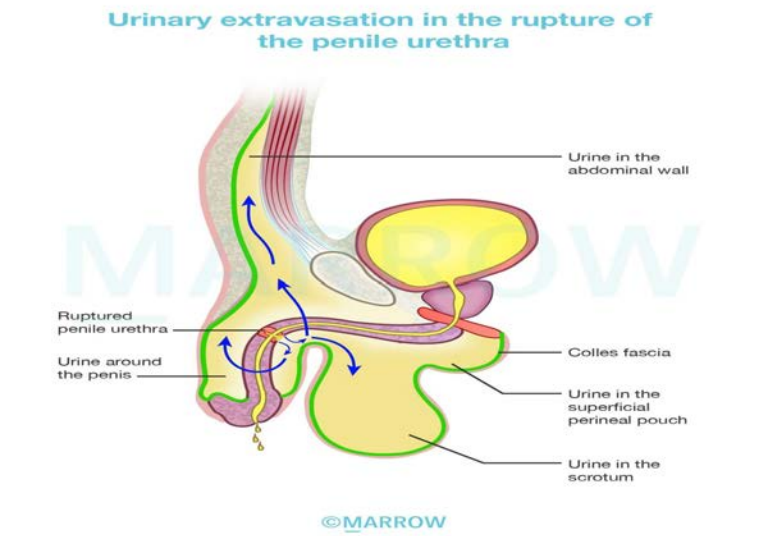
But, the ischiorectal fossa would be a better answer because of the following reasons:

• Bulbourethral glands that lie in the deep perineal space open their ducts into the spongy urethra, which is related to the superficial perineal space. Also, the muscles surrounding these glands were recently found to be a continuation of the deep transverse perinei and tail of the external urethral sphincter, both of which are components of the deep perineal space. Injury to the penile urethra can damage bulbourethral glands' ducts, which can lead to damage to the above-mentioned structures and may cause extravasation of urine into the deep perineal space.

• Previously, the perineal membrane was thought to be a triangular membrane. However, recent studies show that it is contiguous anteriorly with the structures that support the urethra. Posteriorly, it is related to the support of the perineal body and lateral vaginal wall. So damage to the urethra might damage the anterior part of the perineal membrane which can make way for extravasation of blood into the deep perineal space.

• Deep perineal pouch: It was believed initially that the urogenital diaphragm was formed by 3 layers: An inferior fascia (also called the perineal membrane), deep perineal space, and a superior fascia. The superior fascia formed the inferior border of the ischioanal fossa. The Colles fascia also separates the perineal membrane from the ischioanal fossa. So, extravasation of blood into the deep perineal space is possible but extravasation into the ischioanal fossa due to penile urethral injury is highly unlikely. Recent studies have shown that this might be a slightly more complex structure.





Solution to Question 21:

Genitofemoral nerve is blocked when the local anesthetic is given below the inguinal ligament during femoral vein catheterization.

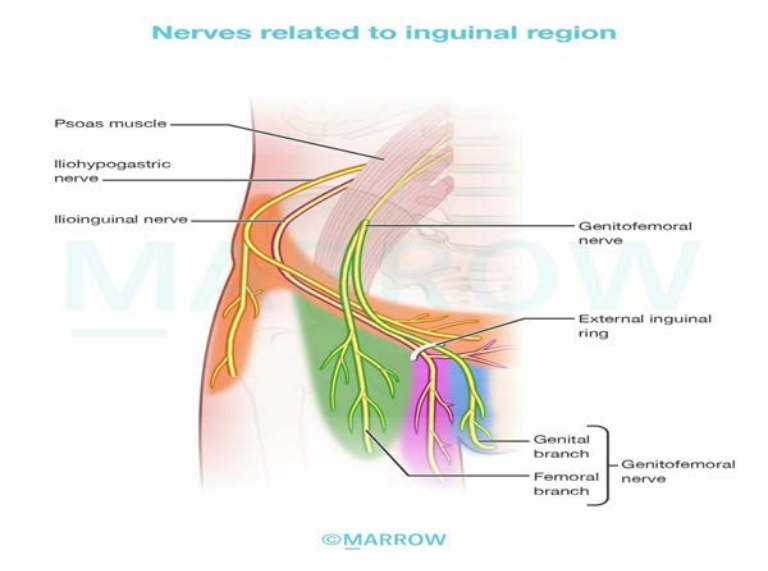
The genitofemoral nerve originates from the L1 and L2 ventral rami. It divides into the genital and femoral branches after crossing behind the ureter.

The genital branch enters the inguinal canal through the deep ring and accompanies the spermatic cord or round ligament. It exits the superficial inguinal ring and supplies the cremaster muscle and skin of the external genitalia.

The femoral branch descends lateral to the external iliac artery to pass behind the inguinal ligament and enter the femoral sheath lateral to the femoral artery. It pierces the anterior wall of the femoral sheath and fascia lata and supplies them.

The genitofemoral nerve gives sensory supply to the anteromedial thigh via the femoral branch. The genital branch supplies skin of the scrotum in males and mons pubis and labium majus in females. The genitofemoral nerve also innervates the cremaster muscle via the genital branch and is responsible for the cremasteric reflex.

The image given below shows nerves related to the inguinal region:



Other options:

Option A: Femoral nerve arises from the posterior division of ventral rami of L2-L4 spinal segments on the posterior abdominal wall. It enters the femoral triangle by passing under the inguinal ligament. In the femoral triangle, it lies lateral to the femoral artery and outside the femoral sheath. Later, it is divided into anterior and posterior branches by the lateral circumflex femoral artery.

Option C: Lateral cutaneous nerve (a.k.a lateral femoral cutaneous nerve) of the thigh is most commonly injured at the site where it leaves the pelvis. An injury to the lateral cutaneous nerve of the thigh leads to pain and paresthesia over the anterolateral region of the thigh, a condition called meralgia paresthetica.

Option D: Ilioinguinal nerve is most commonly injured within the inguinal canal in open hernia repair due to traction or thermal injury. Injury causes loss of sensation in the root of the penis and adjacent part of the scrotum.

Solution to Question 22:

The structure marked in the given image is the neck of fibula. The nerve passing around the neck of fibula is the common peroneal nerve (common fibular nerve).

The common peroneal nerve is derived from the dorsal branches of the ventral rami of L4, L5, S1, and S2. The sciatic nerve divides into the tibial nerve and the common fibular nerve.

The common fibular nerve runs obliquely along the lateral side of the popliteal fossa to the fibular head. It lies between the biceps femoris and the lateral head of the gastrocnemius. It then curves

laterally around the neck of the fibula and gets divided into superficial and deep fibular nerves.

Superficial fibular nerve:

Motor innervation:

• Peroneus longus

• Peroneus brevis

Sensory innervation:

• Lateral aspect of the lower leg

• Dorsum of the toes except for the lateral side of the 5th toe and the first interdigital webspace

Deep fibular nerve:

Motor innervation:

• Extensor digitorum longus

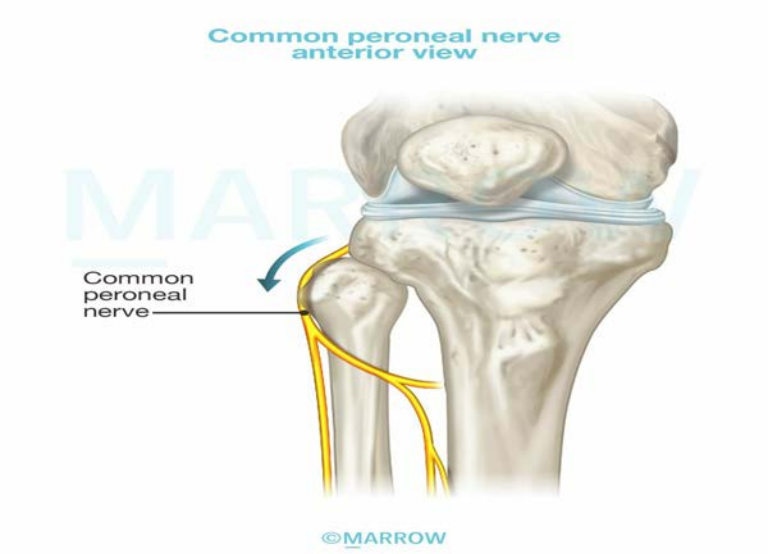
• Extensor hallucis longus

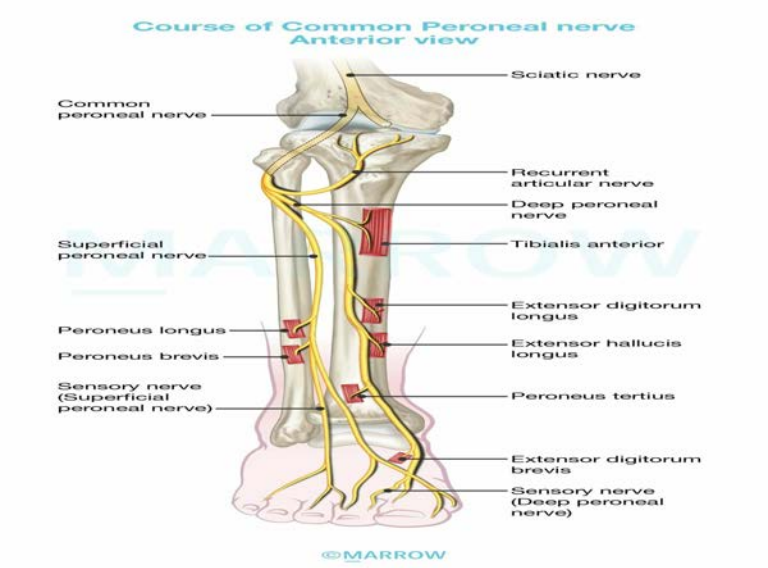
• Tibialis anterior

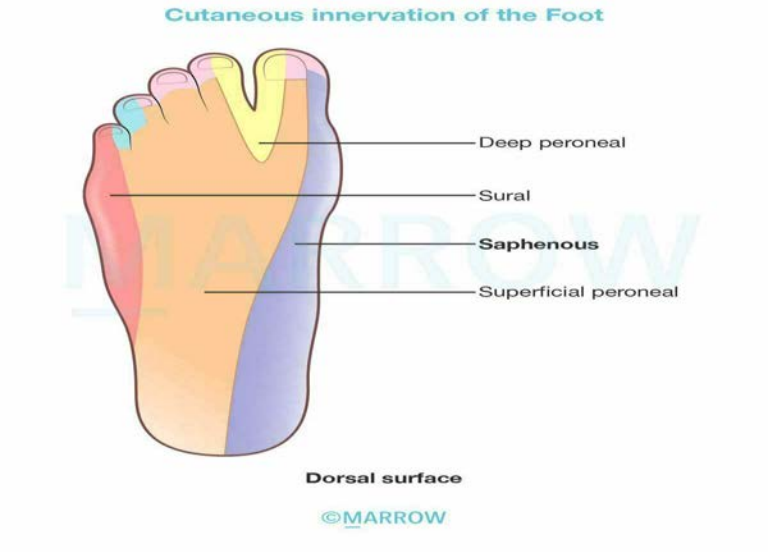
• Peroneus tertius

Sensory innervation:

• The first interdigital space





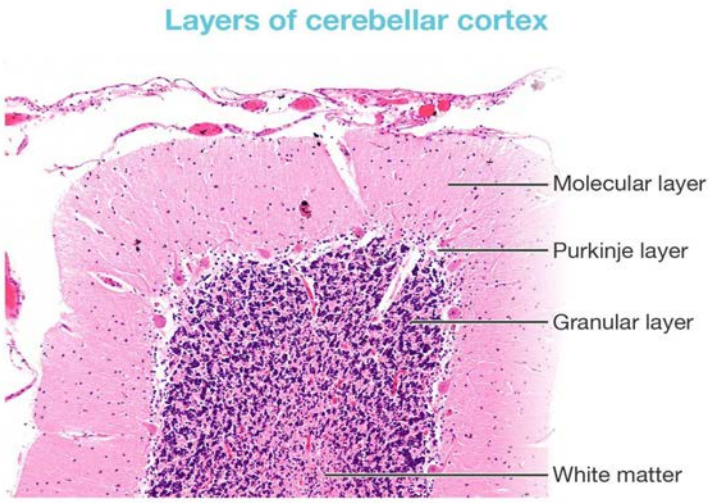


The common peroneal nerve is more prone to injury as it lies superficial at the level of the lateral aspect of the neck of the fibula. Injury results in foot drop (which causes high-stepping gait), loss of eversion of the foot, and sensory loss on the dorsum of the foot.

Solution to Question 23:

The molecular layer of the cerebellum contains stellate and basket cells.

The molecular layer is the outermost layer that contains stellate cells and basket cells, and dendrites of Purkinje cells. They receive excitatory input from the parallel fibers and form inhibitory synapses on the Purkinje cells. This layer contains many myelinated and unmyelinated nerve fibers and appears pale on H&E staining.



Solution to Question 24:

The image showing a bleed over the arachnoid layer but under the dura is suggestive of a subdural hemorrhage. Most commonly, it results from the shearing of cortical bridging veins.

Subdural hemorrhage (SDH) is a collection of blood between the dura and the arachnoid layers of the meninges. The causes of SDH include

• trauma

• anticoagulants, antiplatelets

• alcohol abuse

• battered baby syndrome.

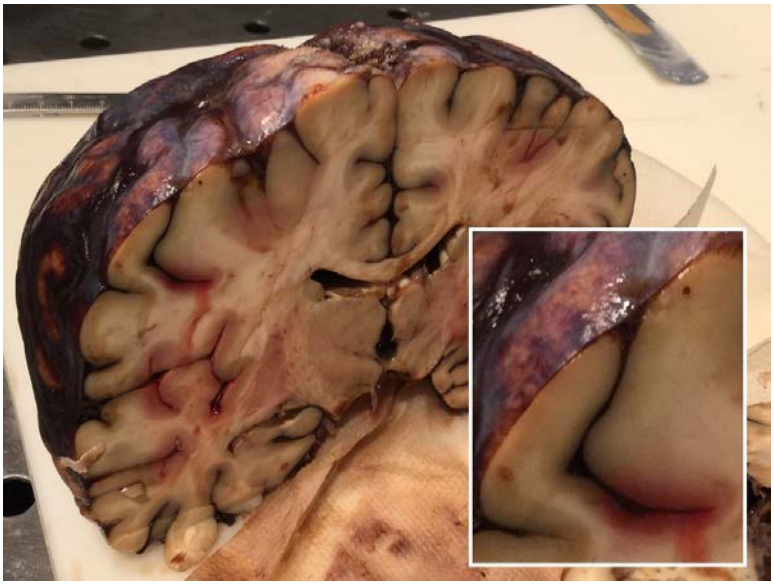
Non-contrast CT is the investigation of choice.

Other options:

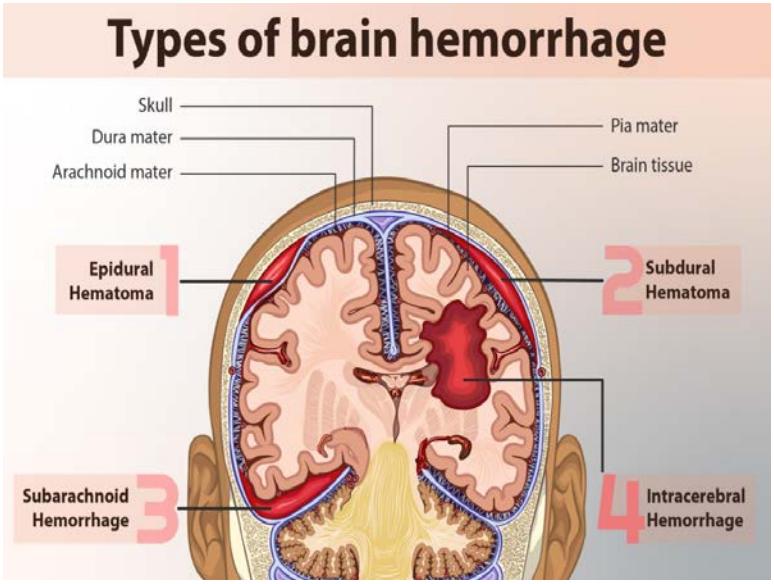
Middle meningeal artery rupture would result in an extradural hemorrhage.

Lenticulostriate artery would lead to an intraparenchymal hemorrhage.

Vertebral artery dissection leads to subarachnoid hemorrhage or sometimes intraparenchymal hemorrhage.



The given image shows types of brain hemorrhage:



Solution to Question 25:

Statements 1, 2, and 4 are true about the internal capsule.

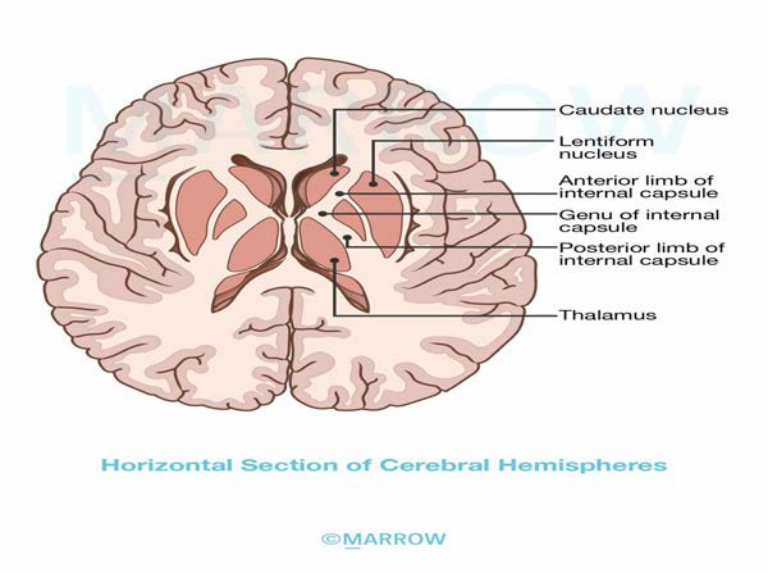
The charcot's artery of hemorrhage is a larger lenticulostriate or lateral striate artery. Lateral striate arteries supply the anterior limb, genu and the posterior limb of the internal capsule. These arteries are also commonly involved in ischemic and hemorrhagic strokes.

The retrolentiform part of the internal capsule carries fibers mainly from optic radiation. A lesion here produces homonymous hemianopia, superior quadrantanopia, or inferior quadrantanopia.

The anterior limb of the internal capsule carries fronto-pontine fibers. A lesion here produces confusion, impaired attention, agitation, and dysarthria.

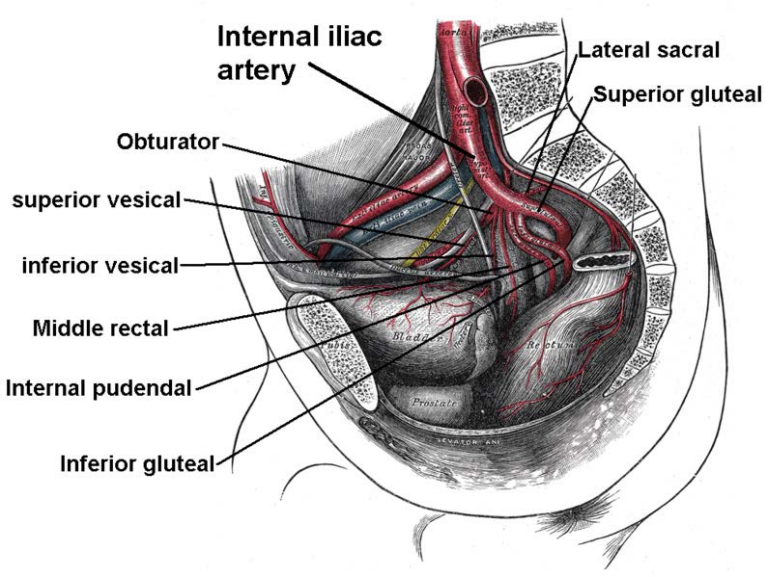
The posterior limb of the internal capsule carries cortico-spinal motor fibers in the anterior part and the lesion here produces contralateral hemiparesis. The posterior part of the posterior limb of the internal capsule carries sensory fibers and lesions here may produce contralateral hemi-sensory deficits.

The internal capsule predominantly contains projection fibers, not commissural fibers. Projection fibers are the fibers that project from higher to lower centers or vice versa in CNS.



Solution to Question 26:

The inferior gluteal artery is a branch of the anterior division of the internal iliac artery.



Branches of the anterior trunk of the internal iliac artery:

• Obturator artery

• Superior vesical artery

• Inferior vesical artery

• Inferior gluteal artery

• Middle rectal artery

• Vaginal artery (in females)

• Uterine artery (in females)

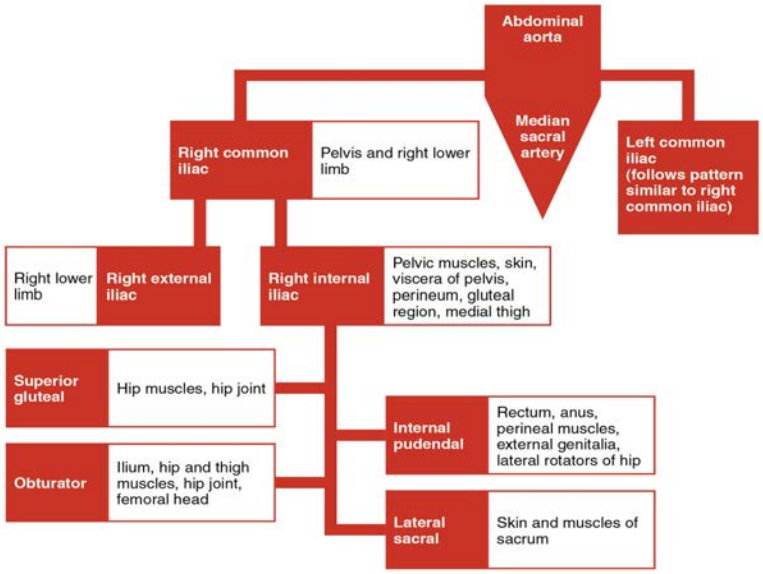
• Internal pudendal artery

Branches of the posterior trunk of the internal iliac artery:

• Iliolumbar artery

• Lateral sacral arteries

• Superior gluteal artery



Solution to Question 27:

The structure marked in the image is the pterion. The incorrect statement is statement 3, which is the accessory middle meningeal artery lies under this structure.

The pterion is an H-shaped sutural junction between four bones of the skull:

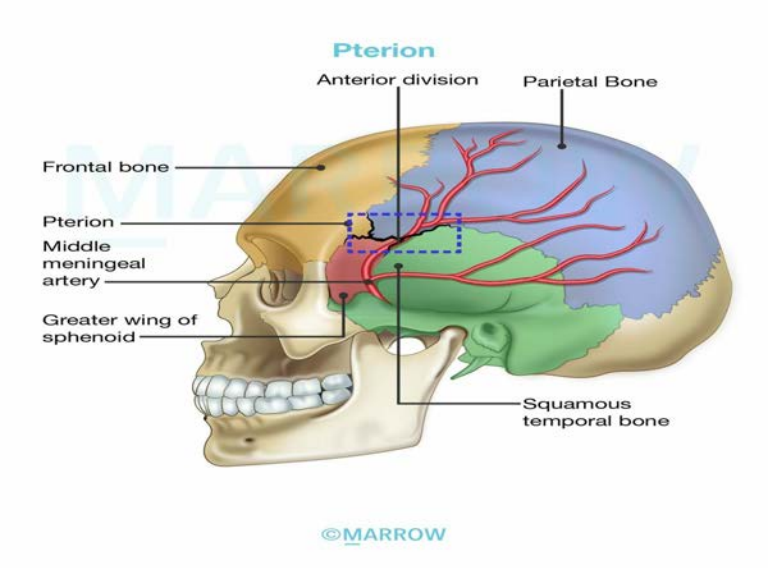
• Frontal bone

• Squamous part of the temporal bone

• Greater wing of the sphenoid bone

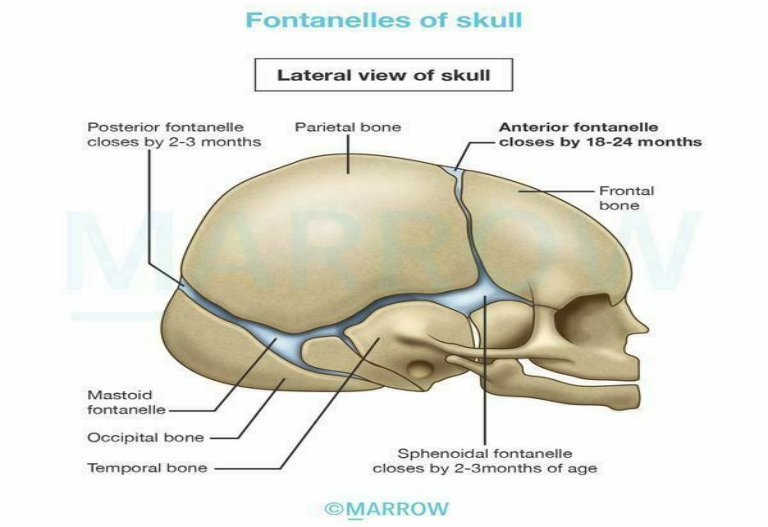
• Parietal bone

It is located approximately 4 cm above the midpoint of the zygomatic arch.



The pterion overlies the anterior branch of the middle meningeal artery and the lateral fissure of the cerebral hemisphere. The bone in this area is thin, and any injury to this area may lead to rupture of the middle meningeal artery, leading to extradural hematoma.

The pterion also corresponds to the site of the anterolateral (sphenoidal) fontanelle of the neonatal skull, which closes in the third month after birth.



The accessory meningeal artery may be a branch of the middle meningeal artery or might arise directly from the maxillary artery. It reaches the cranium via the foramen ovale and distributes principally in the extracranial region. It is distributed over the medial and lateral pterygoids, tensor veli palatini, greater wing and pterygoid processes of the sphenoid bone, mandibular nerve, and the otic ganglion. So, it supplies the trigeminal ganglion, dura mater and bone. But in some people, it may be replaced by small separate arteries.

Solution to Question 28:

The cells shown in the image are neural crest cells (NCC) present adjacent to the neural tube (NT). NCCs contribute to many organs and tissues, and the neural crest is sometimes referred to as the fourth germ layer:

• In the trunk region, they form:

• Melanocytes

• Sensory ganglia

• Sympathetic and enteric neurons

• Schwann cells

• Adrenal medulla cells

• In the cranial region, they contribute to the:

• Craniofacial skeleton

• Neurons for cranial ganglia

• Satellite glial cells

• Melanocytes

• Some of the other neural crest derivatives are

• C cells of the thyroid gland

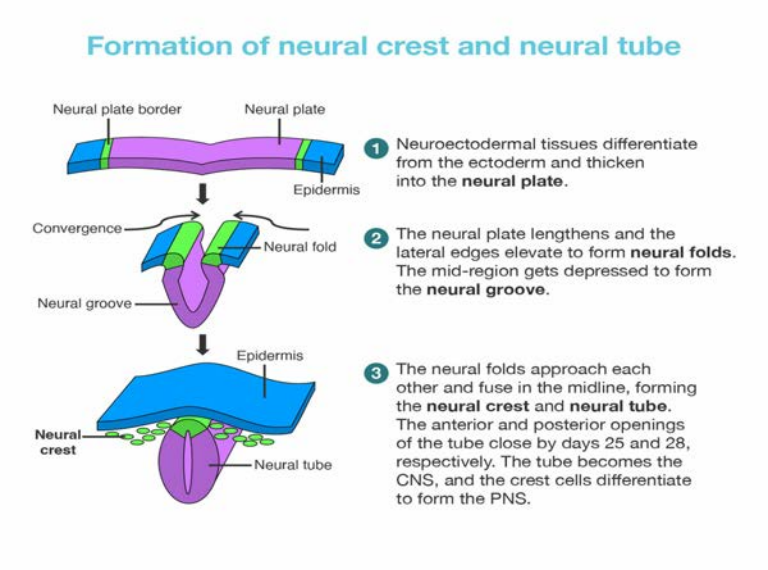
• Conotruncal septum in the heart

• Odontoblasts

• Smooth muscle cells to blood vessels to the face and forebrain.

The intermediate mesoderm is a longitudinal strip of intraembryonic mesoderm that connects the paraxial with the lateral plate mesoderm. The intermediate mesoderm develops into the genital ridge and nephrogenic cord.

The majority of the heart, including the right ventricle and outflow tract, is derived from the bulbus cordis, which is further derived from the pharyngeal mesoderm.



Solution to Question 29:

Iliococcygeus and pubococcygeus are parts of the pelvic diaphragm, which is also known as the levator ani.

The levator ani muscle is a complex unit that consists of 3 muscle components:

• Pubococcygeus

• Pubovaginalis - elevates the urethra and hence contributes to urinary continence

• Puboperinealis - draws the perineal body towards the pubic symphysis

• Puboanalis - elevates the anus and keeps the urogenital hiatus narrowed

• Puborectalis

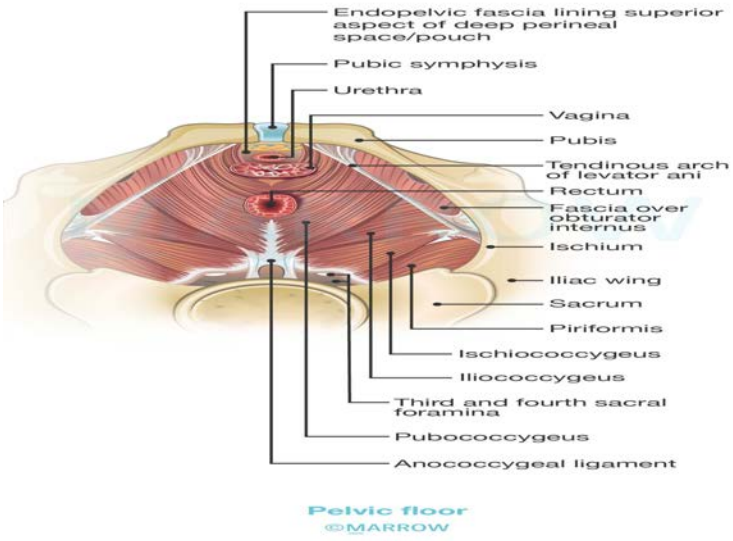
• Iliococcygeus

Levator ani muscles are the most important muscles in the pelvic floor and maintain a constant state of contraction. They provide a stable floor and support the weight of the abdominopelvic contents against intra-abdominal forces. Weakening of levator ani and pelvic fascia from stretching or tearing during childbirth, may decrease support for the vagina, bladder, uterus, or rectum or alter the position of the neck of the bladder and urethra.

Other options:

The obturator internus forms the lateral wall of the ischioanal fossa and is not a part of the levator ani.

The deep transverse perineal muscle is the content of the deep perineal space and contributes to the formation of the perineal body.



Solution to Question 30:

The area marked by an arrow in the given image is pterion and the artery that passes in close proximity to this area is the middle meningeal artery.

The pterion is an H shaped sutural junction between four bones of the skull:

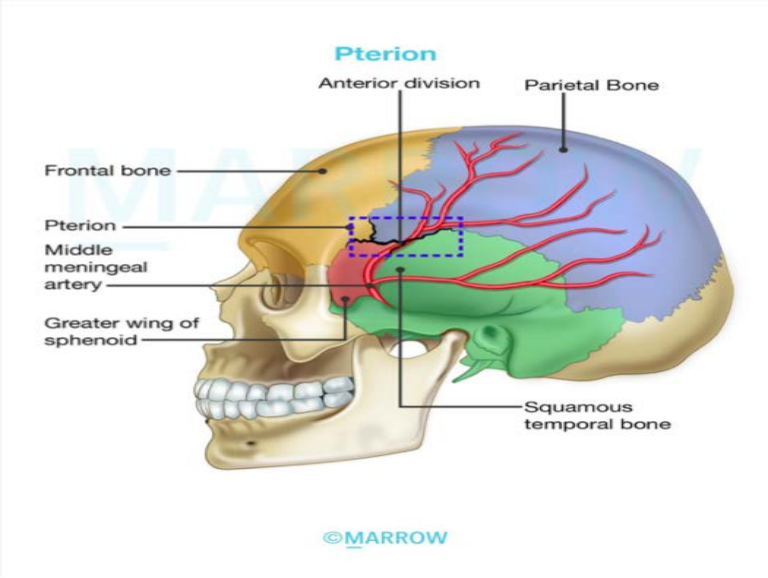
• Frontal bone

• Squamous part of the temporal bone

• Greater wing of the sphenoid bone

• Parietal bone.

It is an important structure as it overlies the anterior branch of the middle meningeal artery and lateral fissure of the cerebral hemisphere. The bone in this area is thin and any injury to this area may lead to rupture of the middle meningeal artery leading to extradural hematoma.



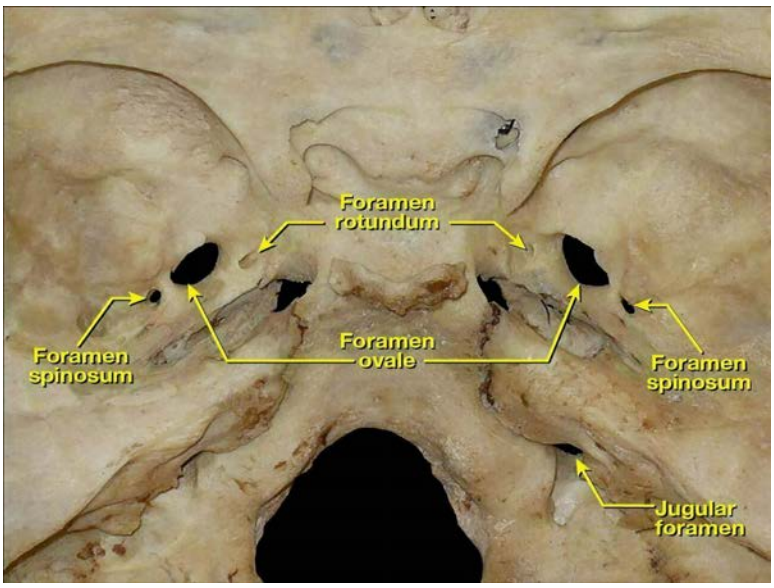
Solution to Question 31:

Fracture of the jugular canal affects glossopharyngeal nerve and presents as loss of taste sensation in the posterior 1/3rd of the tongue.

The lingual nerve which is a branch of the mandibular division of the trigeminal nerve gives general sensation, chorda tympani branch of facial nerve gives taste sensation for the anterior 2/3rd of tongue. Both taste and general sensation of the posterior 1/3rd is by the glossopharyngeal nerve. The muscles of the tongue, with the exception of palatoglossus, are supplied by the hypoglossal nerve. Palatoglossus is supplied via the pharyngeal plexus.

The other nerves passing through the jugular foramen are glossopharyngeal(cranial nerve IX), vagus(cranial nerve X), and accessory nerve(cranial nerve XI).

The following is an image of the base of skull showing jugular foramen:



Solution to Question 32:

The characteristic clinical finding in Klumpke's paralysis is a complete claw hand.

Klumpke's paralysis is caused by injury of the lower trunk of the brachial plexus-mainly T1 and partially C8, due to traction injury of the lower trunk that may be seen in undue abduction of the arm (outstretched arm grabbing an object during a fall from height) or birth injury (traction of the extended arm during delivery)

This leads to paralysis of the intrinsic muscles of the hand (T1) that are responsible for flexion at metacarpophalangeal joints (MCP) and extension at proximal and distal interphalangeal joints(PIP and DIP). The unopposed action of extensor digitorum at MCP causes hyperextension. The unopposed action of flexor digitorum superficialis and profundus at PIP and DIP causes flexion. Thus giving rise to the characteristic claw hand.

Other changes include anesthesia and analgesia along the ulnar border of the forearm, vasomotor changes, absence of sweating, and trophic changes in long-standing cases. If the C8 is also damaged, the extent of anesthesia will be greater and will involve the medial side of the forearm, hand, and medial two fingers.

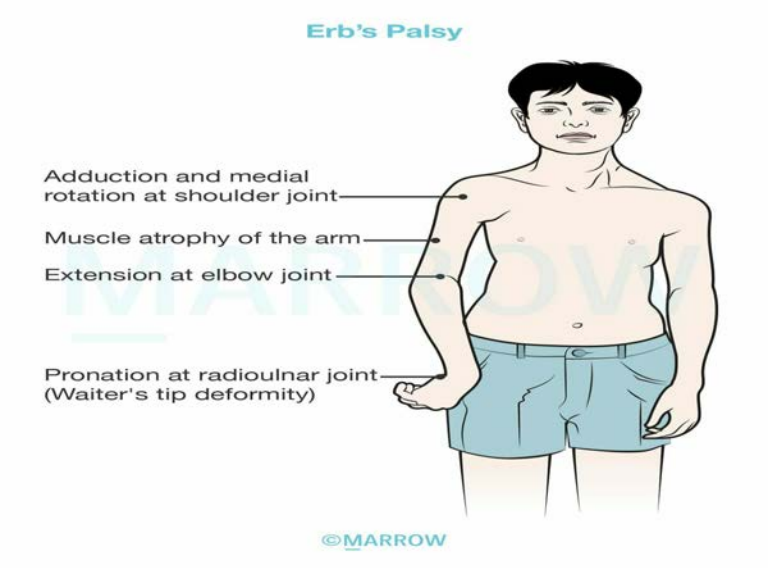
Horner's syndrome (option D) may occur in one-third of the cases due to injury of sympathetic fibers to the head and neck that leave the spinal cord through nerve T1.

The following image shows a complete claw hand in Klumpke's paralysis:

Other options:

Option A: Policeman tip deformity, also known as waiter's tip hand or porter's tip hand, is a finding of Erb's palsy due to injury of the upper trunk of the brachial plexus involving C5 and C6. The hand is adducted, medially rotated, and hangs by the side with the elbow extended and pronated.

The following image shows policeman tip deformity in Erb's palsy:



Option B: Wrist drop is a feature of radial nerve injury in the axilla, radial groove, anterolateral side of the lower arm, or injury of the deep branch in the cubital fossa.

Option D: Horner's syndrome is caused due to the disruption of sympathetic supply to the face. It causes ptosis, miosis, anhydrosis, enophthalmos, and loss of ciliospinal reflex of the affected eye. It may occur in some cases of Klumpke's paralysis and is not a characteristic finding.

The following image shows the ocular manifestation of Horner syndrome:

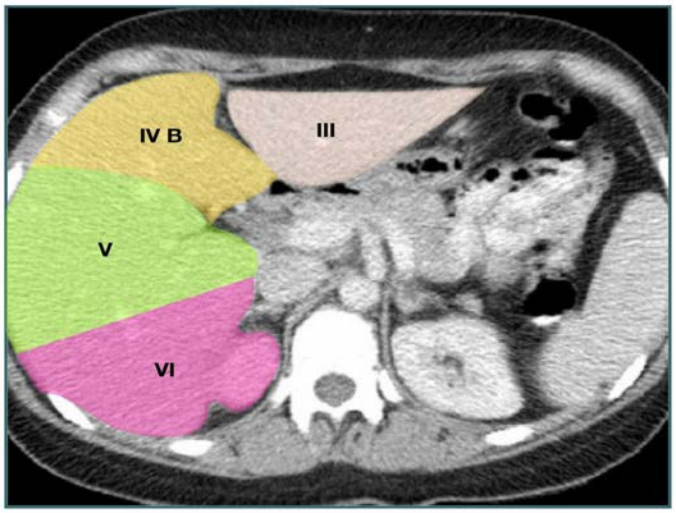
Solution to Question 33:

The liver segment highlighted in green in this CT section is segment V. The section of the CT given is taken below the portal vein as the cross-section of the portal vein before its bifurcation can be viewed.

A horizontal plane known as the portal plane divides the liver where the portal vein bifurcates and becomes horizontal. This divides each section of the liver into superior and inferior segments:

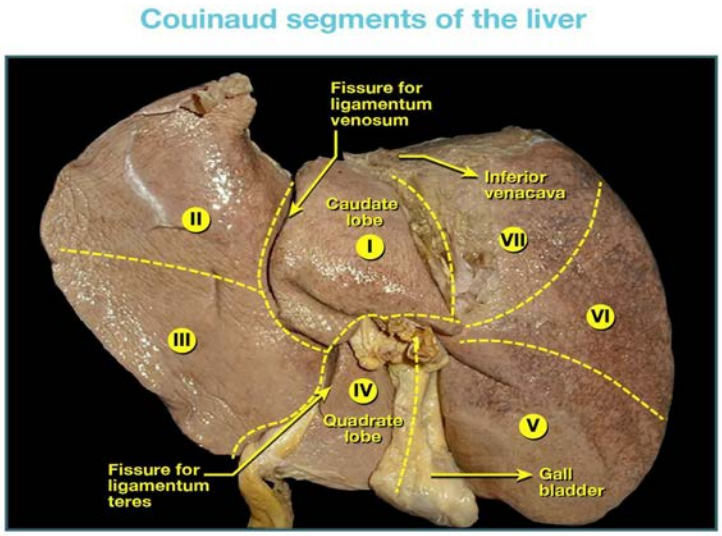
- Left lateral section: segment II above and segment III below the portal plane
- Left medial section: segment IVa above and segment IVb below the portal plane
- Right anterior (or medial) section: segment VIII above and segment V below the portal plane
- Right posterior (or lateral) section: segment VII above and segment VI below the portal plane

Shown below is a section from below the portal plane.



Couinaud classification is the commonly used classification of the liver. It divides the liver is divided into eight segments. It is based on the distribution of portal venous branches in the liver parenchyma. Each segment has its own vascular supply, biliary drainage, and lymphatic drainage.

The Couinaud's liver segments are as follows:



Solution to Question 34:

The upper part of the right inferior lobe is prone to aspiration in the supine position. It is commonly seen in alcoholics.

The posterior segment of the right superior lobe and the superior segment of the inferior lobes are the most commonly involved lung sites when aspiration occurs in a recumbent patient.

The location of aspiration depends on the position of the patient since it is gravity-dependent. Aspiration while standing leads to infiltration of bilateral inferior lobes because of larger and more vertical corresponding bronchi, the middle lobes and the lingula.

Aspiration of contents into foreign substances into the bronchial tree, usually oral or gastric contents, produces aspiration pneumonia. Chemical (gastric acid) injury or bacterial infection complicates the condition.

Solution to Question 35:

The structure marked in the image is the abducens nerve that arises from the pontomedullary junction.

In the groove between the medulla and pons, abducens, facial, and vestibulocochlear nerves emerge arranged medially to laterally.

The abducens nerve is the 6th cranial nerve that arises from the brainstem at the pontomedullary junction, passes through Dorello's canal, and enters the cavernous sinus where it lies lateral to the internal carotid artery. It then enters the orbit through the common tendinous ring in the superior orbital fissure to supply the lateral rectus.

Solution to Question 36:

The amygdala, hippocampus, and thalamus are all a part of the limbic system.

The limbic system refers to the interconnected neuronal circuit in the basal part of the brain that controls emotional behavior and other vegetative functions such as body temperature, the osmolality of the body fluids, and the drives to eat and drink and to control body weight.

The limbic system includes the following:

• Subcallosal gyrus

• Cingulate gyrus

• Parahippocampal gyrus

• Hippocampal formation

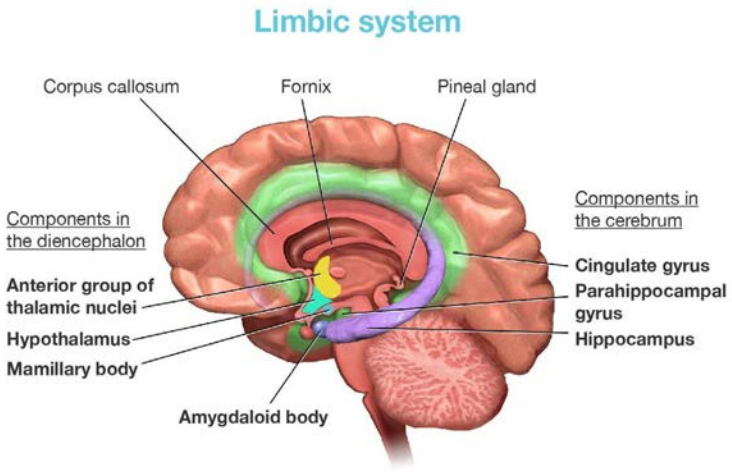
• Amygdaloid nucleus

• Mammillary bodies

• Anterior thalamic nucleus

• Hypothalamus

The connecting pathways for this system comprise the alveus, the fimbria, the fornix, the mammillothalamic tract, and the stria terminalis.



Solution to Question 37:

Positive Trendelenburg test on the right side indicates a right superior gluteal nerve injury.

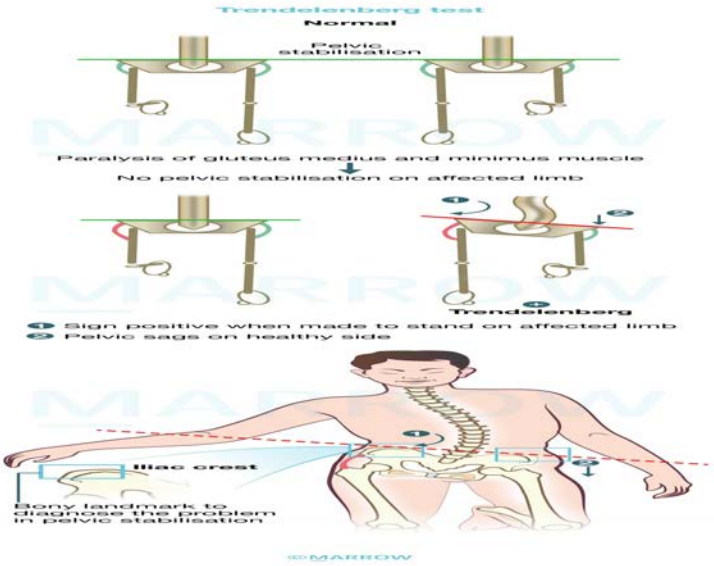
When the patient stands on his right foot, there is drooping of the left pelvis, this is a Positive Trendelenburg test on the right side.

The gluteus medius and minimus are powerful abductors of the hip supplied by the superior gluteal nerve.

Normally, when the leg is lifted off the ground, the gluteus medius and minimus on the opposite (unsupported) side exert traction on the hip bone. This results in a slight raising of the pelvis on the unsupported side, which helps maintain the trunk upright position.

If the gluteus medius and minimus are paralyzed, the pelvis drops on the contralateral side. This is known as a positive Trendelenburg sign. It is positive in the paralysis of the hip abductors, and in developmental dysplasia of the hip. A characteristic lurching gait is seen.

The image below shows the Trendelenburg test.

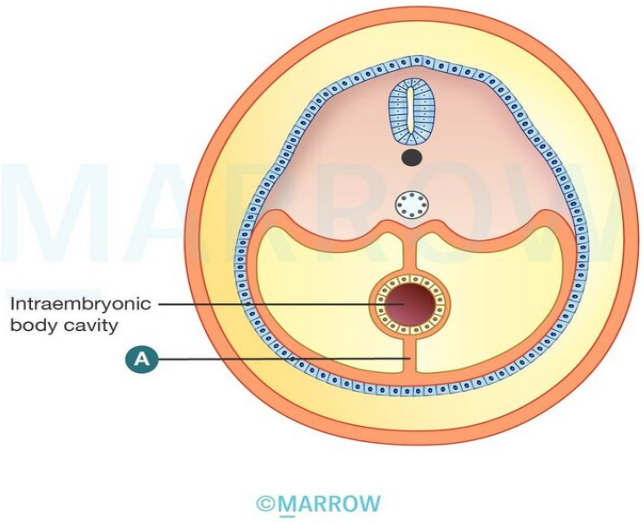


Trendelenberg test
Normal
Pelvic stabilisation
Paralysis of gluteus medius and minimus muscle
No pelvic stabilisation on affected limb
Trendelenberg
Sign positive when made to stand on affected limb
Pelvic sags on healthy side
Iliac crest
Bony landmark to diagnose this problem in pelvic stabilisation
MARROW

Anatomy NEET 2022

Question 1:

The structure marked A in the image below gives rise to which of the following structures?



a) Gastrosplenic ligament

b) Lienorenal ligament

c) Falciform ligament

d) Gastrophrenic ligament

Question 2:

A patient underwent surgery for the varicose vein. He now complains of sensory loss over the medial aspect of the leg and foot. Which of the following nerves is most likely to be injured?

a) Sural nerve

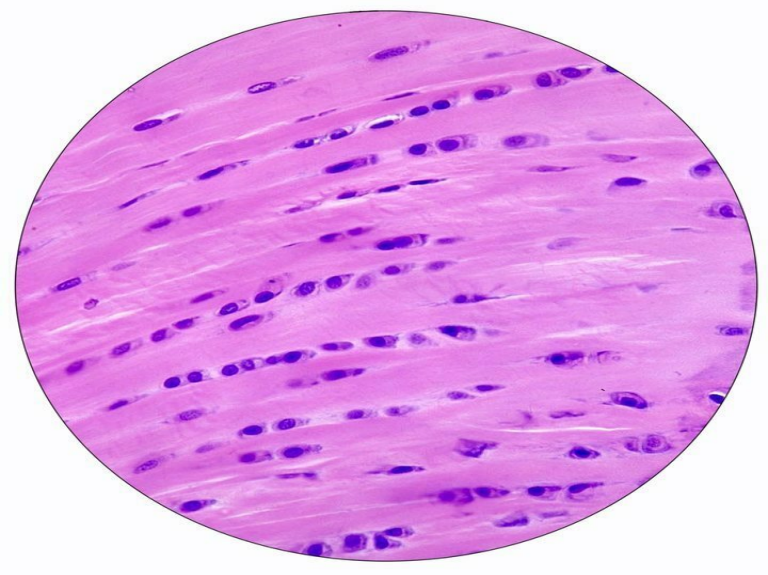
b) Superficial peroneal nerve

c) Deep peroneal nerve

d) Saphenous nerve

Question 3:

Identify the cartilage given below:



a) Non articular hyaline cartilage

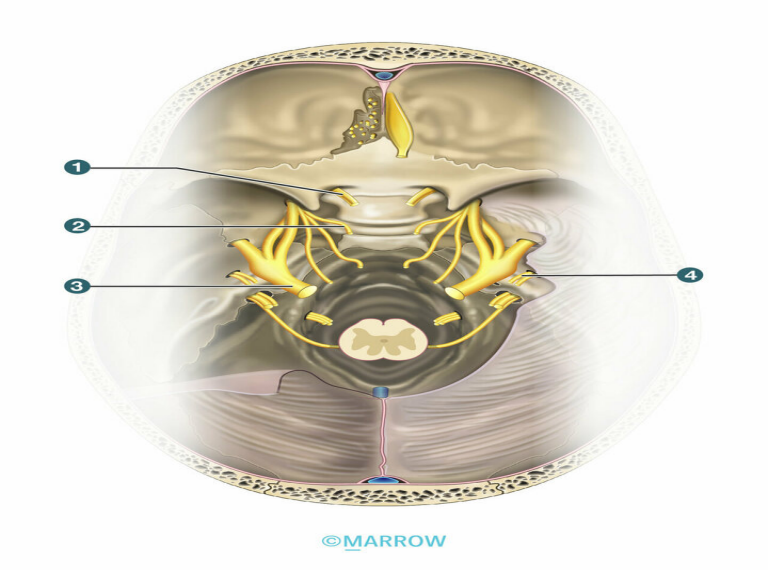
b) Articular hyaline cartilage

c) Yellow cartilage

d) White fibrocartilage

Question 4:

A patient presents with a unilateral throbbing headache, photophobia, and excessive lacrimation. He also complains of hemifacial pain on clenching of teeth. On examination, pupillary reaction, light reflex, and accommodation reflex are normal. Which of the following marked nerves is involved in the above scenario?



a) 1

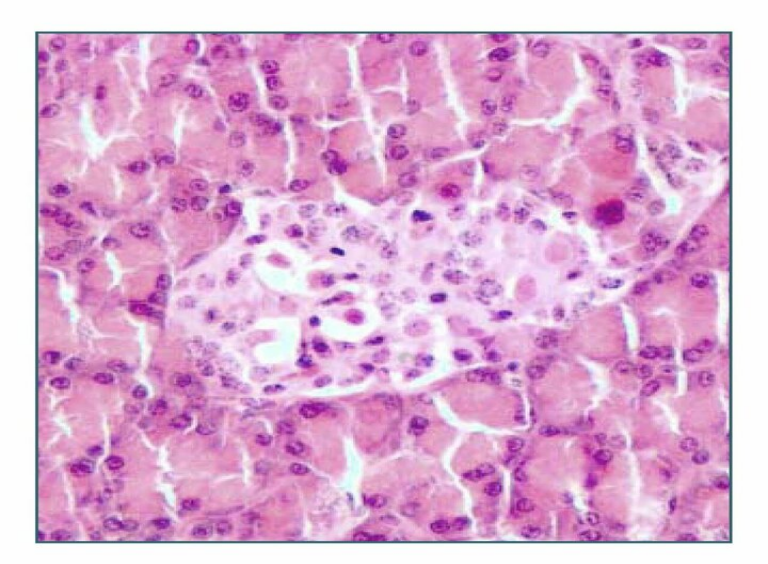
b) 2

c) 3

d) 4

Question 5:

Identify the given structure:



a) Lymph node

b) Glomerulus

c) Spleen

d) Pancreatic islet cells

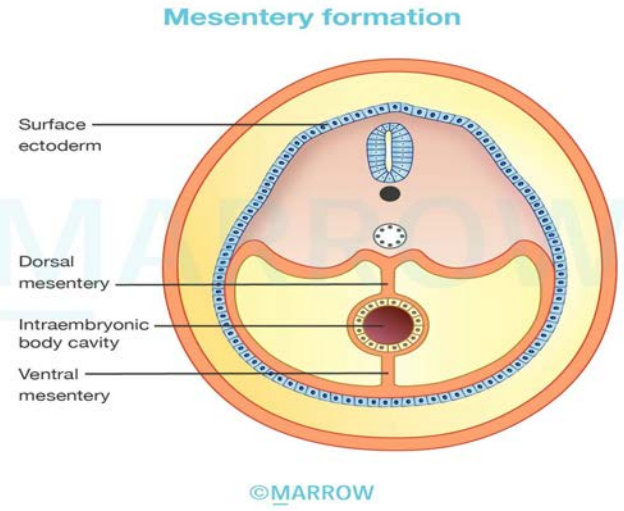
Answer Key

Question No.	Correct Option
1	c
2	d
3	d
4	c
5	d

Detailed Explanations

Solution to Question 1:

The structure marked A is ventral mesentery. The falciform ligament is a derivative of the ventral mesentery.



Mesenteries are double layers of the peritoneum that enclose an organ and connect it to the body wall. They provide pathways for vessels, nerves, and lymphatics to and from the abdominal viscera.

• Ventral mesentery: Only the foregut has a ventral mesentery. It is attached to the terminal part of the esophagus, the stomach, and the upper part of the duodenum. The ventral mesentery is derived from the septum transversum. When the liver grows into the mesenchyme of the septum transversum, it divides the ventral mesentery into 2 parts:

• Lesser omentum- extends from the lower portion of the esophagus, the stomach, and the upper portion of the duodenum to the liver

• Ligaments of the liver- all ligaments of the liver (falciform ligament, right and left triangular ligaments, and coronary ligaments), except ligamentum teres

• Dorsal mesentery: The foregut, midgut, and hindgut have a dorsal mesentery. This connects the organs to the posterior abdominal wall. It runs from the lower end of the esophagus to the cloacal region of the hindgut. It has the following special names in different regions:

• Dorsal mesogastrium (or greater omentum)- stomach

• Dorsal mesoduodenum- duodenum

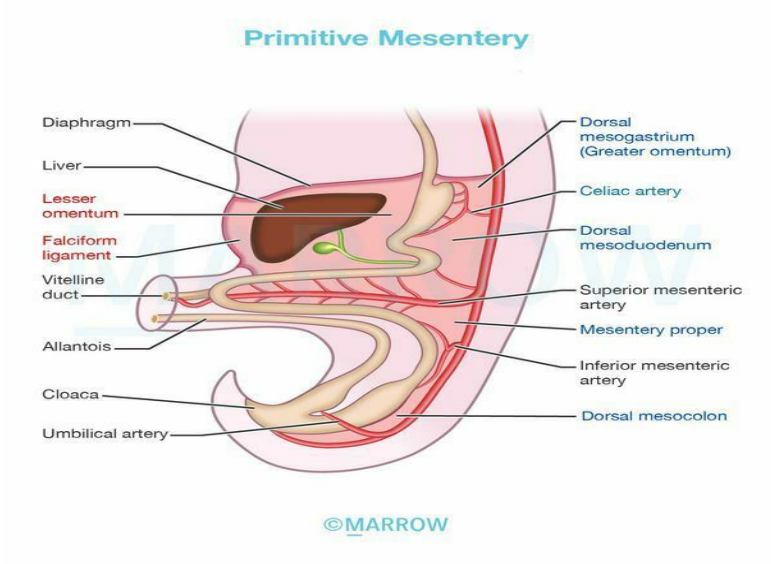
• Mesentery proper- jejunum and ileum

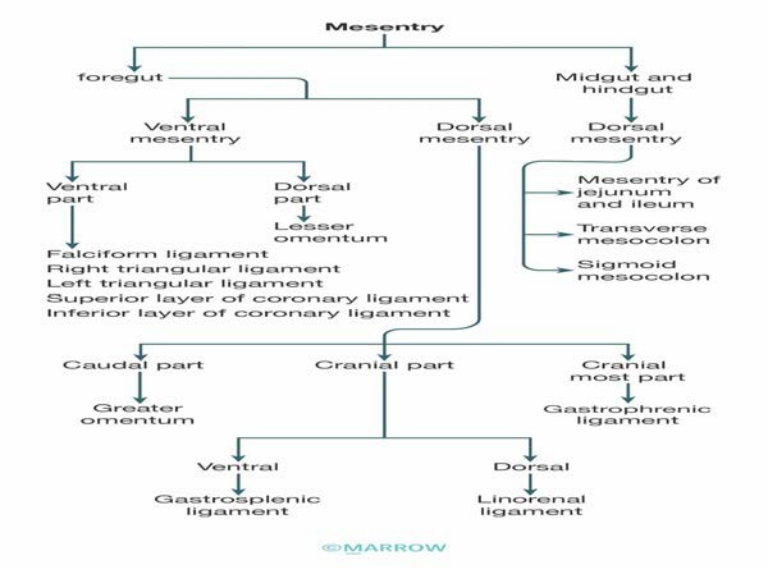
• Mesoappendix- appendix

• Transverse mesocolon- transverse colon

• Sigmoid mesocolon- sigmoid colon

• Gastrosplenic ligament (stomach to the spleen), lienorenal ligament (spleen to the left kidney), and gastrophrenic ligament (stomach to diaphragm) are derived from the dorsal mesentery.



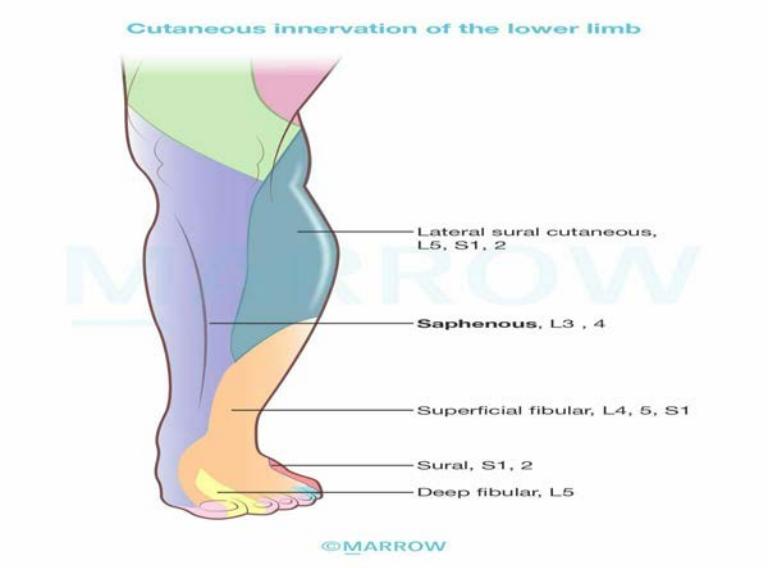


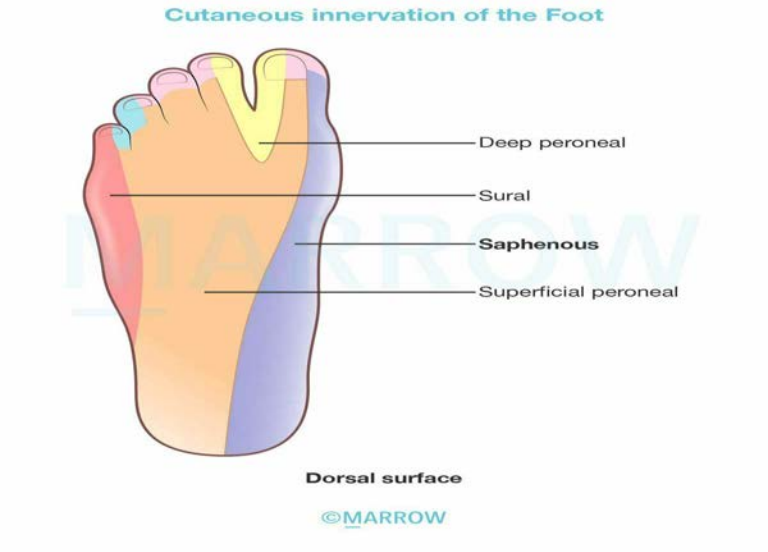
Solution to Question 2:

The given clinical scenario in a patient with sensory loss over the medial aspect of the leg and foot is suggestive of injury to the saphenous nerve. Injury to the saphenous nerve is common following varicose vein surgery.

The saphenous nerve is the longest and largest cutaneous branch of the femoral nerve and is the longest nerve in the body. It arises from the posterior division of the femoral nerve. It then enters the adductor canal and exits it by piercing the fascia lata between the gracilis and sartorius and supplies the skin over the patella. The saphenous nerve then descends along the medial border of the tibia along with the great saphenous vein (anterior to the vein) and supplies the skin on the medial side of the knee, leg, and foot up to the first metatarsophalangeal joint.

During stripping of veins in varicose surgery, injury to the saphenous nerve is common as it closely travels with the great saphenous vein. Sensory loss over the medial side of the knee, leg, and foot is observed in saphenous nerve injury.





Other options:

Option A: Sural nerve injury causes sensory loss over the posterior and lateral aspects of the distal third of the leg and lateral side of the foot and fifth toe. It is often used as an autologous peripheral nerve graft as it is readily identified and easy to harvest.

Option B: Superficial peroneal nerve injury causes sensory loss over the lateral aspect of the leg and the dorsum of the foot. It also causes weakness of foot eversion.

Option C: Deep peroneal nerve injury causes weakness of ankle dorsiflexion and toe extension but normal eversion of the foot.

Solution to Question 3:

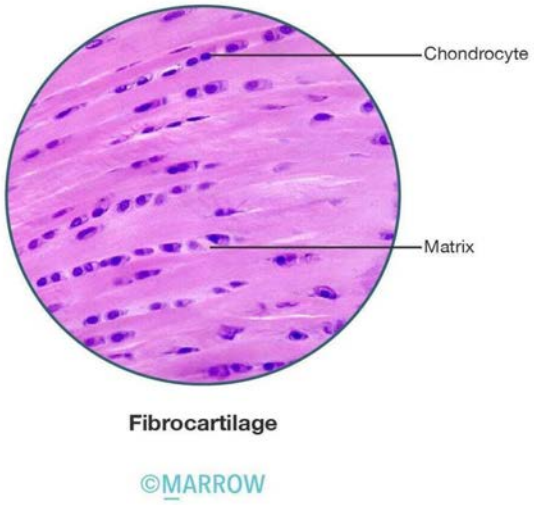
The given image shows prominent collagen fibers arranged in bundles with intervening rows of chondrocytes. This is suggestive of white fibrocartilage.

Microscopy of fibrocartilage shows the following:

• Chondrocytes- round in shape (in tendons they are flattened and elongated)

• Ground tissue with collagen fibers- type I collagen fibers

• Absence of perichondrium



Fibrocartilage is found in:

• Articular discs (temporomandibular joint and sternoclavicular joint)

• Intervertebral discs

• Menisci

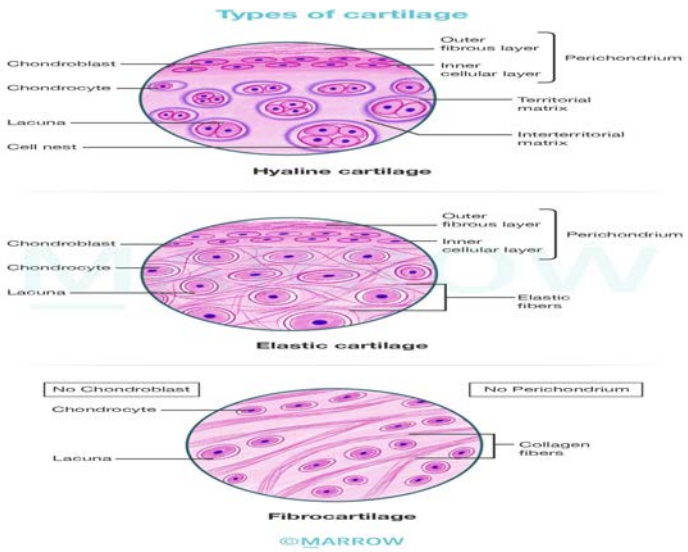
• Glenoid and acetabular labrum

• Pubic symphysis

• Manubriosternal joint

• The lining of the bony grooves for tendons

The image below describes the histology of different types of catilages.



Solution to Question 4:

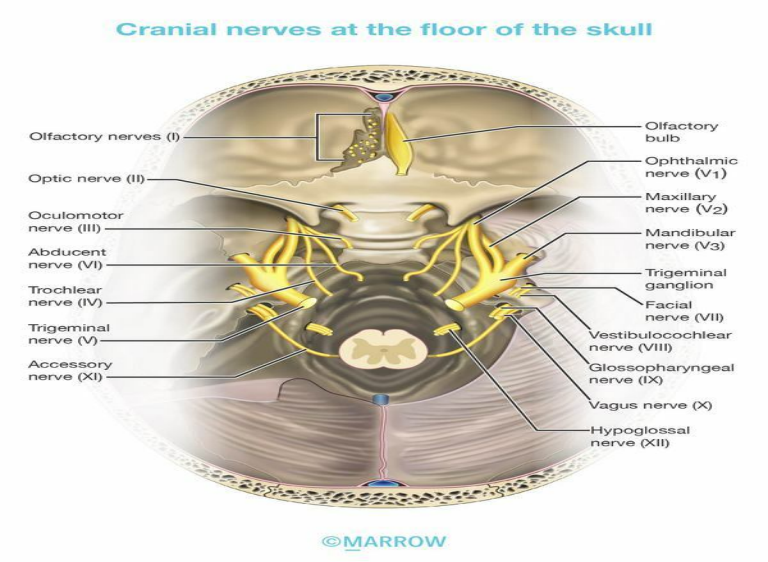
The above patient presents with features suggesting an involvement of the trigeminal nerve. The structure marked 3 is the trigeminal nerve.

Other marked structures:

• 1- Optic nerve. The normal visual field and light reflex rules out the involvement of the optic nerve.

• 2- Oculomotor nerve. Normal accommodation and pupillary reflex rule out the involvement of the oculomotor nerve.

• 4- Facial nerve. Absence of motor involvement of the face rule out the involvement of the facial nerve.



The trigeminal nerve leaves the anterior aspect of the pons as a small motor root and a large sensory root. The large sensory root expands to form the crescent-shaped trigeminal ganglion, which lies within a pouch of dura mater called the trigeminal or Meckel's cave. The ophthalmic, maxillary, and mandibular nerves arise from the anterior border of the ganglion.

Branches of the trigeminal nerve:

• The ophthalmic nerve (V1)

• Leaves the skull through the superior orbital fissure to enter the orbital cavity.

• Contains only sensory fibers

• Cornea (photophobia)

• The skin of the forehead, scalp, eyelids, and nose

• The mucous membrane of paranasal sinuses and nasal cavity

• The maxillary nerve (V2)

• Leaves the skull through the foramen rotundum.

• Contains only sensory fibers from

• Teeth of the upper jaw

• The skin of the face over the maxilla

• The mucous membrane of the nose, the maxillary sinus, and the palate

• The mandibular nerve (V3)

• Leaves the skull through the foramen ovale.

• Contains both sensory and motor fibers.

• Sensory from:

• The skin of the cheek, over mandible, and side of the head

• Teeth of the lower jaw and temporomandibular joint (hemifacial pain on clenching of teeth)

• The mucous membrane of the mouth and anterior part of the tongue

• Motor to:

• Muscles of mastication (pterygoids, masseter, and temporalis)

• Tensor tympani

• Anterior belly of digastric

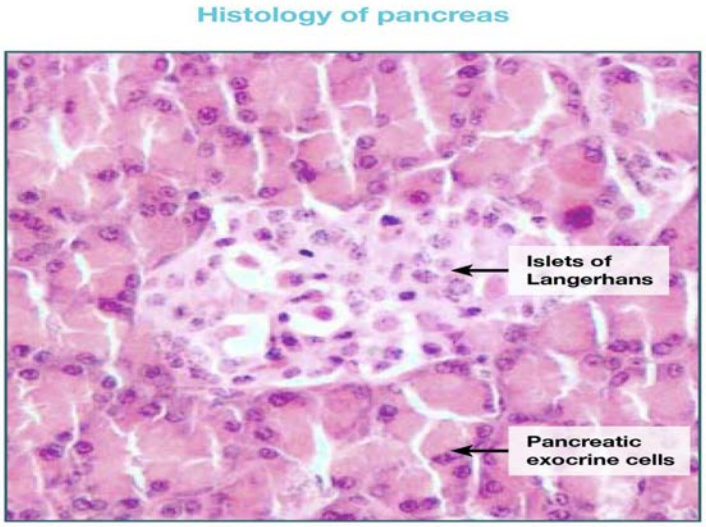
• Mylohyoid

Solution to Question 5:

The above image shows pancreatic islet cells. Islet of Langerhans makes up the endocrine part of the pancreas.

Islets are characterized by secretory cells supported by reticulin fibers, and containing numerous fenestrated capillaries. There is a delicate capsule around each islet. They are paler than the surrounding exocrine cells, as they have less rough endoplasmic reticulum.

The image given below shows the histology of the pancreas.



The islets of Langerhans contain four major and two minor cell types:

• Four main types are β, α, δ, and PP (pancreatic polypeptide) cells:

• α or A cells- located peripherally and secrete glucagon

• β or B cells- located centrally and produce insulin

• δ or D cells- scattered between beta cells and secrete somatostatin

• PP cells- are present in islets and also in the exocrine pancreas. They secrete a pancreatic polypeptide, which exerts several gastrointestinal effects, such as stimulation of secretion of gastric and intestinal enzymes and inhibition of intestinal motility.

• Minor cell types:

• D1 cells secrete vasoactive intestinal peptide (VIP), a hormone that induces glycogenolysis and hyperglycemia. It also stimulates gastrointestinal fluid secretion and causes secretory diarrhea.

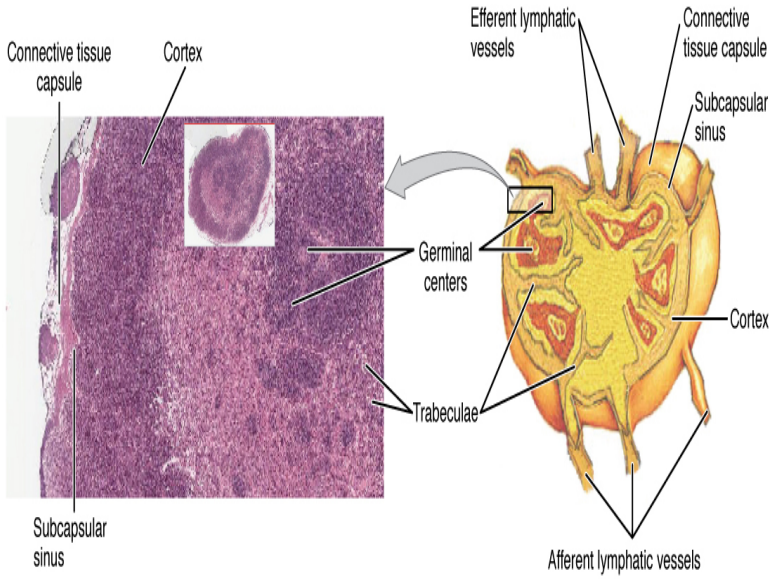
• Enterochromaffin cells synthesize serotonin and are the source of pancreatic tumors that cause carcinoid syndrome.

Other options:

Option A: Lymph nodes are secondary lymphoid organs. The structure of lymph nodes consists of an outer cortex and inner medulla. The cortex contains an aggregation of B-lymphocytes (primary follicles) and quiescent secondary follicles with a pale central germinal center.

The inner medulla consists of medullary cords (lymphocytes and plasma cells) and medullary sinuses. Between the cortex and medulla, there is an ill-defined zone called the paracortex, which contains T lymphocytes.

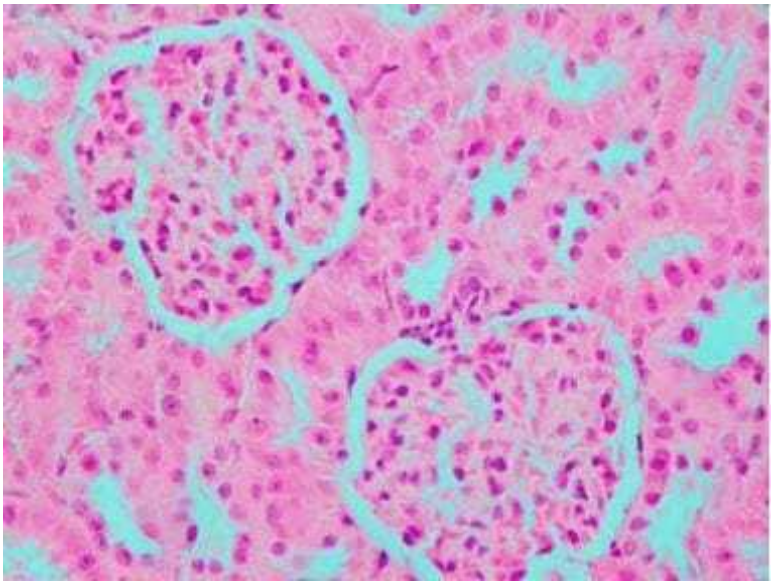
The image given below shows the histology of the lymph node.



Option B: Glomerulus is a rounded tuft of anastomosing capillaries. The glomerular capillary wall is the filtering membrane and consists of fenestrated endothelial cells, basement membrane, and visceral epithelial cells called podocytes, which contain foot processes.

The glomerular tuft is supported by the mesangium containing mesangial cells and a non-cellular mesangial matrix.

The image given below shows the histology of the glomerulus.

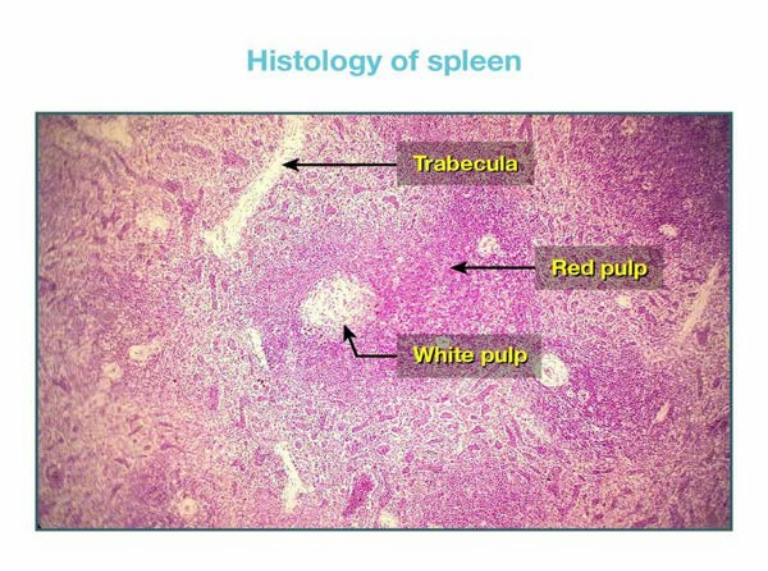


Option C: Spleen is a secondary lymphoid organ. It contains round white pulp surrounded by red pulp. The white pulp is made up of aggregations of lymphocytes that surround a small artery or arterioles. Lymphocytes surrounding the arteriole are called peri-arterial lymphatic sheath (PALS) and contain T cells. Follicles in white pulp contain B cells.

The red pulp is a modified lymphoid tissue infiltrated with all the cells of circulating blood. It is like a sponge permeated by spaces (splenic sinusoids) lined by reticular cells. The zone of red pulp immediately surrounding white pulp is the marginal zone. This zone has a rich network of

sinusoids.

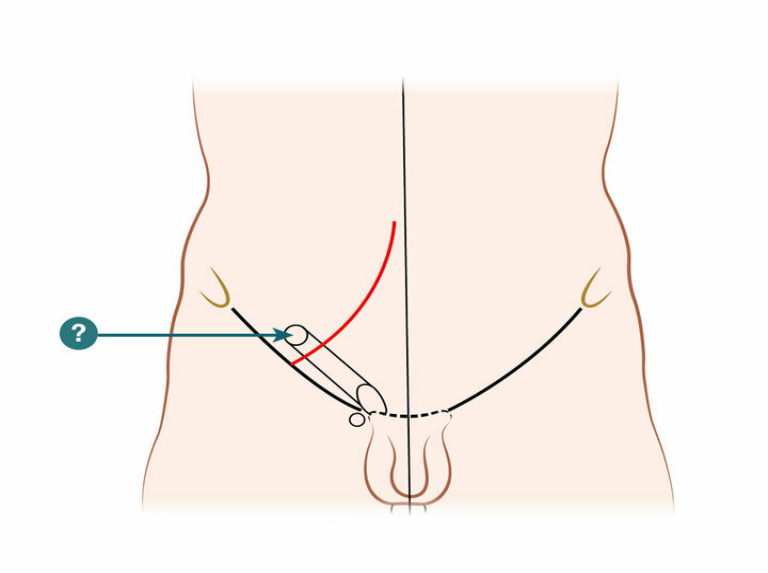
The image given below shows the histology of the spleen.



Anatomy NEET 2023

Question 1:

A defect in which of the following forms the structure marked below?



a) Internal oblique

b) External oblique

c) Parietal peritoneum

d) Fascia transversalis

Question 2:

A student had his jaw locked while yawning. Which of the following muscles is attached to the articular disc of the temporomandibular joint?

a) Lateral pterygoid

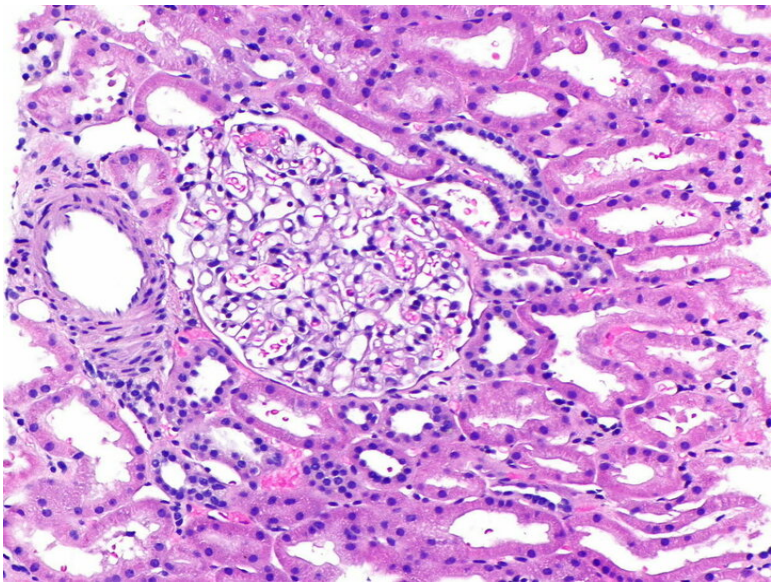
b) Temporalis

c) Medial pterygoid

d) Masseter

Question 3:

Identify the structure(s) in the following histological image.



a) Leydig cells of testis

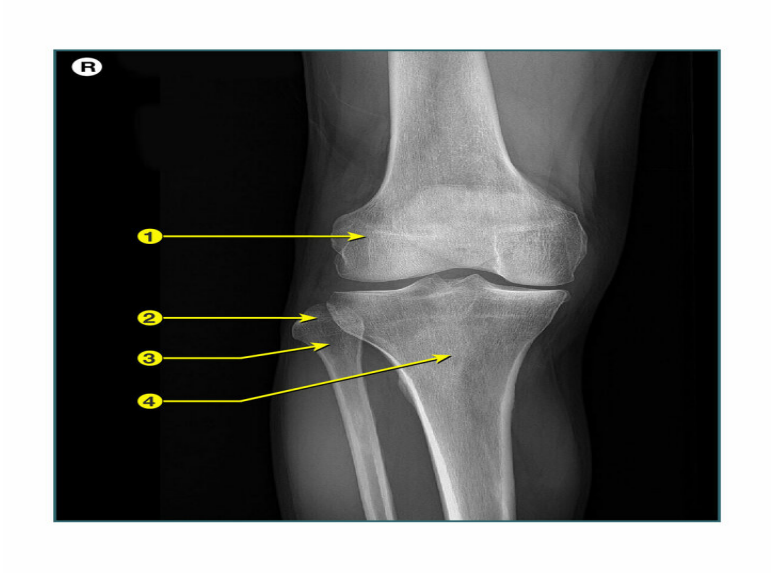
b) Pancreatic islet cells

c) Hassall's corpuscles

d) Glomerulus

Question 4:

Injury at which of the following marked sites causes failure of dorsiflexion?



a) 3

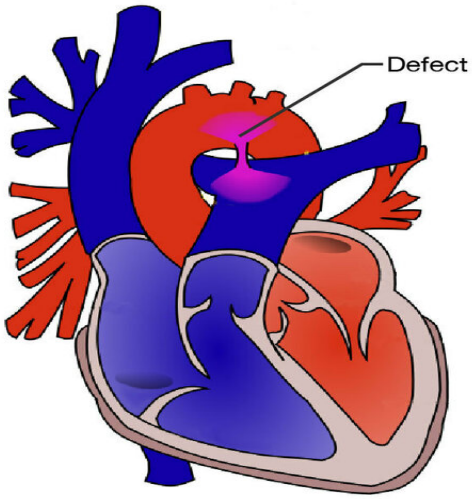
b) 2

c) 1

d) 4

Question 5:

A defect in which of the following aortic arches causes the defect shown in the image?



a) 4th right

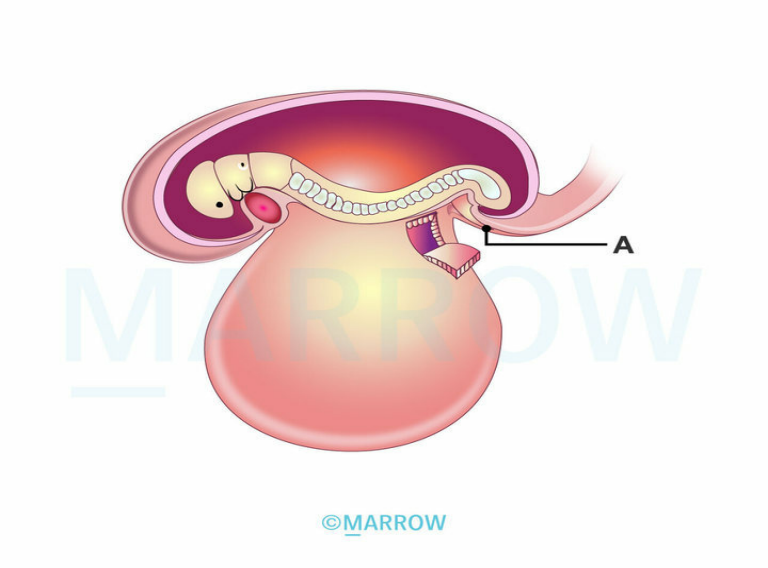
b) 4th left

c) 6th right

d) 6th left

Question 6:

Which of the following structures develops from the structure marked A?



a) Medial umbilical ligament

b) Median umbilical ligament

c) Meckel's diverticulum

d) Ligamentum teres

Question 7:

A patient comes with abdominal pain, jaundice, and portal hypertension. Anastomosis between which of the following veins is seen?

a) Left colic vein and middle colic veins

b) Esophageal veins and left gastric veins

c) Superior rectal and phrenic veins

d) Sigmoid and superior rectal veins

Question 8:

A patient presents with swelling under the left ear lobule and complains of pain. Which of the following structures is the likely cause of the pain?

a) Facial nerve

b) Greater auricular nerve

c) Auriculotemporal nerve

d) Investing layer of deep cervical fascia

Answer Key

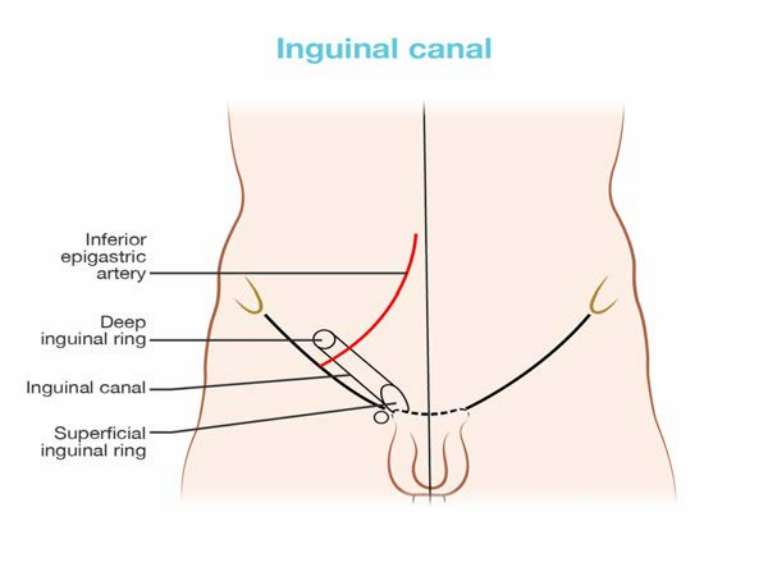
Question No.	Correct Option
1	d
2	a
3	d
4	a
5	d
6	b
7	b
8	b

Detailed Explanations

Solution to Question 1:

The structure marked is the deep inguinal ring, which is formed by a defect in fascia transversalis.

The deep inguinal ring is an opening in the transversalis fascia present 1 cm above the inguinal ligament, midway between the anterior superior iliac spine and the pubic symphysis. An indirect inguinal hernia arises through the deep inguinal ring lateral to the inferior epigastric vessel.



Solution to Question 2:

The muscle that is attached to the articular disc of the temporomandibular joint is the lateral pterygoid.

Lateral pterygoid muscle:

• Origin - Upper head arises from the infratemporal surface and infratemporal crest of the greater wing of the sphenoid bone. The lower head arises from the lateral surface of the lateral pterygoid plate.

• Insertion - It is inserted into the pterygoid fovea, the capsule of the temporomandibular joint, and the articular disc.

The action of lateral pterygoid muscle is depression, protrusion, and side-to-side movement of the jaw.

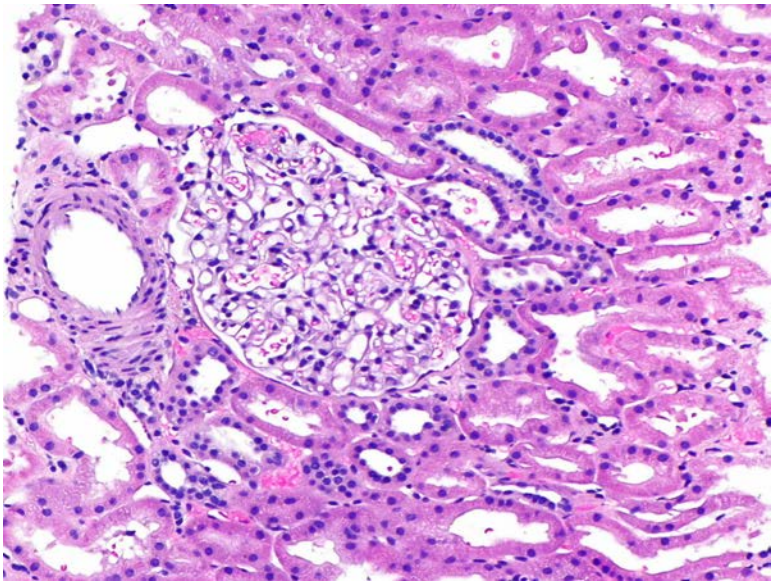
Solution to Question 3:

The above histology image shows the glomerulus.

Glomerulus is a rounded tuft of anastomosing capillaries lined by fenestrated endothelium. Blood enters the tuft through an afferent arteriole and leaves it through an efferent arteriole. It is supported by the mesangium containing mesangial cells and a non-cellular mesangial matrix.

The glomerular capillary wall is the filtering membrane and consists of fenestrated endothelial cells, basement membrane, and visceral epithelial cells called podocytes, which contain foot processes.

The image given below shows the histology of the glomerulus.

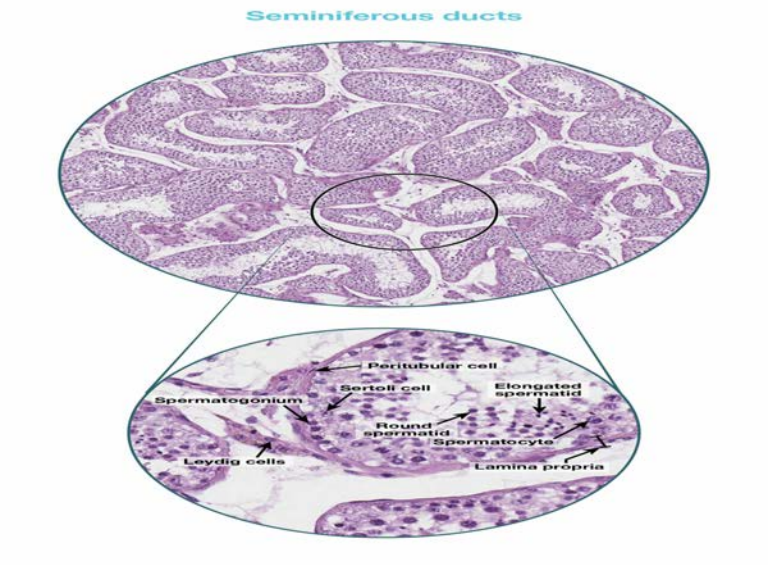


Option A: Leydig cells, also known as interstitial cells of Leydig, are present in the interstitial connective between seminiferous tubules.

The testis contains numerous seminiferous tubules separated by connective tissue in between. Seminiferous tubules are lined by several spermatogonia cells, which produce spermatozoa, and Sertoli (sustentacular) cells, which have a supportive function.

The connective tissue in between the tubules is made up of Leydig cells, collagen fibers, fibroblasts, macrophages, mast cells, blood vessels, and lymphatics. Leydig cells are large, round, or polyhedral cells with eccentric nuclei. They are lightly stained and often have a foamy appearance. They secrete testosterone upon stimulation by luteinizing hormone from the anterior pituitary.

The image below shows seminiferous tubules and Leydig cells.



Option B: Islets of Langerhans makes up the endocrine part of the pancreas.

Islets are characterized by secretory cells supported by reticulin fibers and contain numerous fenestrated capillaries. There is a delicate capsule around each islet. The islet cells are paler than the surrounding exocrine cells, as they have less rough endoplasmic reticulum.

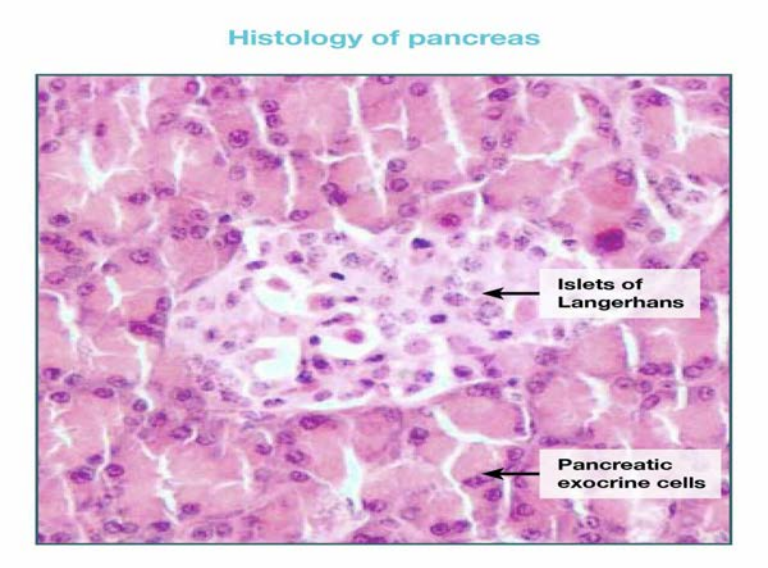
The islet of Langerhans is mainly composed of three types of cells:

• α or A cells - located peripherally and secrete glucagon

• β or B cells - located centrally and produce insulin

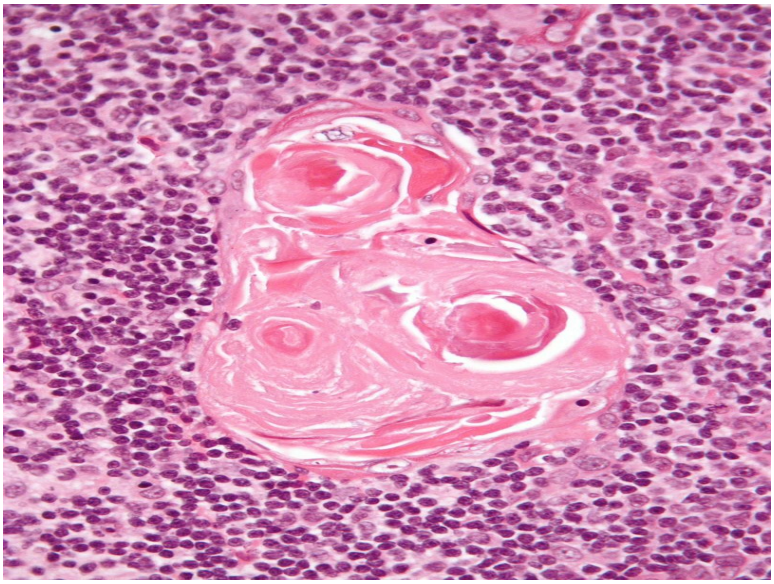
• δ or D cells - scattered between beta cells and secrete somatostatin

The image given below shows the islets of Langerhans.



Option C: Hassall's corpuscles are small rounded structures present in the medulla of the thymus. Each corpuscle has a central core of degenerated epithelial cells and macrophages surrounded by concentrically arranged epithelial cells. The degenerated cells ultimately give pink staining hyaline mass. The function of the corpuscles of Hassall is still not known.

The image given below shows Hassall's corpuscle.

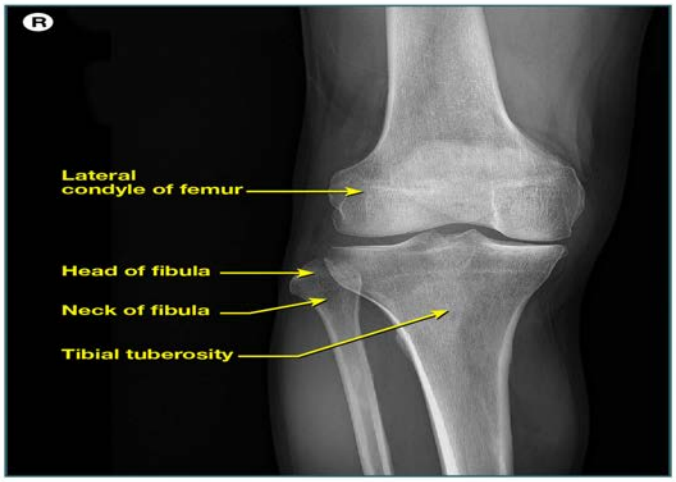


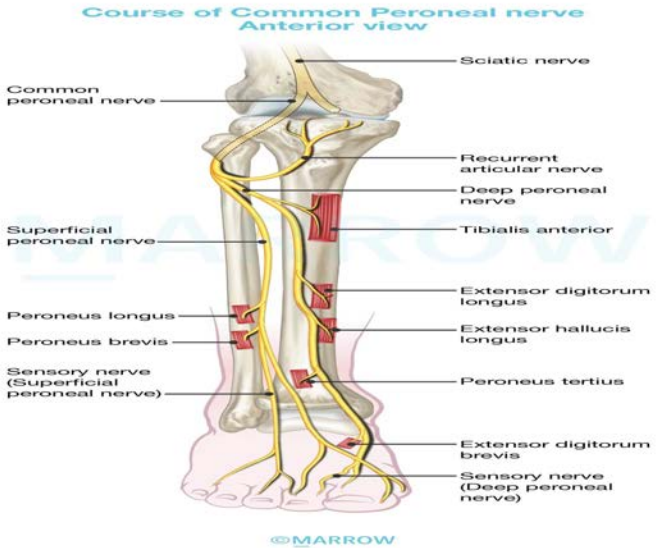
Solution to Question 4:

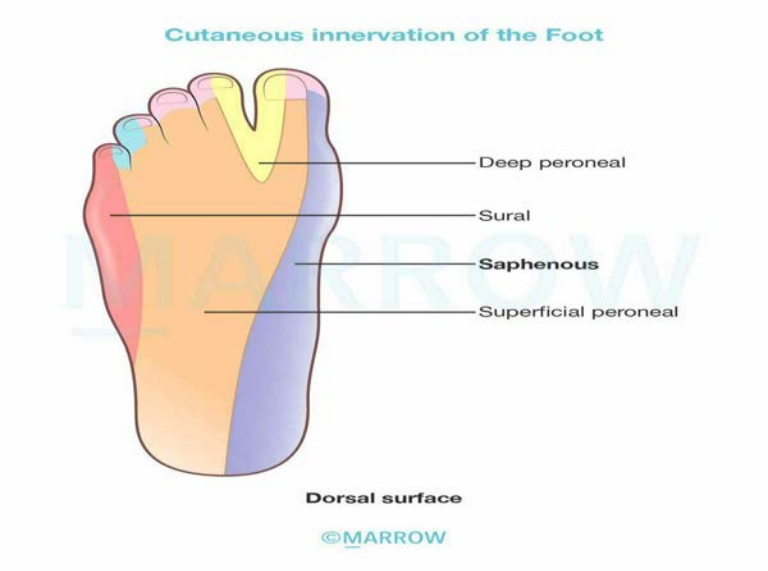
The site marked as '3' in the x-ray given above is the neck of the fibula. Injury at this site causes failure of dorsiflexion (foot drop) due to injury to the common fibular nerve (also know as common peroneal nerve)

The common fibular nerve is derived from the dorsal branches of the 4th and 5th lumbar and 1st and 2nd sacral ventral rami. It runs obliquely along the lateral side of the popliteal fossa to the fibular head. It lies between the biceps femoris and the lateral head of the gastrocnemius. It then curves laterally around the neck of the fibula and gets divided into superficial and deep fibular nerves.

	Superficial fibular nerve	Deep fibular nerve
Motor innervation	Peroneus longusPeroneus brevis	Extensor digitorum longusExtensor hallucis longusTibialis anteriorPeroneus tertius
Sensory innervation	Lateral aspect of the lower legDorsum of the toes except for the lateral side of the 5th toe and the first interdigital web-space	The first interdigital space







Injury to the common peroneal nerve (common fibular nerve) at the level of the neck of the fibula causes foot drop. Ankle dorsiflexion, toe extension, and eversion of the foot are lost, while the inversion and plantar flexion are usually preserved. Sensory innervation to the dorsum of the foot, including the first web space, is lost. The ankle reflex is usually preserved.

Solution to Question 5:

The image above shows a patent ductus arteriosus due to a defect in the left side of the 6th aortic arch.

Usually, in term infants, the ductus arteriosus closes within 72 hours of birth. Failure of the ductus arteriosus to close results in patent ductus arteriosus (PDA).

PDA usually presents with a hyperdynamic precordium, bounding peripheral pulses, wide pulse pressure, a machine-like continuous or systolic murmur, cardiomegaly, increased pulmonary vascular markings, hepatomegaly, increasing oxygen dependence, carbon dioxide retention, and renal failure.

In a majority of cases, PDA closes spontaneously. If spontaneous closure fails to occur, COX inhibitors like indomethacin or ibuprofen can be used. Surgical ligation is indicated in case of contraindications to medical management or failure of the same.

Other options

Option A: The 4th right aortic arch gives rise to the proximal part of the right subclavian artery.

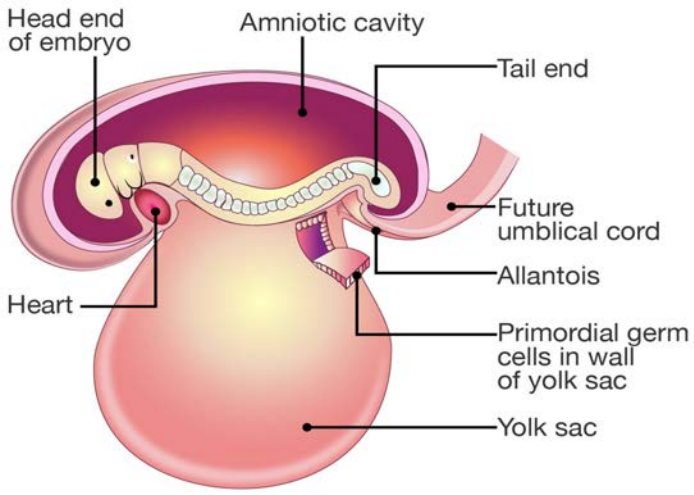
Option B: The 4th left aortic arch gives rise to the arch of the aorta. Defects involving the 4th left aortic arch could cause a variety of aortic arch anomalies, such as interruption of the aortic arch, but not PDA.

Option C: The 6th right aortic arch forms the proximal part of the right pulmonary artery.

Solution to Question 6:

The structure marked A is the allantois. Its distal portion forms the urachus, which in turn gives rise to the median umbilical ligament.

The given image shows an embryo at the end of the third week.



Meckel's diverticulum is a congenital diverticulum arising from anti-mesenteric border of ileum. It is a remnant of the proximal part of the vitelline duct, which is made up of pluripotent cell lining. Meckel's diverticulum may harbor abnormal tissues, containing embryonic remnants of other tissue types, mostly gastric mucosa.

Solution to Question 7:

In the given scenario of a patient with portal hypertension, anastomosis between esophageal veins and left gastric veins can be seen.

In portal hypertension, increased pressure within the portal venous system may result in the dilation of portal venous tributaries and reversed flow at sites of portosystemic anastomoses.

Common sites of porto-systemic anastomoses and their clinical presentations are as follows:

Portal	Systemic	Clinical presentation
Left gastric vein	Distal esophageal veins	Esophageal and gastric varices
Superior rectal vein	Middle and inferior rectal veins	Rectal varices
Persistent tributaries of the left branch of the portal vein in ligamentum teres	Periumbilical branches ofepigastric and intercostal veins	Caput medusae

Portal	Systemic	Clinical presentation
Right branch of portal vein	Retroperitoneal veins draining into azygos, hemiazygos, lumbar, intercostal, and phrenic veins	Dilated retroperitoneal veins at risk during surgery or interventions
Omental and colonic veins	Retroperitoneal veins near hepatic and splenic ■exures	At risk during surgery

Solution to Question 8:

The cause of the pain in this patient complaining of pain in the parotid region is likely to be the greater auricular nerve.

The greater auricular nerve provides sensory innervation to the skin overlying the parotid gland and the ear lobule. Pain associated with swelling and inflammation in the parotid region could be transmitted through the greater auricular nerve. The parotid gland is covered by a parotid capsule that is derived from the investing layer of deep cervical fascia. Any acute inflammation of the gland such as acute sialadenitis results in pain in the preauricular region. The pain is mainly due to stretching of the capsule resulting in stimulation of the greater auricular nerve.

Other options:

Option A: The facial nerve is not the primary cause of pain in the parotid region due to swelling. The Hitzelberger sign(numbness in the posterosuperior meatal wall of the external auditory canal), associated with facial nerve involvement, is seen in acoustic neuroma and is not the cause of pain in this scenario.

Option D: Investing layer of deep cervical fascia is not the correct answer because the investing layer of deep cervical fascia itself does not transmit pain sensation. The investing layer of deep cervical fascia is a layer of connective tissue that envelops the neck and extends to cover the parotid gland, forming the parotid capsule. While inflammation or swelling in the parotid gland can stretch the capsule and cause pain, the actual transmission of pain sensation is mediated by sensory nerves, such as the greater auricular nerve, which innervates the skin over the parotid gland and the ear lobule.

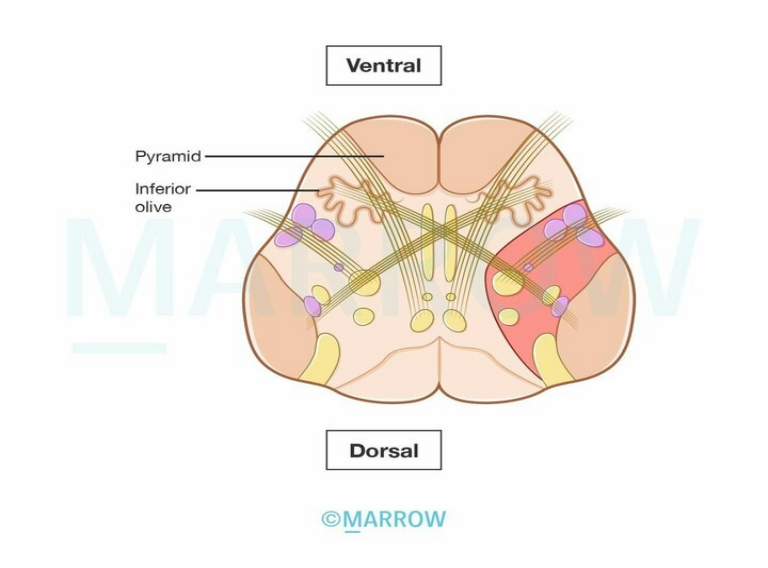
The greater auricular nerve (Option B) is a more appropriate answer in this context, as it is responsible for carrying the pain sensation from the area of swelling and inflammation in the parotid region.

Option C: The auriculotemporal nerve can cause referred pain due to caries tooth, ulcerative lesions of the oral cavity, temporomandibular joint disorders, and sphenopalatine neuralgia. However, it is not the primary cause of pain in the parotid region due to swelling.

Anatomy INI-CET 2023

Question 1:

Which of the following vessels is involved in the condition affecting the region marked in red in the image shown below?



a) Superior Cerebellar Artery

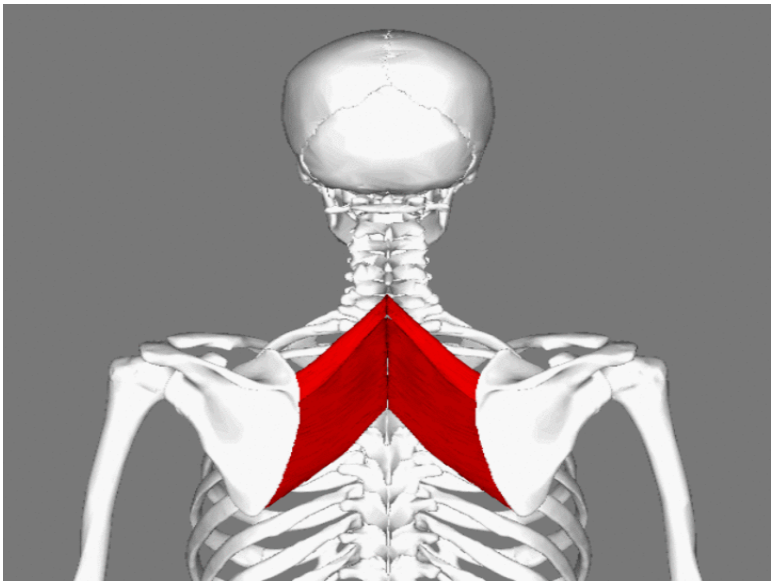
b) Posterior Inferior Cerebellar Artery

c) Posterior Superior Cerebellar Artery

d) Cerebral artery

Question 2:

Which of the statements given below regarding the muscle shown in the image are correct?



a) 1, 2, 3

b) 1, 2, 4

c) Only 1

d) 2, 3, 4

Question 3:

Match the following:

a) 1-D, 2-C, 3-A, 4-B

b) 1-C, 2-A, 3-B, 4-D

c) 1-A, 2-B, 3-C, 4-D

d) 1-B, 2-A, 3-C, 4-D

Question 4:

Which of the following muscles are supplied by Superior Gluteal Nerve?

a) 1, 2, 4

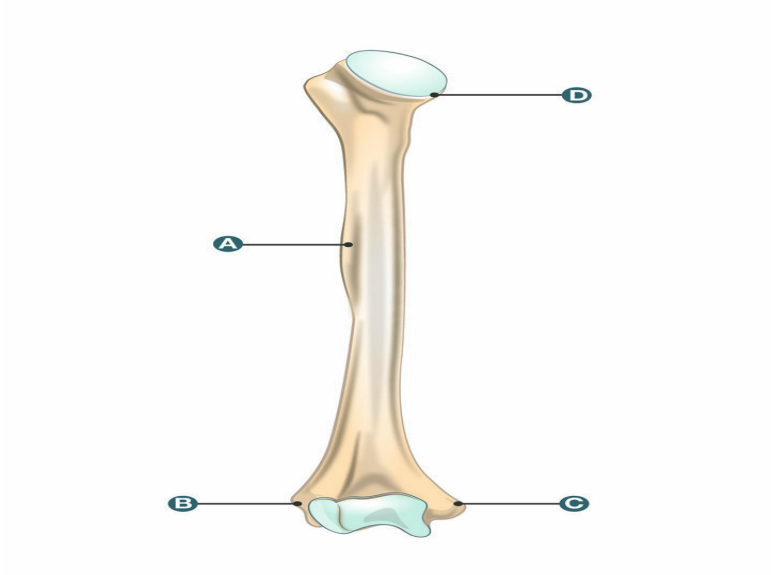
b) 2, 3, 4

c) 1, 2, 3

d) 1, 3, 4

Question 5:

A 25-year-old male presented with symptoms of inability to flex the distal interphalangeal joint of the 4th and 5th digits. He was also not able to hold a piece of paper between his fingers. What is the likely site of injury?



a) A

b) B

c) C

d) D

Question 6:

Which of the following muscles form the pelvic diaphragm?

a) A, B

b) A, B, C, D

c) A, B, D

d) A,D

Question 7:

Anterior relations of the third part of the duodenum are all except:

a) Superior mesenteric vessels

b) Loops of jejunum

c) Root of mesentery

d) Fundus and body of Gall bladder

Question 8:

Arrange the following afferent columns in the floor of the fourth ventricle from medial to lateral.

a) 3, 1, 4, 2

b) 2, 4, 1, 3

c) 1, 2, 3, 4

d) 4, 3, 2, 1

Question 9:

Match the following muscles with their respective actions at the shoulder joint.

a) A-3, B-4, C-1, D-2

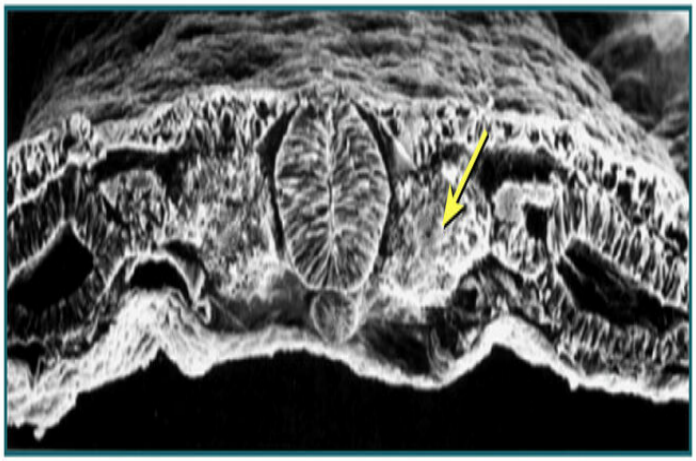
b) A-1, B-3, C-2, D-4

c) A-2, B-4, C-3, D-1

d) A-2, B-1, C-3, D-4

Question 10:

Given below is the image of a 33-hour chick embryo. Which of the following is derived from the marked structure?



a) Kidney

b) Dorsal root ganglion

c) Ribs

d) Parietal pleura

Question 11:

Which of the following is false regarding the anatomy of the adrenal glands?

a) The right adrenal gland is semi lunar in shape

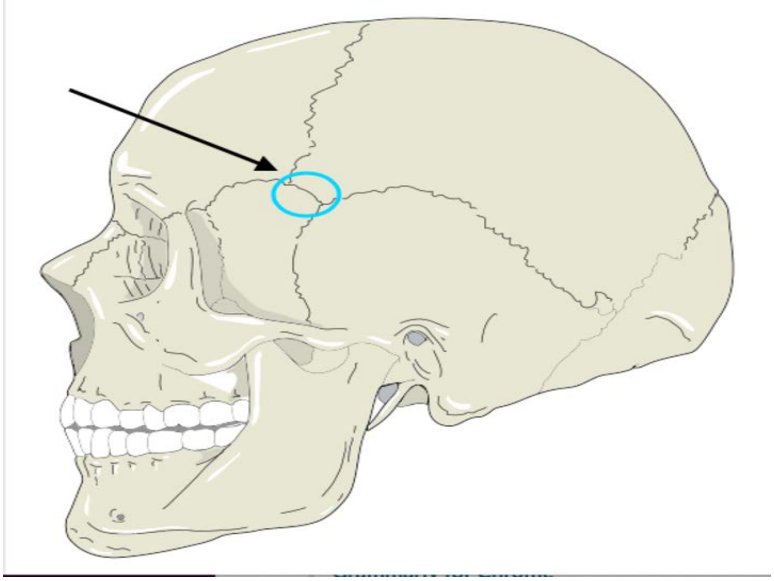
b) The left adrenal gland is closely related with tail of pancreas and spleen

c) The adrenals are yellow on gross appearance

d) The adrenals are retroperitoneal in location

Question 12:

The sulcus located deep to the marked structure is?



a) Central sulcus

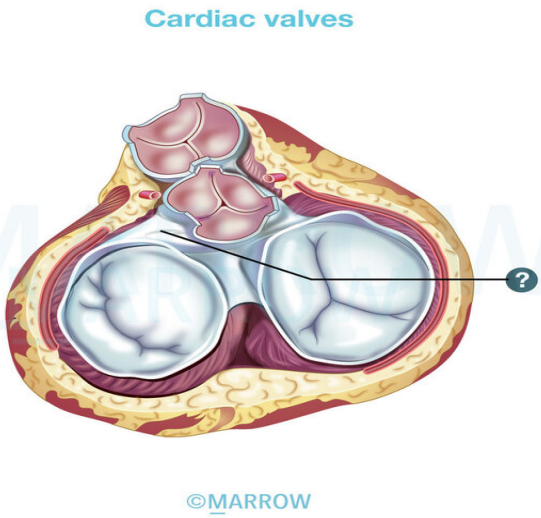
b) Stem of the lateral sulcus

c) Inferior frontal sulcus

d) Superior temporal sulcus

Question 13:

Given below is an illustration of a transverse section of the heart. Identify the marked structure.



a) Sub-aortic curtain

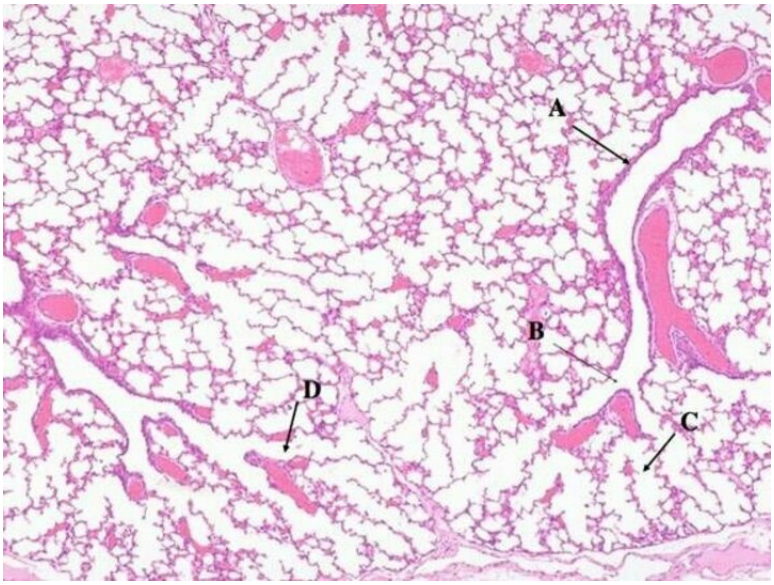
b) Posterior leaflet of mitral valve

c) Aortic valve leaflet

d) Anterior aortic sinus

Question 14:

Identify the structure marked as A.



a) Intra-pulmonary bronchus

b) Terminal bronchiole

c) Respiratory bronchiole

d) Alveolar sac

Question 15:

The fibres of the internal oblique muscle and transverse abdominus muscle contribute to which boundaries of the inguinal canal walls:

a) ii and iv

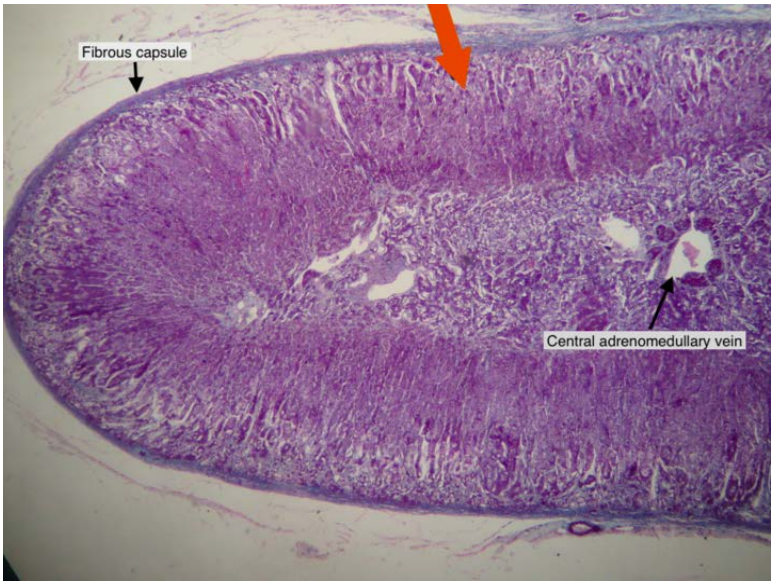
b) i, ii and iv

c) i and iii

d) iii and iv

Question 16:

Which of the following is a function of the marked layer?



a) Gluconeogenesis

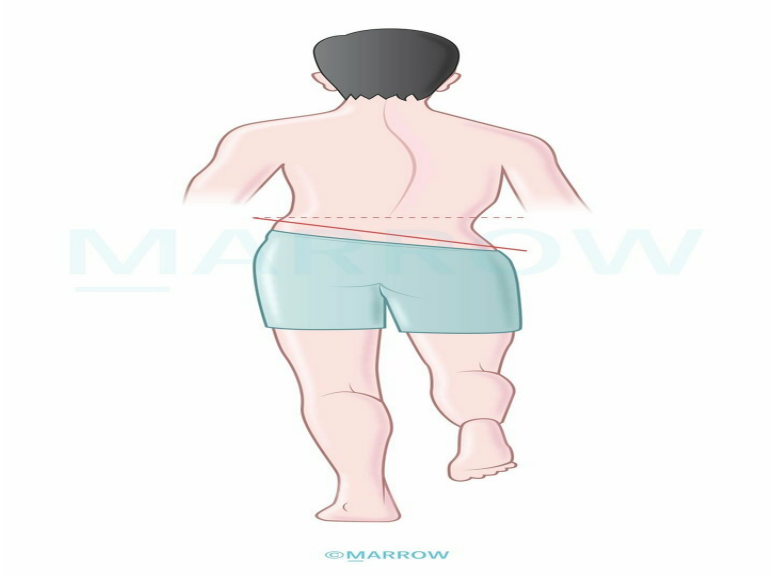
b) Sodium and water retention

c) Increased sex hormones

d) Immune cell interaction

Question 17:

A patient's right hip drops when he takes the right foot off the ground. Which of the following would not be involved in the patient?



a) Superior gluteal nerve

b) Gluteus medius

c) Gluteus minimus

d) Sciatic nerve

Question 18:

Which of the following statements is incorrect about the anomaly shown below?

a) It occurs due to the persistance of prechordal plate

b) It occurs due to the defective migration of primordial cells to the genital ridge

c) It contains skin, cartilage and bone

d) It is a benign tumor of coccyx

Question 19:

Identify the arrow-marked structure.

a) Carina

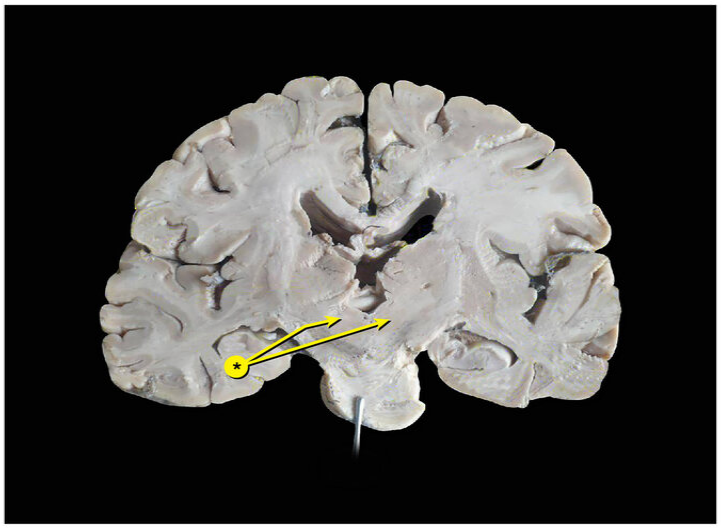
b) Superior Vena Cava

c) Pulmonary Trunk

d) Arch of Aorta

Question 20:

What is the role of the marked structure in the given image?



a) Motor function

b) Reward-punishment

c) Judgement

d) Memory

Question 21:

Which of the following muscles are supplied by the lateral plantar nerve?

a) 2 and 5

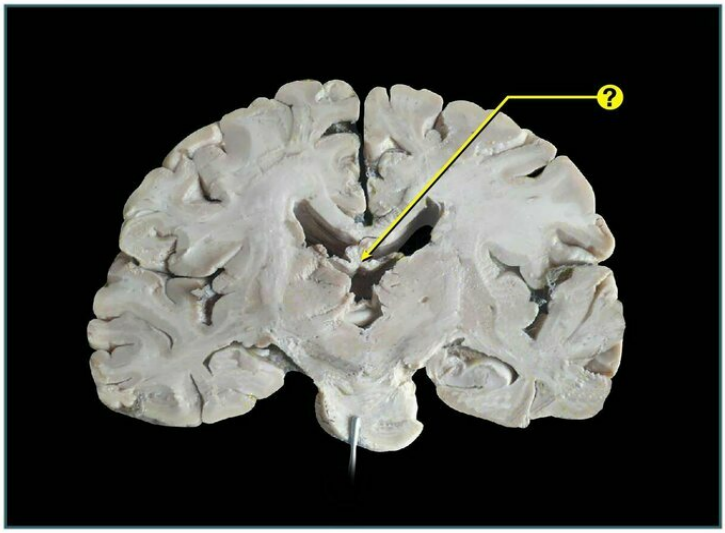
b) 3 and 4

c) 1 and 3

d) 2 and 4

Question 22:

The marked structure sends efferents to which nucleus of the thalamus?



a) Pulvinar

b) Ventro-postero-lateral nucleus

c) Anterior nucleus

d) Lateral nucleus

Question 23:

On neurologic examination, a patient is not able to identify an object but is able to recognize the object from its texture, colour and pattern. Which of the following is likely to have been affected?

a) Occipital lobe

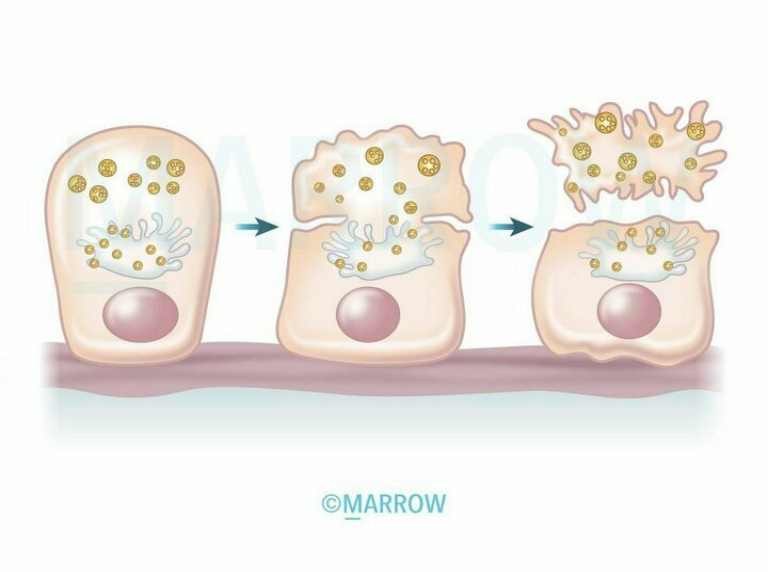
b) Lateral parietal lobe

c) Medial parietal lobe

d) Inferior temporal lobe

Question 24:

Apocrine glands are present in which of the following?



a) Face

b) Scalp

c) Palms and soles

d) Axilla

Question 25:

Which of the following is a tributary of the inferior vena cava?

a) Left inferior phrenic vein

b) Left supra-renal vein

c) Left gonadal vein

d) Right ascending lumbar vein

Answer Key

Question No.	Correct Option
1	b
2	a
3	d
4	c
5	c

25	a

Detailed Explanations

Solution to Question 1:

The given image is suggestive of lateral medullary syndrome/Wallenberg syndrome. This may result from a stroke affecting the Posterior Inferior Cerebellar Artery.

The clinical findings correspond to the neuroanatomical structures affected in the lateral portion of the medulla:

• Descending tract and nucleus of CN V (trigeminal)- loss of pain and sensation over the ipsilateral half of the face.

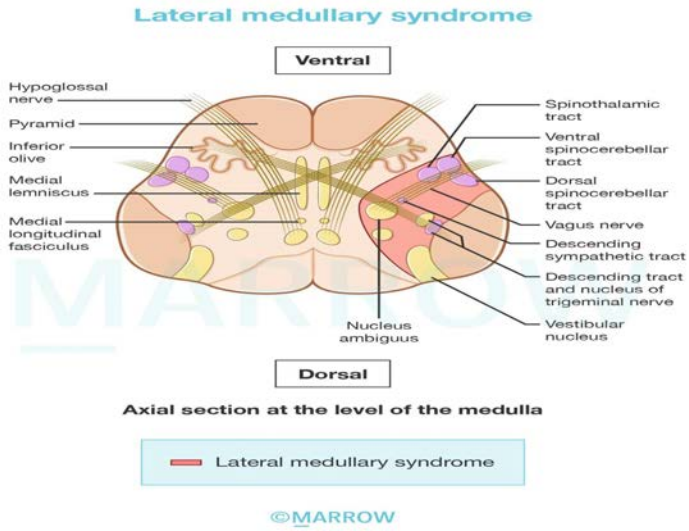
• Inferior cerebellar peduncle – ipsilateral ataxia (gait and limb)

• Lateral spinothalamic tract – loss of pain and temperature sensation over the contralateral half of the body.

• IX and X CN - ipsilateral paralysis of palate, vocal cord, diminished gag reflex giving rise to dysphagia, dysarthria.

• Vestibular nucleus - Nystagmus, diplopia, vertigo, nausea

• Descending sympathetic tract – ipsilateral Horner's syndrome (miosis, ptosis, and anhidrosis).



Solution to Question 2:

The muscles marked in the above image are rhomboids minor and major. These muscles cause retraction and elevation of the scapula and they rotate the scapula tilting the glenoid cavity inferiorly.

Rhomboids minor and major are innervated by the dorsal scapular nerve. They are supplied by the dorsal scapular artery or the deep branch of the transverse cervical artery.

Muscles involved in movements of the scapula are:

• Protraction (forward movement): Serratus anterior and pectoralis minor are prime movers. Rhomboid muscles control the rate and range of movements. The upper part of the latissimus dorsi acts like a strap across the inferior scapular angle in protraction.

• Retraction (backward movement): Middle trapezius and rhomboids.

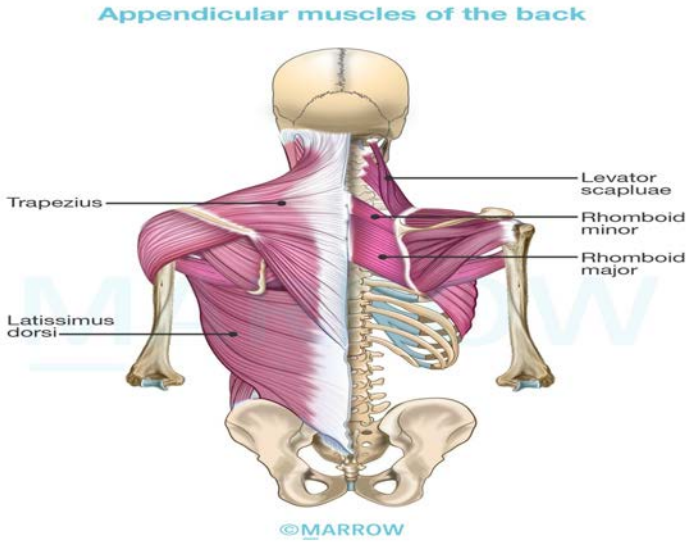
• Elevation: Trapezius, Levator scapulae and rhomboids.

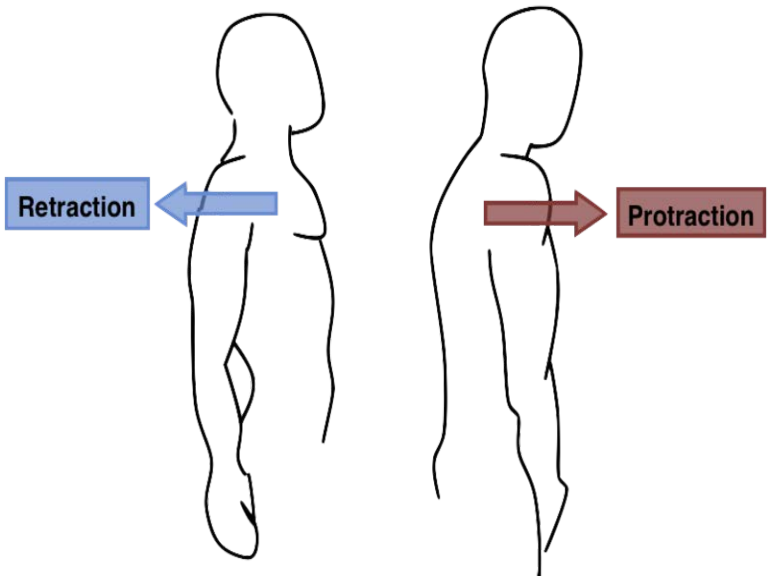
• Depression: Usually gravity alone is sufficient for the depression of the scapula. When required, a part of the serratus anterior, pectoralis minor, and trapezius are used.

Appendicular group of back muscles and their innervations:

Muscle	Nerve Supply	Action
Trapezius	Accessory nerve	Elevation of the scapula, rota tion of scapula during abduct ion of humerus above horizo ntal; middle fibers retract sca pula; lower fibers depress the scapula

Muscle	Nerve Supply	Action
Latissimus dorsi	Thoracodorsal nerve	Adduction, medial rotation, a nd extension of the arm at th e glenohumeral joint
Levator scapulae	Dorsal scapular nerveBranch es directly from anterior rami of C3 and C4	Elevation of the scapula
Rhomboid major and m inor	Dorsal scapular nerve	Elevation and retraction of th e scapula





Solution to Question 3:

The correct match is as follows:

Chorda tympani nerve which is a branch of facial nerve carries taste from anterior 2/3rd of the tongue.

The trapezius is innervated by the spinal accessory nerve (CN XI). It causes retraction of scapula, shrugging of the shoulder and overhead abduction (along with serratus anterior). Paralysis of trapezius causes drooping of the shoulder and slight winging of the scapula (the superior angle of scapula becomes more prominent).

The glossopharyngeal nerve carries taste sensation from the posterior 1/3rd of the tongue.

The mandibular nerve (V3) is responsible for chewing movements as it gives motor supply to muscles of mastication. It contains both sensory and motor fibers.

• Sensory from

• Skin of cheek, over mandible and side of head

• Teeth of lower jaw and temporomandibular joint

• Mucous membrane of mouth and anterior part of tongue

• Motor to

• Muscles of mastication (pterygoids, masster and temporalis)

• Tensor tympani

• Anterior belly of digastric

• Mylohyoid

1. Facial nerve	B. Taste from anterior two th ird of the tongue
2. Spinal accessory nerve	A. Shrugging of shoulder
3. Glossopharyngeal nerv e	C. Taste from posterior one-t hird of the tongue
4. Mandibular nerve	D. Chewing

Solution to Question 4:

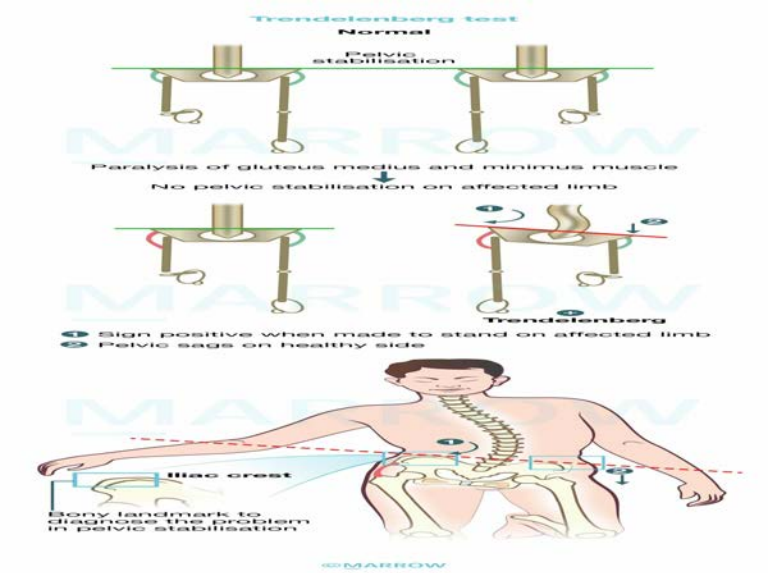
Gluteus Medius, Gluteus Minimus, and Tensor fascia lata are supplied by Superior Gluteal Nerve. Piriformis is supplied by the nerve to the piriformis.

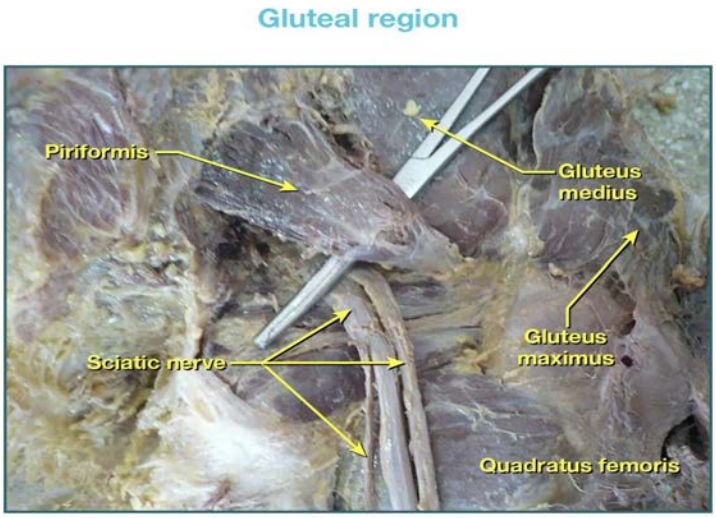
The dorsal branches of the L4, L5, and S1 rami give rise to the superior gluteal nerve. It is accompanied by superior gluteal vessels. This nerve leaves the pelvis via the greater sciatic foramen above piriformis and divides into superior and inferior branches. It supplies gluteus medius, gluteus minimus, and tensor fasciae latae.

The dorsal divisions of the S1 and S2 rami give rise to the nerve to the piriformis.

Gluteus medius and gluteus minimus act as the abductors of the hip joint. Stabilizing the pelvis on the femur during walking is done by these muscles. It is demonstrated by asking the subject to stand on one limb. If the ipsilateral abductors are normal, the pelvis remains in a horizontal

position. If the ipsilateral abductors are weak, then the pelvis tilts towards the opposite (unsupported) side. This is called positive Trendelenburg's sign.





Solution to Question 5:

The given clinical situation with a positive card test and an inability to flex the distal interphalangeal joint of the 4th and 5th digits, suggests an ulnar nerve injury. The most likely site of injury would thus be medial epicondyle: site C

Injury at the medial epicondyle damages the ulnar nerve, leading to paralysis of flexor carpi ulnaris (loss of ulnar deviation) and medial half of flexor digitorum profundus (loss of distal interphalangeal joint flexion). It leads to hypothenar paralysis (lead to atrophy) and sensory loss. Also, flexor digitorum superficialis (supplied by median nerve) and extensor digitorum (supplied by the radial nerve) are still functional. Hence complete paralysis of the 3rd and 4th digits

is not seen. The positive card test is due to the weakness of palmar interossei leading to loss of adduction.

Ulnar nerve branches and supply:

Superficial branch supplies palmaris brevis, skin on the palmar surface of medial 1½ fingers. The deep branch runs within the concavity of deep palmar arch and supplies all intrinsic muscles of the hand (except first 2 lumbricals and thenar muscles).

Injury to the Ulnar nerve:

Other tests seen in ulnar nerve lesions are as follows:

• Claw hand deformity

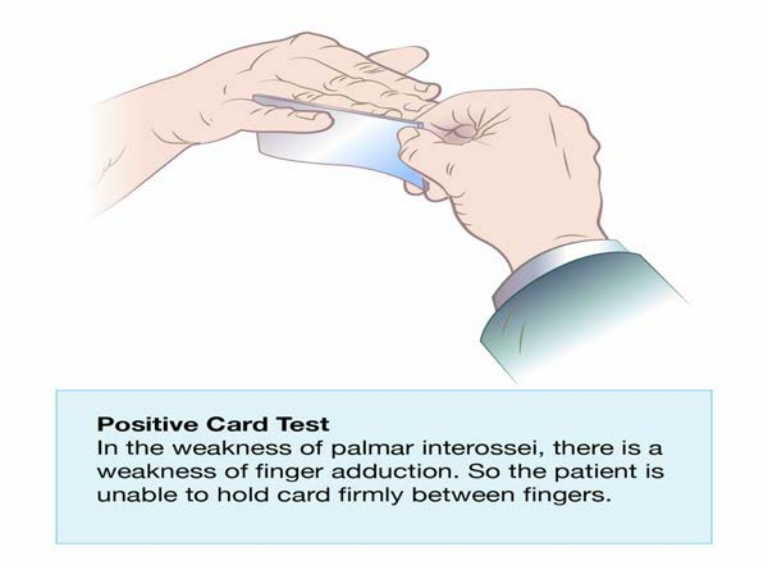
• Froment's sign positive

• Wartenberg sign

• Palmaris brevis sign

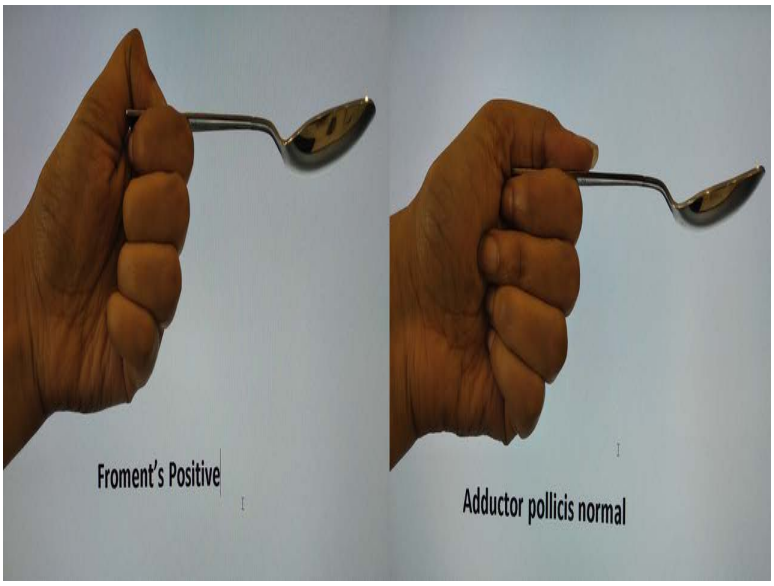
	High lesion(Elbow)	Low lesion(Wrist)
Site of injury	Fracture/dislocation of theme dial epicondyleCubital tunnel syndromeCompression betw een the two heads of FCUTar dy ulnar nerve palsy (Valgus deformity)	Wrist laceration/ slashingGuy on's canalsyndrome
Motor loss	Claw-handdeformityHypothe nar & interosseous wastingLo ss of:• Abduction & adduction of fingers(Card test- Positive) • Adduction of thumb(Frome nt sign-Positive)• Flexion of MCP jointsWeakness of wrist flexion (radial deviation)	Claw-handdeformity(more pr onounced)Hypothenar & inte rosseous wastingLoss of:• Ab duction & adduction of finger s(Card test- Positive)• Adduct ion of thumb(Froment sign-P ositive)
Sensory loss	Over palmar & dorsal aspect of themedial thirdof thehand Over palmar & dorsal aspect of themedial 11/2fingers	No sensory lossover palmar & dorsal aspect of the medial third of the handOver palmar & dorsal aspect of themedial 11/2fingers

The image below shows a positive card test.



Positive Card Test
In the weakness of palmar interossei, there is a weakness of finger adduction. So the patient is unable to hold card firmly between fingers.

Wartenberg's sign: (Weakness of palmar interossei), Sensory loss Palmar and dorsal surface of the medial third of hand and medial 1 and a half fingers.



Other options:

• Option A: Radial groove - Radial nerve

• Option D: Neck of humerus - Axillary nerve

• Option B: Lateral epicondyle – May lead to tardy ulnar nerve palsy after fracture but the incidence is less.

Solution to Question 6:

Iliococcygeus and pubococcygeus are parts of the pelvic diaphragm, which is also known as the levator ani.

The levator ani muscle is a complex unit that consists of 3 muscle components:

• Pubococcygeus

• Pubovaginalis - elevates the urethra and hence contributes to urinary continence

• Puboperinealis - draws the perineal body towards the pubic symphysis

• Puboanalis - elevates the anus and keeps the urogenital hiatus narrowed

• Puborectalis

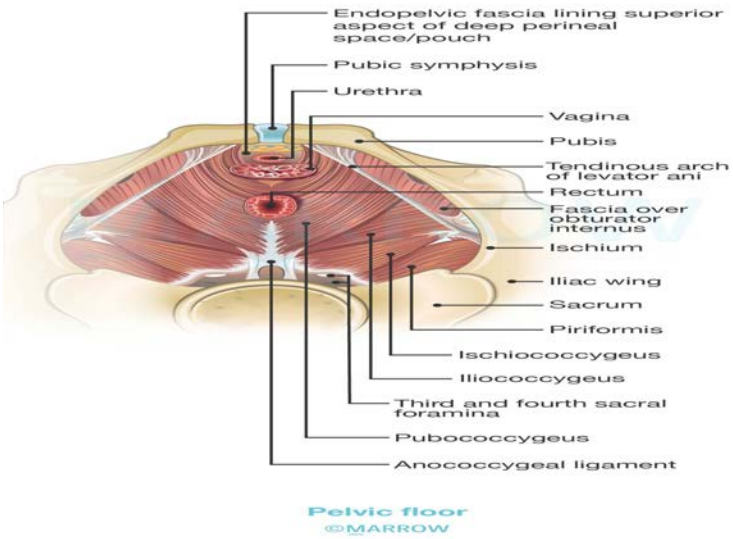
• Iliococcygeus

Levator ani muscles are the most important muscles in the pelvic floor and maintain a constant state of contraction. They provide a stable floor and support the weight of the abdominopelvic contents against intra-abdominal forces. Weakening of levator ani and pelvic fascia from stretching or tearing during childbirth, may decrease support for the vagina, bladder, uterus, or rectum or alter the position of the neck of the bladder and urethra.

Other options:

The obturator internus forms the lateral wall of the ischioanal fossa and is not a part of the levator ani.

The deep transverse perineal muscle is the content of the deep perineal space and contributes to the formation of the perineal body.



Solution to Question 7:

Anterior relations of the third part of the duodenum include the Superior mesenteric vessels, the Root of the mesentery, and Loops of the jejunum.

Relations of the 3rd part of duodenum:

• Posterior relations of 3rd part of duodenum include right ureter, right psoas major, right gonadal vessels, inferior vena cava and abdominal aorta (at the origin of the inferior mesenteric artery).

• Anterior relations: Loops of jejunum, Root of mesentery and Superior mesenteric vessels.

• Superiorly related to head of the pancreas and Inferiorly to loops of jejunum.

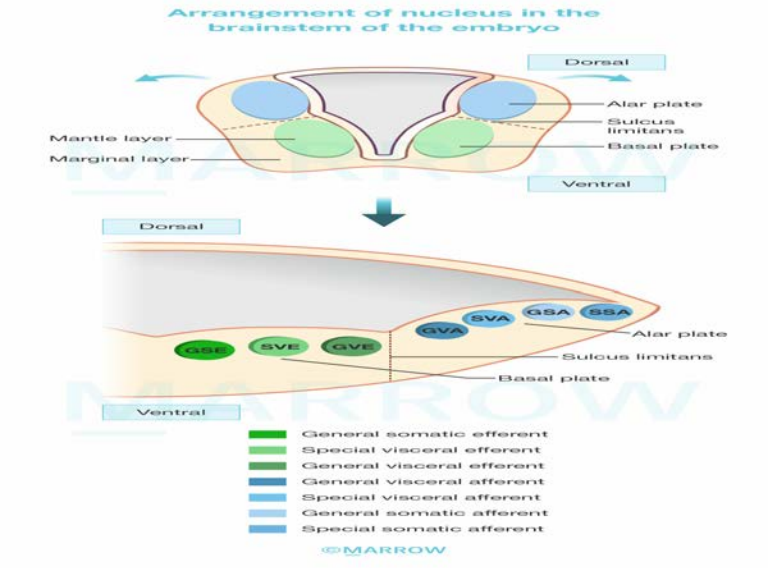
Note: Root of mesentery (containing Superior mesenteric vessels) lies anterior to the 3rd part of Duodenum. Hence, posterior relations of 3rd part of duodenum are the same as structures crossed by root of mesentery.

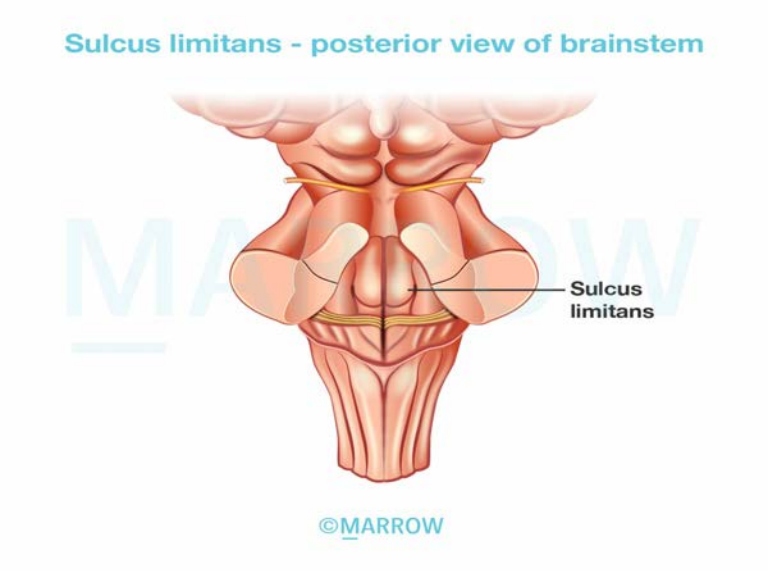
Solution to Question 8:

From medial to lateral, the afferent columns in the floor of the fourth ventricle are general visceral, special visceral, general somatic, special somatic.

Embryologically, the continuous addition of neuroblasts to the mantle layer of the neural tube produces thickenings ventrally and dorsally - producing the basal and alar plates respectively. A longitudinal groove, called sulcus limitans, marks the boundary between the two.

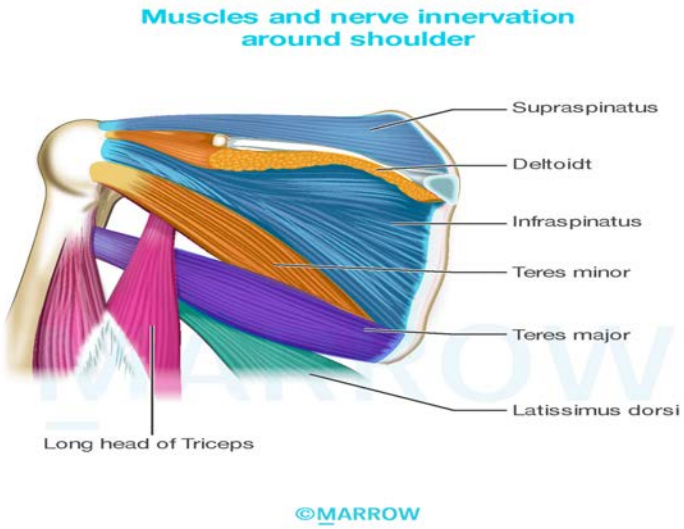
Basal Plate	Alar plate
Ventralthickening	Dorsalthickenings
Give rise tomotor nuclei-general visceral efferent nuclei, special visceral efferent of CN IX, X, and XII; and somatic efferent of XII	Give rise tosensory nucleiCN V, VII, VIII, IX, X, inferior olivary nucleus, and mesencephalic nucleus of CN V
Forms the motor part of the spinal cord (ventral horns)	Forms the sensory part of the spinal cord (dorsal horns).The rhombic lip develops into the cerebellum and its nuclei.





Solution to Question 9:

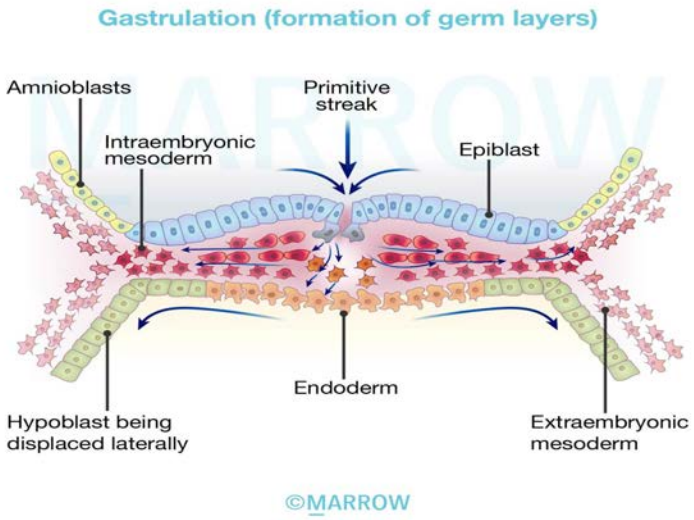
Muscles	Actions
Supraspinatus	Steadies the head of the humerus during movements,abduction of shoulder joint from 0 -15°
Deltoid	Abduction, anterior fibers - flexors and medial rotators, posterior fibers - extensors and lateral rotators
Infraspinatus	Lateral rotatorof the arm
Teres minor	Lateral rotator of the arm
Teres major	Adduction and medial rotation of the arm
Latissimus Dorsi	Adduction, medial rotation, andextension of the arm
The long head of the triceps	Extension of elbow joint
Pectoralis major	Adduction, medial rotation, andflexion of the arm

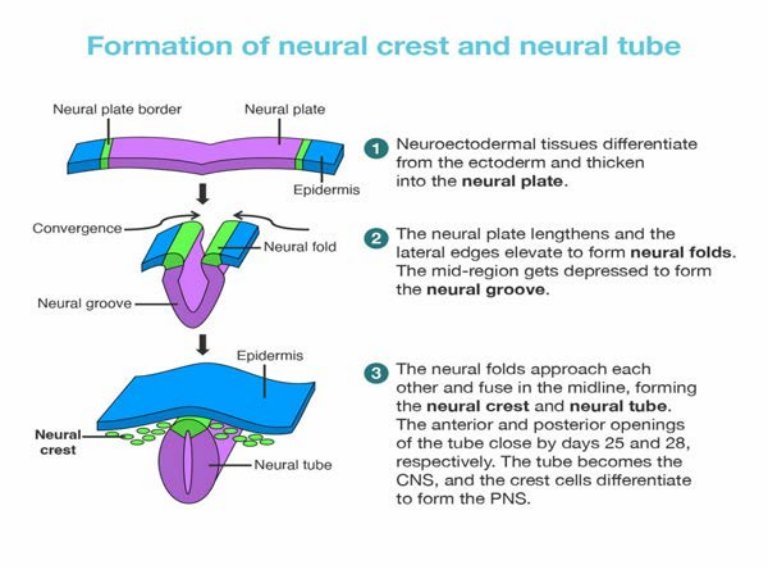


Solution to Question 10:

The structure marked in the given image is the para-axial mesoderm. The ribs are derived from the para-axial mesoderm.

During the third week of embryological development, the process of gastrulation occurs, which refers to the formation of the three germ layers: ectoderm, mesoderm and endoderm. This is followed by the formation of the notochord, which is the axial structure, which induces the formation of the neural tube above it. During the formation of the neural tube, some cells at the lateral border dissociate and form the neural crest cells, which is sometimes referred to as the fourth germ layer.





After the formation of the notochord, which is the axial structure, the mesoderm on either side can be seen to be organized into three layers as follows:

1. Para-axial mesoderm - Thickened plate of the mesoderm close to the midline, on either side of the notochord. This forms the somitomeres and somites, which have the following derivatives:

• Dermatome: Forms the segmental dermis of the skin

• Myotome: Forms the skeletal muscle

• Sclerotome: Forms the vertebral column and ribs

2. Intermediate mesoderm - Longitudinal strip of mesoderm that connects the para-axial with the lateral plate mesoderm. The urinary (Option A) and genital systems are derived from the intermediate mesoderm.

3. Lateral plate mesoderm - A thinner layer of mesoderm that lies laterally. This layer develops a large cavity called the intraembryonic coelom that gives rise to pericardial, pleural (Option C), and peritoneal cavities.

The neural crest cells also contribute to the formation of structures as follows:

In the trunk region, they form melanocytes, sensory ganglia (Option B), sympathetic and enteric neurons, Schwann cells, and adrenal medulla cells.

In the cranial region, they contribute to the craniofacial skeleton, neurons for cranial ganglia, satellite glial cells, and melanocytes.

Solution to Question 11:

Option A is false as the right adrenal gland is pyramidal in shape while the left adrenal gland is semi-lunar/crescent shaped.

The adrenal glands, also called the supra-renal glands, are endocrine glands which are located at the upper pole of each kidney. They are grossly yellow in appearance and are retroperitoneal in

location. Both glands are surrounded by areolar tissue and perirenal fascia. The following are the key differences between the right and the left adrenal glands and their relations:

Each gland is supplied by:

• Superior suprarenal artery - branch of the inferior phrenic artery.

• .Middle suprarenal artery - branch of the abdominal aorta.

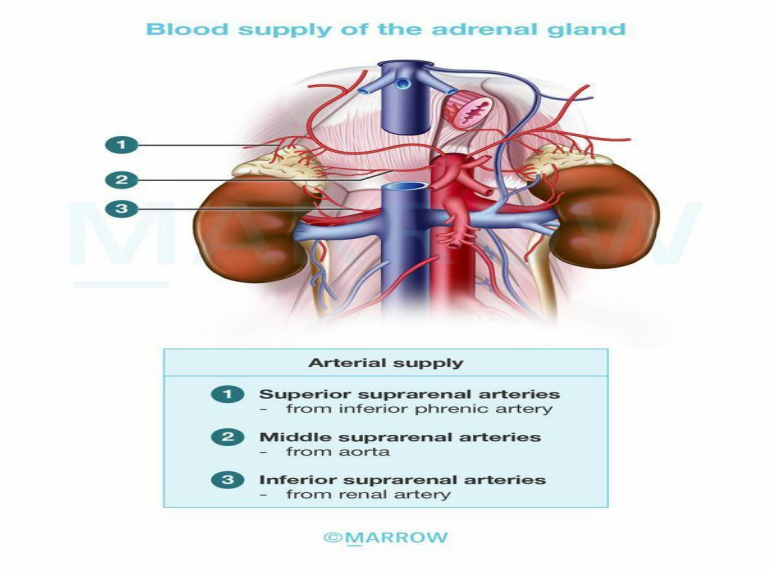
• Inferior suprarenal artery - branch of the renal artery.

Each gland has one draining vein.

• The right suprarenal vein drains into the IVC.

• The left suprarenal vein drains into the left renal vein.

	Right Adrenal Gland	Left Adrenal Gland
Shape	Pyramidal or triangular	Semi-lunar or crescenteric
Parts	Apex and base	Upper end and lower end
Superior relation	Bare area of liver	Spleen
Inferior relation	Right kidney	Left kidney and left supra-re nal vein
Anterior relation	IVC, bare area of liver	Stomach and tail of pancreas with splenic artery
Posterior relation	Right crus of diaphragm, righ t kidney	Left crus of diaphragm, left k idney
Medial relation	Coeliac ganglion	Coeliac ganglion
Lateral relation	Liver	Stomach



Solution to Question 12:

The area marked by an arrow in the given image is pterion and the stem of the lateral sulcus lies under it.

The pterion is an H-shaped sutural junction between four bones of the skull:

• Frontal bone

• Squamous part of the temporal bone

• Greater wing of the sphenoid bone

• Parietal bone.

The surface of the cerebrum consists of folds called gyri separated by fissures called sulci. The lateral sulcus, also called the Sylvian Fissure, is present on the infero-lateral surface of each cerebral hemisphere and separates the frontal lobe from the temporal lobe. The lateral sulcus consists of a stem which divides into three rami, which are, the anterior horizontal, anterior ascending, and the posterior rami.

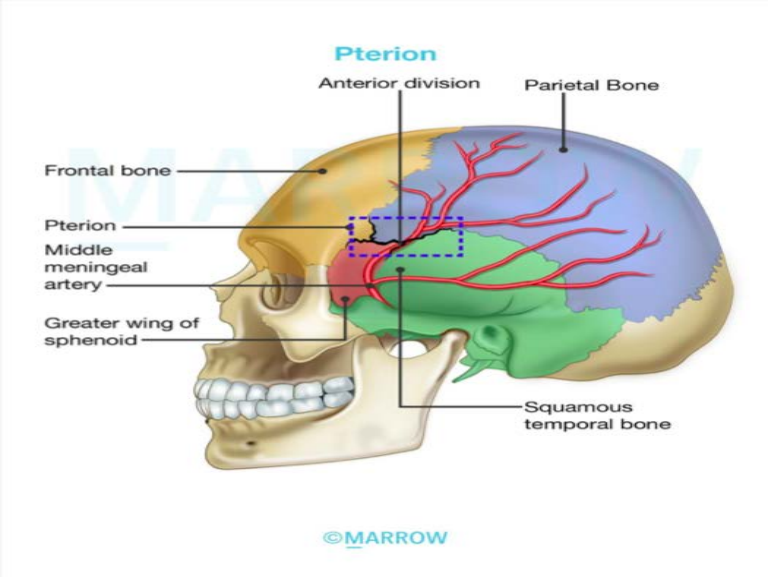
The structures lying deep to the pterion are:

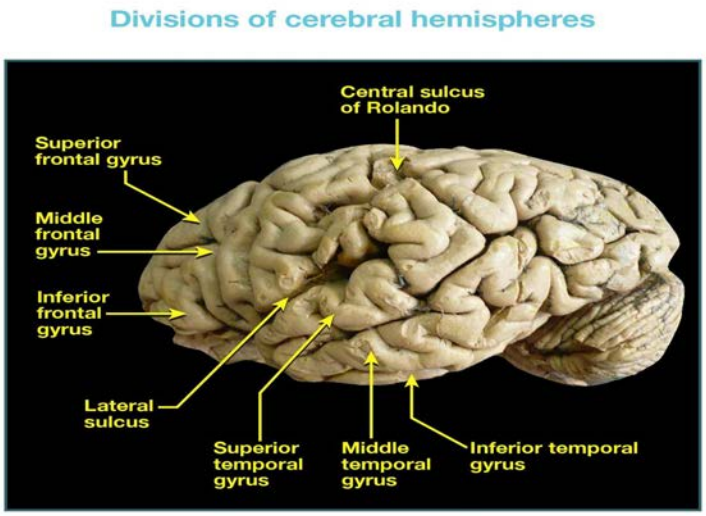
• The anterior branch of the middle meningeal artery

• The middle meningeal vein

• The stem of the lateral sulcus (Sylvian fissure)

The bone in this area is thin and an injury to this area may lead to rupture of the middle meningeal artery leading to extradural hematoma.





Solution to Question 13:

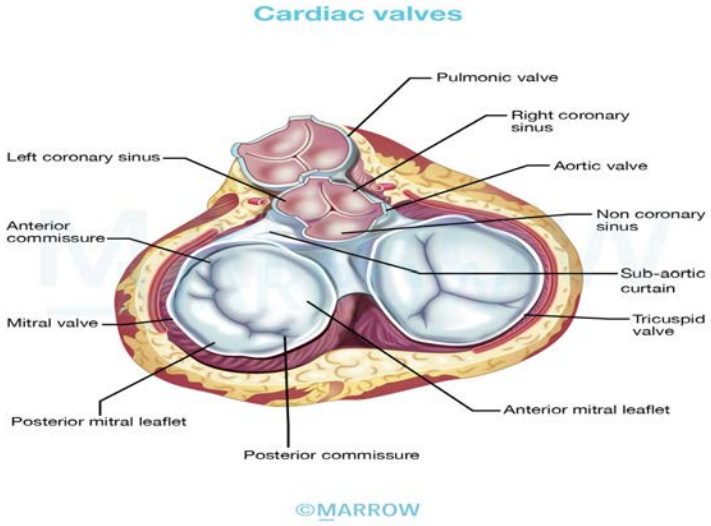
The marked structure is the sub-aortic curtain. It is also called the trigonum fibrosum sinistrum.

The fibrous skeleton of the heart is formed by fibrous tissue that is continuous between the atrio-ventricular and arterial orifices. They exist to keep the valves competent, allow attachment of cardiac musculature, and act as an insulating layer for the conducting system of the heart. The fibrous rings of importance are:

• The atrioventricular fibrous rings - existing in a figure of 8 configuration, connecting the atria, ventricles and the membranous part of the interventricular septum.

• The trigonum fibrosum dextrum - between the atrioventricular rings and the aortic ring.

• The trigonum fibrosum sinistrum - between the mitral valve and the aortic valve.



Solution to Question 14:

The arrow-marked structure in the given image is the terminal bronchiole. It can be identified by the absence of cartilage, which would be present in the bronchus, and the presence of cilia and stratified columnar epithelium, which would not be seen in respiratory bronchioles and alveolar sac.

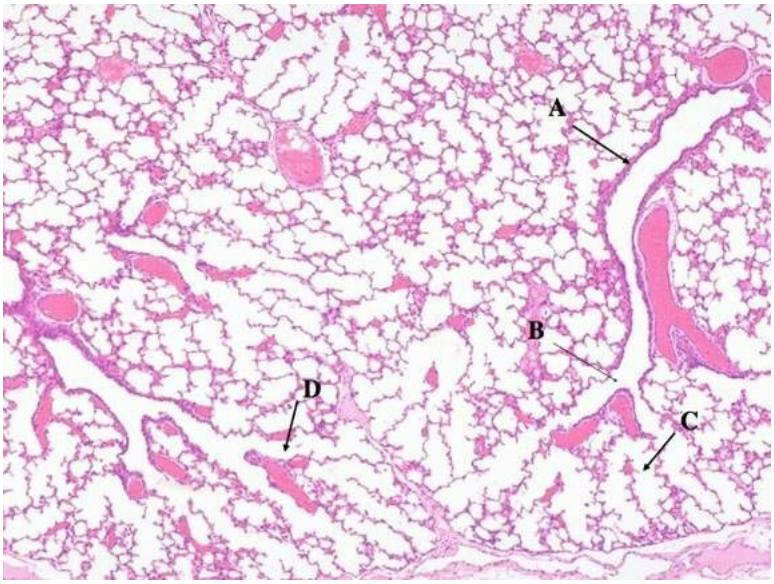
The following is a summary of the intrapulmonary passages:

Trachea → Main Bronchi → Lobar Bronchi → Segmental Bronchi → Terminal Bronchiole → Respiratory Bronchiole → Alveolar Duct → Alveolar Sac → Alveoli

Bronchi and bronchioles can be distinguished by the presence of cartilage and glands in the bronchi which are not present in the bronchioles.

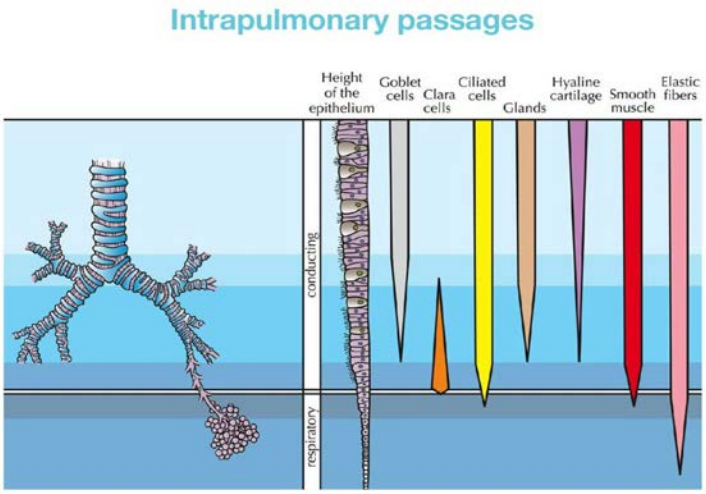
Terminal bronchioles represent the most distal parts of the conducting passage. Each terminal bronchiole ends by dividing into respiratory bronchioles. Terminal bronchioles contain cilia and stratified columnar epithelium, whereas respiratory bronchioles contain few or no cilia, and simple cuboidal epithelium. Another differentiating point between the two is that terminal bronchioles would not communicate with the alveoli but respiratory bronchioles would have a communication with the alveoli.

Each respiratory bronchiole ends by dividing into a few alveolar ducts. Each alveolar duct ends in a passage, the atrium, which leads into a number of rounded alveolar sacs. Each alveolar sac is studded with a number of air sacs or alveoli.



A: Terminal Bronchiole, B: Respiratory Bronchiole, C: Alveolar Sac, D: Alveolar Duct

The coloured strips in the following illustration represent the location of different cells/structures in the trachea and bronchial tree.



Note - The image in the question has been updated for better clarity

Solution to Question 15:

The fibres of the internal oblique muscle and transverse abdominus muscle contribute to the roof and posterior wall of the inguinal canal walls.

The boundaries of the inguinal canal walls are as follows:

• Anterior wall: Formed by the external oblique aponeurosis.

• Roof: Formed by the arched fibres of the internal oblique and transversus abdominis muscles.

• Floor: Formed by the grooved upper surface of the Abdomen and Pelvis inguinal ligament.

• Posterior wall: Consists of the transversalis fascia and conjoint tendon (the lowest fibres of the transverses abdominis muscle fuse with the lowest fibres of the internal oblique to form the conjoint tendon).

Solution to Question 16:

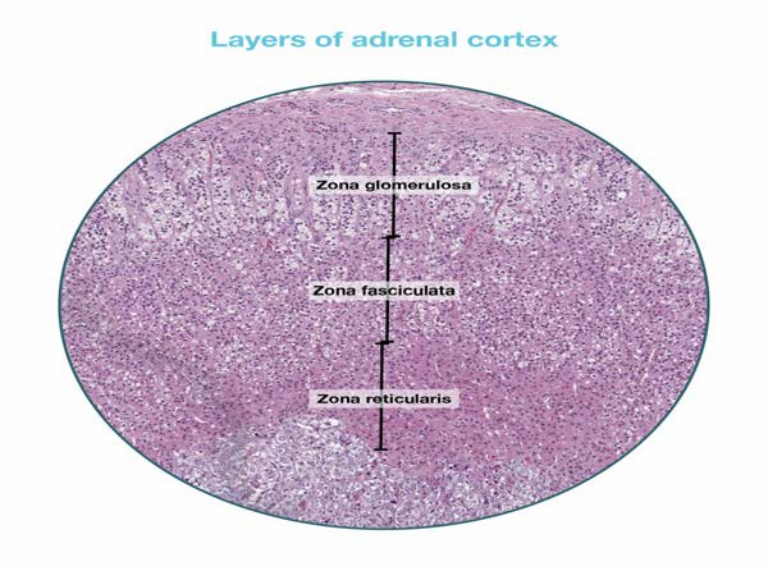
The image shows a histological section of the adrenal gland and the layer marked is the outermost layer, ie, the zona glomerulosa, which secretes the mineralocorticoid - aldosterone, responsible for sodium and water retention.

Based on structure and function, the adrenal cortex has three zones, which from outer to inner, are:

• Zona glomerulosa: Secretes mineralocorticoids (aldosterone) - which acts in response to the activation of the renin-angiotensin-aldosterone-system (RAAS) and acts at the distal convoluted tubule and the collecting ducts favouring sodium and water retention and potassium excretion.

• Zona fasiculata: Secretes glucocorticoids (cortisol and corticosterone) - which has multiple functions that include metabolic effects which induce hyperglycemia inducing gluconeogenesis (Option A) and mediates anti-inflammatory and immunosuppresive effects by interacting with the cells of the immune system (Option D).

• Zona reticularis: Secretes sex steroids (dehydroepiandrosterone, androstenedione, estrogens, and glucocorticoids) (Option C)



Solution to Question 17:

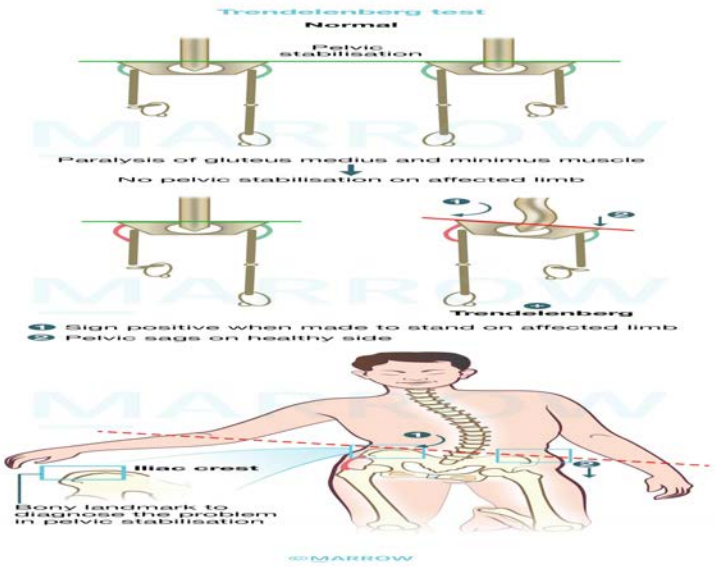
A patient with dropping of the right hip on lifting the right foot off the ground, has a positive Trendelenburg's sign. The sciatic nerve would not be involved.

A positive Trendelenburg's sign is seen in the paralysis of the gluteus medius and gluteus minimus muscles, both of which are supplied by the superior gluteal nerve. In the scenario mentioned, since the patient has dropping of the hip on the right side, the structures on the left side would be affected.

Mechanism of actions of gluteus medius and minimus:

• When the leg on one side is lifted off the ground, making it the unsupported side, gluteus medius and minimus muscles on the opposite side, which is the supported side, exert traction on the hip bone by acting from the femur. This action results in slight raising of the pelvis on the unsupported side, which helps maintain the trunk in the upright position.

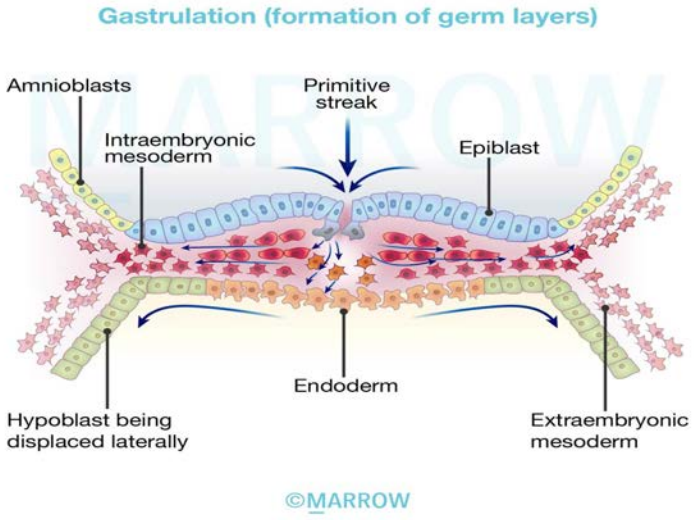
• When the gluteus medius and minimus are paralyzed, the pelvis on the unsupported side sinks when the patient lifts the foot off the ground. This causes the patients to have a characteristic lurching gait.



Solution to Question 18:

The image shows a sacrococcygeal teratoma, which occurs due to the persistence of pluripotent cells of the primitive streak in the sacrococcygeal region.

During the third week of embryological development, the process of gastrulation occurs, which refers to the formation of the three germ layers. These germ layers are formed from the primordial germ cells of the epiblast, which are pluripotent. The process begins with the formation of the primitive streak on the epiblast, which develops into the primitive node in the cranial region, and a primitive pit. The cells from the epiblast, migrate towards the primitive streak and invaginate into the primitive pit and organizes itself into cells arranged in three layers, which eventually develop into ectoderm, mesoderm, and endoderm. The prechordal plate simply refers to the cells that have invaginated in the cranial region.



Sacrococcygeal teratomas occur due to remnants of pluripotent cells from the primitive streak due to defective migration of the cells (Option B). As these cells are from the epiblast, teratomas contain tissues from all germ layers which may include skin, hair, cartilage and bone (Option C). These tumors are benign in nature (Option D), but may rarely become malignant. If they occur in the cranial end of the primitive streak, they form oro-pharyngeal teratomas (as shown below), whereas if they occur in the caudal end of the primitive streak in the coccygeal region, they are called sacro-coccygeal teratomas.

Solution to Question 19:

The arrow marks the bifurcation of the pulmonary trunk.

The image shows a cross section of a cadaver at the T5 vertebral level. This corresponds anteriorly to the level of the sternal angle, and is also the level of division between the superior and inferior mediastinum.

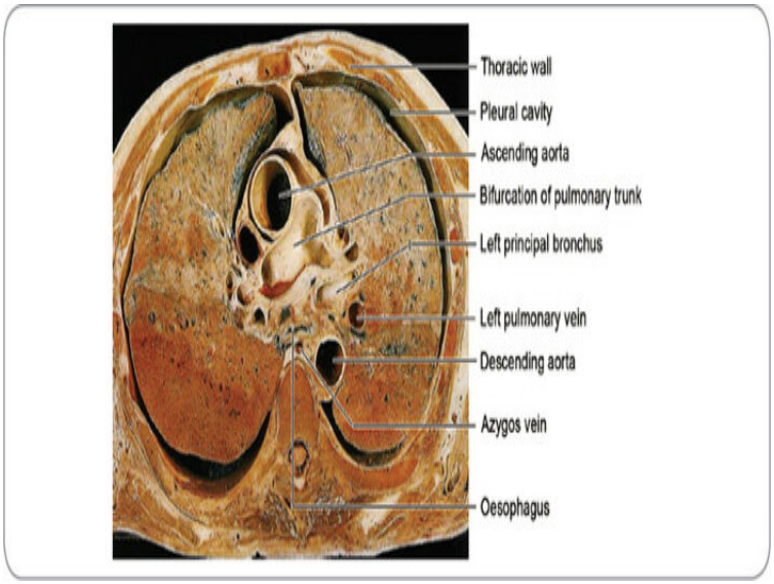
At this level, the other structures visible are:

• The origin and termination of the arch of aorta. The descending aorta can be identified to the left of the oesophagus. The arch of the aorta (Option D) would be visible at the T3-T4 cross sectional level.

• The superior vena cava (Option B), just lateral to the origin of the aorta, which can visually differentiated from the aorta based on the wall thickness. At this level, it penetrates the right atrium.

• The bifurcation of the pulmonary trunk.

• The left and right main bronchi. The carina (Option A) is not visible as the trachea bifurcates more proximally at the T4 level.

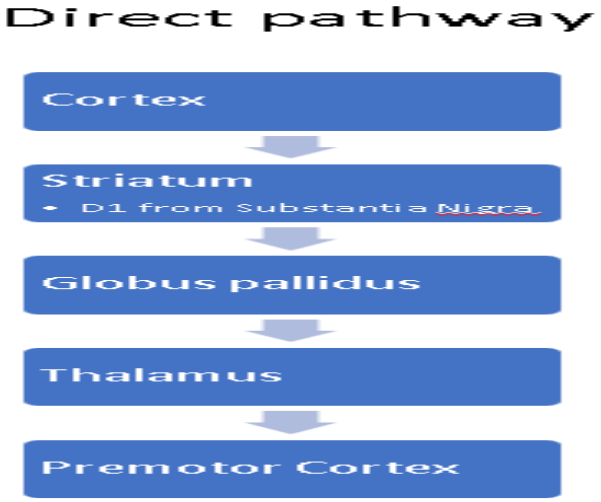


Solution to Question 20:

The marked structure is the subthalamic nucleus, which is a part of the basal ganglia and is concerned with motor function.

The basal ganglia refers to the mass of grey matter located within the cerebral white matter and is responsible for a number of coordinated functions including the control of extra-pyramidal pathways for motor coordination. There are two major pathways involved which are, the direct and indirect pathways.

The direct pathway stimulates the cortex to produce movement, whereas the indirect pathway inhibits it. The striatal activity in the direct pathway is mediated by D1 dopamine receptors and in the indirect pathway by D2 dopamine receptors. The subthalamic nucleus is a part of the indirect pathway. A lesion at subthalamic nuclei leads to loss of inhibitory effect of the indirect pathway resulting in dopaminergic overactivity responsible for features of hemiballismus.

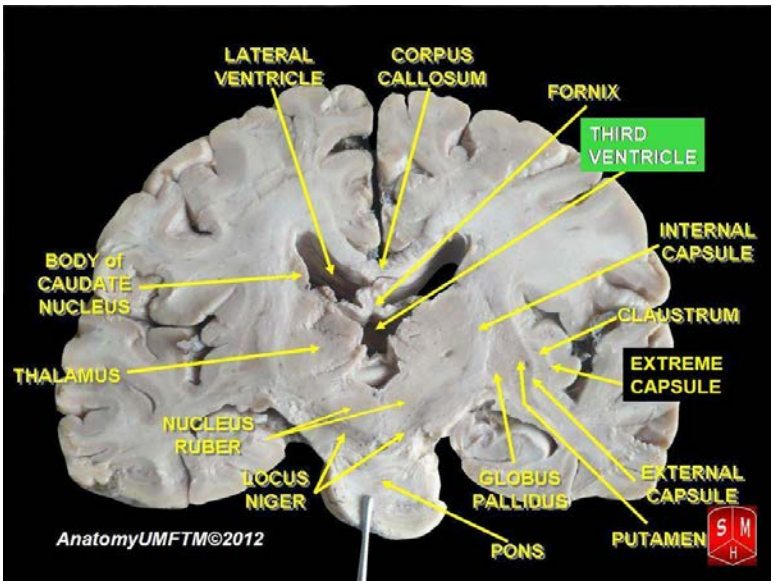


Other Options:

Option B: Reward-punishment is associated with the prefrontal area and the dopaminergic connections linked to it from the ventral tegmental area.

Option C: Judgement is controlled by the frontal lobe.

Option D: Memory is controlled by the hippocampus.



Solution to Question 21:

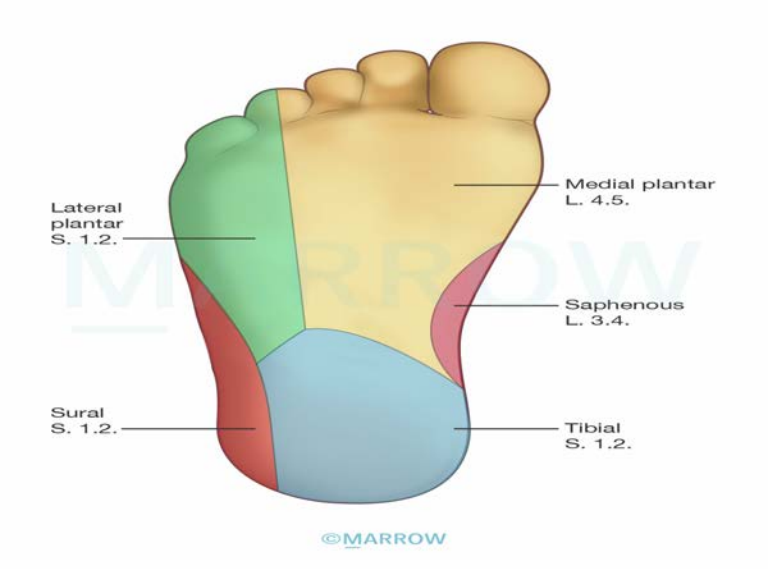
From the given list, the muscles supplied by the lateral plantar nerve are the flexor digitorum accesorius and the first interossei.

The sole of the foot is supplied by the medial and lateral plantar nerves which are both branches of the tibial nerve.

All the muscles of the sole of the foot are supplied by the lateral plantar nerve, except for the following four muscles which are supplied by the medial plantar nerve:

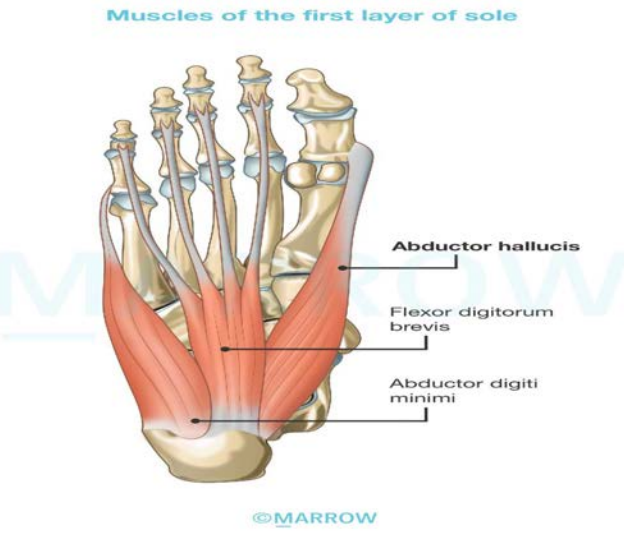
- Abductor hallucis
- Flexor digitorum brevis
- Flexor hallucis brevis
- First lumbrical

The sensory supply of the sole of the foot is as shown in the illustration below.

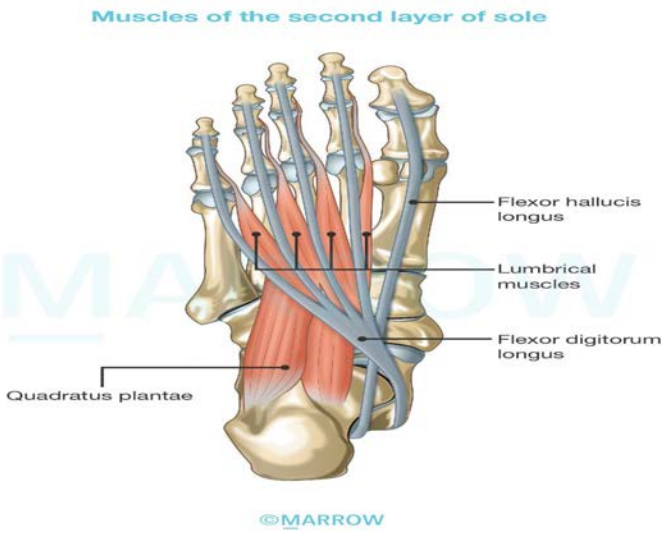


The muscles of the sole of the foot are arranged in 4 layers as shown below:

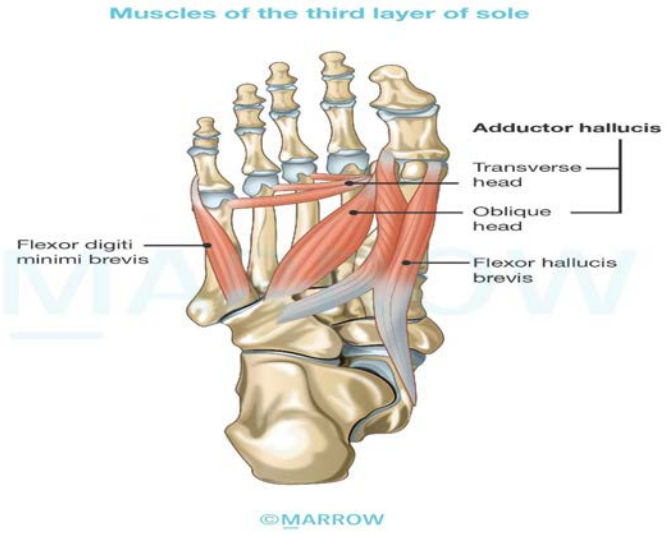
1st layer: It consists of the abductor hallucis, flexor digitorum brevis and abductor digiti minimi.



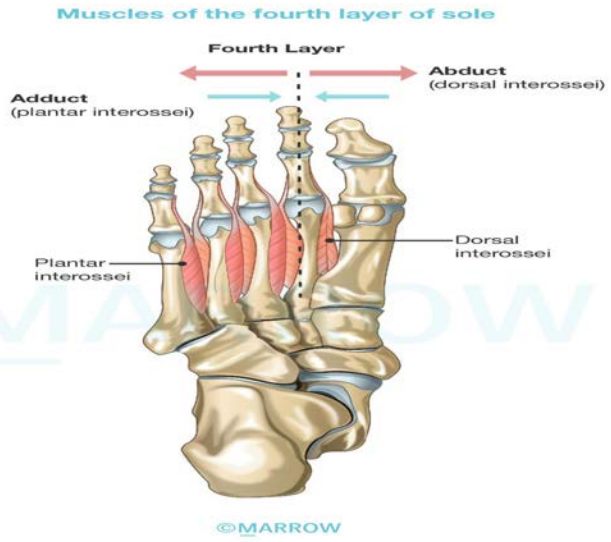
2nd layer: It consists of flexor accessorius and the four lumbrical muscles,the tendons of flexor hallucis longus and flexor digitorum longus run in the same plane as the muscles of the second layer.



3rd layer: It consists of the shorter intrinsic muscles of the toes, which are flexor hallucis brevis, adductor hallucis and flexor digiti minimi brevis.



4th layer: It consists of plantar and dorsal interossei and the tendons of tibialis posterior and fibularis longus.



Solution to Question 22:

The marked structure in the given coronal section of the brain is the fornix. The fornix carries associations from the hippocampus to the anterior nucleus of the thalamus via the mamillary bodies.

The Papez circuit is a part of the limbic system concerned with the control of emotional behaviour and memory.

It consists of the following structures, which can be remembered using the given mnemonic:

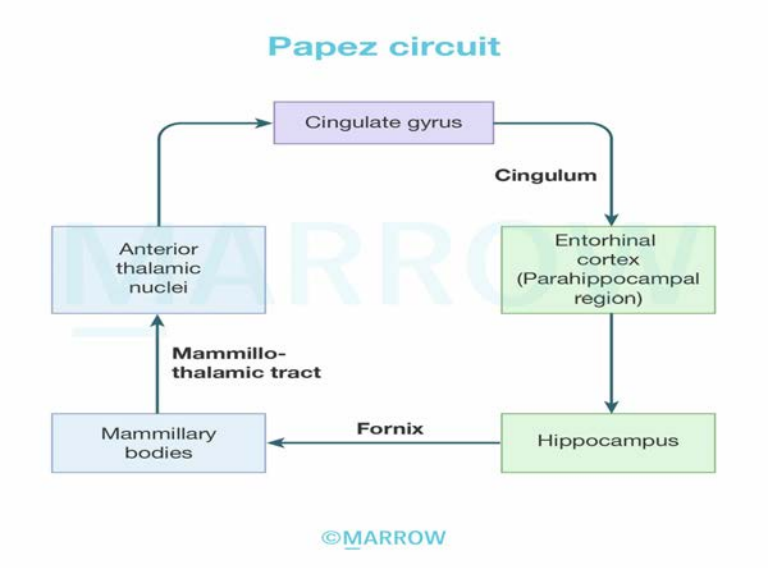
• Hippocampus (He)

• Mamillary body (Man)

• Anterior thalamus (Ate)

• Cingulate gyrus (Cat)

(Mnemonic-He Man Ate Cat)



Solution to Question 23:

The clinical scenario suggests that the patient has visual agnosia and the likely site of involvement would be the inferior temporal lobe.

• Agnosia refers to the inability to visually identify objects and is also called optic aphasia. According to De Jong, visual agnosia is further classified into:

• Apperceptive visual agnosia - the visual image appears distorted to the patient and hence they are unable to recognise it. This occurs due lesions in the parieto-occipital region

• Associative visual agnosia - inability to visually identify objects in the absence of visual impairment, with ability to identify the object using other sensory modalities (as suggested in the scenario). This occurs due to lesions of occipito-temporal junction, which is present in the inferior temporal lobe. Prosopagnosia is a type of associatetive visual agnosia which refers to the inability to visually identify faces.

The occipital lobe acts as the primary visual area and a lesion in this region would result in cortical blindness and achromatopsia, which is the inability to visualise colour. In the given scenario, as the patient is also able to identify colour, it indicates that the occipital lobe (Option A) is unaffected and (hence inferior temporal lobe is the better answer).

Stereognosis is the ability to identify an object by a perception of the form and nature of an object without looking at it. In the given scenario, the patient is able to recognize the object from its texture and pattern which indicates that stereognosis is intact. Loss of this ability is known as astereognosis which occurs in lesions of the superior parietal lobule (Options B and C) and dorsal column pathways.

Solution to Question 24:

Apocrine glands are present in the axilla.

Exocrine glands can be classified into three subtypes, based on the manner in which their secretions are poured out of the cells:

• Apocrine

• Merocrine

• Holocrine

In apocrine glands, the apical parts of the cells are shed off to discharge the secretion. Examples of apocrine glands are :

• Secretion of milk fat by mammary glands

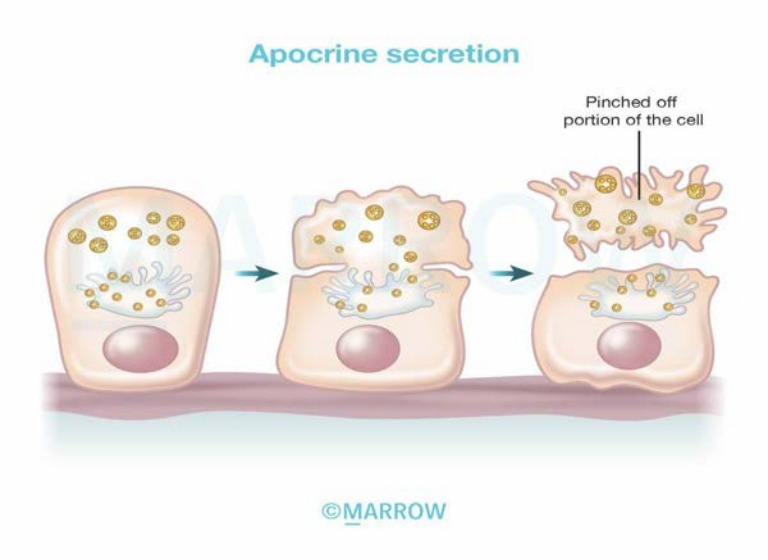
• Atypical sweat glands in the axilla, perianal region, periumbilical skin, mons pubis.

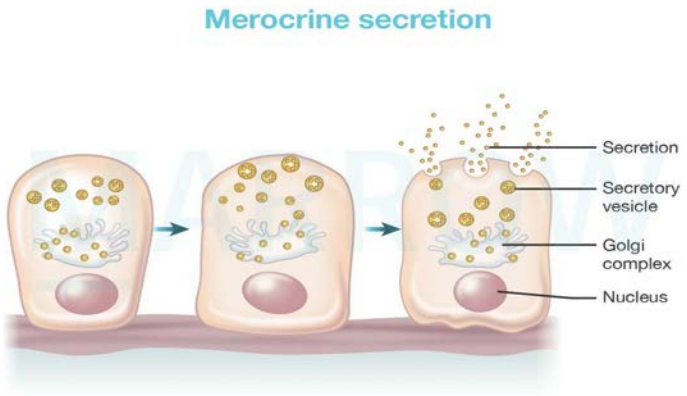
• Ceruminous glands of the external auditory meatus are modified apocrine glands

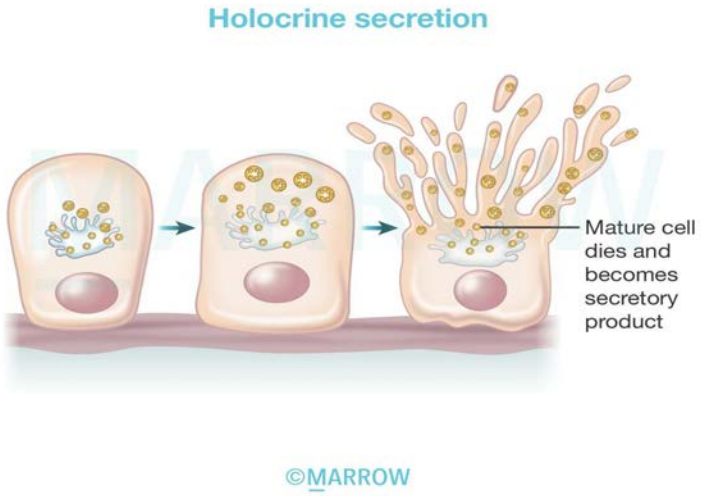
Apocrine glands are large glands found in the dermis or subcutaneous fat. They are a type of sweat gland. It consists of a basal secretory coil followed by a straight duct that opens into the pilary canal above the duct of the sebaceous gland. In hairless skin, it directly opens onto the skin surface.

Apocrine activity is minimal before puberty, after which it is androgen-dependent and responsive to emotional stimuli. It is controlled by adrenergic nerves and is sensitive to adrenaline and noradrenaline. The secretion is initially sterile and odorless, but it undergoes bacterial decomposition to generate odorous and musky compounds. Obstruction of apocrine sweat ducts and associated upper hair follicles in the axillae, breast areolae, and pubic region, mainly in women, is thought to cause Fox–Fordyce disease. It is also implicated in the causation of a painful, occasionally debilitating condition called hidradenitis suppurativa.

The given image shows an illustration of apocrine secretion.







Solution to Question 25:

The left inferior phrenic vein is a tributary of the inferior vena cava (IVC).

From inferior to superior, the following vessels are direct tributaries of the IVC:

- Common iliac veins (left and right common iliac veins merge to form the IVC)
- Median sacral vein
- Four pairs of lumbar veins
- Right gonadal vein
- Renal veins (both left and right)
- Right supra-renal vein

• Hepatic veins

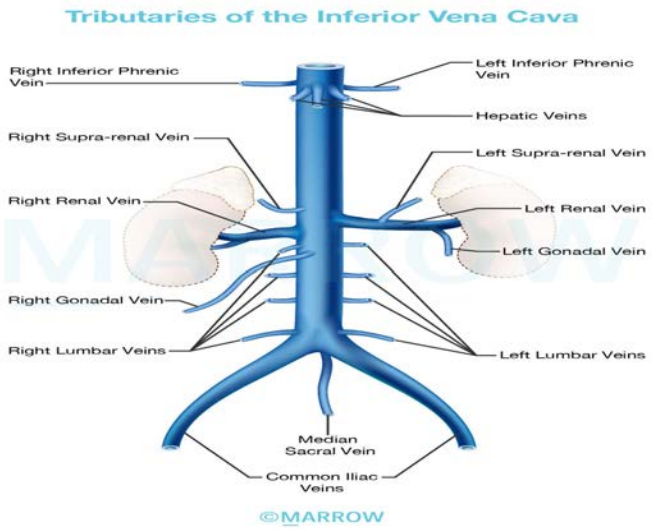
• Inferior phrenic veins (both left and right)

Other Options:

Option B: The left supra-renal vein drains into the left renal vein.

Option C: The left gonadal vein drains into the left renal vein.

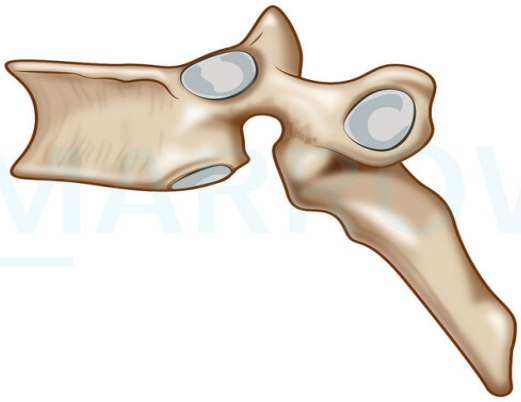
Option D: The right ascending lumbar vein joins the subcostal vein on the right side to form the azygos vein. The left ascending lumbar vein joins the subcostal vein on the left side to form the hemi-azygos vein.



Anatomy INI-CET 2024

Question 1:

Which of the following joints is not formed by the structure shown in the picture?



a) Synchondrosis

b) Syndesmosis

c) Symphysis

d) Plane synovial joint

Question 2:

The spinal sensory nucleus of the trigeminal nerve has 2nd order neurons to carry which sensation?

a) Proprioception

b) Two point discrimination

c) Pain

d) Vibration

Question 3:

Which of the following is not seen in the floor of the inferior horn of the lateral ventricle?

a) Fimbria

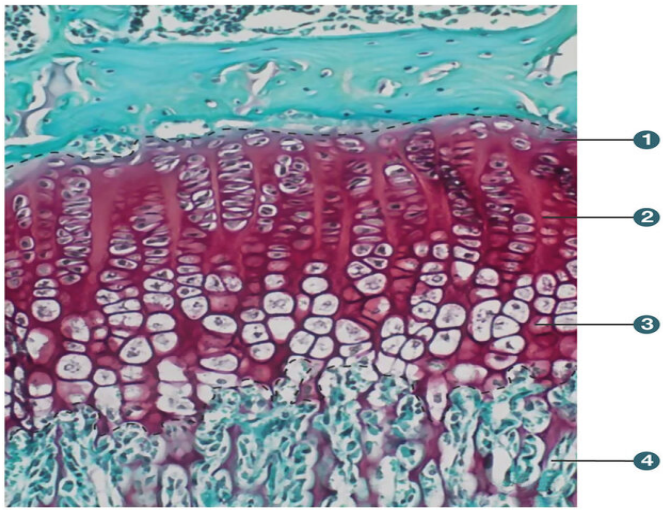
b) Collateral eminence

c) Hippocampus

d) Tail of caudate nucleus

Question 4:

Which of the following marked areas in the histopathological specimen shows calcification?



a) 1

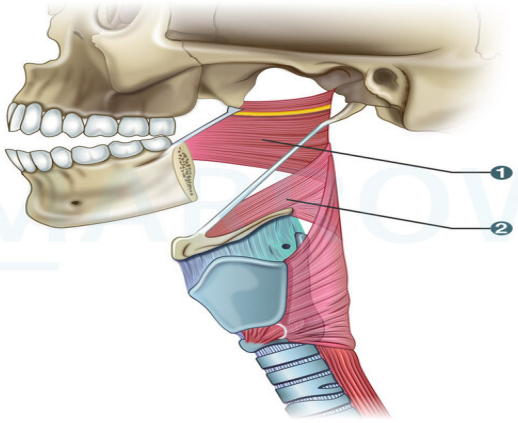
b) 2

c) 3

d) 4

Question 5:

What are the structures passing between the muscles marked as 1 and 2?



©MARROW

a) Recurrent laryngeal nerve and inferior thyroid vessels

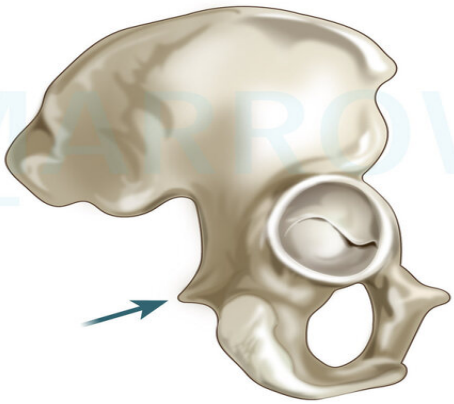
b) Internal laryngeal nerve and superior laryngeal artery

c) Auditory tube and levator palitini

d) Glossopharyngeal nerve and stylopharyngeus muscle

Question 6:

At what vertebral level does the part marked in the image lie in a normal anatomical position?



©MARROW

a) S3 spine

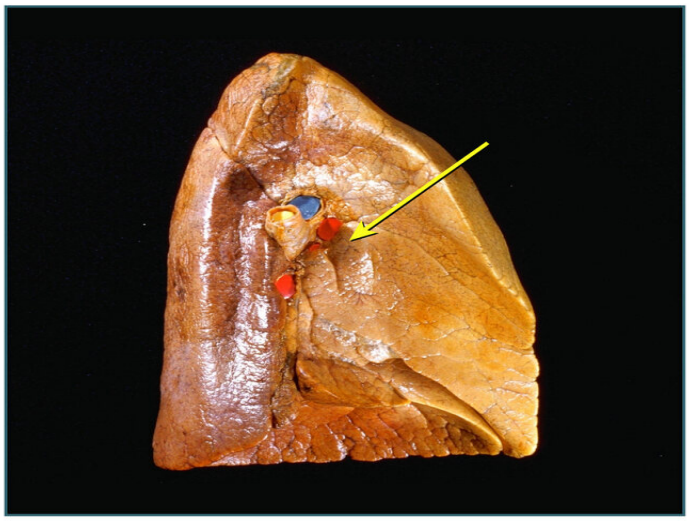
b) Upper border of L5

c) Tip of coccyx

d) Disc space between L4 and L5

Question 7:

The nerve related to the area marked in the picture has its root value from?



a) Ventral horn of C4

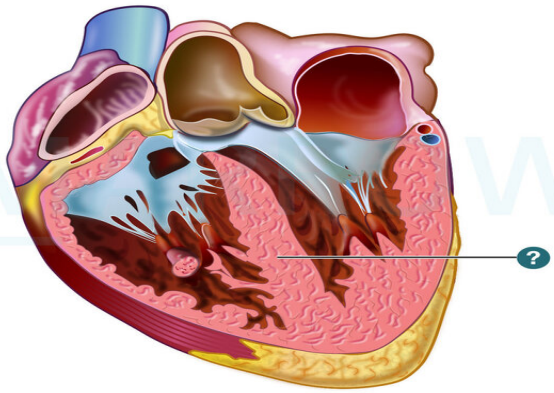
b) Intermediate Horn of T2-T6

c) Open part of Medulla Oblongata

d) Dorsal root ganglia of T1 and T2

Question 8:

The area marked by the arrow is supplied by which of the following arteries?



©MARROW

a) Diagonal artery

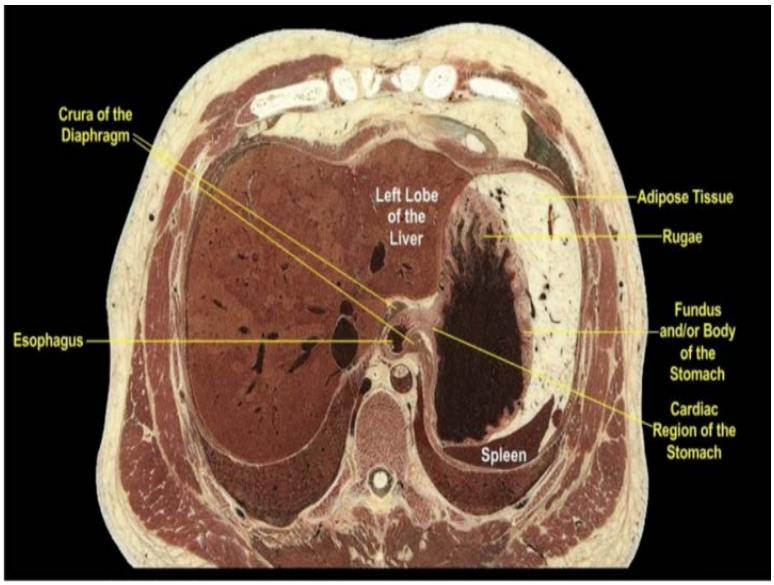
b) Right Marginal artery

c) Anterior interventricular artery

d) Left circumflex artery

Question 9:

What level of the vertebral column does the given cross-sectional image correspond to?



a) T12

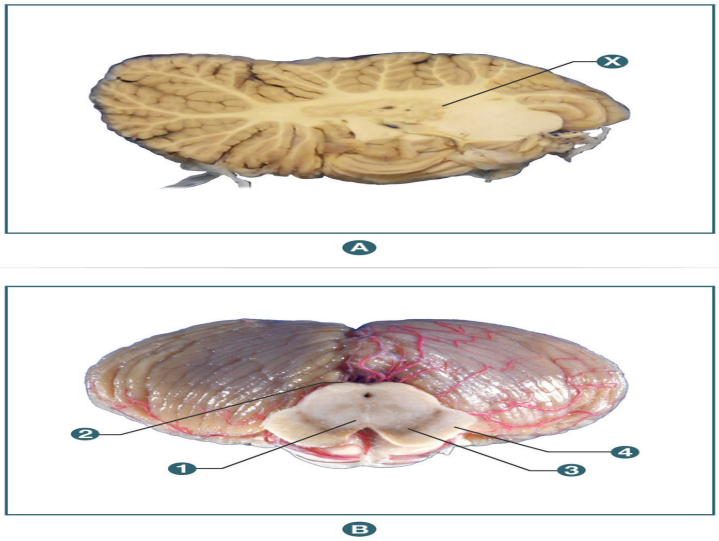
b) T9

c) T10

d) T11

Question 10:

The structure marked as 'X' in image A has a direct connection with which of the following structures marked in image B?



a) 1

b) 2

c) 3

d) 4

Question 11:

Which of the following statements is true concerning the anatomy of the breast?

a) Inner quadrants contain most breast tissue

b) Ligaments of cooper are found only in lower quadrants

c) Tail of Spence extends across anterior axillary fold

d) Breast is made of 10 lobes

Question 12:

A professor underwent a left parotidectomy. Post surgery she complains of left lower lip paralysis. Which structure is involved?

a) Facial nerve - Main trunk

b) Facial nerve- Cervical branch

c) Facial nerve-Temporal branch

d) Parotid duct

Question 13:

Identify the normal anatomical variation given in the following CT image.

a) Tracheal diverticulum

b) Esophageal duplication

c) Aberrant right subclavian artery

d) Right aortic arch

Question 14:

Identify the marked structure

a) Superficial temporal artery

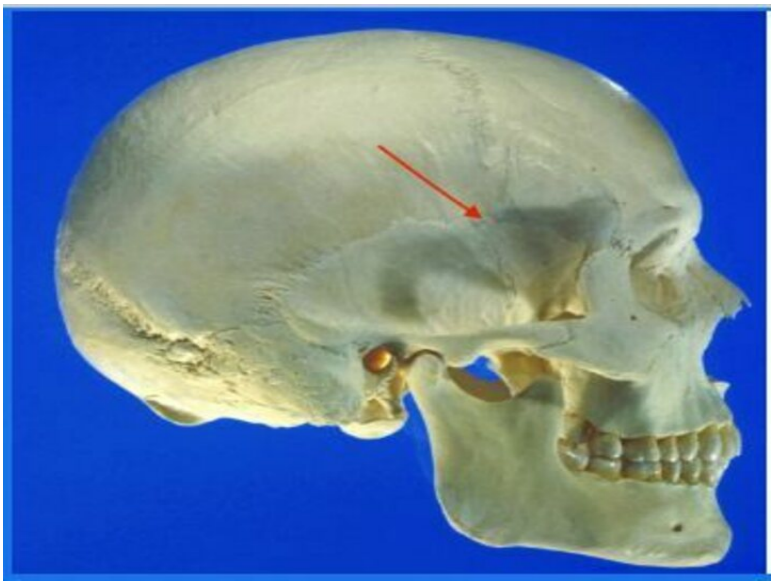
b) Posterior auricular artery

c) Middle meningeal artery

d) Occipital artery

Question 15:

The marked structure serves as a surface landmark for which anatomical structure?



a) Pineal gland

b) Wenicke's area

c) Stem of the lateral sulcus

d) Internal carotid artery siphon

Question 16:

A 60-year-old male recovering from facial nerve palsy complains of food getting stuck between the cheek and teeth while eating. What is the muscle affected in this case?

a) Buccinator

b) Levator labii superioris

c) Zygomaticus major

d) Orbicularis oris

Question 17:

Which of the following is not a derivative of neural crest cells?

a) Ciliary muscles

b) Retinal pigment epithelium

c) Ciliary ganglion

d) Melanocytes

Question 18:

The cranial component of the neural crest cells leads to the formation of?

a) SA node

b) AV cushion

c) Conotruncal septum

d) Chordae tendinae

Question 19:

A 15-year-old boy underwent splenectomy for immune thrombocytopenic purpura. During the procedure, the surgeon noticed bleeding while separating the spleen from the stomach. Which vessels are most likely implicated in this bleeding?

a) Left gastric vessels

b) Short gastric vessels

c) Right gastro-epiploic vessels

d) Splenic vessels

Question 20:

Identify the marked structure

a) Primitive streak

b) Notochord

c) Neural groove

d) Secondary neural plate

Question 21:

Which of the following is the first to be formed by the migration of the epiblast along the primitive streak?

a) Endoderm

b) Cardiac mesoderm

c) Epidermis

d) Neural groove

Question 22:

During walking, the hip bone on the side of the suspended leg is raised by the action of which muscle present in the supporting leg?

a) Gluteus Medius

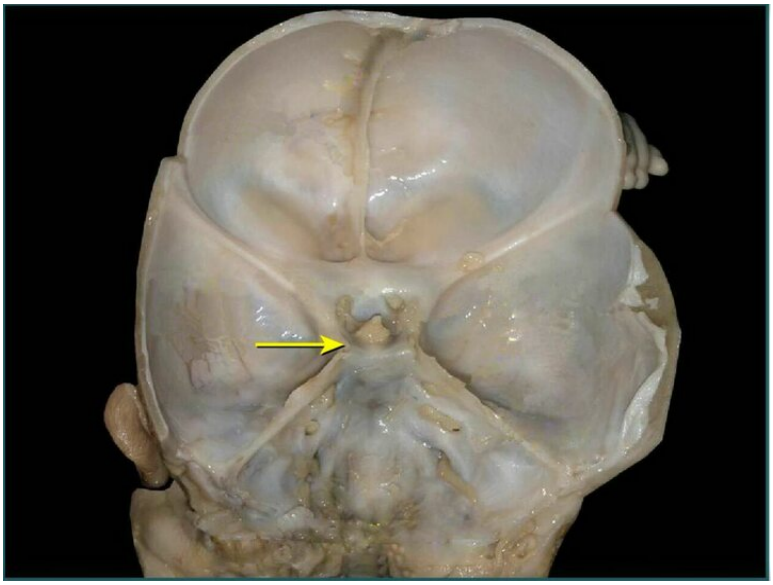
b) Gluteus Maximus

c) Obdurator Internus

d) Quadratus Femoris

Question 23:

Identify the marked structure?



a) Oculomotor nerve

b) Abducens nerve

c) Trochlear nerve

d) Ophthalmic division

Question 24:

Injury to the posterior interosseous nerve leads to?

a) Loss of extension of digits

b) Loss of extension of the wrist

c) Loss of supination

d) Wrist drop

Answer Key

Detailed Explanations

Solution to Question 1:

The provided image depicts a thoracic vertebra, which does not participate in forming a synchondrosis-type joint. The example for a synchondrosis is the costochondral joint formed between the ribs and the costal cartilage.

A vertebral bone participates in the following joints :

• Intervertebral joint - secondary cartilaginous joint (symphysis type)

• Costovertebral joint - plane synovial joint

• costotransverse joint - plane synovial joint

• Facet joints or zygapophysial joints - synovial joint

A syndesmosis is a type of complex fibrous joint between two bones connected by ligaments and a strong membrane[1] with slight movement allowed.The vertebra is connected by a anterior and posterior ligament where some degree of syndesmosis type of joint is seen.

Structurally, joints are classified as fibrous joints, cartilaginous joints, and synovial joints.

Type	Subtypes
Fibrous joints	SuturesSyndesmosisGomphosis
Cartilaginous joints	Primary cartilaginous (synchondrosis)Secondary cartilaginous (symphysis)
Synovial joints	Ball-and-socket or spheroidal jointsSellar or saddle jointsCondylar or bicondylar jointsEllipsoid jointsHinge jointsPivot or trochoid jointsPlane joints

Solution to Question 2:

The trigeminal nerve (cranial nerve V) is responsible for sensory input from the face, as well as motor functions such as chewing. Its sensory pathway involves three branches: the ophthalmic (V1), maxillary (V2), and mandibular (V3) divisions. The first-order neurons for each division originate from different sensory ganglia:

1.Ophthalmic Division (V1):

First-order neurons: Cell bodies are located in the trigeminal ganglion (also called the semilunar or Gasserian ganglion).

2. Maxillary Division (V2):

First-order neurons: Cell bodies are located in the trigeminal ganglion.

3. Mandibular Division (V3):

First-order neurons: Cell bodies are located in the trigeminal ganglion.

These first-order neurons carry sensory information from the face to the brainstem. Upon entering the brainstem, the fibers synapse with second-order neurons in specific nuclei:

1. Principal Sensory Nucleus (Main Sensory Nucleus):
   a. Receives input from all three divisions of the trigeminal nerve.
   b. Located in the pons.
   c. Second-order neurons here carry discriminative touch and proprioceptive information.
2. Spinal Trigeminal Nucleus (Spinal Nucleus of Trigeminal):
   a. Receives input mainly from the maxillary and mandibular divisions.
   b. Located in the medulla.
   c. Second-order neurons here carry pain and temperature sensations.

After synapsing in these nuclei, the sensory information is further relayed to higher brain centers for processing and perception.

Solution to Question 3:

The tail of the caudate nucleus is not seen on the floor of the inferior horn of the lateral ventricle. It is present on the roof of the inferior horn of the lateral ventricle.

The inferior horn is the largest compartment of the lateral ventricle and extends up to 2.5 cm from the temporal pole. The relations are:

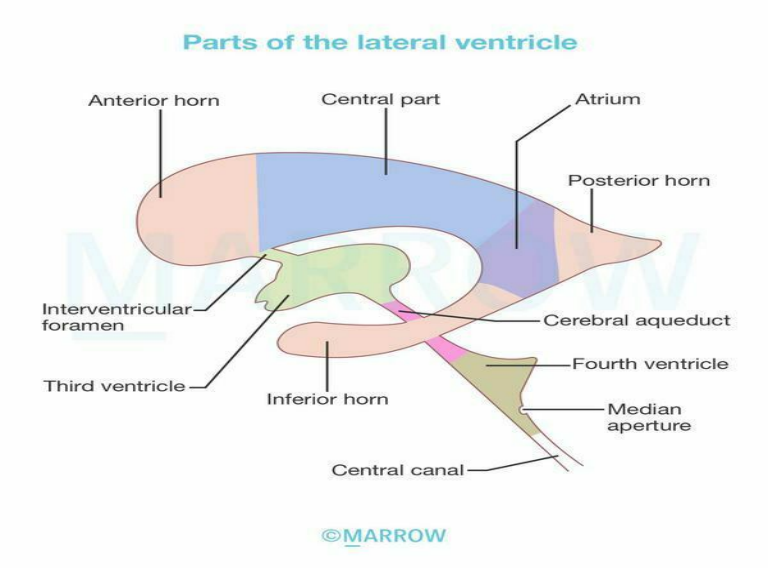
Roof - Tapetum of corpus callosum laterally and tail of caudate nucleus medially.

Floor (lateral to medial) - Collateral eminence produced by collateral fissure, hippocampus.

The floor of the temporal horn consists of the hippocampus medially and the collateral eminence, formed by the infolding of the collateral sulcus, laterally. The inferior part of the choroidal fissure, located between the fimbria of the fornix and the inferolateral aspect of the thalamus, lies in the medial wall.

The lateral ventricle is divided into the body and 3 horns. The locations of the parts are:

- Body - parietal lobe
- Anterior horn - frontal lobe
- Posterior horn - occipital lobe
- Inferior horn - temporal lobe.



The anterior horn extends from the genu of the corpus callosum up to the interventricular foramen. The relations of the anterior horn are:

• Anteriorly - Genu and rostrum of the corpus callosum

• Roof - Anterior part of the body of the corpus callosum

• Floor and lateral wall - Caudate nucleus

• Medial wall - Septum pellucidum and anterior column of fornix

The body or central part extends from the interventricular foramen to the splenium of the corpus callosum. The relations of the body are:

• Roof - Body of the corpus callosum

• Medial wall - Septum pellucidum

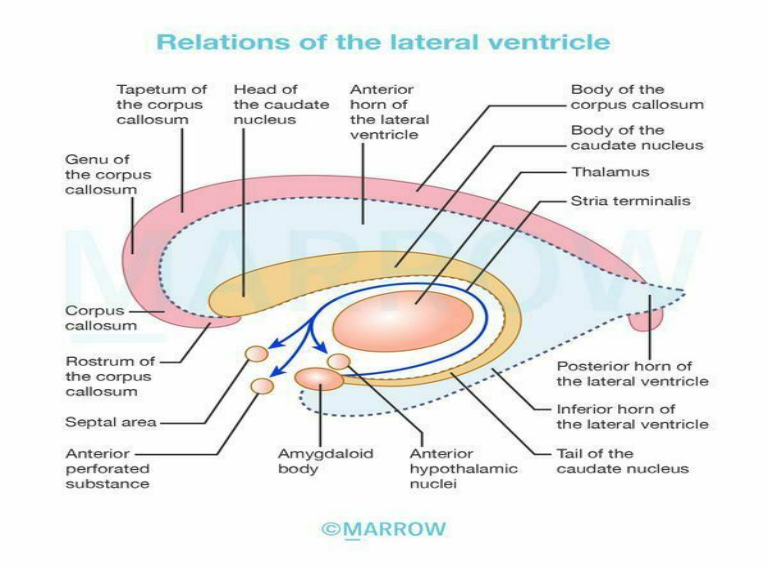
• Floor (from lateral to medial) - Caudate nucleus, stria terminalis, thalamostriate vein, thalamus, choroid plexus, and body of the fornix

The posterior horn extends from the splenium to the occipital pole. The relations are:

• Roof and lateral wall - Tapetum of corpus callosum

• Medial wall - Forceps major and calcar avis (calcarine sulcus

Note: There is no lateral wall for the lateral ventricle.



Solution to Question 4:

The given specimen is that of an epiphyseal cartilage, where zone 3 corresponds to the zone of calcification.

Epiphyseal cartilage is divided into five zones :

• The resting zone consists of hyaline cartilage without morphological changes in the cells (option 1)

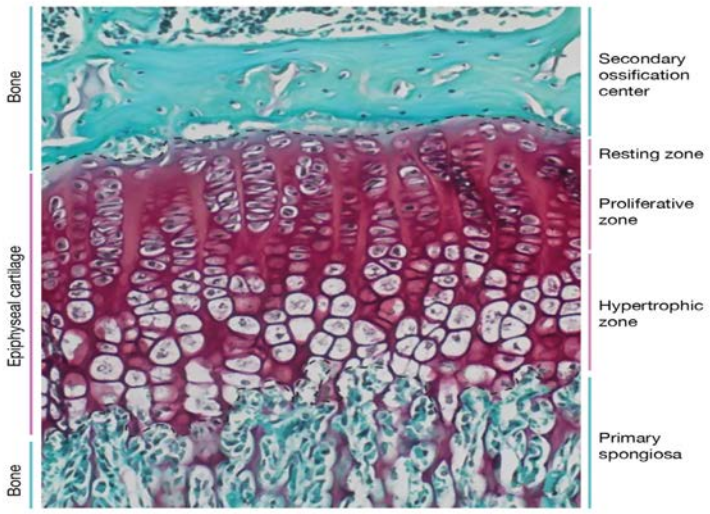
• In the proliferative zone, chondrocytes divide rapidly and form columns of stacked cells parallel to the long axis of the bone (option 2)

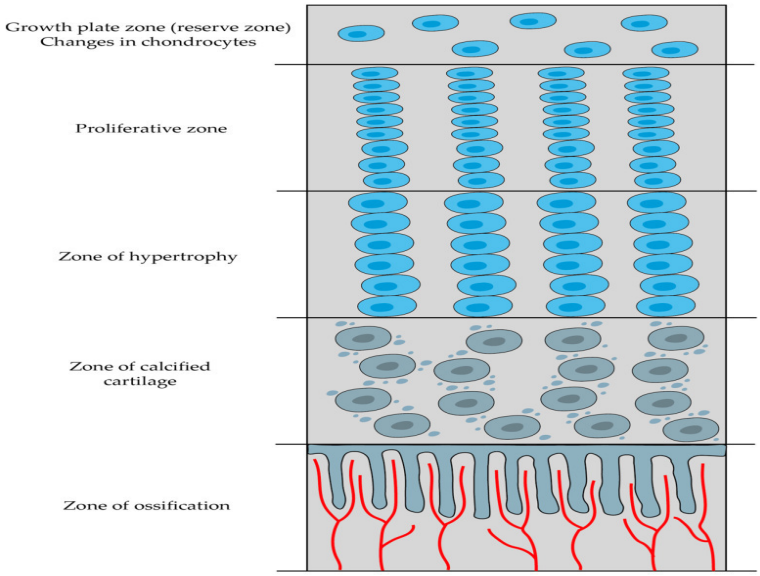
• The hypertrophic cartilage zone contains large chondrocytes whose cytoplasm has accumulated glycogen. The resorbed matrix is reduced to thin septa between the chondrocytes.

• Simultaneous with the death of chondrocytes in the calcified cartilage zone, the thin septa of cartilage matrix become calcified by the deposit of hydroxyapatite.

• In the ossification zone, endochondral bone tissue appears (option 4). Blood capillaries and osteoprogenitor cells formed by mitosis of cells originating from the periosteum invade the cavities left by the chondrocytes. The osteoprogenitor cells form osteoblasts, which are distributed in a discontinuous layer over the septa of the calcified cartilage matrix. Ultimately, the osteoblasts deposit bone matrix over the three-dimensional calcified cartilage matrix.

The epiphyseal cartilage is responsible for the growth in the length of bone and it disappears in adults, which is why bone growth ceases in adulthood.





Solution to Question 5:

The structures passing in between the superior constrictor muscle (structure 1) and middle constrictor muscle (structure 2) are glossopharyngeal nerve and stylopharyngeus muscle.

The structures passing in between pharyngeal muscles are as follows:

1. Sinus of Morgagni - It is a semilunar space that exists between the upper concave border of the superior constrictor and the skull base. It is closed off by the upper sturdy portion of the pharyngobasilar fascia. Structures passing through this space include:

a. The auditory tube

b. The levator veli palatini muscle (Option C)

c. The ascending palatine artery

d. Palatine branch of the ascending pharyngeal artery.

2. Between the superior and middle constrictors - the stylopharyngeus muscle and the glossopharyngeal nerve.

3. Between the middle and inferior constrictors -the internal laryngeal nerve and the superior laryngeal vessels penetrate the thyrohyoid membrane (Option B).

4. Between the lower border of the inferior constrictor and the esophagus - The recurrent laryngeal nerve and the inferior laryngeal vessels.

Solution to Question 6:

In the right pelvic bone given above the marked structure is the ischial spine which lies approximately at the level of the fifth sacral vertebrae in a normal anatomical position. As the tip of the coccyx is the closest option relating to the spine , it can be the most appropriate answer.

The ischial spine is a bony prominence found on the ischium, one of the three bones that make up the hip bone. The ischial spine forms a part of the plane of least pelvic dimensions or narrow pelvic plane which comprises of :

• lower border of the symphysis pubis

• the tip of ischial spines

• fifth sacral vertebra

The interspinous distance is the distance between the tip of two ischial spines. (Bispinous diameter = 10.5 cm or 4.5")

The important events occurring at the narrowest plane in the pelvis :

• It corresponds roughly to the origin of levator ani muscles.

• The internal rotation of the fetal head occurs during labour at this plane.

• It marks the beginning of the forward curve of the pelvic axis

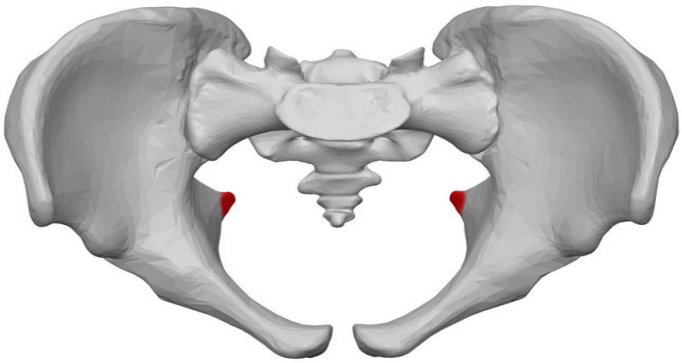
• This level of ischial spines indicates station ‘O’

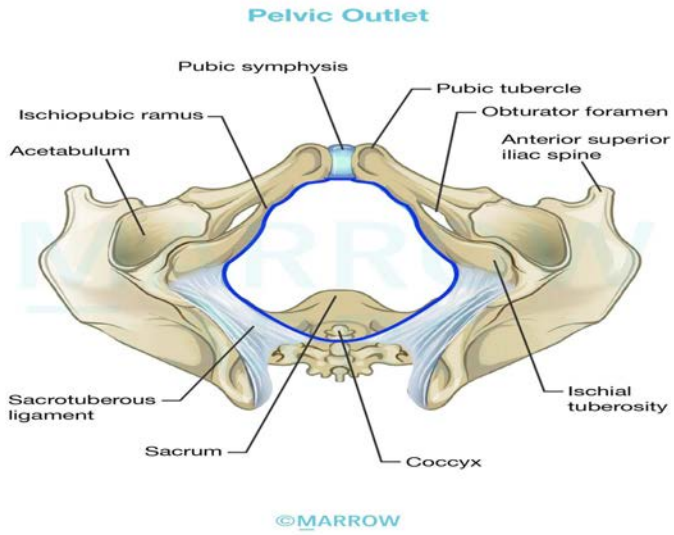
• When the fetal head station is at ‘O’, the head is considered to be engaged.

• Deep transverse arrest occurs at this plane.

• The ischial spine can serve as a landmark in pudendal anaesthesia, as the pudendal nerve lies close to the ischial spine

The image given below highlights the interspinous distance seen through the pelvic inlet.





Solution to Question 7:

The above is an image of the left lung with the arrow pointing at the nerve passing anterior to the left hilum. The phrenic nerve passes in front of the left hilum and has its root value from the ventral horn of C4.

In the given image, the left lung is identified by the vertical sequence of structures at the left hilum - pulmonary artery, principal (hyparterial) bronchus, and inferior pulmonary vein. The image also shows an oblique fissure dividing the lung into superior and inferior lobes.

The phrenic nerve, originating from the cervical nerves C3–C5, is a mixed nerve that carries motor fibres to the diaphragm and sensory fibres from the mediastinal pleura, pericardium, and a portion of the peritoneum.

The course of the left phrenic nerve:

Cervical region - both phrenic nerves pass, Anterior to scalenus anterior muscle

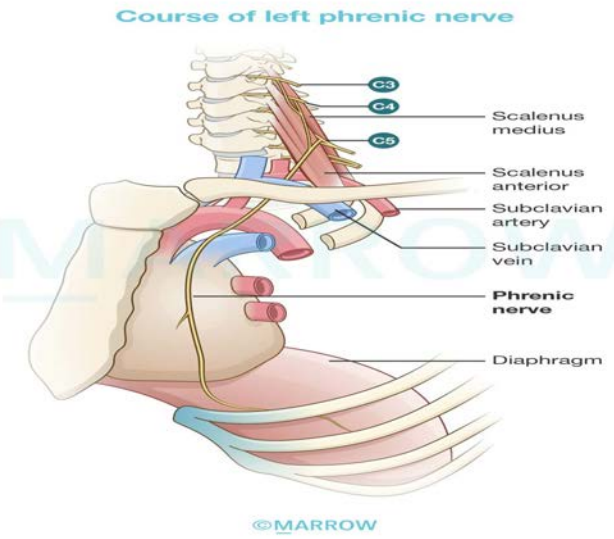
Posterior to sternocleidomastoid and inferior belly of omohyoid

Posterior to internal jugular vein, transverse cervical artery, and suprascapular artery

Posterior to the thoracic duct on the left

Root of the neck - It lies medial to the trunks of the brachial plexus in the neck. At the root of the neck, it runs anterior to the second part of the subclavian artery and posterior to the subclavian vein.

Thorax - The phrenic nerve enters the thorax by crossing medially in front of the internal thoracic artery. Within the thorax, the phrenic nerve descends anterior to the pulmonary hilum between the fibrous pericardium and mediastinal pleura, accompanied by the pericardiacophrenic vessels.



Solution to Question 8:

The marked structure represents the interventricular septum, which is supplied by the anterior interventricular artery.

Blood Supply to the ventricular septum is as follows :

• Septal branch from posterior interventricular artery - Posterior one-third of the ventricular septum

• Septal branch from anterior interventricular artery - Anterior two-thirds of ventricular septum

Blood Supply of Heart :

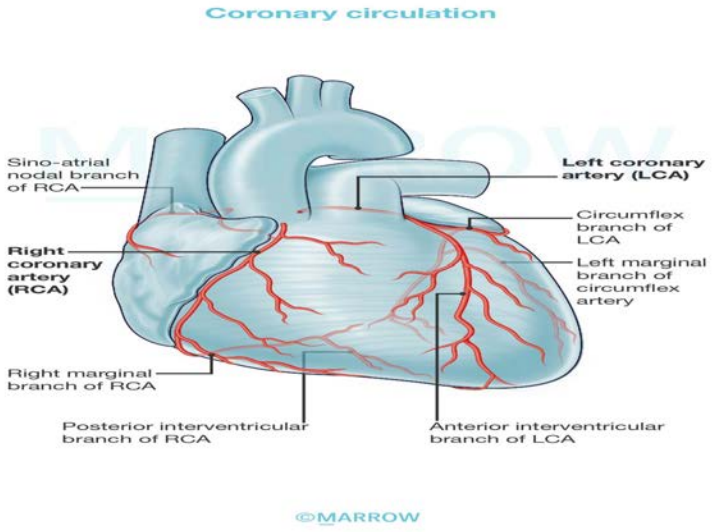
Other options :

Option A - Diagonal artery supplies the left ventricle.

Option B - Right marginal artery supplies the right ventricle and the apex of the heart.

Option D - Left circumflex artery supplies the left atrium and the left ventricle.

	Right coronary artery	Left coronary artery
Origin	Anterior aortic sinus of ascending aorta, diameter less than left coronary artery	Left posterior aortic sinus of ascending aorta. (Right posterior aortic sinus – noncoronary sinus)
Branches	Right conus artery (third coronary artery)Right anterior ventricular artery – supplies sternocostal surface of right ventricle.Atrial rami – supplies right atrium.Posterior interventricular artery – supplies diaphragmatic surface of right and left ventricle.Right posterior atrial and ventricular rami	Anterior interventricular arteryAnterior ventricular ramiCircumflex arterySA nodal branch arise from this in 35% of subjectsSingle Left marginal (obtuse)arteryAtrial branch
Areas of distribution	The whole of right atriumMost of the right ventricle except a strip along the anterior interventricular groovePart left ventricle adjoining posterior interventricular groove	Most of the left atriumMost of the left ventricle except area adjoining the posterior interventricular grooveA small part of right ventricle along anterior interventricular groove



Solution to Question 9:

The above cross-sectional picture is denoted to be T10 because ,

At the level of the T10 vertebra, we observe:

• The esophagus enters the abdomen through the diaphragm (at the level of T10), connecting shortly afterward to the stomach at the cardiac orifice. In this image, the esophagus is positioned slightly left to the midline and is surrounded by the crura of the diaphragm.

• Adipose tissue around the stomach representing greater omentum

• Nearby structures include the spleen posteriorly, and the right and anterior left lobes of the liver.

• The inferior vena cava (IVC), slightly right of midline, is mostly surrounded by the liver.

• The descending aorta, azygos vein, and thoracic duct are within the thorax.

• A small portion of the left and right lung are still visible.

• Small cross-sectional area of the sternum and the costal cartilages of the 7th ribs. The 7th ribs are the last true ribs with costal cartilages articulating with the sternum

• Predominance of thoracic and upper limb musculature.

• Diaphragm encircling the abdominal cavity, still positioned deep to the thoracic wall.

Solution to Question 10:

Image A shows a section of the cerebellum and image B shows a section of the midbrain. The structure labeled as 'X' represents the dentate nucleus of the cerebellum, which has a direct connection with the structure marked as '1', which is the red nucleus.

The dentate nucleus is the largest of the cerebellar nuclei. It has the shape of a crumpled bag with the opening facing medially. The interior of the bag is filled with white matter made up of efferent fibers that leave the nucleus through the opening to form a large part of the superior cerebellar peduncle.

The efferent pathways from the dentate nucleus connect to the thalamus and the red nucleus, via the dentato- rubro -thalamic pathway.

Other structures in the image B :

2 - Represents superior colliculus, which receives afferents from the retina and the occipital cortex.

3 - Represents substantia nigra, which receives afferents mainly from the caudate nucleus

4 - Represents the crus cerebri, which contains fibers from the cerebral cortex.

Solution to Question 11:

The tail of Spence extends across the anterior axillary fold and is a small extension of the upper lateral quadrant of the breast.

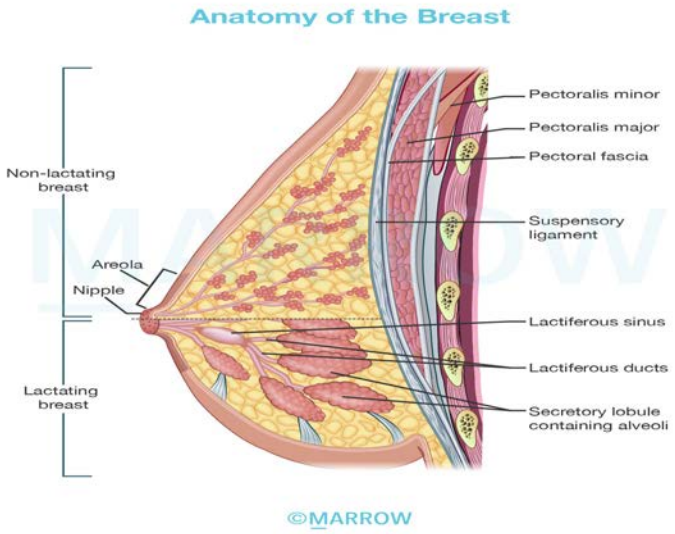
The breast lies in the superficial fascia of the pectoral region. It is divided into four quadrants, i.e. upper medial, upper lateral, lower medial and lower lateral.

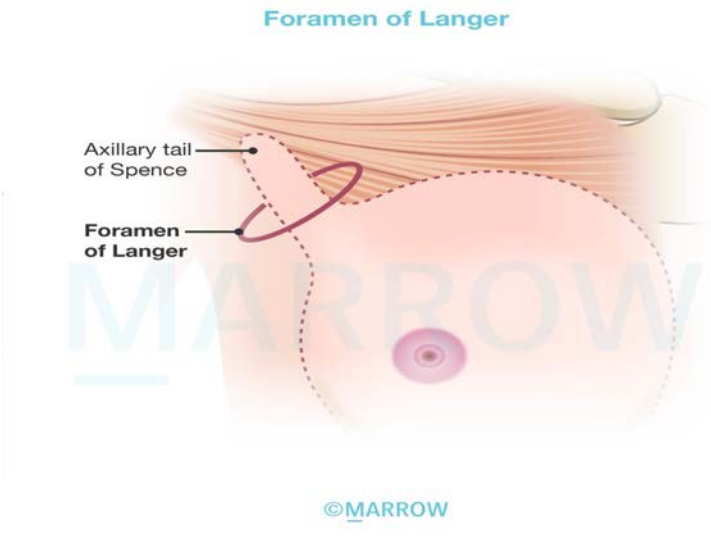
Vertically, it extends from the second to the sixth ribs. Horizontally, it extends from the lateral border of the sternum to the midaxillary line. A small extension of the upper lateral quadrant, called the axillary tail of Spence, passes through an opening in the deep fascia and lies in the axilla. The opening is called the foramen of Langer.

The breast lies on the deep pectoral fascia covering the pectoralis major and serratus anterior superiorly, the external abdominal oblique and its aponeurosis inferiorly, and the clavipectoral fascia laterally. Fibrous strands or sheets consisting of condensations of connective tissue extend between the posterior lamina of the superficial fascia and the dermis. These suspensory ligaments (retinacula or Cooper's ligaments) are often well-developed in the superior parts of the breast and support the breast tissue, helping to minimize drooping.

The breasts normally comprise up to 20 discrete lobes that contain ductal-glandular tissue consisting of branching ducts and terminal secretory lobules in a connective tissue stroma. Each lobe is derived by branching from one central lactiferous duct in the nipple. The terminal duct lobular unit (TDLU or lobule) is the functional milk secretory component of the breast.

The upper outer quadrant of the breast contains a greater volume of tissue than the other quadrants. This is the reason for the majority of the carcinomas arising in the upper outer quadrant.





Solution to Question 12:

Lower lip paralysis is caused by damage to the cervical branch of the facial nerve.

The cervical branch of the facial nerve is responsible for innervating the platysma muscle, which is one of the muscles involved in the movements of the lower lip. Damage to this nerve can potentially lead to paralysis of the lower lip.

The facial nerve is the motor nerve of the face. Its five terminal branches emerge from the parotid gland and diverge to supply the various facial muscles as follows :

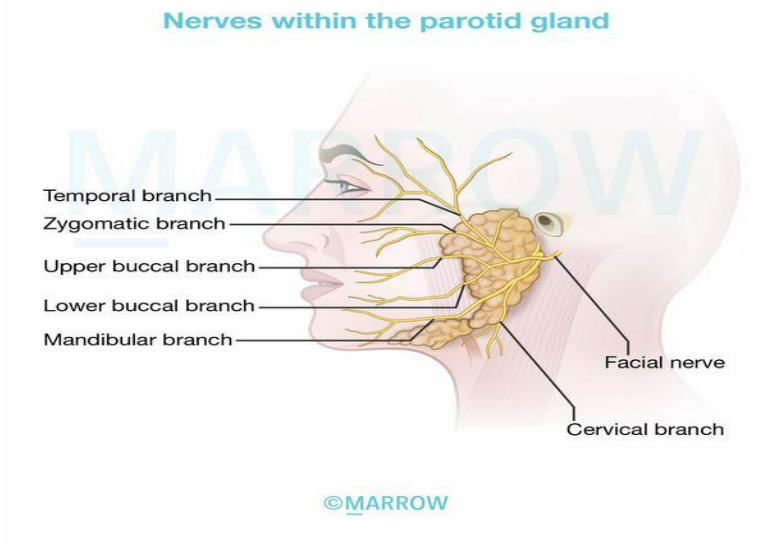
• Temporal — frontalis, auricular muscles, orbicularis oculi

• Zygomatic — orbicularis oculi (lower eyelid part)

• Buccal — muscles of the cheek and upper lip

• Marginal mandibular — muscles of the lower lip

• Cervical — platysma



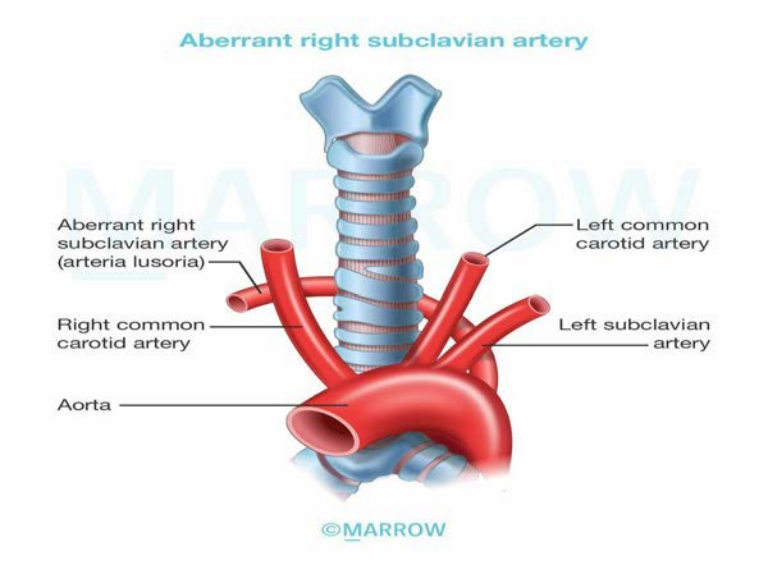
Solution to Question 13:

The CT finding in the image is suggestive of an aberrant right subclavian artery.

An aberrant right subclavian artery occurs when the right fourth aortic arch and right dorsal aorta involute cranial to the seventh intersegmental artery.

This artery arises distal to the left subclavian artery and crosses the midline posterior to the esophagus. Because of the absence of a normal right subclavian-carotid junction to pull down the right recurrent laryngeal nerve (RLN) during embryologic development, the right RLN follows a straight path from the vagus to the larynx and is called a non-recurrent right laryngeal nerve.

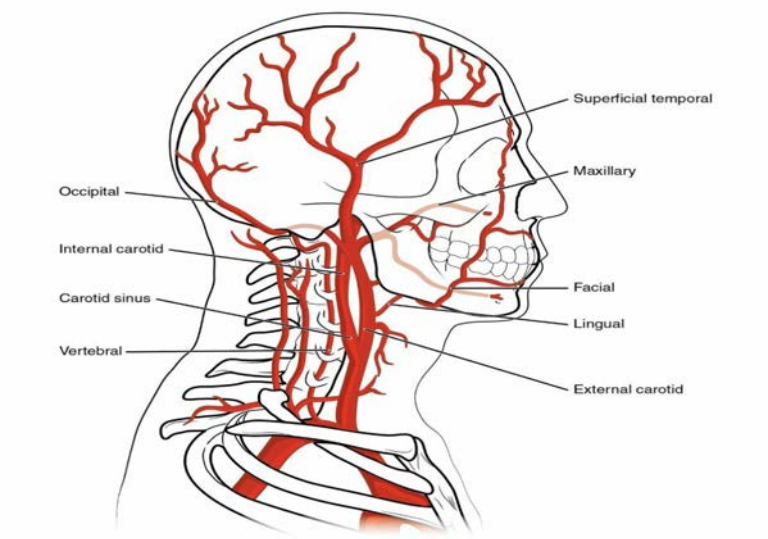
Most patients with this anomaly are asymptomatic, and the aberrant subclavian artery is of no clinical consequence. Dysphagia caused by compression of the esophagus by an abnormal subclavian artery is called dysphagia lusoria.



Solution to Question 14:

The marked structure is superficial temporal artery.

The superficial temporal artery is one of the terminal branches of the external carotid artery, along with the maxillary artery. It ascends in front of the ear, passing over the zygomatic arch and travels superficially, supplying the scalp and areas around the temple.



Other Options:

Option B: The posterior auricular artery is smaller and located posterior to the ear.

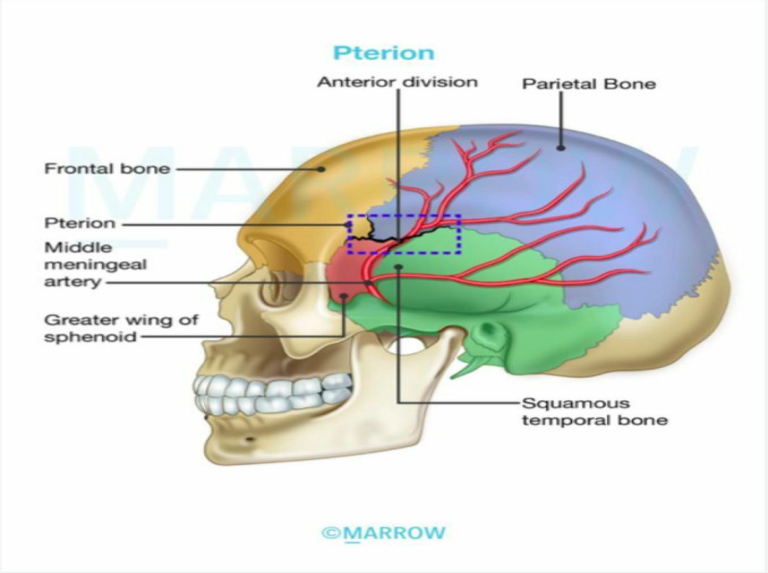
Option C: The middle meningeal artery is deep within the cranial cavity and supplies the meninges.

Option D: The occipital artery lies posteriorly and supplies the scalp at the back of the head.

Solution to Question 15:

The marked structure indicates the pterion and it serves as a landmark for the stem of the lateral sulcus.

The frontal, parietal, temporal, and sphenoid bones meet at the pterion. It is a landmark for the stem of the lateral sulcus (Sylvian fissure), the most prominent sulcus of the cerebral hemisphere. It separates the frontal lobe from the temporal lobe. Deep to the lateral sulcus lies the insular cortex.



Pterion marks as a surface landmark for the following structures:

• Middle meningeal artery and vein: fractures in this area can rupture the middle meningeal artery, leading to an epidural hematoma.

• Broca's area: Located in the dominant hemisphere (usually left) in the inferior frontal gyrus, it lies in proximity to the pterion

• The insular cortex and parts of the basal ganglia, such as the putamen, are located deep to the pterion, beneath the lateral sulcus.

• Stem of the lateral sulcus, also called the Sylvian fissure. It houses the middle cerebral artery and its branches, playing a crucial role in brain vascularization and cortical organization.

During surgeries, the pterion is a common site for trephining (making a hole in the skull).

Other Options:

Option A: The pineal gland is located in the posterior aspect of the cranial fossa in the brain. It is located deep in the brain, near the midline.

Option B: Wenicke's area is in the superior temporal gyrus in the dominant cerebral hemisphere. It is found in the posterior part of the superior temporal gyrus.

Option D: The internal carotid artery siphon is a part of the internal carotid artery's course. Characterized by its S-shaped curvature as it traverses the cavernous sinus and enters the cranial cavity. This configuration helps dissipate pulsatile energy, reducing stress on cerebral vessels, and allows adaptability to cranial movements while maintaining cerebral perfusion.

Solution to Question 16:

This patient, recovering from facial nerve palsy, getting food stuck between the cheek and teeth while eating, is because of the buccinator being affected.

The buccinator is a muscle of facial expression. It is innervated by the facial nerve. It is known as the whistling muscle.

The buccinator muscle is primarily responsible for keeping food between the teeth during mastication by pressing the cheek against the teeth (involved in flattening the cheeks against the gums and teeth).

In facial nerve palsy, paralysis of the buccinator muscle can lead to food accumulating in the cheek pouch, as the muscle is unable to contract properly.

Other options:

Option B: Levator Labii Superioris: This muscle elevates the upper lip and contributes to facial expressions like showing the upper teeth and dilates the nostrils. It is not involved in keeping food in place during chewing.

Option C : Zygomaticus Major: Responsible for pulling the corner of the mouth upward and outward, contributing to smiling. It does not influence food placement during mastication.

Option D : Orbicularis Oris: Encircles the mouth and helps in closing the lips. While it is involved in mastication and speech, its paralysis would not cause food to accumulate in the cheek.

Solution to Question 17:

Retinal pigment epithelium is not a derivative of neural crest cells.

Retinal pigment epithelium (RPE) is derived from the neuroectoderm. The RPE develops from the outer layer of the optic cup, a structure that arises from the neural tube (neuroectodermal origin), not from neural crest cells.

Neural crest cells are a group of cells that migrate during embryonic development and give rise to various structures, including parts of the nervous system, face, and heart.

Neural crest cells (NCC) are present adjacent to the neural tube and are sometimes referred to as the fourth germ layer. It contributes to the formation of many organs and tissues:

In the trunk region, they form:

• Melanocytes (Option D)

• Sensory ganglia

• Sympathetic and enteric neurons

• Schwann cells

• Adrenal medulla cells

In the cranial region, they contribute to the:

• Craniofacial skeleton

• Neurons for cranial ganglia-Ciliary ganglion (Option C)

• Ciliary muscles (Option A)

• Satellite glial cells

• Melanocytes

Some of the other neural crest derivatives are:

• C cells of the thyroid gland

• Conotruncal septum in the heart

• Odontoblasts

• Smooth muscle cells to blood vessels to the face and forebrain.

Solution to Question 18:

The cranial component of neural crest cells (NCC) leads to the formation of Conotruncal septum.

The conotruncal septum is also known as the aortopulmonary septum. The formation of the aortopulmonary septum in the truncus arteriosus divides the outflow channel of the heart into the ventral aorta and the pulmonary trunk. Persistent truncus arteriosus results when the conotruncal ridges fail to form.

The development of the heart begins in the third week of embryogenesis with the formation of the cardiogenic mesoderm. The heart tube forms through fusion of paired endocardial tubes, which then undergo looping and septation to establish the four chambers. By the end of the eighth week, the heart achieves its definitive structure, with separate atria, ventricles, and major vessels.

The heart develops from mesodermal origins, with different parts deriving from specific embryonic structures:

• First Heart Field (Primary Heart Field): Forms the left ventricle and part of the atria.

• Second Heart Field: Contributes to the right ventricle, outflow tract (conus arteriosus and truncus arteriosus), and part of the atria.

• Neural Crest Cells: Contribute to the septation of the outflow tract and the formation of the aorticopulmonary septum.

• Proepicardium (Epicardial Cells): Forms the epicardium and contributes to coronary vessels.

• Sinus Venosus: Forms part of the right atrium (sinus venarum) and the coronary sinus.

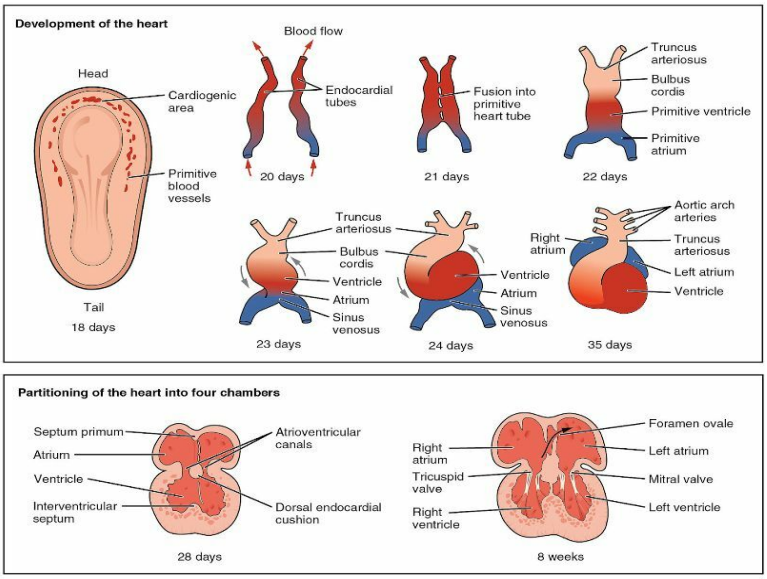
• Endocardial Cushions: Form the atrioventricular valves and contribute to septation.

Other options:

Option A: SA node is derived from the primary heart field - sinus venosus.

Option B: AV cushions are derived from adjacent endocardial cells. The endocardial cells along with the epicardium and mesenchyme, form the AV cushions.

Option D: Chordae tendineae are formed from mesenchymal tissue within the heart.

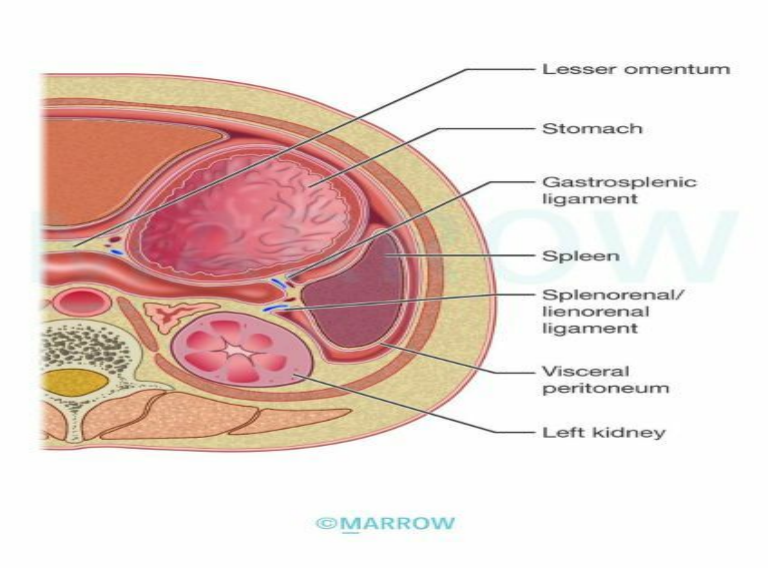


Solution to Question 19:

This patient, undergoing splenectomy, while separating the spleen from the stomach, is likely bleeding from the short gastric vessels.

In an open splenectomy, the gastrosplenic ligament is opened and short gastric vessels are ligated and divided.

The spleen is attached to the stomach through the gastrosplenic ligament. The gastrosplenic ligament attaches the greater curvature of stomach to the upper pole of the spleen.



Contents of the gastrosplenic ligament include:

• Short gastric vessels

• Left gastroepiploic vessels

Hence, while separating the spleen from the stomach, there are maximum chances of bleeding if there is injury to the short gastric vessels.

Other Options:

Option A: Left gastric vessels: Left gastric vessels run along the lesser curvature of the stomach. It is unlikely to be the source of bleeding in this case.

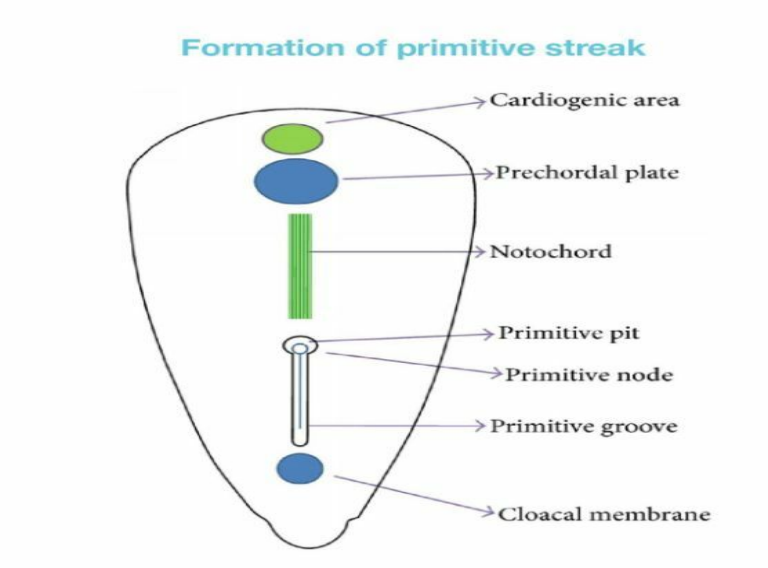
Option C: Right gastro-epiploic vessels: The right gastroepiploic vessels run along the pylorus and inferior region of the greater curvature of the stomach. It is not a part of the gastrosplenic ligament.

Option D: Splenic vessels: The splenic artery and vein run along the superior border of the pancreas. They are not directly involved in the separation of the spleen from the stomach.

Solution to Question 20:

The marked structure is the primitive streak.

The primitive streak appears in the early stages of gastrulation, a process that reorganizes the epiblast into three germ layers: ectoderm, mesoderm, and endoderm. It appears as a linear thickening on the dorsal surface of the epiblast in the bilaminar embryonic disc. It is found in the caudal (tail-end) region of the developing embryo.



Functions of the primitive streak:

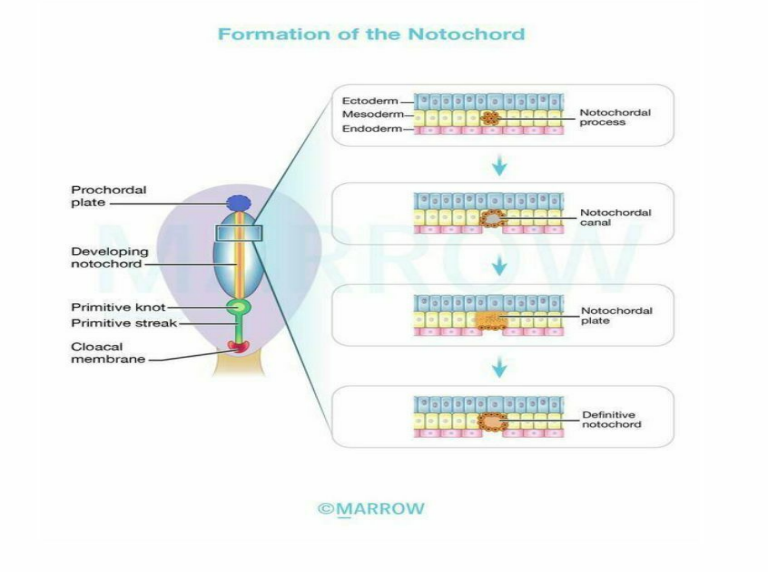
• Serves as the site where cells migrate inward to form the mesoderm and endoderm.

• Marks the beginning of gastrulation.

• Defines the body axis (head-to-tail, left-to-right).

Other Options:

Option B: Notochord: A rod-like structure derived from mesoderm that forms after the primitive streak and is crucial for the development of the neural tube. Located cranially relative to the primitive streak.



Option C: Neural Groove: A depression in the ectoderm that forms during neurulation, leading to the development of the neural tube. It appears after the primitive streak.

Option D: Secondary Neural Plate: Part of the neural plate involved in the later stages of neural tube development. It is not directly related to the primitive streak.

Solution to Question 21:

Endoderm is the first to be formed by the migration of the epiblast along the primitive streak.

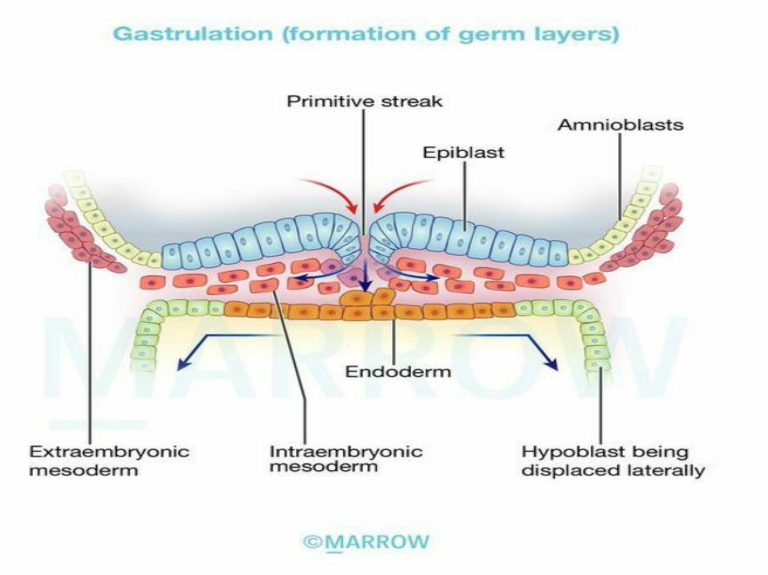
Gastrulation is when the single-layered blastula reorganizes into a multi-layered structure called the gastrula. This process establishes the three primary germ layers that give rise to all tissues and organs of the body. During gastrulation, epiblast cells migrate through the primitive streak to form the three germ layers: endoderm, mesoderm, and ectoderm.

Cells from the epiblast migrate inward (invagination) through the primitive streak.

The first group of migrating epiblast cells replaces the hypoblast to form the definitive endoderm. The endoderm gives rise to structures like the gastrointestinal tract, liver, and lungs.

Subsequent migrating cells spread between the epiblast and the newly formed endoderm to create the mesoderm, which forms structures like muscles, bones, and the cardiovascular system.

Remaining epiblast cells that do not migrate through the primitive streak form the ectoderm, which gives rise to the epidermis and the nervous system.



Other Options:

Option B: Cardiac Mesoderm: The mesoderm forms after the endoderm and differentiates later into subtypes, including the cardiac mesoderm.

Option C: Epidermis: The epidermis arises from the ectoderm, which forms after both the endoderm and mesoderm.

Option D: Neural Groove: The neural groove is part of the ectoderm and forms during neurulation, which occurs much later than the formation of the endoderm.

Solution to Question 22:

Gluteus Medius of the supporting leg is responsible for raising the hip bone on the side of the suspended leg.

Actions of Gluteus Medius:

- Hip abduction
- Stabilizes the pelvis during gait.
- Assists the internal rotation of the thigh.

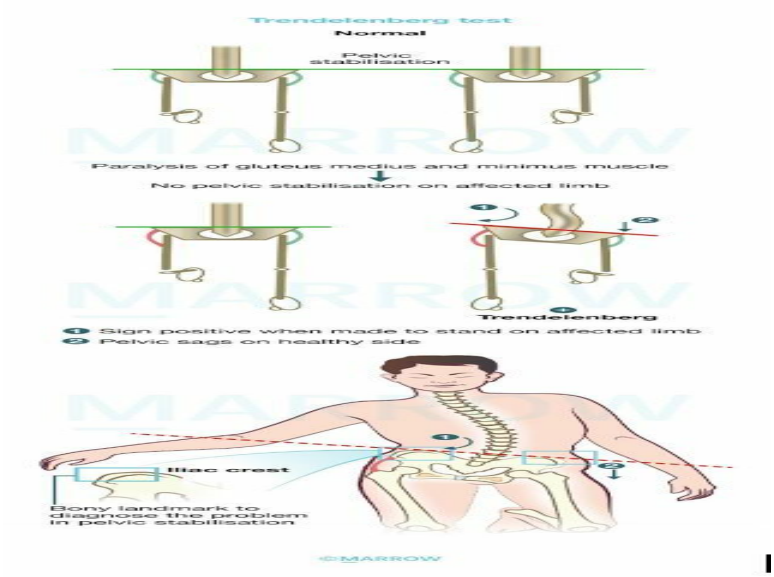
Gluteus medius and gluteus minimus act as the abductors of the hip joint. Stabilizing the pelvis on the femur during walking is done by these muscles. It is demonstrated by asking the subject to stand on one limb.

Trendelenburg Sign:

Trendelenburg sign is a clinical sign used to assess the function of the gluteus medius.

It is positive when the pelvis drops on the opposite side of the stance leg, indicating weakness or dysfunction of the gluteus medius on the supporting leg.

In a healthy individual, the gluteus medius contracts to prevent the pelvis from tilting when one leg is lifted. If the gluteus medius is weak or paralyzed, the pelvis tilts toward the side of the suspended leg.



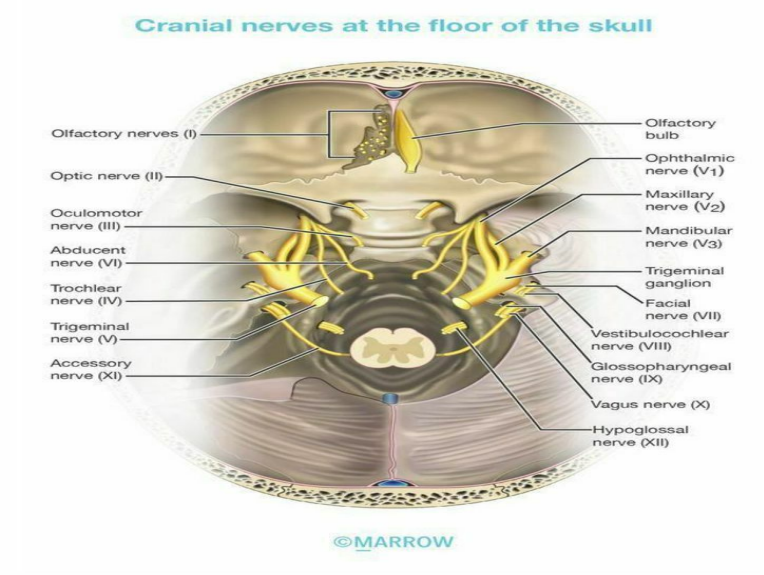
Option B: Gluteus Maximus: Extends and externally rotates the hip; key for climbing stairs and rising from sitting. Weakness causes difficulty in hip extension, affecting activities like standing up or climbing.

Option C: Obturator Internus: Externally rotates and stabilizes the hip joint; abducts the thigh when the hip is flexed. Dysfunction can impair hip rotation, commonly affected in pelvic injuries.

Option D: Quadratus Femoris: Externally rotates and adducts the hip. Injury or entrapment of the nerve to quadratus femoris can cause deep hip pain and weakness in rotation.

Solution to Question 23:

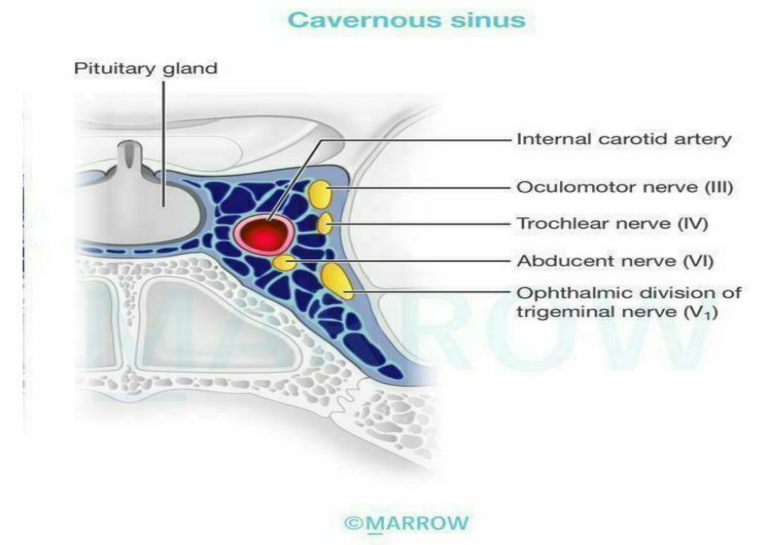
The structure shown in the above image is the oculomotor nerve. The oculomotor nerve (CN III) passes through the superior orbital fissure, which lies within the region of the cavernous sinus.



Option B: The abducens nerve (CN VI) also passes through the cavernous sinus and superior orbital fissure. However, it is located more medially in the sinus and the fissure compared to the oculomotor nerve.

Option C: The trochlear nerve (CN IV) passes through the superior orbital fissure as well, but it is the smallest cranial nerve and follows a higher and more lateral path than the oculomotor nerve.

Option D: The ophthalmic division of the trigeminal nerve enters the lateral wall of the cavernous sinus, below the oculomotor nerve and trochlear nerve.



Solution to Question 24:

Injury to the posterior interosseous nerve leads to loss of extension of digits.

The posterior interosseous nerve (PIN) is a continuation of the deep branch of the radial nerve. It originates from the radial nerve in the cubital fossa, near the lateral epicondyle of the humerus. After passing through the supinator muscle, it transitions into the PIN.

The PIN is purely a motor nerve and supplies the posterior compartment of the forearm.

Clinical correlation based on location of lesion:

Monteggia fracture involves a fracture of the proximal ulna with a dislocation of the radial head. The radial nerve, especially its posterior interosseous branch, is at risk due to its proximity to the fracture site and leads to loss of extension of digits.

Level of lesion	Nerve affected	Cause	Clinical feature
Low	Posterior interosseous nerve and Superficial Cutaneous	Fracture or dislocations of the elbow.- Commonly seen in Monteggia fracture	Cannot extend the MCP joint (digits)(Option A).Weakness in the extension of the thumb. Radial deviation of the wrist.
High	Radial nerve in spiral groove	Humerus fracture.	Wrist drop (Option D)"Saturday night palsy" due to compression of the radial nerveThumb drop, finger drop
Very High	Radial nerve proper	Lesions around the shoulder joint & axilla and crutch palsy	Loss of extension of the wrist and hand.(Option B)Inability to extend elbow

Anatomy NEET 2024

Question 1:

An absent gag reflex can result from injury to which of the following nerves?

a) ■ and ■

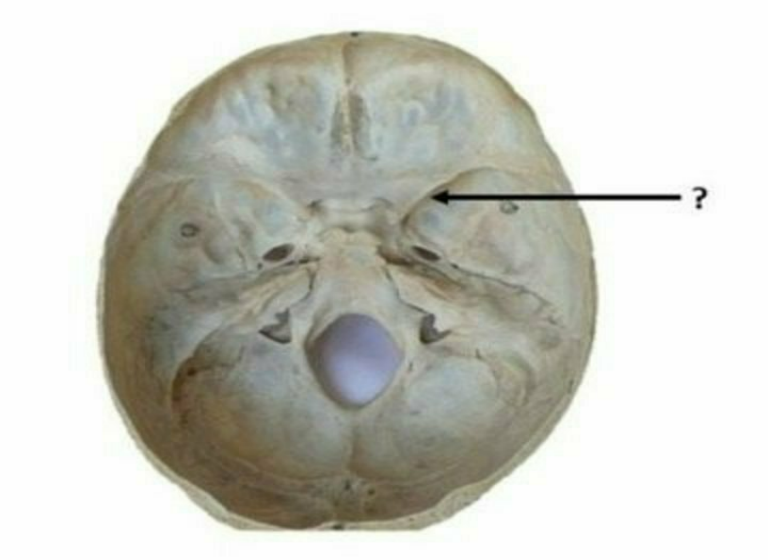
b) ■ and ■

c) ■ and ■

d) ■ and ■

Question 2:

If a tumor compresses the structures passing through the opening marked in the given image, which of the following sensations would be affected?



a) Sensation of the nasopharynx

b) Mucosa of the nasal cavity

c) Sensation in the anterior scalp and dorsum of the nose

d) Sensation of the chin

Question 3:

A chronic tobacco consumer went to the dental clinic with bleeding lesions on his tongue and was diagnosed with carcinoma of the tongue. Which of the following papillae, which do not have taste buds, is least likely to be involved in such a cancer?

a) Circumvallate

b) Filiform

c) Fungiform

d) Foliate

Question 4:

Which artery is used for arteriovenous shunting with the great saphenous vein for hemodialysis, and is located behind the medial malleolus and 2.5 cm in front of the tendocalcaneus?

a) Anterior tibial artery

b) Posterior tibial artery

c) Peroneal artery

d) Circumflex fibular artery

Question 5:

What is the outer covering of the condition shown in the image?

a) Chorion

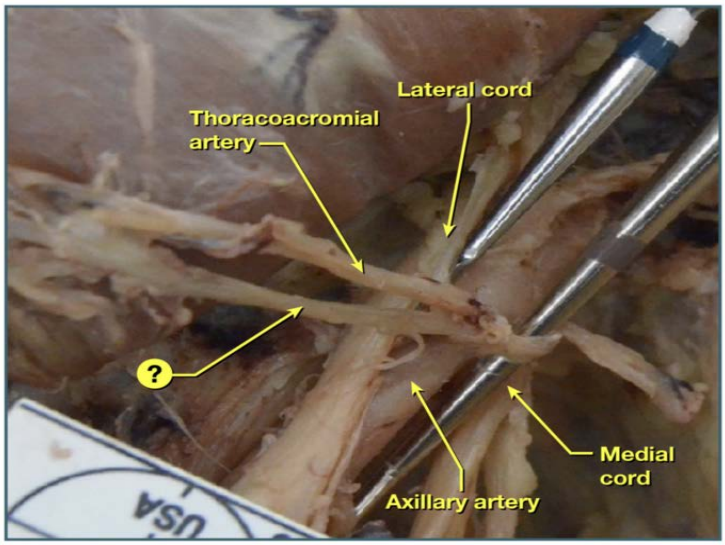
b) Amnion

c) Endoderm

d) Ectoderm

Question 6:

Identify the marked structure.



a) Thoracodorsal nerve

b) Medial pectoral nerve

c) Subscapular nerve

d) Long thoracic nerve

Question 7:

A patient presents with sciatica and tenderness in the hamstring muscles. Which nerve supplies the hybrid muscle that is likely to be spared in this condition?

a) Common peroneal nerve

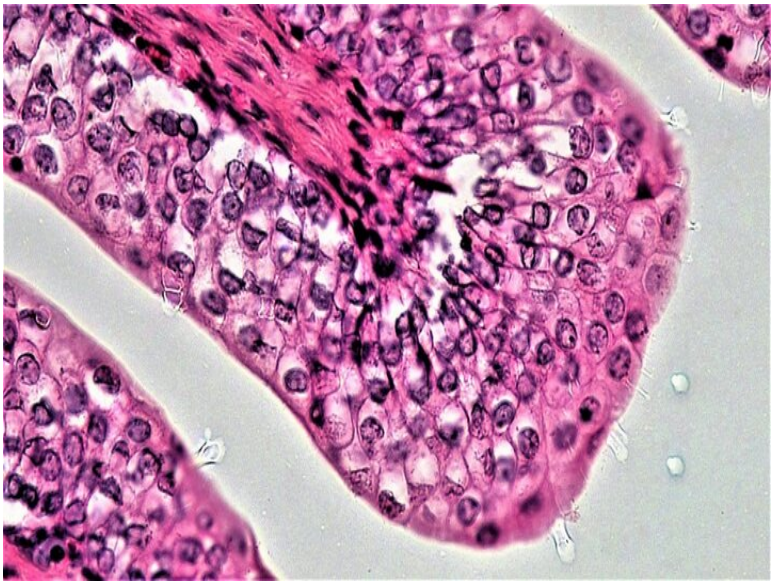
b) Tibial nerve

c) Femoral nerve

d) Obturator nerve

Question 8:

Where will you find the epithelium shown in the image?



a) Gall bladder

b) Trachea

c) Ureter

d) Duodenum

Question 9:

During the examination of a patient, a professor asks the patient to invert his foot and points to a prominent tendon located behind the medial malleolus. Which tendon is being highlighted?

a) Tibialis anterior

b) Extensor digitorum

c) Tibialis posterior

d) Extensor hallucis longus

Question 10:

An elderly woman reports difficulty in buttoning her shirt and increased clumsiness during daily activities. On examination, she is unable to make an 'O' shape by opposing her thumb and index finger. Which of the following muscles is most likely involved?

a) Opponens pollicis

b) Palmar interossei

c) Flexor pollicis brevis

d) Abductor pollicis brevis

Answer Key

Question No.	Correct Option
1	a
2	c
3	b
4	b
5	b
6	b
7	d
8	c
9	c
10	d

Detailed Explanations

Solution to Question 1:

An absent gag reflex can result from injury to the glossopharyngeal nerve (IX) and the vagus nerve (X).

The afferent nerve for the gag reflex is the glossopharyngeal nerve, while the efferent nerve consists of both the glossopharyngeal (to the stylopharyngeus muscle) and vagus. Both these nerves pass through the jugular foramen and damage to them may be the cause for loss of gag reflex.

Pharyngeal branches of the glossopharyngeal nerve and vagus nerve form the pharyngeal plexus of nerves. These plexes mainly supply the pharynx. It also has contributions from the superior cervical ganglion.

Nerve supply by the pharyngeal branch of the vagus nerve are:

• All the muscles of the soft palate(except tensor veli palatini - supplied by mandibular division of the trigeminal nerve)

• All the muscles of the pharynx(except the stylopharyngeus - supplied by the glossopharyngeal nerve).

The glossopharyngeal nerve is rarely damaged alone. Lesions will result in loss of sensation of the posterior third of the tongue, reduced gag reflex, loss of sensation over the ipsilateral soft palate, etc. Motor fibres to the stylopharyngeus and parasympathetic secretomotor fibres to the parotid gland are also supplied by the glossopharyngeal nerve. Sensory supply includes uvula, posterior one-third of the tongue, tympanic cavity etc.

The main functions of IX and X can be tested together by assessing swallowing, phonation/articulation and sensation from the pharynx/larynx.

Glossopharyngeal and vagus nerve examinations include:

• Observing the position and symmetry of the palate and uvula at rest and with phonation (“aah”).

• By assessing the strength of the cough

Solution to Question 2:

The marked foramen is the superior orbital fissure. If a tumour compresses the structures passing through this foramen, it would impair sensation in the anterior scalp and dorsum of the nose, as this would affect the frontal nerve and nasociliary nerve.

The superior orbital fissure is an important anatomical opening in the skull that allows several critical structures to pass through. Among these structures, the frontal nerve and nasociliary nerve are branches of the ophthalmic nerve, the first division of the trigeminal nerve (CN V1), which is responsible for sensory innervation to parts of the face.

The frontal nerve provides sensation to the forehead, the anterior scalp, and the dorsum of the nose, while the nasociliary nerve supplies sensation to parts of the nasal cavity. Therefore, if a tumour or lesion compresses the structures passing through the superior orbital fissure, it would likely affect the sensation in the anterior scalp and dorsum of the nose because these areas are innervated by the branches of the trigeminal nerve that pass through this fissure.

Other options:

Option A: Sensation of the nasopharynx is innervated by other branches of the trigeminal and glossopharyngeal nerve, not by structures passing through the superior orbital fissure.

Option B: While some sensation from the nasal cavity comes from the trigeminal nerve, the specific branches affected by a lesion in the superior orbital fissure are more focused on the anterior areas of the face.

Option D: Sensation of the chin is primarily innervated by the mandibular branch (CN V3) of the trigeminal nerve, which passes through the foramen ovale, not the superior orbital fissure.

Solution to Question 3:

Among the different types of papillae on the tongue, the one that does not have taste buds is the filiform papillae.

Filiform papillae are minute cylindrical or conical projections that are mainly present on the dorsal part of the anterior 2/3rd of the tongue. The filiform papillae do not contain taste buds. They are covered by keratinized stratified squamous epithelium.

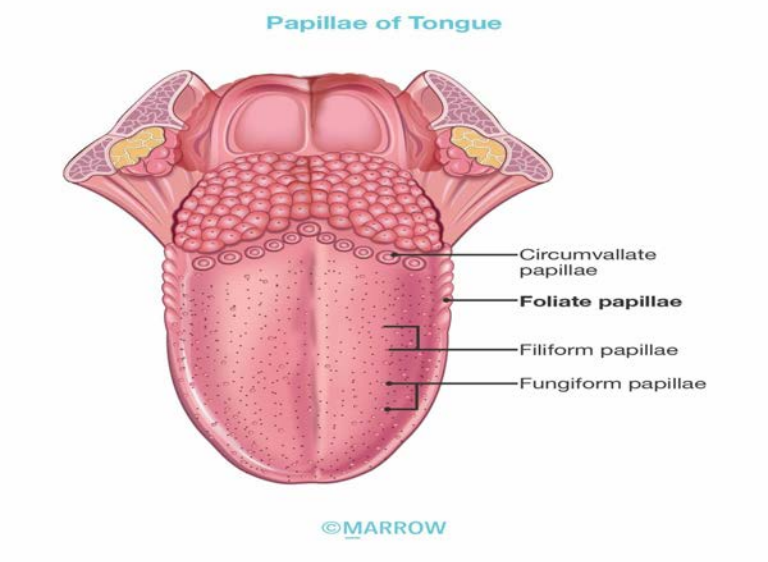
Other papillae of the tongue are:

Circumvallate papillae are 8-12 in number which are large cylindrical structures. They form a V-shaped row just in front of the sulcus terminalis. Usually, the entire papillae are covered by non-keratinized stratified squamous epithelium. Taste buds are present in the lateral wall of these papillae which surrounds the papillae circumferentially.

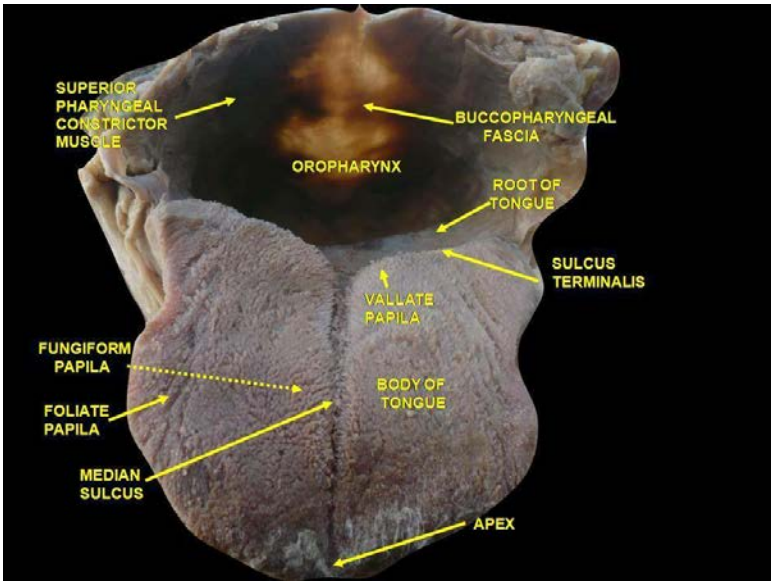
Fungiform papillae are large, rounded, and red and are mainly present on the lingual margins and also on the dorsal surface of the tongue. They are covered by non-keratinized stratified squamous epithelium. They are supplied by the facial nerve.

Foliate papillae are red, leaf-like mucosal ridges that are present bilaterally in two zones at the sides of the tongue near the sulcus terminalis. They are covered by non-keratinized stratified squamous epithelium.

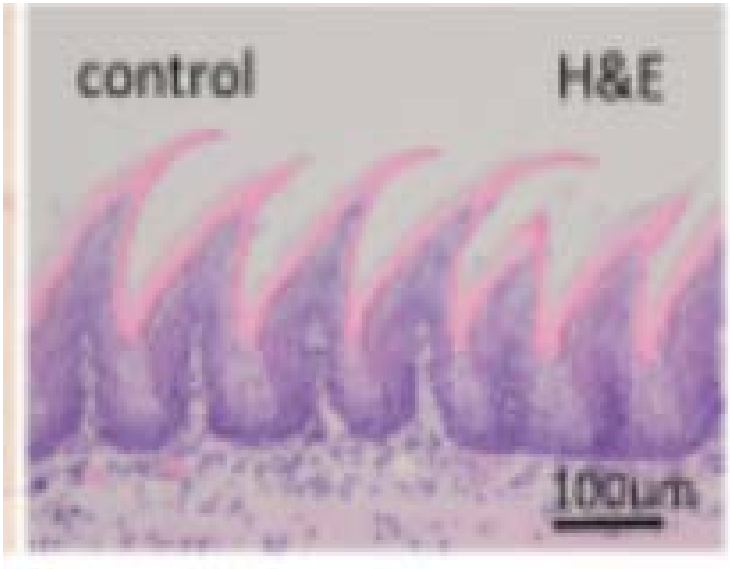
A diagrammatic representation of the various papillae of the tongue is given below:



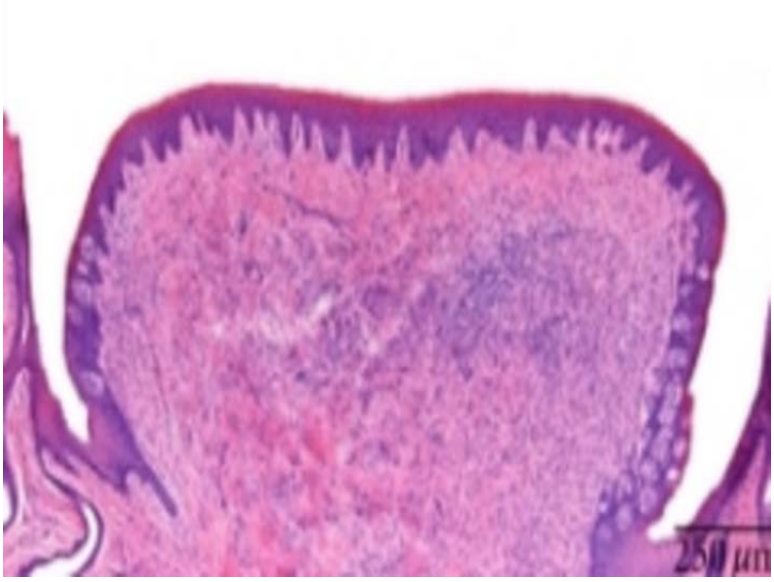
Below is the image showing the various parts of the tongue.



The given image depicts the histology image of filiform papillae:

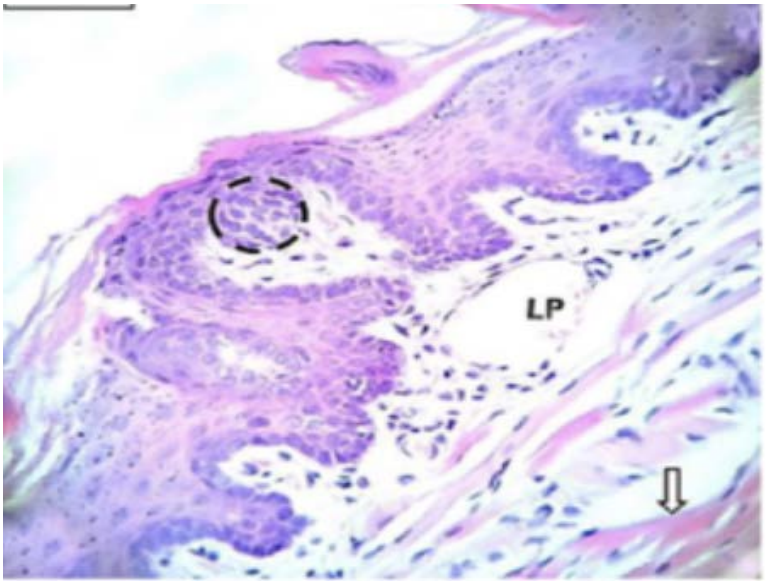


The given image depicts the histology image of circumvallate papillae:



The given image depicts the histology image of foliate papillae:

The given image depicts the histology image of fungiform papillae:



Solution to Question 4:

The posterior tibial artery, located behind the medial malleolus and 2.5 cm in front of the tendocalcaneus, that is used for arteriovenous (AV) shunting with the great saphenous vein for hemodialysis.

The posterior tibial artery is situated behind the medial malleolus and approximately 2.5 cm in front of the tendocalcaneus, making it a suitable site for creating an AV fistula with the great saphenous vein. This location allows for optimal access and ensures that the shunt can handle the necessary blood flow for effective dialysis with the great saphenous vein. However, they are not commonly used for AV shunting in common practices.

Arteries used for AV shunting include the radial artery and the brachial artery in the upper arm, which are frequently employed for hemodialysis access. In the lower leg, the anterior tibial artery and the peroneal (fibular) artery are less commonly used for this procedure.

Other options:

Option A: In comparison, the anterior tibial artery is located on the anterior aspect of the leg and runs down the front of the tibia, not behind the medial malleolus.

Option C: The peroneal (fibular) artery is situated on the lateral side of the leg, travelling alongside the fibula, and is also not located behind the medial malleolus.

Option D: The fibular circumflex artery is a small artery and is not commonly used for hemodialysis access. It is not a standard choice and does not fit the anatomical location described, as it is a branch of the anterior tibial artery.

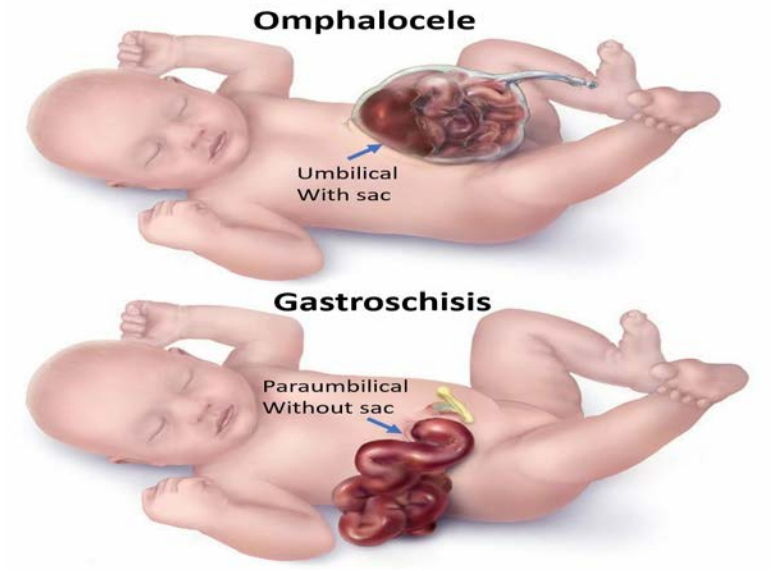
Solution to Question 5:

The diagnosis based on the given image is omphalocele and is covered by the amnion.

Omphalocele is a midline abdominal wall defect where the bowel and other solid viscera protrude through the umbilicus. In this condition, the herniated organs are covered by both peritoneum and an amnion. The umbilical cord inserts directly into this sac, which helps in identifying the condition. The defect occurs due to the failure of the physiological hernia to return to the body cavity by the 11th week of gestation.

The size of an omphalocele can vary significantly. It may be relatively small, containing only the gut, or it can be classified as a giant omphalocele if it measures 4 cm or more in diameter, encompassing the gut, liver, and other abdominal organs. The condition is often associated with other congenital anomalies such as trisomies 13, 15, 18, or 21, Beckwith-Wiedemann syndrome, exstrophy of the bladder or cloaca, and pentalogy of Cantrell.

Treatment for omphalocele involves covering the exposed organs to prevent fluid loss and protect them from infection. Prophylactic antibiotics may be administered in case of rupture. Surgical correction is usually performed once the baby is stable. In omphalocele, since the umbilicus is covered by a reflection of the amnion, this membrane also covers the omphalocele itself, differentiating it from other types of abdominal wall defects.



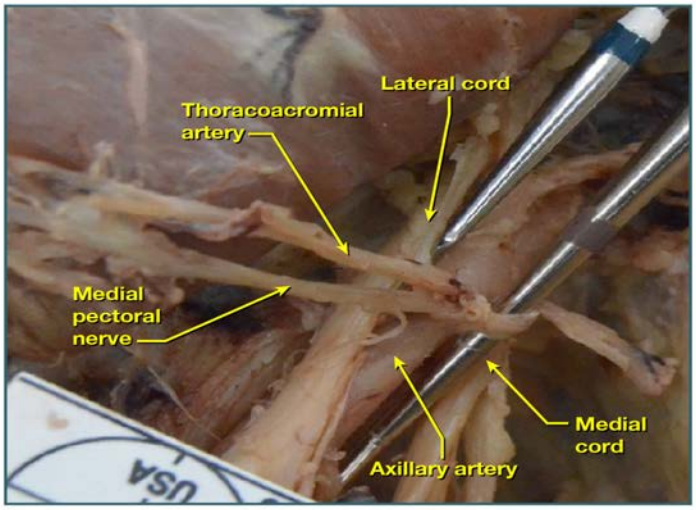
Note : Gastroschisis is a condition where the intestinal loops herniate through the defect in the abdominal wall. The defect usually lies on one side of the umbilicus (right side commonly). The loops of the bowel are not covered by amnion. It is associated with elevated alpha-fetoprotein levels.

Solution to Question 6:

The marked structure in the image is the medial pectoral nerve.

The given image shows the medial pectoral nerve arising from the medial cord of the brachial plexus. It also shows the axillary artery traversing inferior to the median pectoral nerve and the thoracoacromial artery. The medial pectoral nerve and the thoracoacromial artery both contribute to the neurovascular supply of the pectoral muscles.

After originating from the medial cord, the medial pectoral nerve passes anterior to the axillary artery. This nerve is specifically known for its anatomical path of piercing the pectoralis minor muscle before branching out to supply both the pectoralis minor and the pectoralis major muscles.



Solution to Question 7:

The adductor magnus is the hybrid muscle that is likely to be spared in this condition.

In sciatica, the sciatic nerve is typically affected, which branches into the tibial nerve and the common peroneal nerve. The adductor magnus muscle is an example of a hybrid muscle with dual innervation:

• The adductor part of the adductor magnus is innervated by the obturator nerve.

• The hamstring part of the adductor magnus is innervated by the tibial nerve.

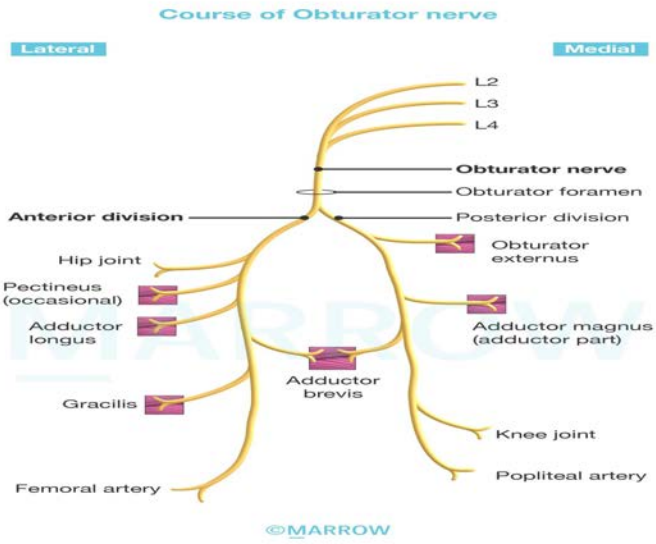
During sciatica, the tibial nerve is often affected, which would impact the hamstring part of the adductor magnus. However, because the adductor part of the adductor magnus is innervated by the obturator nerve, it remains functional and is likely to be spared.

The obturator nerve arises from the anterior division of the ventral rami of L2-L4. Near the obturator foramen, it divides into anterior and posterior branches.

• Anterior division supplies pectineus, adductor longus, adductor brevis, and gracilis

• Posterior division supplies adductor magnus, obturator externus. It also supplies adductor brevis if the muscle is not supplied by the anterior division

The image given below shows the course of the obturator nerve.



Other options:

Option A: The common peroneal nerve is a branch of the sciatic nerve and can also be affected in sciatica. It is responsible for innervating muscles in the anterior and lateral compartments of the leg.

Option B: The tibial nerve is a branch of the sciatic nerve and is often affected in sciatica. It supplies the hamstring part of the adductor magnus, which would be impacted during sciatica.

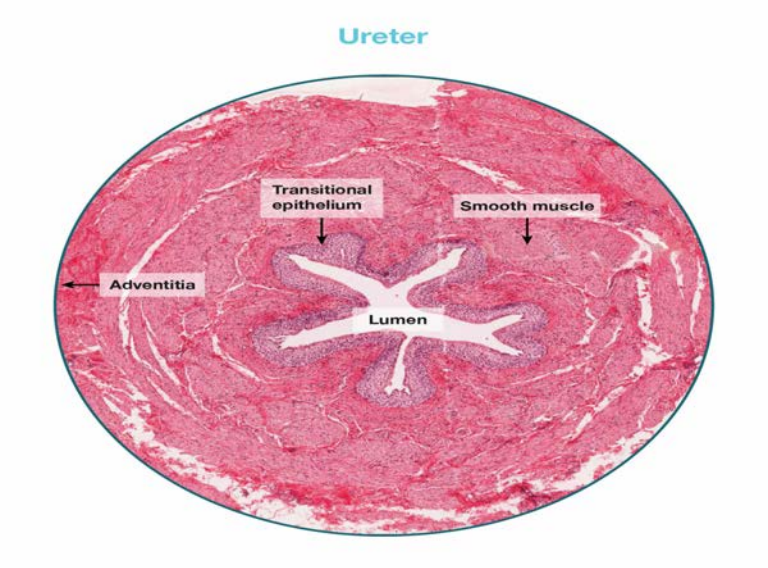
Option C: The femoral nerve is not involved in sciatica. It supplies the quadriceps and other muscles in the anterior compartment of the thigh, and does not innervate the adductor magnus.

Solution to Question 8:

The epithelium shown in the above image can be found in the ureter.

The ureter is lined by transitional epithelium (also called urothelium), similar to the urinary bladder. This specialized epithelium allows stretching, which is crucial as the urine passes through. The presence of transitional epithelium is characteristic of structures in the urinary system, such as the ureters, bladder, and part of the urethra.

Given below is a cross-section of the ureter showing the transitional epithelium and the layer of smooth muscle.



Other options:

Option A: Gall bladder: The gall bladder is lined by simple columnar epithelium, which facilitates the absorption of water and electrolytes from bile.

Option B: Trachea: The trachea is lined by pseudostratified columnar ciliated epithelium with goblet cells, which helps trap and remove particles from the respiratory tract.

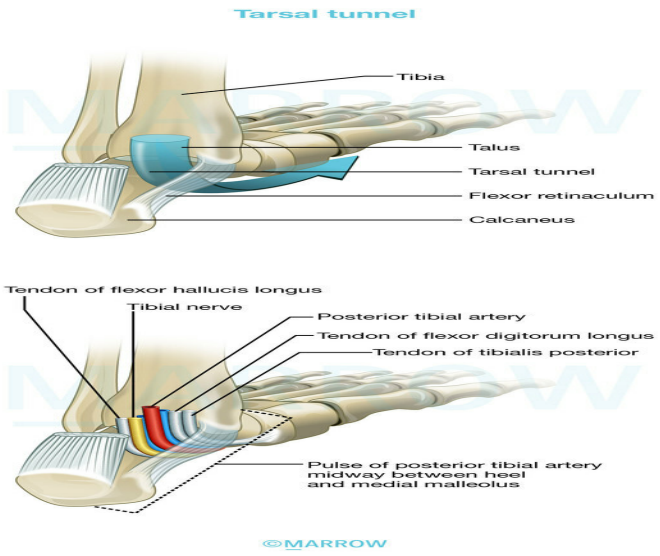
Option D: Duodenum: The duodenum is lined by simple columnar epithelium with goblet cells, aiding in digestion and nutrient absorption.

Solution to Question 9:

The tendon being highlighted here is of the tibialis posterior.

It passes behind the medial malleolus and is a key muscle responsible for foot inversion. The tendon of this muscle becomes prominent in this area during foot inversion. Dysfunction of this tendon can lead to flatfoot deformity.

The given image shows the tarsal tunnel and position of the tendon of tibialis posterior:



Other options:

Option A: Tibialis anterior lies anterior to the medial malleolus and aids in dorsiflexion and inversion of the foot but is not located behind the medial malleolus.

Option B: Extensor digitorum is involved in extending the toes and runs anteriorly to the foot, not behind the medial malleolus.

Option D: Extensor hallucis longus extends the big toe and runs along the anterior portion of the foot, also not behind the medial malleolus.

Solution to Question 10:

The difficulty in buttoning the shirt and the inability to make the "O" shape with fingers suggest the involvement of the abductor pollicis brevis muscle.

This is a case of anterior interosseous nerve (AIN) syndrome. The AIN is a purely motor branch of the median nerve that affects specific muscles in the forearm, the flexor pollicis longus and flexor digitorum profundus leading to difficulty in performing tasks requiring fine motor control, such as the "OK" sign. Among the options provided, the abductor pollicis brevis is uniquely and consistently innervated by the recurrent motor branch of the median nerve, making it susceptible to dysfunction in conditions affecting the median nerve.

Other options:

Option A: The opponens pollicis is innervated primarily by the lateral terminal branch of the median nerve, with some contributions from a branch of the deep terminal branch of the ulnar nerve. While it plays a role in thumb opposition, it is not consistently affected in anterior interosseous nerve (AIN) syndrome, which primarily impacts deeper flexor muscles like the flexor pollicis longus. Therefore, it is less likely to be the cause of the patient's inability to perform the "OK" sign.

Option B: The palmar interossei muscles are innervated by the deep branch of the ulnar nerve. Because they do not receive any innervation from the median nerve, they are not implicated in

AIN syndrome. Their primary function involves the adduction of the fingers.

Option C: The flexor pollicis brevis has dual innervation: the superficial head is supplied by the recurrent branch of the median nerve, while the deep head is innervated by the deep branch of the ulnar nerve. This dual supply makes it less likely to be solely affected in AIN syndrome.

Physiology AIIMS 2017

Question 1:

Given below is the demonstration of tetanization in the gastrocnemius muscle of a frog. Identify the tetanising frequency.

a) 25-20 Hz

b) 30-35 Hz

c) 15-20 Hz

d) 10-15 Hz

Question 2:

The oxygen carrying capacity of a 18 year old boy with haemoglobin of 14g/dl is

a) 22

b) 16

c) 14

d) 18

Question 3:

A 30-year-old patient with respiratory volume of 500 mL. The intraplueral pressure measured -4 before inspiration and -8 at the end of inspiration. The pulmonary compliance of the patient is

a) 125 ml/cm H2O

b) 150 ml/cm H2O

c) 50 ml/cm H2O

d) 62.5 ml/cm H2O

Question 4:

The function of the Golgi tendon organ is to _____

a) Sense changes in muscle direction

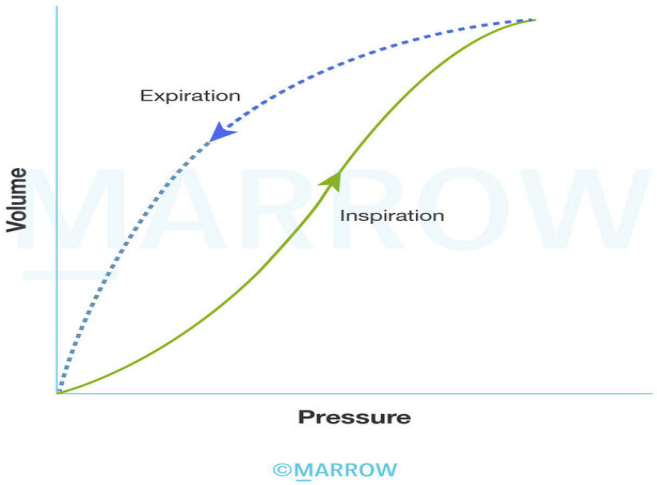
b) Sense changes in muscle tension

c) Sense changes in position of the muscle

d) Sense changes in length of the muscle

Question 5:

Difference in trajectory between inspiratory loop and the expiratory loop in the curve is due to:



a) Difference in alveolar pressure during inspiration and expiration

b) Difference in conc. of surfactant during inspiration and expiration

c) Difference in airway resistance during inspiration and expiration

d) Inspiration is active and expiration is passive

Question 6:

Reflex responsible for tachycardia during right atrial distension is:

a) Bezold-Jarisch reflex

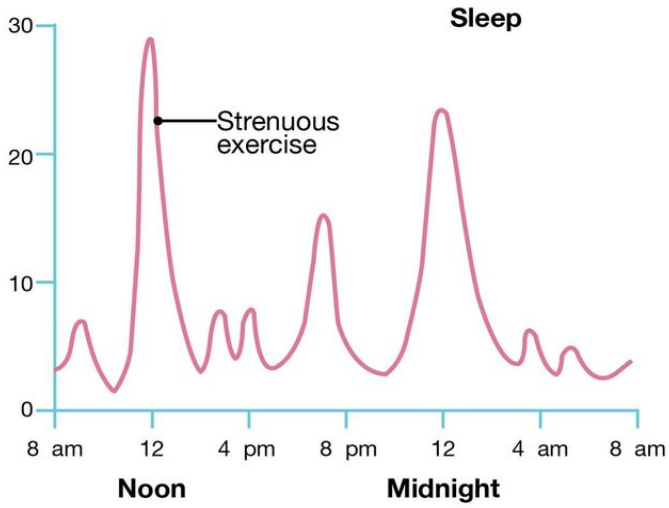
b) Bainbridge reflex

c) Cushing reflex

d) J reflex

Question 7:

Identify the hormone from the picture



a) Growth hormone

b) Cortisol

c) Estrogen

d) Insulin

Question 8:

Feed forward control system is employed during the regulation of

a) Blood volume

b) pH

c) Temperature

d) Blood pressure

Question 9:

Cellular junctions present in a cardiac muscle are all except:

a) Zonula occludens

b) Fascia adherens

c) Gap junctions

d) Macula adherens

Question 10:

Efferent arteriolar constriction causes all except:

a) Decrease in GFR

b) Decreases renal blood flow

c) Decreases oncotic pressure in glomerular capillaries

d) Increases hydrostatic pressure in glomerular capillaries

Question 11:

Absolute refractory period is due to:

a) Opening of calcium channels

b) Closure of potassium channels

c) Closure of active gates of sodium channel

d) Closure of inactive gates of sodium channel

Question 12:

X, Y, Z are three permeable ions. X = -50 and Y = -30. At RMP, if there is no net electrogenic transfer, what is the value of Z?

a) +20

b) -20

c) +80

d) -80

Question 13:

Slow waves are generated by:

a) Myenteric neurons

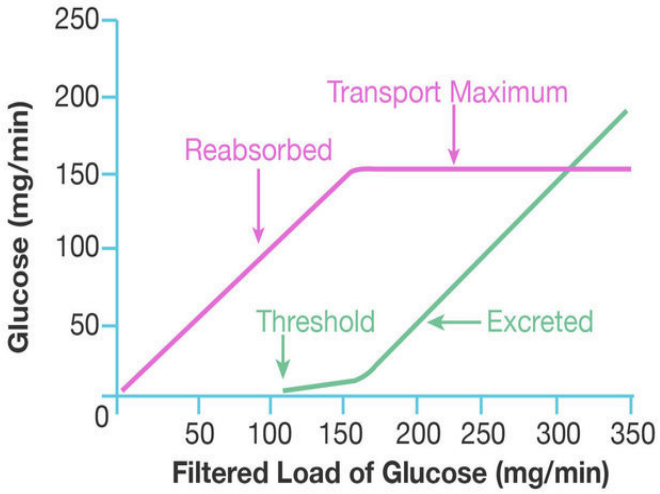
b) Smooth muscle cells

c) Interstitial cells of Cajal

d) Parasympathetic neurons

Question 14:

A patient has a ■blood glucose level of 200 mg/dL and GFR of 90 ml/min. What is the amount of glucose excreted if the transport maximum of the patient is as shown below?



a) 80 mg/min

b) 50 mg/min

c) 40 mg/min

d) 30 mg/min

Question 15:

Which of the following can be responsible for Bezold-Jarisch reflex?

a) Serotonin

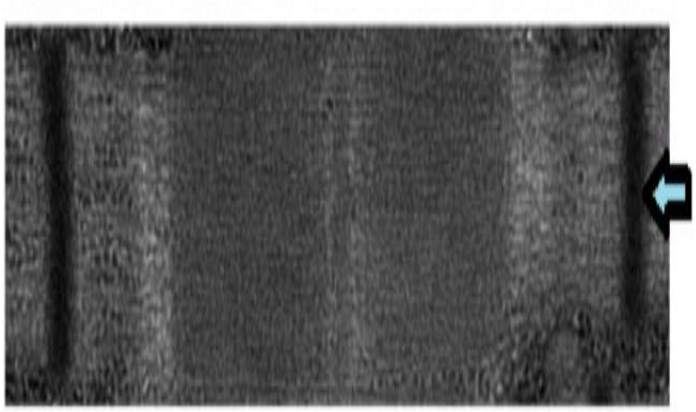
b) Histamine

c) Prostaglandin

d) Angiotensin

Question 16:

Which of the following is the constituent of the marked area in the electron microscopic picture of muscle?



a) Alpha actinin

b) Actin

c) Titin

d) Tropomyosin

Question 17:

The fourth heart sound is caused by:

a) Closure of aortic and pulmonary valves

b) Vibrations in the ventricular wall during systole

c) Ventricular filling

d) Closure of mitral and tricuspid valves

Question 18:

"a" wave on JVP is for

a) Atrial contraction

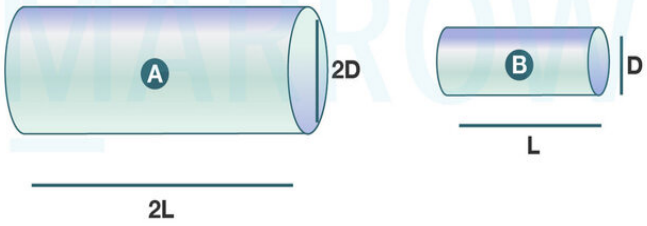
b) Atrial filling

c) Ventricular relaxation

d) Ventricular filling

Question 19:

In the 2 vessels shown below, assume the pressure along both the vessels is the same and both follow linear flow pattern. What will be the amount of blood flow in A compared to B



©MARROW

a) 4 times

b) 32 times

c) 8 times

d) 16 times

Question 20:

A 13-year-old boy presents with involuntary dancing movements of his right hand. He was diagnosed with rheumatic fever. What constitutes the ganglia involved in the presenting complication?

a) Caudate nucleus and globus pallidus

b) Globus pallidus and putamen

c) Globus pallidus and lentiform nucleus

d) Caudate nucleus and putamen

Answer Key

Detailed Explanations

Solution to Question 1:

Tetanizing frequency demonstrated by the muscle is 33Hz. In the above graph, we know,

• The speed of the paper is 1000mm/sec.

• The y-axis represents millivolts, the x-axis represents time.

• The scale on the x-axis is 10mm.

• The area under the graph represents the muscle contraction.

Contraction period (latent period to maximum force of contraction) includes 3 scales = 30 mm.

As paper speed is 1000mm/sec,

Contraction period = 30mm = (30/1000) = 30 msec.

Tetanizing frequency = 1/contraction period = 1000/30 = 33Hz.

Tetanization

The features of muscle contraction can be demonstrated by eliciting single muscle twitches. The adding together of individual twitch contractions to increase the intensity of overall muscle contraction is Summation. Summation occurs in two ways:

• by increasing the number of motor units contracting simultaneously, which is multiple ■ber summations.

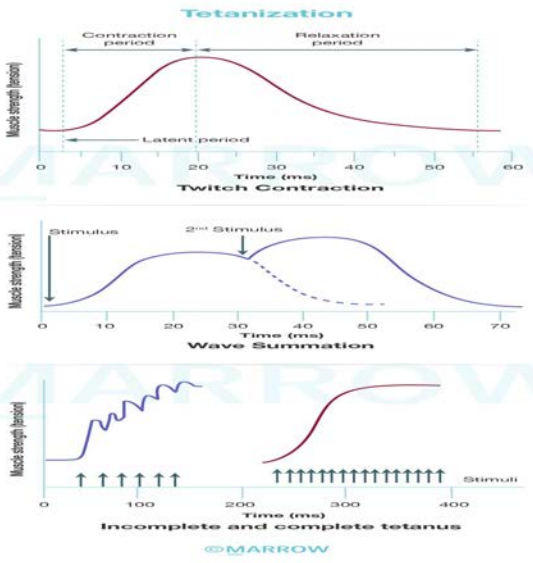
• by increasing the frequency of contraction, which is called frequency summation and can lead to tetanization.

When the frequency of a contraction reaches a critical level, the successive contractions eventually fuse together, and the whole muscle contraction appears to be completely smooth and continuous, this is called tetanization.

Tetanization occurs in two ways:

• Complete tetanus occurs when no relaxation occurs between stimuli.

• Incomplete tetanus when periods of incomplete relaxation take place between the summated stimuli.



Solution to Question 2:

The oxygen carrying capacity of a boy with haemoglobin 14g/dl is 18.

When blood is saturated with 100% O2, the haemoglobin is also 100% saturated and each gram of normal haemoglobin contains 1.39 mL of O2.

However, blood normally contains some inactive haemoglobin derivatives, and the measured value in vivo is thus slightly lower hence, each gram of haemoglobin in vivo contains 1.31 mL of O2 (Hufner's constant).

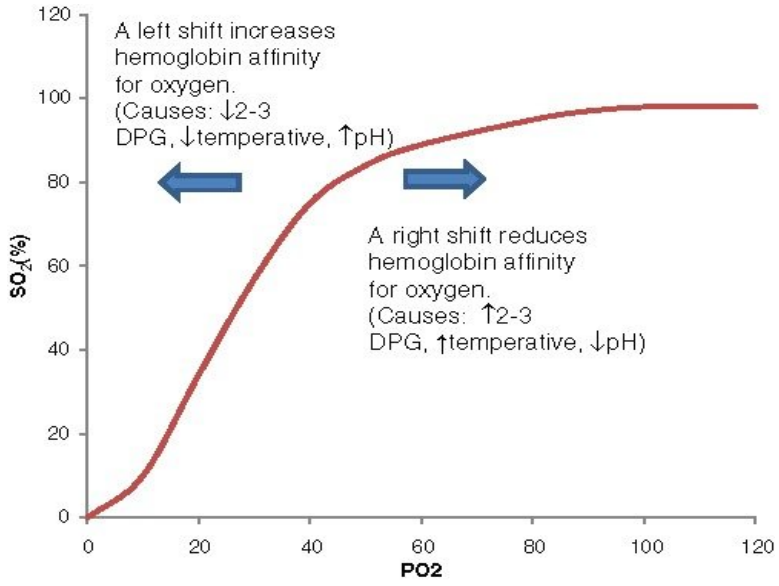
According to the above question, when Hb=14g/dl, O2= 1.31*14= 18.34

The oxygen-hemoglobin dissociation curve

• Demonstrates a progressive increase in the percentage of haemoglobin bound with oxygen as blood Po2 increases, which is called the percent saturation of haemoglobin.

• Blood leaving the lungs and entering the systemic arteries usually has a Po2 of about 95 mm Hg, the usual oxygen saturation of systemic arterial blood averages 97 per cent.

• Conversely, in normal venous blood returning from the peripheral tissues, the Po2 is about 40 mm Hg, and the saturation of haemoglobin averages 75 per cent.



Solution to Question 3:

Pulmonary compliance of this patient is 125 mL/cm of H2O.

Compliance is developed due to the tendency for tissue to resume its original position after an applied force has been removed.

After an expiration during quiet breathing, the lungs have a tendency to collapse and the chest wall has a tendency to expand. The interaction between the recoil of the lungs and recoil of the chest can be measured through a spirometer and a curve of airway pressure plotted against volume is the pressure-volume curve of the total respiratory system (Ptr).

Compliance of the lung and chest wall is measured as the slope of the Ptr curve, or, as a change in lung volume per unit change in airway pressure ($\Delta V/\Delta P$).

Compliance = Change in lung volume / Change in pressure

Compliance = 500/4

Compliance = 125 ml/cm H20

Solution to Question 4:

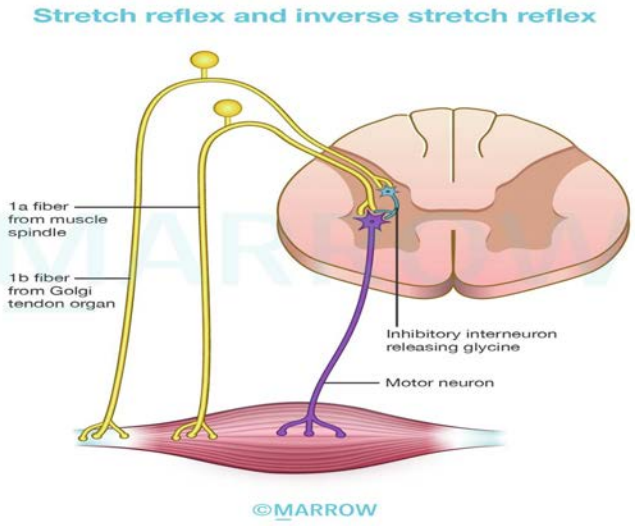
Golgi tendon organ sense changes in muscle tension.

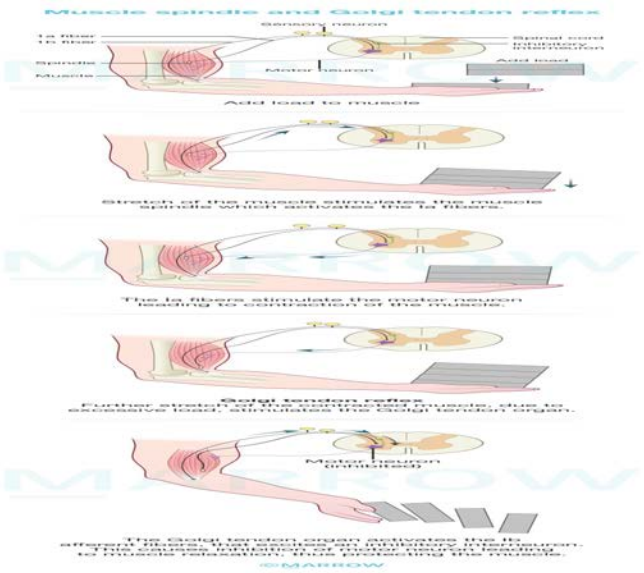
Golgi tendon reflex (Inverse myotatic/ Inverse stretch reflex) is disynaptic, is the opposite of the stretch reflex.

When the tension in a contracted muscle is significantly elevated, the inhibitory effect from the Golgi tendon organ leads to instantaneous relaxation of the entire muscle. This effect is called the lengthening reaction.

It is a protective mechanism to prevent tearing of the muscle or avulsion of the tendon from its attachments to the bone.

Note: Muscle spindles senses changes in muscle length (stretch).





Solution to Question 5:

The difference between the inflation and the deflation paths is called hysteresis.

It exists because a greater transpulmonary pressure is required to open a previously closed airway, due to a deficit of surfactant at the air-water interface, than to keep an open airway from closing, as then it has abundant surfactant.

Solution to Question 6:

Reflex responsible for tachycardia during right atrial distension is Bainbridge Reflex.

The stretch receptors of the atria that elicit the Bainbridge reflex transmit their afferent signals through the vagus nerves to the medulla of the brain. Then efferent signals are transmitted back through vagal and sympathetic nerves to increase heart rate and strength of heart contraction. Thus, this reflex helps prevent damming of blood in the veins, atria, and pulmonary circulation.

Other options:

Option A: Bezold–Jarisch Reflex: Activation of chemosensitive vagal C fibers in the cardiopulmonary region causes profound bradycardia, hypotension and a brief period of apnoea followed by rapid shallow breathing.

Option C: Cushing Reflex: When intracranial pressure is increased, the blood supply to Rostral Ventro-Lateral Medulla (RVLM) neurons is compromised. The local hypoxia and hypercapnia cause an increase in discharge from the neurons, producing hypertension, bradycardia, and irregular respiration.

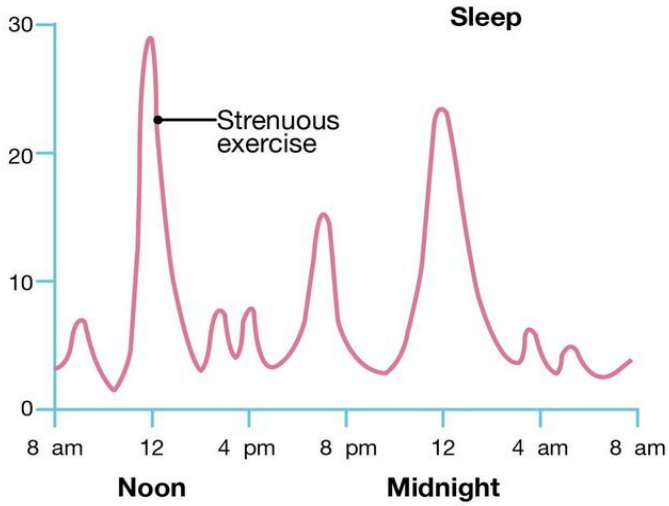
Option D: J Reflex: The stimulation of the J-receptors (C receptors/juxta-pulmonary capillary receptors) causes apnea followed by rapid breathing, bradycardia, and hypotension.

Solution to Question 7:

The image depicts the fluctuations of secretion of growth hormone throughout the day.

• Growth hormone is found at relatively low levels during the day unless specific triggers such as strenuous exercise are present.

• During sleep, on the other hand, large pulsatile bursts of growth hormone secretion occur.



Stimuli that Affect Growth Hormone Secretion in Humans

Note:

The early morning surge of Growth Hormone during sleep, as seen in the image, plays a role in the Dawn Phenomenon

Stimuli that Increase Secretion	Stimuli that Decrease Secretion
ExerciseGoing to sleepFasting/HypoglycemiaStressful stimuli (including various psychological stresses)High Protein MealGlucagonEstrogens and androgensPyrogen	GlucoseCortisolFFAMedroxyprogesteroneGrowth hormone and IGF-I

Solution to Question 8:

Feed forward control system is employed during regulation of temperature.

Feed forward control

There is a control system in our body when no stimulus is required but still the system anticipates and makes corrective changes.

Such a system is called Feed forward or Anticipatory or Adaptive Control.

Examples include

• Temperature control – Thermoregulatory responses are initiated by hypothalamus BEFORE the changes in environmental temperature have succeeded in changing the body's core body temperature

• Cephalic phase of gastric secretion- Just thinking about food increases gastric acid production

• Thinking about exercise itself increases heart rate & respiratory rate

• Role of cerebellum in motor coordination

Solution to Question 9:

Zonula occludens is the other name for the tight junction. It is absent in a cardiac muscle.

Cardiac muscle cells are connected by Fascia adherens (a structural analog of zonula adherens), Gap junctions and Macula adherens.

Cardiac muscle fibers are made up of many individual cells connected in series and parallel to one another. The areas where the end of one muscle fiber abuts on another are called intercalated disks. At each intercalated disc, the plasma membrane fuses with one another forming gap junction which provides low resistance bridges for the spread of excitation from one fiber to another permitting the cardiac muscle to function as a syncytium.

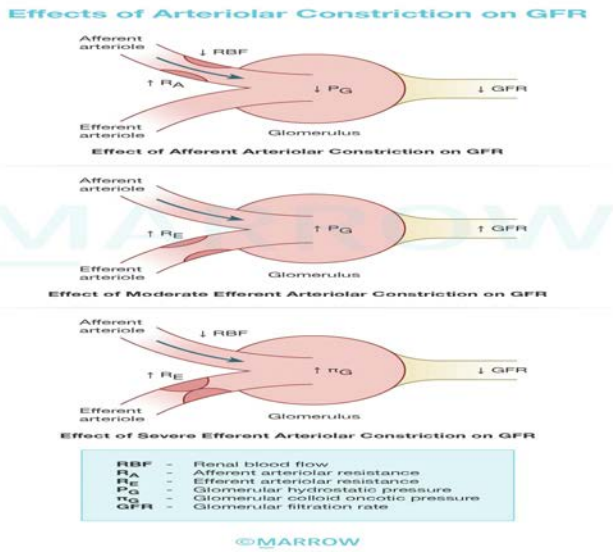
Solution to Question 10:

Efferent arteriolar constriction increases oncotic pressure in glomerular capillaries.

Efferent arteriolar constriction has a biphasic response on GFR depending on the severity of resistance.

Moderate efferent arteriolar constriction causes increased glomerular hydrostatic pressure and slightly increased GFR.

However, in cases of severe efferent arteriolar constriction (more than threefold increase in efferent arteriolar resistance), the renal blood flow is significantly reduced. This results in increased plasma protein concentration, thereby increasing the glomerular colloid oncotic pressure. As the increase in colloid oncotic pressure exceeds the increase in hydrostatic pressure, the net force for filtration decreases, resulting in decreased GFR.

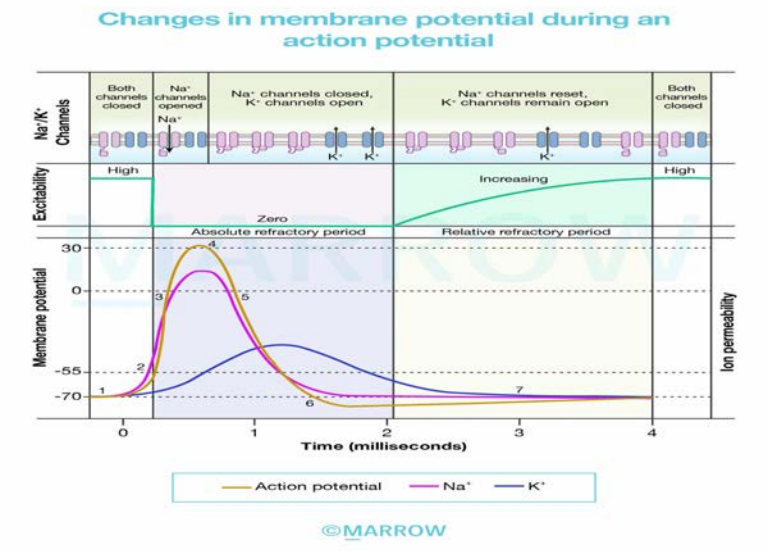


Solution to Question 11:

Absolute refractory period is due to closure of inactive gates of sodium channel.

Voltage-gated sodium channels have 3 states that you can find them in. They can either be closed, open, or inactive.

When the stimulus causes activation of the open gates, sodium rushes into the cell causing the membrane potential to become more positive. After 0.5 to 1 millisecond, the inactive gate automatically closes and no stimulus, no matter how strong, can excite the nerve. This is called the absolute refractory period.



Solution to Question 12:

No net electro genic transfer at RMP means X + Y + Z = 0

Since X = -50 and Y = -30, then Z must be +80 since (-80 +80 = 0)

Solution to Question 13:

The interstitial cells of Cajal undergo cyclic changes in membrane potential due to unique ion channels that periodically open and produce inward (pacemaker) currents that generate slow-wave activity.

Interstitial cells of Cajal are the pacemaker cells of the GIT that initiate the basic electrical rhythm (BER). These are stellate mesenchymal pacemaker cells with smooth muscle-like features.

In the stomach and the small intestine, these cells are located in the circular smooth muscle layer near the myenteric plexus. In the colon, they are at the submucosal border of the circular muscle layer.

The slow waves usually do not by themselves cause muscle contraction in most parts of the gastrointestinal tract, except perhaps in the stomach. Instead, they mainly excite the appearance of intermittent spike potentials, and the spike potentials in turn actually excite the muscle contraction.

Note: Gastrointestinal stromal tumors arise from the interstitial cells of Cajal.

Solution to Question 14:

The amount of glucose excreted in the above scenario is 30 mg/min.

Calculation:

Step 1: Calculate total filtered glucose:

In this question,

• GFR = 90 ml/min

• Plasma glucose concentration = 200 mg/dL= 2 mg/ml (1 dL=100 ml).

• Total filtered glucose = GFR X Plasma glucose concentration.

= 90 ml/min X 2 mg/ml

= 180 mg/min.

Step 2: Check transport maximum:

In the above question transport maximum is 150 mg/min.

Step 3: Calculate the excretion:

Excretion = Total filtered glucose - Total reabsorbed glucose (Transport Maximum)

= 180-150 mg/min

= 30 mg/min

Solution to Question 15:

Serotonin can be responsible for Bezold–Jarisch reflex.

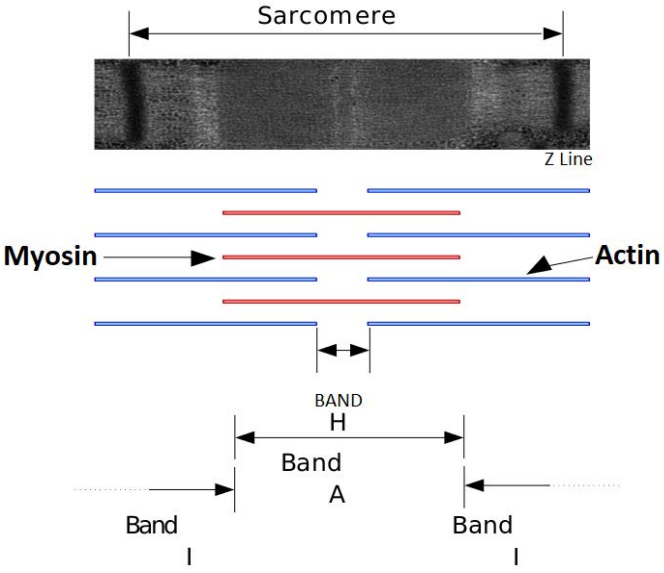
Activation of chemosensitive vagal C fibers located in the cardiopulmonary region (ex: ventricles, atria, great veins, pulmonary artery, juxtacapillary region of alveoli) causes profound bradycardia, hypotension, and apnea followed by rapid shallow breathing. This response is called Bezold-Jarisch reflex.

Other substances that can cause Bezold–Jarisch reflex are capsaicin, phenyl biguanide, and veratridine.

Solution to Question 16:

Alpha actinin is the constituent of the marked area.

The image depicts sarcomere and the arrow points towards Z-line. Alpha actinin binds actin to Z-lines.



The orderly arrangement of actin, myosin, and related proteins that produces this pattern. The area between two Z-lines is called sarcomere.

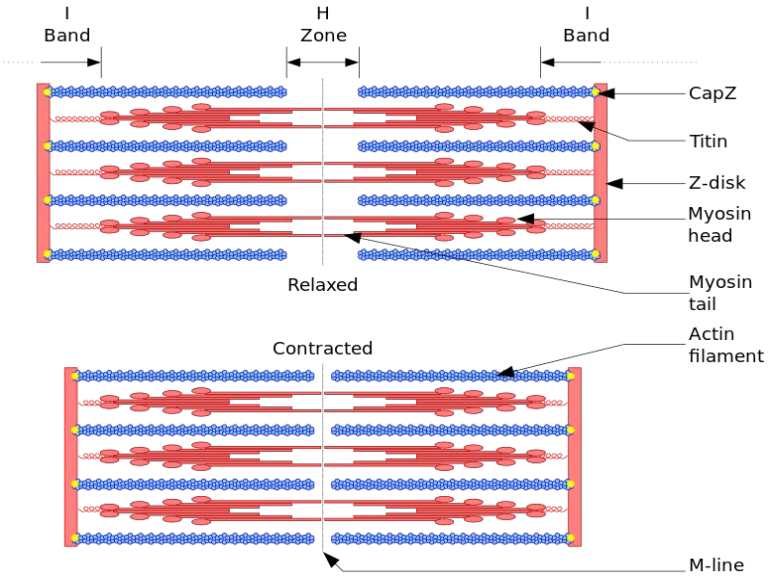
The thick filaments, which are about twice the diameter of the thin filaments, are made up of myosin, which are lined to form A bands; the thin filaments are made up of actin, tropomyosin, and troponin. The array of thin filaments extends out of the A band and into the less dense staining I bands.

The lighter H bands in the center of the A bands are the regions where, when the muscle is relaxed, the thin filaments do not overlap the thick filaments. The Z lines allow for anchoring of

the thin filaments.

Actinin, titin and desmin are additional structural proteins.Titin connects Z-lines to the M line and provides the scaffolding to the sarcomere. Desmin adds structure to Z-lines by connecting Z-line to plasma membrane.

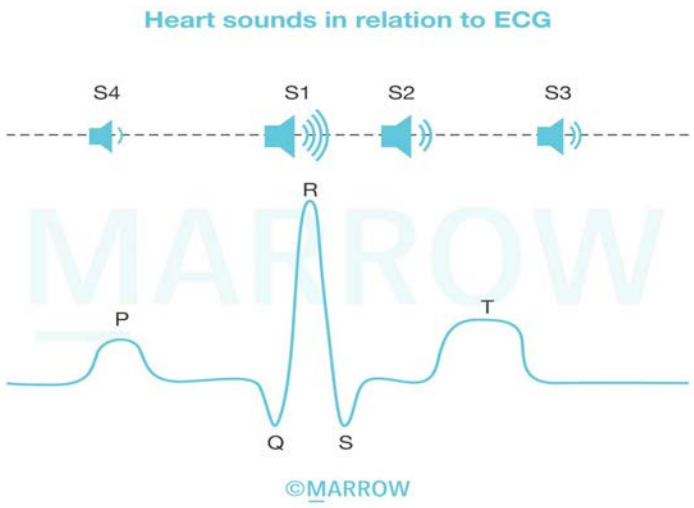
Note: Some sources say that even titin is a component of Z-disc so if alpha actinin is not given in the options titin is the second best answer.



Solution to Question 17:

The fourth heart sound is caused by ventricular filling.

A fourth sound is heard immediately before the first sound when atrial pressure is high or the ventricle is stiff in conditions such as ventricular hypertrophy. It is due to ventricular filling and is rarely heard in normal adults.



Solution to Question 18:

"a" wave in JVP represents atrial contraction.

Waves of JVP :

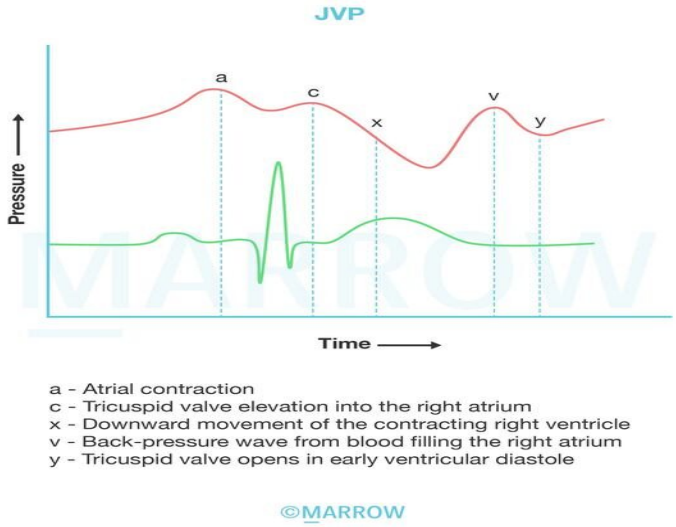
• a- atrial systole pushing the blood to the ventricles.

• c- isovolumetric contraction of ventricles causing the tricuspid valve to bulge.

• x'- fall in atrial pressure during ventricular systole due to pull of valve leaflets.

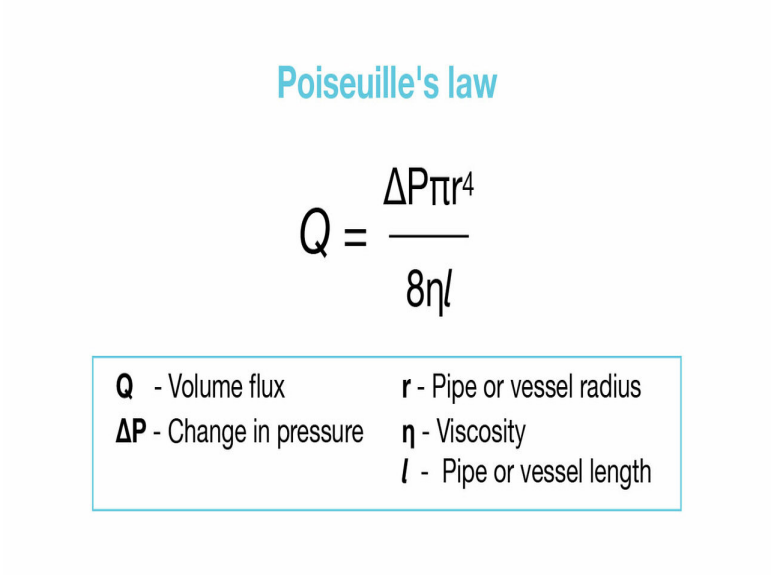
• v- venous filling which creates an increase in atrial pressure.

• y- passive filling of ventricles by a passive flow of the blood from the right atrium.



Solution to Question 19:

The relationship between the flow in a long narrow tube, the viscosity of the fluid, and the radius of the tube is expressed mathematically in the formula called as Poiseuille's law :



Blood flow (F) inside the vessel depends on:

• Pressure difference: directly proportional

• Viscosity: inversely proportional

• Radius: directly proportional to the fourth power

• Length of the vessel: inversely proportional

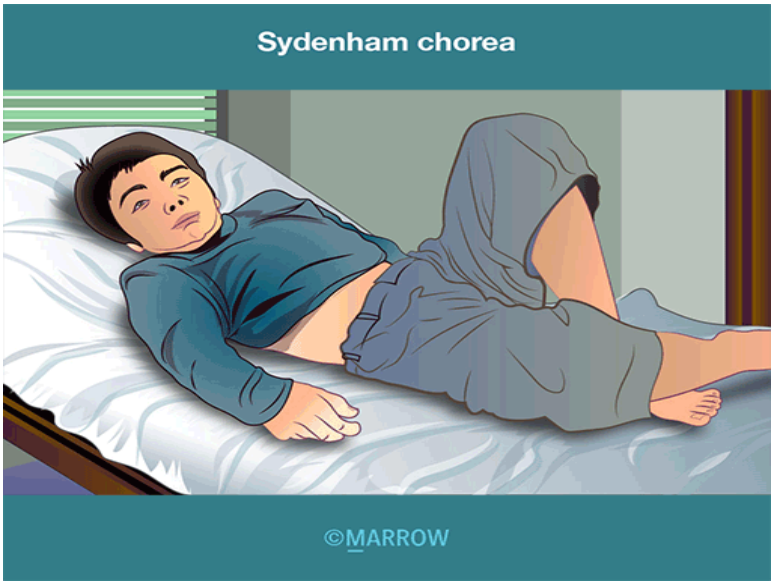
Here, the radius is doubled so the flow increases by 2 to the power of 4 = 16.

the length of the vessel is also doubled, so the flow decreases by half (÷2) = 8

Solution to Question 20:

The given clinical scenario is suggestive of Sydenham's chorea, a complication of rheumatic fever. The choreic movements are caused by the destruction of D2 neurons of the striatum. The neostriatum consists of the caudate nucleus and putamen.

The image given below shows Sydenham's chorea in a patient.

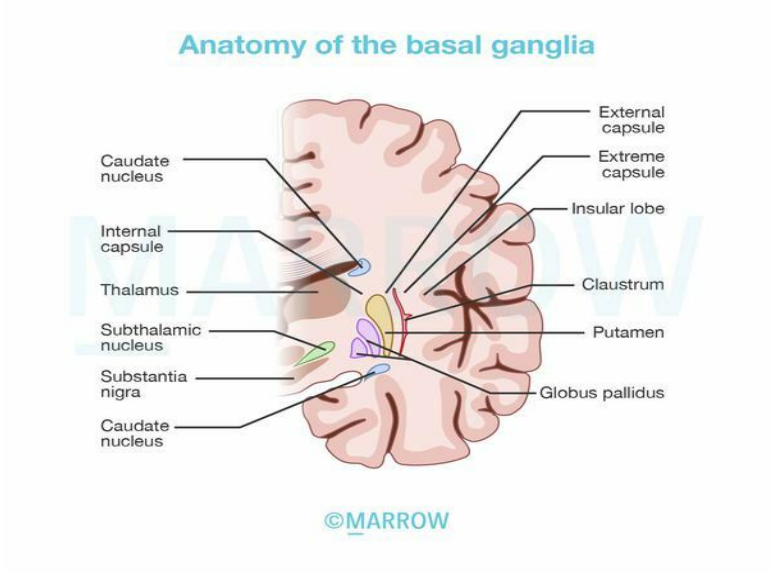


Nomenclature of basal ganglia:

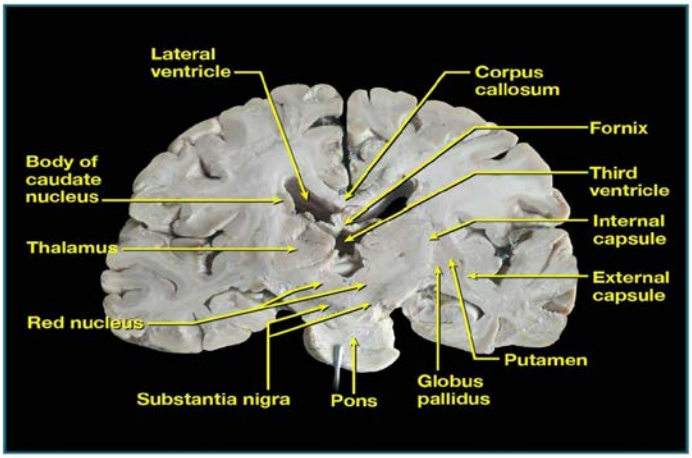
• Corpus striatum: Caudate nucleus + putamen+ globus pallidus

• Lentiform nucleus: Putamen + globus pallidus

• Neostriatum: Caudate nucleus + putamen



Coronal section of human brain



Physiology AIIMS 2018

Question 1:

Which of the following is the diluting segment of the kidney?

a) PCT

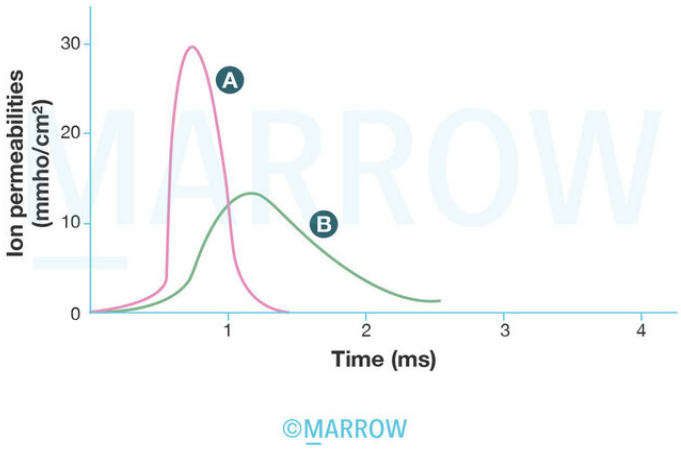
b) Collecting duct

c) Ascending thick loop of Henle

d) Descending loop of Henle

Question 2:

Identify the ions A and B based on conductance graph of a neuron shown below:



a) Na, K

b) K, Na

c) Na, Ca

d) Ca, Na

Question 3:

How is an electrical synapse different from a chemical synapse?

a) No cytoplasmic continuity between presynaptic and postsynaptic membrane

b) Direction of impulse is unidirectional

c) Connexons are involved in electrical synapse

d) Electrical synapse has more latent period than chemical synapse

Question 4:

Hormone degradation as an important mechanism for regulating local concentrations is seen in _____.

a) 11β-hydroxysteroid dehydrogenase inactivation of glucocorticoids

b) Thyroid hormone deiodinases inactivating T3

c) Degradation of retinoic acid by Cyp26b1 in primordial germ cells of males

d) All of the above

Question 5:

The factors that can cause a person to drink water due to stimulation of thirst mechanism is/are _____.

a) Dehydration

b) Hemorrhage

c) Prandial Drinking

d) All of the above

Question 6:

On performing a histamine test on an individual with brachial plexus trunk injury, you can expect _____.

a) Central capillary dilatation → wheal → Surrounding flare

b) Central capillary dilatation → wheal without surrounding flare

c) Central capillary dilatation → wheal with exaggerated surrounding flare

d) Absent triple response

Question 7:

GFR is increased by all except

a) Increased renal blood flow

b) Efferent arteriolar constriction

c) Ureteric stone

d) Decreased oncotic pressure

Question 8:

Baroreceptor provides _____

a) Negative feedback

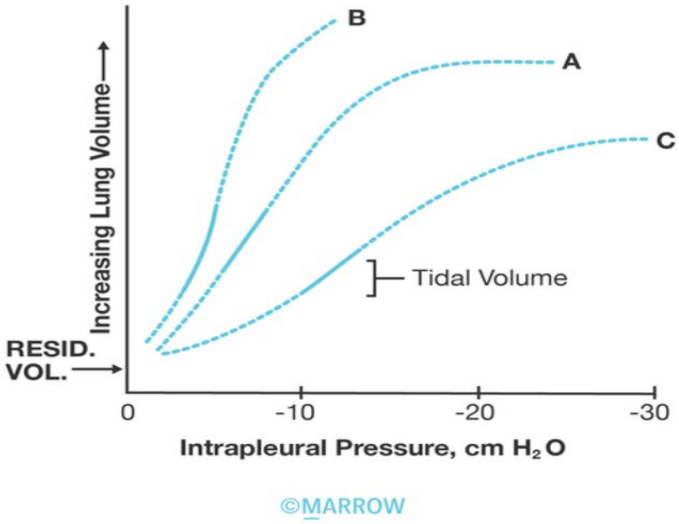
b) Positive feedback

c) Both negative and positive feedback

d) Feedforward control

Question 9:

The diagram below shows the pressure-volume curves for 3 different lungs. Which of the following is the best representation of compliance between the three lungs?



a) A<B<C

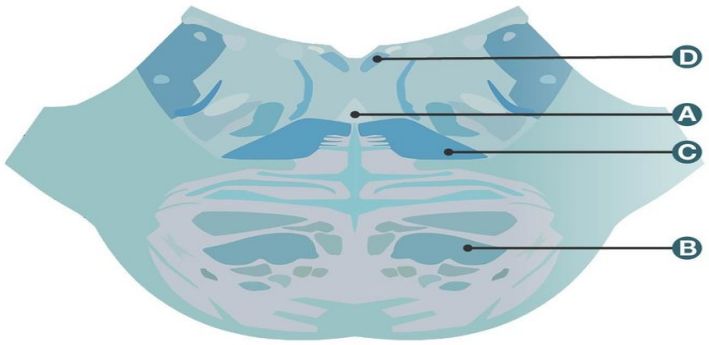
b) B>A>C

c) B>C>A

d) C>A>B

Question 10:

Identify the site which is responsible for relieving pain when pressure is applied to the painful area.



©MARROW

a) A

b) B

c) C

d) D

Question 11:

Inhibitory control by the hypothalamus is exerted on:

a) Prolactin only

b) Prolactin and growth hormone

c) Growth hormone only

d) Neither

Question 12:

Which of the following hormones play a permissive role in the attainment of puberty?

a) GnRH

b) Leptin

c) Insulin

d) GH

Question 13:

Weber-Fechner law relates magnitude of sensation to ____.

a) Strength of muscle contraction

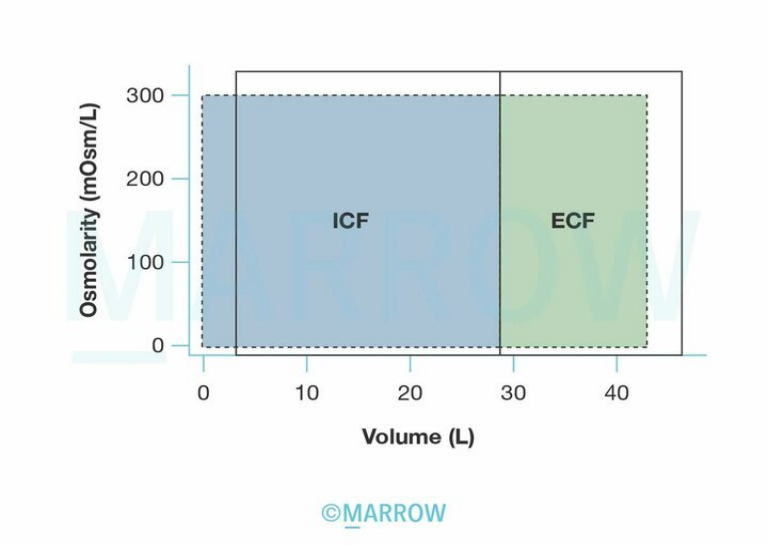
b) Log of Intensity of stimulus

c) Amplitude of action potential

d) Duration of stimulus

Question 14:

The following Darrow Yannet diagram is suggestive of which condition? Note : The solid line is the original fluid compartment and the colour shaded compartment within the dotted line denotes the change caused by the condition.



a) Excessive sweating

b) Adrenal Insufficiency

c) Diarrhoea

d) SIADH

Question 15:

The mechanism by which glucose is absorbed in the intestine is:

a) Primary active transport

b) Secondary active transport

c) Facilitated diffusion

d) Any of the above

Question 16:

The earliest stage at which erythropoietin is effective in red blood cell formation is?

a) Burst forming units

b) Colony forming units

c) Late erythroblast stage

d) Normoblast stage

Question 17:

Integrin connects with:

a) Cadherin

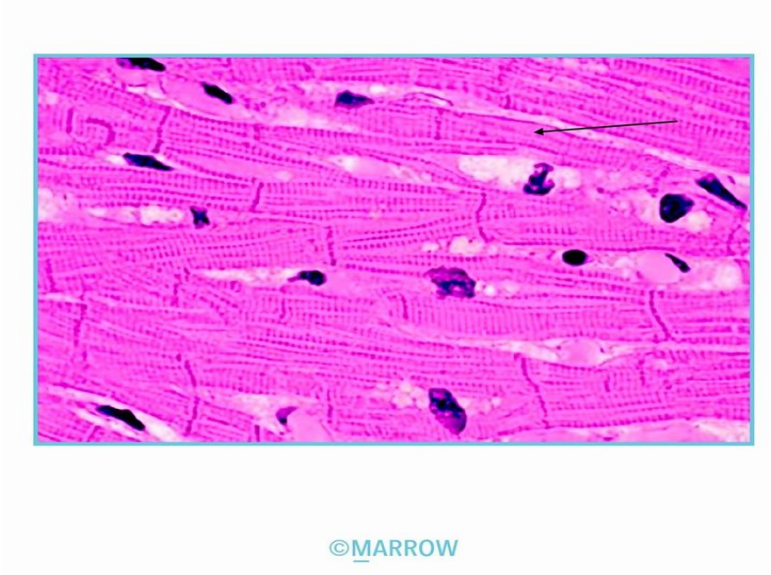
b) Vitronectin

c) Fibronectin

d) Selectin

Question 18:

Which of the following organelles is absent in the area of the cardiac muscle marked:



a) Mitochondria

b) Lysosome

c) Golgi bodies

d) Endoplasmic reticulum

Question 19:

Which of the following fibres reach the Purkinje cell directly?

a) Inferior olivary nucleus

b) Raphe nucleus

c) Vestibular nucleus

d) Locus coeruleus

Question 20:

Calculate the net filtration pressure across the GBM for a patient with Glomerular ultrafiltration coefficient = 6 Glomerular hydrostatic pressure =45 Glomerular capillary oncotic pressure =20 Bowman's capsule hydrostatic pressure =10 Bowman's capsule oncotic pressure =0

a) 90 mmHg

b) 60 mmHg

c) 30 mmHg

d) 15 mmHg

Question 21:

In a 100-m dash, most of the energy consumed by skeletal muscles to replenish ATP is derived from _____

a) Phosphocreatine

b) Aerobic glycolysis

c) Oxidation of Fatty acids

d) None of the above

Question 22:

In the homunculus, which of the following has maximum representation?

a) Low control and skilled movements

b) More muscle fibres are present

c) Increased preciseness of movements

d) None of the above

Question 23:

What is the usual position of the Golgi apparatus in serous acinar cells?

a) Supranuclear

b) Basal

c) Adjacent to nucleus

d) Apical

Detailed Explanations

Solution to Question 1:

The ascending thick limb of the loop of Henle is called the diluting segment.

In the ascending limb, there is the movement of Na+ and Cl– out of the tubular lumen, and the tubular fluid becomes more dilute.

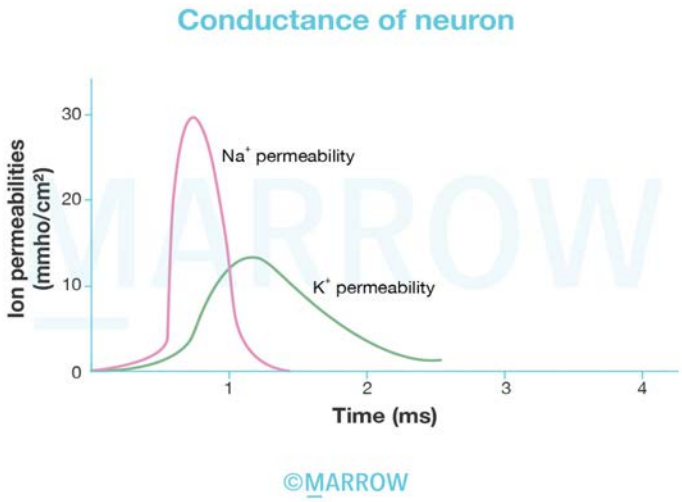
When the fluid reaches the top of the ascending limb, it becomes hypotonic to plasma.

Solution to Question 2:

Channel A: Na+, Channel B: K+

Na+ channels are fast activating and are responsible for depolarization phase of action potential.

K+ channels are slow activating and open for prolonged duration than the sodium channels. They are responsible for repolarization phase of action potential. Also, the postassium channels return slowly to their closed state, which is responsible for after-hyperpolarization.



The sequence of events during the action potential occur in 7 steps as described below.

1. Resting state - Both channels are closed

2. Na+ channels open in response to depolarizing stimulus. Sodium enters into the cell. The membrane reaches threshold potential.

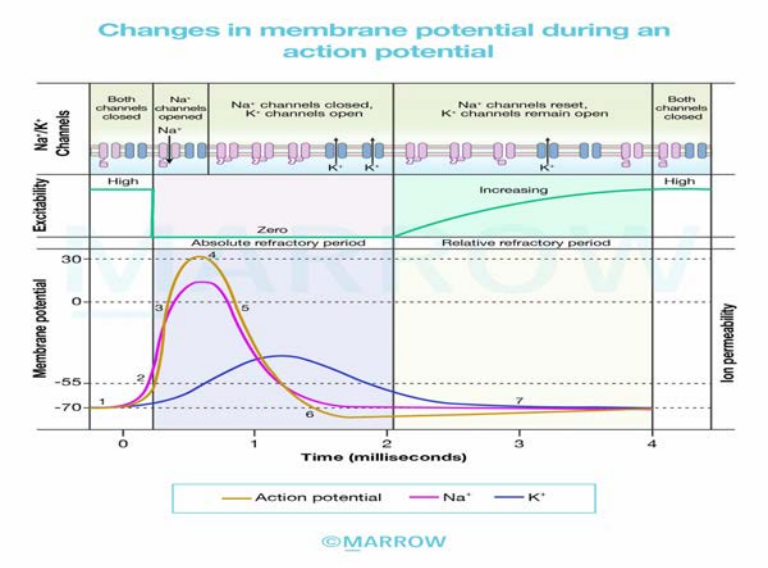
3. The sodium influx causes opening of more sodium channels through positive feedback mechanism. Rapid depolarization occurs.

4. Sodium conductance decreases.

5. Na+ channels close and K+ channels open. Repolarization occurs.

6. Sodium channels are reset, and are ready to respond to another depolarizing stimulus (relative refractory period). During this phase, the potassium channels remain open and slowly return to closed state causing after-hyperpolarization.

7. Both channels are closed. The membrane returns to RMP.



Solution to Question 3:

In electrical synapses, the cytoplasm of adjacent cells is directly connected by gap junctions (connexons) that allow free movement of ions from the interior of one cell to the interior of the next cell.

The transmission in electrical synapses is bidirectional and there is no synaptic delay. Unlike chemical synapses, electrical synapse has cytoplasmic continuity.

Note:

Most of the synapses used for signal transmission in the central nervous system are chemical synapses.

Solution to Question 4:

Hormone degradation as an important mechanism for regulating local concentrations is seen in all of the above.

11β-hydroxysteroid dehydrogenase inactivates glucocorticoids in renal tubular cells, preventing actions through the mineralocorticoid receptor.

During development, degradation of retinoic acid by Cyp26b1 prevents the primordial germ cells in the male from entering meiosis, which occurs in the female ovary.

The thyroid hormone deiodinases convert T4 to T3 and can inactivate T3. All the three are hence examples of local hormone degradation being utilized as a method for regulation of hormone concentration locally.

Solution to Question 5:

Dehydration, hemorrhage, and prandial drinking: All three can cause increased thirst resulting in water drinking.

Increased osmolality acts via osmoreceptors in the anterior hypothalamus.

The decreased plasma volume, as in hemorrhage, acts via

1. Renin-angiotensin system

2. Baroreceptors in heart and blood vessels.

The intake of liquids during a meal is known as prandial drinking. The increase is known as learned or habit response but is not understood completely.

The following factors are thought to play a role

1. Increase in plasma osmolality due to food absorption

2. Action on hypothalamus by one or more gastrointestinal hormones

Solution to Question 6:

Brachial plexus trunk injury leads to anesthetized skin over the region. On performing a histamine test on such an individual, one can expect central capillary dilatation → wheal without surrounding flare. The incomplete triple response over the anesthetic skin is characteristic of postganglionic lesions.

Intradermal injection of histamine usually causes a triple response in the surrounding skin i.e, red reaction→ flare → wheal

• Red reaction is independent of innervation and is due to histamine-mediated relaxation of the precapillary sphincters

• Flare reaction (Flush, Axon reflex) is due to Substance P mediated arteriolar dilatation (antidromic conduction of afferent impulses via collaterals of the sensory nerve fiber that lead to the release of vasoactive mediators)

• Wheal (skin edema) is due to histamine-mediated increased capillary permeability

• The triple response persists after total sympathectomy

• Flare is absent in locally anesthetized skin

Solution to Question 7:

Ureteric stone causes a reduction in glomerular filtration rate (GFR).

Following ureteral obstruction, there is a progressive fall in glomerular filtration rate (GFR) due to a reduction in a single-nephron glomerular filtration rate (SNGFR) and a reduced number of filtering nephrons.

All the other factors/options increase GFR.

Solution to Question 8:

Baroreceptors provide negative feedback in response to an increase in blood pressure.

Increased baroreceptor discharge inhibits the tonic discharge of sympathetic nerves and excites the vagal innervation of the heart.

Baroreceptor reflex

• Increased BP → stimulation of baroreceptors → stimulation of NTS → inhibition of RVLM → inhibition of sympathetic system

• Stimulation of NTS also stimulates CVC → parasympathetic stimulation

• Net effect = sympathetic inhibition and parasympathetic stimulation → decreased HR and BP

NTS - Nucleus tractus solitarius

CVC - Cardiovagal center

RVLM - Rostral ventrolateral medulla

HR- Heart rate

BP - Blood pressure

Solution to Question 9:

• The pressure-volume relationship is the fundamental relation between the work of breathing and lung mechanics.

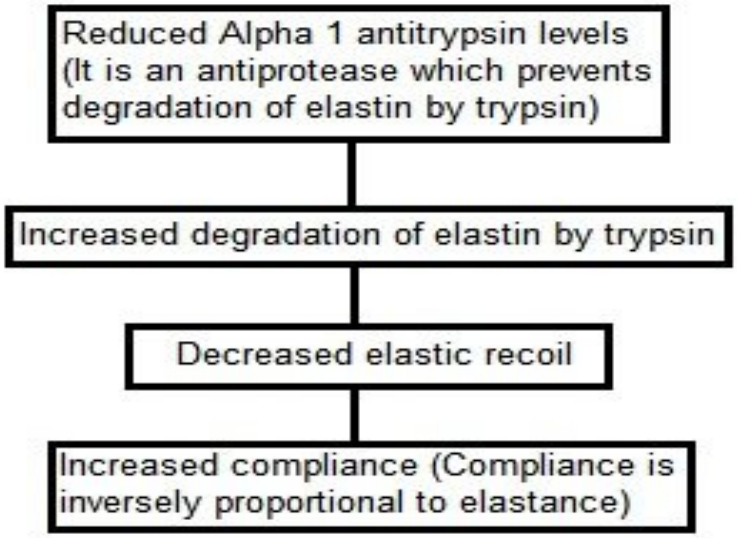
• The diagram depicts the change in volume with respect to the change in intrapleural pressure, which is compliance. Here, the change is more (steep curve) with B and least (flat curve) with C.

• The “stiffer” lung displays a more horizontal curve (C), meaning that it takes a greater pressure to achieve the same inflation volume compared with a normal lung (A). These lungs are called less compliant.

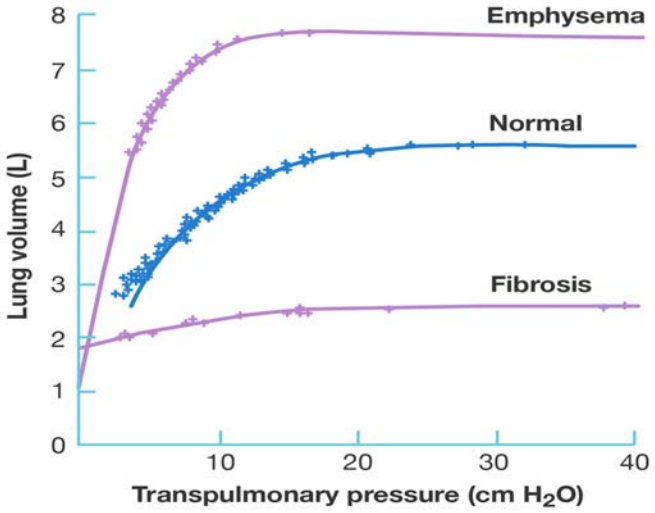
• Curve (B) is more compliant as it takes lesser pressure to achieve the same inflation volume compared to normal (A).

Applied aspect:

Compliance is increased in emphysema. The mechanism is shown in the flow chart below.



Compliance is decreased in case of pulmonary edema or fibrosis.



Solution to Question 10:

It is a cross section of brain stem at pons.

• A is a periaqueductal gray matter which also consists of raphe nucleus.

• Descending pathways from the mesencephalic periaqueductal gray matter inhibit transmission in nociceptive pathways. This descending pathway includes a synapse in the ventromedial medulla (Raphe nucleus) and the release of endogenous opiates. So periaqueductal gray matter releases endogenous opiates.

Other marked structures are

B: Corticospinal tract

C: Medial lemniscus

D: Medial longitudinal fasciculus

Solution to Question 11:

Inhibitory control by the hypothalamus is exerted mainly on prolactin and growth hormone.

The major hypothalamic releasing hormones are:

• Thyrotropin releasing hormone (TRH)

• Corticotropin releasing hormone (CRH)

• Growth hormone releasing hormone (GHRH)

• Gonadotropin releasing hormone (GnRH)

The major hypothalamic inhibitory hormones are:

• Prolactin inhibitory hormone or dopamine

• Growth hormone inhibitory hormone (GHIH), also called Somatostatin.

Solution to Question 12:

The hormone that plays a permissive role in the attainment of puberty is leptin.

It now appears that leptin may be the link between body weight and puberty. Leptin is a satiety-producing hormone secreted by adipocytes. High leptin levels reduce appetite and increase energy expenditure.

Evidence for which is given by:

• Obese ob/ob mice that cannot make leptin are infertile, and their fertility is restored by injections of leptin.

• Leptin treatment also induces precocious puberty in immature female mice.

• However, the way that leptin fits into the overall control of puberty remains to be determined.

Leptin also accelerates GnRH pulsatility in neurons, fastening puberty.

Solution to Question 13:

Weber-Fechner Law states that the magnitude of sensation felt is proportionate to the log of the intensity of the stimulus.

Other Laws in Physiology:

• Doctrine of specific nerve energies - When the nerve pathways from a particular sense organ are stimulated, the sensation evoked is that for which the receptor is specialized no matter how or

where along the pathway the activity is initiated.

• Law of projection - No matter where a particular sensory pathway is stimulated along its course to the cortex, the conscious sensation produced is referred to the location of the receptor. This principle is called the law of projection.

Solution to Question 14:

In adrenal insufficiency there is hypo-osmotic volume contraction. Aldosterone deficiency leads to increased sodium loss (loss of hyperosmotic fluid).

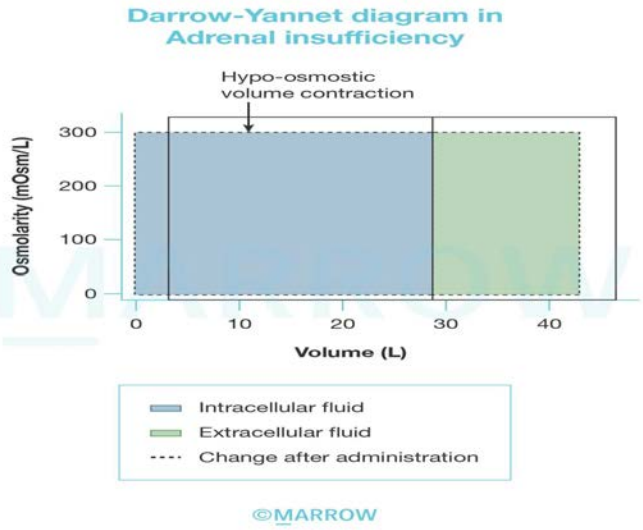
• The osmolarity of ECF decreases.

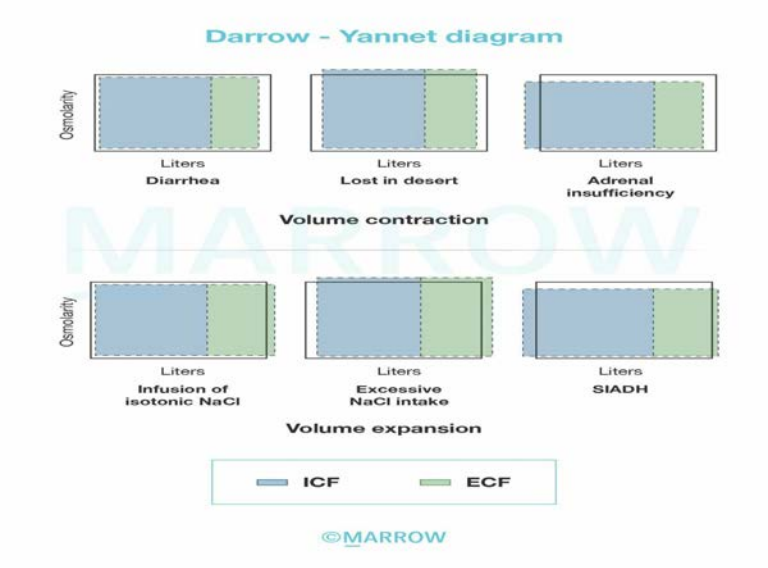
• ECF volume decreases because of the loss of volume.

• Water shifts into ICF; as a result of the shift, ICF osmolarity decreases until it is equal to ECF osmolarity, and ICF volume increases.

• So, loss of hypertonic fluid causes hypotonic volume contraction.

Please note that in the diagram, the horizontal axis represents volume and vertical axis represents osmolarity.





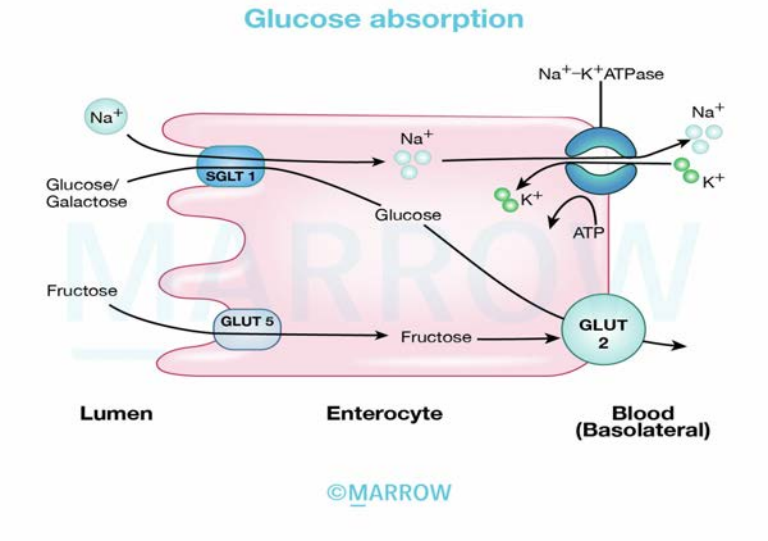
The Darrow Yannet diagrams of various conditions are shown above.

Solution to Question 15:

Glucose is absorbed in the intestine by secondary active transport.

On the basolateral side, there is active transport of sodium ions out of the cell into the interstitial fluid. This depletes sodium inside the cell. Because of this Na+ concentration difference, more Na+ binds to the SGLT on the luminal side. This increases the affinity of SGLT for glucose and glucose binds to it.

Then, both the Na+ and glucose are transported together to the interior of the cell. Thus, glucose is absorbed in the intestine by secondary active transport. The energy for glucose transport is provided indirectly, by the active transport of Na+ out of the cell. The glucose moves out of the cell into the blood across the basolateral membrane by facilitated diffusion mediated via GLUT.



Solution to Question 16:

BFU is the earliest stage of hematopoiesis where erythropoietin (EPO) acts

Under the influence of EPO, both BFU and CFU grow in semisolid culture media and give rise to colonies of well-hemoglobinized erythroblasts.

Erythroid burst-forming unit (BFU-E) is the most primitive single lineage committed erythroid progenitor. In addition to EPO, they form the sub-population of Erythroid Colony Forming Units (CFU-E).

CFU is derived from burst-forming units.

Note: While CFUs have the highest number of receptors for EPO, the earliest stage at which it acts is on the BFU.

Solution to Question 17:

Integrin connects with fibronectin.

Integrins are transmembrane glycoproteins (integral proteins) that allow cells to attach to extracellular matrix constituents such as laminin, fibronectin and collagen. It helps in linking the intracellular cytoskeleton functionally and structurally with the outside world.

Solution to Question 18:

The area of the cardiac muscle marked is devoid of nuclei. Lysosomes are commonly observed in perinuclear areas. Other organelles are present in abundance throughout the cell.

Solution to Question 19:

The fibres of inferior olivary nucleus (climbing fibres) reach the purkinje cell directly.

Note:

The input from the Purkinje cells to the deep nuclei is inhibitory.

However, the deep nuclei output is always excitatory.

Solution to Question 20:

Net filtration pressure = Hydrostatic pressure in the glomerular capillaries - Pressure in Bowman's capsule - Oncotic pressure in the glomerular capillaries.

Net filtration pressure= [PG -PB- πG+ πB]

Therefore,

Net filtration pressure = (45-10-20+0)

= 25-10

= 15 mmHg

Note:

Here, just the net filtration pressure is asked and not the GFR.

GFR= Kf [PG -PB- πG+ πB]

Solution to Question 21:

In a 100-m dash that takes 10 s, 85% of the energy consumed is derived anaerobically by phosphocreatine, which is hydrolyzed to creatine and phosphate groups with the release of considerable energy.

The ATP concentration in a muscle is low enough (4 millimolar) to sustain contractions for 1-2 seconds after which ATP is dephosphorylated into ADP. The ADP is re-phosphorylated by phosphocreatine for the next 5 to 8 seconds.

ADP is re-phosphorylated by 3 sources.

• Phosphocreatine after 2 seconds upto 10 seconds.

• Glycolysis (anaerobic) after 10 seconds upto a minute

• Oxidative metabolism - after a minute upto 2-4 hours.

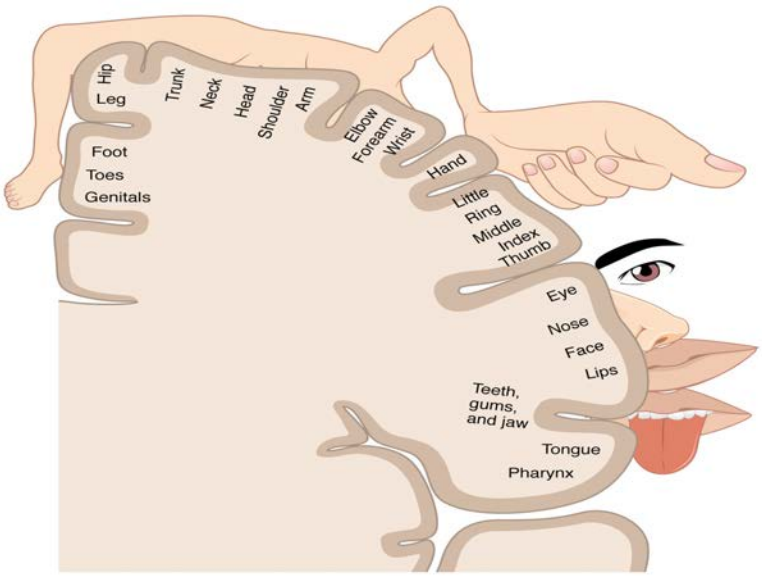
Solution to Question 22:

In a homunculus, the more the representation of an area, the more precise the movements are.

• The relative sizes of the cortical receiving areas of the sensory homunculus are proportionate to the use of the part.

• The sizes of these areas are directly proportional to the number of specialized sensory receptors in each respective peripheral area of the body.

• Some body parts are represented by large areas in the somatic cortex—the lips the greatest of all, followed by the face and thumb, whereas the trunk and lower part of the body are represented by relatively small areas.



Solution to Question 23:

Golgi complex is located in supranuclear cytoplasm in serous acinar cells. Serous acinar cells are generally found in pancreas and the submandibular salivary glands.

Physiology AIIMS 2019 (May & Nov)

Question 1:

The function of the Golgi tendon organ is to _____

a) Sense changes in muscle direction

b) Sense changes in muscle tension

c) Sense changes in position of the muscle

d) Sense changes in length of the muscle

Question 2:

Which is the first-order neuron in the optic pathway?

a) Rods and cones

b) Ganglion cells

c) Cells in lateral geniculate body

d) Bipolar cells

Question 3:

Pacemaker generating the rhythm for breathing is _____

a) Pneumotaxic centre

b) Dorsal group of neurons in the medulla

c) Pre-B■tzinger complex

d) Apneustic centre

Question 4:

Which of the following is not an example of feed forward control mechanism?

a) Temperature Regulation

b) Cephalic phase of gastric secretion

c) Cerebellar action in motor coordination

d) Exercise resulting in heart rate increase

Question 5:

Single breath nitrogen method is used for measuring ____

a) Dead space volume

b) FRC

c) Tidal volume

d) Diffusion capacity

Question 6:

I-125 labelled albumin is used for measurement of:

a) Plasma volume

b) Interstitial fluid volume

c) ICF

d) ECF

Question 7:

Which of the following hormones is exclusively secreted by adrenal gland but not by the ovaries of females?

a) Progesterone

b) DHEA

c) Estrogen

d) DHEA-S

Question 8:

Which hormone crosses the plasma membrane for its action?

a) Epinephrine

b) Thyroxine

c) Glucagon

d) Insulin

Question 9:

Afferent fibers from baroreceptors for blood pressure control goes to?

a) Nucleus ambiguous

b) Rostral-ventro lateral medulla

c) Nucleus Tractus Solitarius

d) Caudal ventrolateral medulla

Question 10:

If the lung is allowed to undergo elastic recoil without the chest wall, the resultant volume of the lung would be?

a) Minimum volume

b) Zero

c) Functional residual capacity

d) Residual volume

Question 11:

Myosin head detaches from actin by which of the following mechanism?

a) Binding of ATP

b) Entry of calcium into sarcoplasmic reticulum

c) Change in troponin C configuration

d) Release of ADP and Pi

Question 12:

You are an intern and want to determine the quantity of IV fluids needed for a patient. How much amount of transient loss/insensible loss per day would you account for in your calculations?

a) 150-200 ml

b) 500-600 ml

c) 200-350 ml

d) 350-400 ml

Question 13:

A soldier posted in Siachen is brought to you in the ER. In order to rule out hypothermia, how do you best measure his temperature?

a) Oral

b) Rectal

c) Infrared tympanic thermometer

d) Axillary

Question 14:

"Vasopressin escape" in SIADH results due to:

a) Downregulation of aquaporin 2 production

b) Increase in urine osmolarity

c) Decrease in ADH secretion

d) Upregulation of aquaporin 2 production

Question 15:

Which of the following hormones do not act on the pancreas?

a) Secretin

b) Gastrin

c) Cholecystokinin

d) GIP

Answer Key

Detailed Explanations

Solution to Question 1:

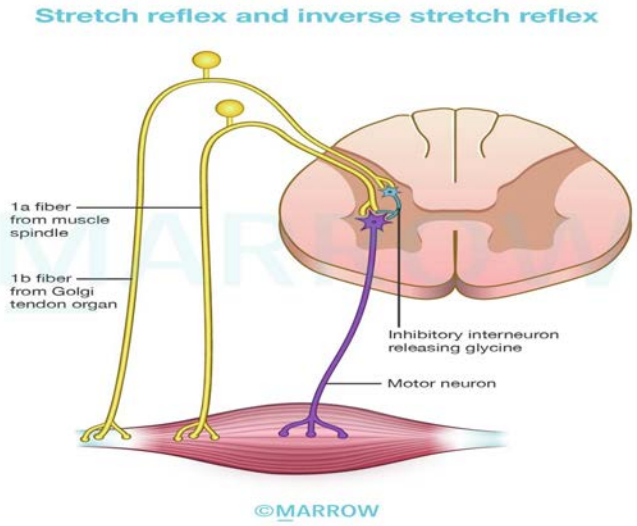
Golgi tendon organ sense changes in muscle tension.

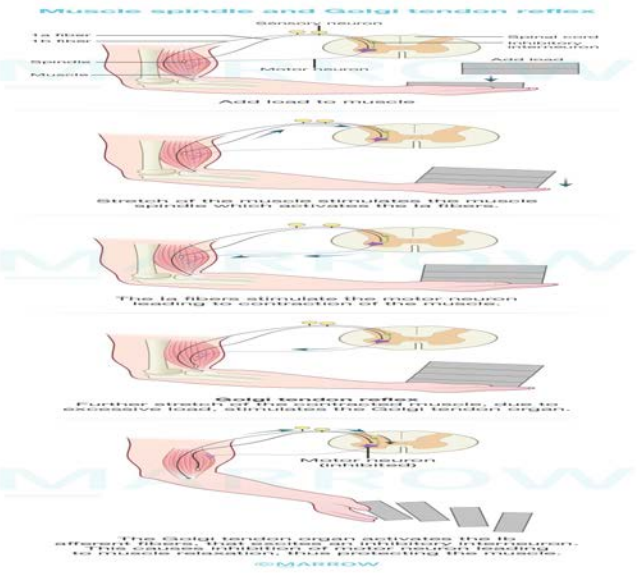
Golgi tendon reflex (Inverse myotatic/ Inverse stretch reflex) is disynaptic, is the opposite of the stretch reflex.

When the tension in a contracted muscle is significantly elevated, the inhibitory effect from the Golgi tendon organ leads to instantaneous relaxation of the entire muscle. This effect is called the lengthening reaction.

It is a protective mechanism to prevent tearing of the muscle or avulsion of the tendon from its attachments to the bone.

Note: Muscle spindles senses changes in muscle length (stretch).





Solution to Question 2:

Photoreceptors - rods and cones are the first-order neurons in the visual pathway.

Solution to Question 3:

Pre-Botzinger complex generates the rhythm for automated breathing.

- These are also known as pacemaker cells located in the medulla.
- These are the first set of neurons that initiate inspiration.

• These neurons discharge rhythmically, and they produce rhythmic discharges in the phrenic motor neurons.

Breathing is under the control of both the following:

• Voluntary control: Located in the cerebral cortex (via corticospinal tract)

• Automatic control: Driven by pacemaker cells in the medulla (Pre-Botzinger complex). These activate motor neurons via cervical (Phrenic nerve innervating diaphragm) and thoracic spinal cord (external intercostal muscle).

There is a reciprocal innervation to expiratory and inspiratory muscles in that motor neurons supplying expiratory muscles are inactive when motor neurons supplying inspiratory muscles are active, and vice versa.

Inspiration	
Initiation	Pre-Botzinger complex (Pace maker cells) in Medulla
Maintenance	Apneustic center in lower Pons stimulates Dorsal group of neurons in the medulla
Termination	Apneustic center inhibited by Vagus and Pneumotaxic center

Regulation of expiration: During quiet breathing, expiration is a passive process; there is no firing of neurons. Ventral respiratory group of neurons are involved in forceful expiration like during exercise.

Mnemonic DIVE: Dorsal respiratory group for Inspiration and Ventral respiratory group for Expiration.

Solution to Question 4:

Exercise resulting in heart rate increase is not an example of feedforward control mechanism. However, thinking about exercise and it resulting in a heart rate increase would be an example of feedforward control mechanism.

Feedforward control is that which makes an anticipatory or adaptive response without a specific stimulus.

Temperature control - Thermoregulatory responses are initiated by the hypothalamus before the changes in environmental temperature changes the core body temperature. Thus, shivering in response to cold environment would be an example of feedforward control.

In the cephalic phase of gastric secretion, the thought of food itself and not food per se produces a gastric secretion.

The cerebellum has a feed-forward inhibition that limits the duration of the excitation produced by any given afferent volley.

Solution to Question 5:

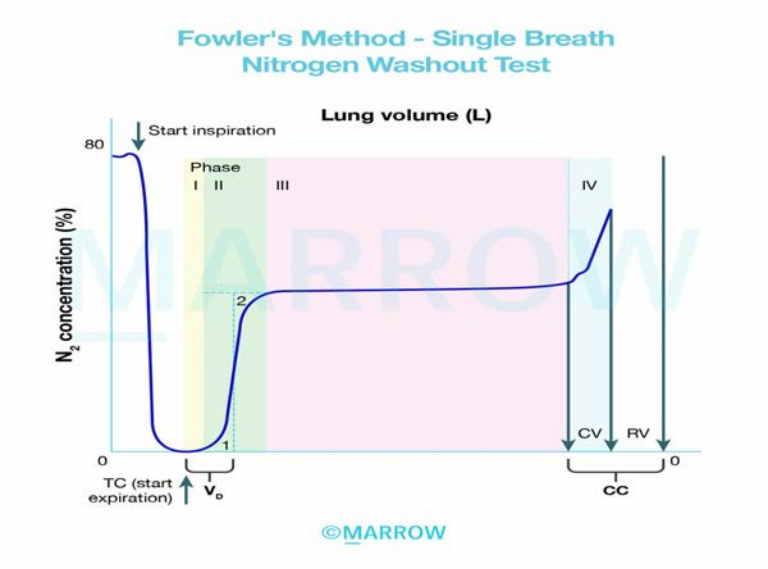
Anatomical dead space can be measured by the single-breath N2 curve (Fowler's method).

• Anatomical dead space is the respiratory system volume exclusive of alveoli.

• Alveolar dead space is the volume of gas not equilibrating with blood i.e. wasted ventilation.

• Physiological/total dead space is the sum of anatomical and alveolar dead space.

• The equation used for the calculation of total/physiological dead space is the Bohr's equation.



The patient takes a deep breath of O2 From mid-inspiration, then exhales steadily. The changes in the N2 concentration of expired gas during expiration are plotted.

Region I - Dead Space (DS)

From I–II is a mixture of DS and alveolar gas.

The transition from III-IV is the closing volume (CV).

End of IV - Residual Volume (RV).

Factors affecting dead space:

Option B: Functional Residual Capacity (FRC) is measured using body plethysmography.

Option C: Tidal volume (TV) is measured using spirometry.

Option D: Diffusion Capacity is measured using carbon monoxide diffusion capacity (DLCO).

Factor	Effect
Posture:UprightSupine	IncreaseDecrease
Position of airway:Neck ExtensionNeck Flexion	IncreaseDecrease

Factor	Effect
Age	Increase
Artificial airway	Decrease
Positive pressure ventilation	Increase
Drug anti-cholinergic	Increase
Pulmonary perfusion:Pulmonary embolismHypotension	IncreaseIncrease
Pulmonary disease:Emphysema	Increase

Solution to Question 6:

I-125 labelled albumin is the most commonly used substance for the measurement of plasma volume.

Solution to Question 7:

DHEAS is exclusively secreted from the adrenals but not by ovaries because ovaries lack the enzyme dehydroepiandrosterone-sulphotransferase needed to form DHEAS.

90% of DHEA is synthesised by the adrenals and 10% comes from the ovaries.

Solution to Question 8:

Thyroxine crosses the plasma membrane for its action.

Thyroid hormones enter the nucleus and bind to thyroid hormone receptors. The hormone-receptor complex in the nucleus binds to DNA via zinc fingers. This increases the expression of a variety of different genes that code for proteins regulating cell function. Although thyroxine is an AA derivative, there are transporters to move it into the cell, hence they are intracellular receptors acting on the nucleus.

Epinephrine, glucagon, and insulin bind to cell surface receptors.

Solution to Question 9:

Afferent fiber for blood pressure control goes to the Nucleus Tractus Solitarius (NTS).

Increased BP stimulates the baroreceptors which provide negative feedback in response to the increase in blood pressure.

Baroreceptor reflex:

• Increased BP → stimulation of baroreceptors → stimulation of NTS → excitation of CVLM → inhibition of RVLM → inhibition of sympathetic system

• Stimulation of NTS also stimulates CVC → parasympathetic stimulation

• Net effect = sympathetic inhibition and parasympathetic stimulation → decreased HR and BP

NTS - Nucleus tractus solitarius

CVC - Cardiovagal centre

CVLM - Caudal ventrolateral medulla

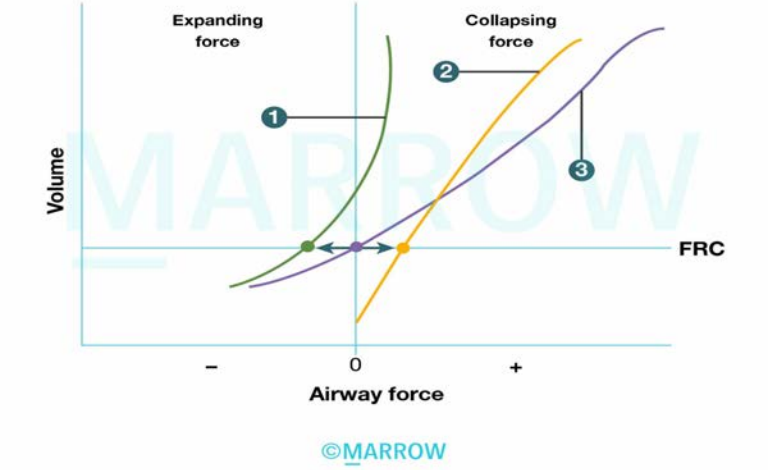
RVLM - Rostral ventrolateral medulla

HR - Heart rate

BP - Blood pressure

Solution to Question 10:

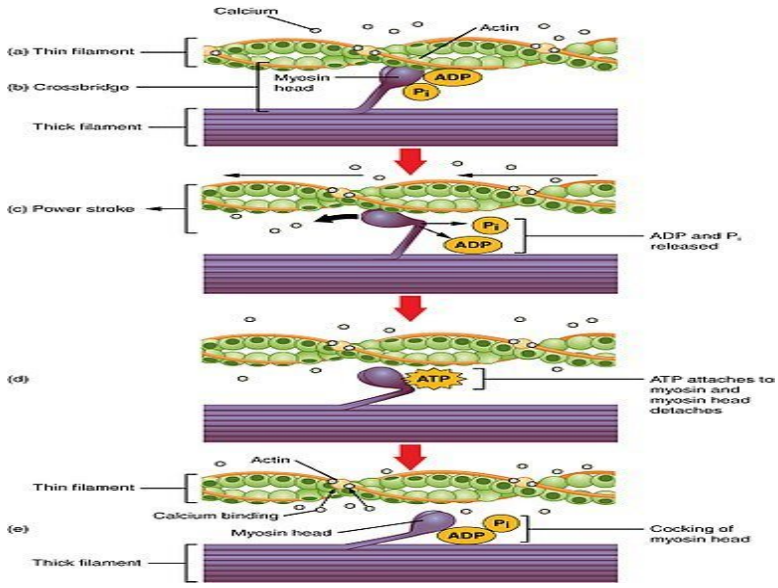
If lung is allowed to undergo elastic recoil without the chest wall, the resultant volume of the lung would be minimum volume as the opposing force by the chest wall would be non existant.



The yellow line in the above graph denotes the compliance of lungs alone. According to the graph, when the pressure (x axis) inside the lung is zero, there is some volume of air lesser than FRC still present (y axis) inside the lungs which is less than the functional residual capacity and residual volume which can be called as minimum volume.

Solution to Question 11:

Binding of ATP on the free site of myosin leads to the detachment of myosin head from the thin filament.



Solution to Question 12:

500-600 ml of transient loss/insensible loss per day would have to be accounted for in the calculation.

Although water is lost through sweating especially in hot climates or during physical exertion, we tend to lose water at rest as well. Physiologically, water evaporates from the skin and lungs at a rate of about 600 to 700 ml/day. This is known as insensible water loss.

Solution to Question 13:

In the given clinical scenario rectal temperature would be the preferred site to measure the core body temperature.

During low or high temperatures like in Siachen, the axillary and the oral temperatures are highly misleading and should not be used to measure the core body temperatures

Infrared tympanic thermometer measures the temperature of the eardrum which is representative of core body temperature. However, more often the thermometer is not inserted adequately or for safety reasons, they are manufactured in such a way that they do not reach deep into the ear canal, or the ear canal contains cerumen which can disturb the measurement. Hence the infrared thermometer more commonly delivers the temperature of ear canal cerumen and hence not a reliable method of measuring the core body temperature.

Solution to Question 14:

Vasopressin escape in SIADH (Syndrome of inappropriate ADH secretion) results due to downregulation of aquaporin 2 production.

Prolonged exposure to elevated levels of vasopressin (ADH) leads eventually to downregulation of aquaporin-2 receptors. This prevents excessive reabsorption of water, despite high serum ADH levels and hence maintains euvolemia. This is known as vasopressin escape. This helps prevent excessive dilutional hyponatremia in SIADH.

Solution to Question 15:

Gastrin does not act upon the pancreas. Gastrin stimulates gastric acid secretion and gastric mucosal growth.

GI hormones acting on the pancreas include:

GIP is also known as Glucose-dependent insulinotropic peptide.

	CCK(Cholecystokinin)	Secretin	GIP(Gastric inhibitory peptide)
Stimulates	Pancreatic enzyme secretion Pancreatic bicarbonate secretionGallbladder contractionGrowth of exocrine pancreas	Pepsin secretionPancreatic bicarbonate secretionBiliary bicarbonate secretionGrowth of exocrine pancreas	Insulin release
Inhibits	Gastric emptying	Gastric acid secretion	Gastric acid secretion

Physiology AIIMS 2020 (May and Nov INI-CET)

Question 1:

A 65-year old patient visits his family practitioner for a yearly examination. On examination, his BP was 190/100 mm Hg. His pulse pressure was 90 mm Hg. What would have decreased resulting in this increase in pulse pressure?

a) Myocardial contractility

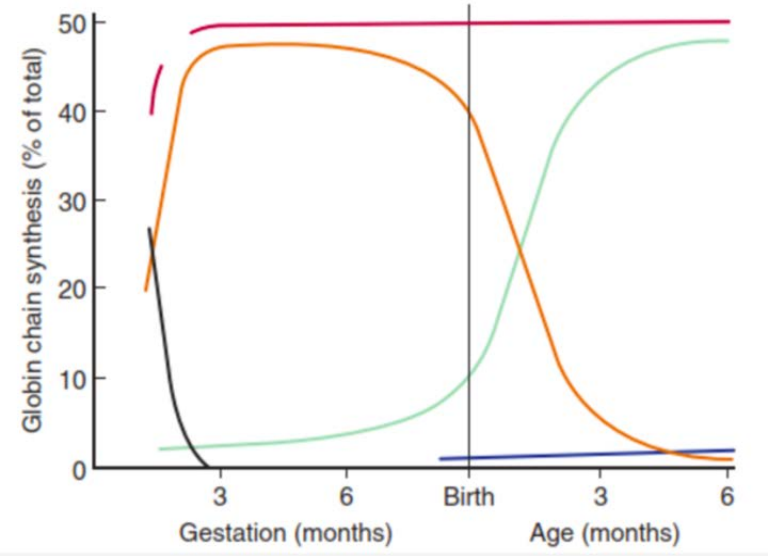
b) Stroke volume

c) Arterial wall compliance

d) Cardiac output

Question 2:

Which of the following curves represents gamma-globin chain production?



a) Green Curve

b) Black Curve

c) Blue Curve

d) Orange curve

Question 3:

Transcutaneous electric nerve stimulation is used to reduce pain. What is the mechanism behind this?

a) Central inhibition

b) Desensitization

c) Gate control theory

d) Descending inhibition

Question 4:

Which of the following is not required for calculation of creatinine clearance?

a) Urine creatinine

b) Serum creatinine

c) 24 hour urine output

d) Volume of serum passing through kidney in 24 hours

Question 5:

A neuron is receiving 400 inputs from 150 sensory neurons. This is an example of?

a) Divergence

b) Convergence

c) Feedback inhibition

d) Feedforward excitation

Question 6:

Calculate the ECF volume in a volunteer in whom 10 gm of mannitol was injected in venous blood. At equilibrium urinary excretion of mannitol was found to be 10% and the plasma concentration of mannitol was 65 mg/100 ml.

a) 14L

b) 10L

c) 28L

d) 20L

Question 7:

Gibbs-Donnan equilibrium is mainly due to?

a) Phosphate

b) Bicarbonate in the intracellular compartment

c) Calcium in the extracellular compartment

d) Intracellular proteins

Question 8:

Which of these hormones have intracellular receptors?

a) Thyroxine

b) Epinephrine

c) Glucagon

d) Parathormone

Question 9:

Intercellular communication in eukaryotes is by?

a) Lysosome

b) Peroxisome

c) Exosome

d) Genome

Question 10:

In skeletal muscle, dihydropyridine and ryanodine receptors are coupled by?

a) Chemically

b) Electrically

c) Chemically and then electrically

d) Mechanically

Question 11:

In negative feedback, feedback gain of infinity is seen in which of the following?

a) Blood volume control by kidney

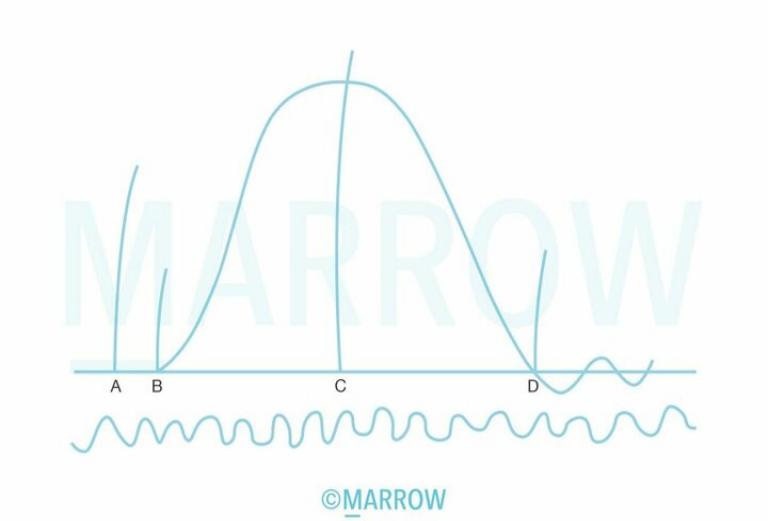
b) Temperature control in hypothalamus

c) BP control by barorecptors

d) Infinite gain is not possible

Question 12:

The image below shows simple muscle twitch along with the time trace, recorded in a frog gastrocnemius muscle. Calculate the minimum tetanizing frequency. (The time tracer was made with a 100Hz tuning fork).



a) 25 per second

b) 15 per second

c) 17 per second

d) 20 per second

Question 13:

Least frequency of slow waves is seen in:

a) Duodenum

b) Ileum

c) Jejunum

d) Stomach

Question 14:

Macula densa is formed by which part of the nephron?

a) PCT

b) DCT

c) Afferent arteriole

d) Bowman's capsule

Question 15:

As filtrate flows through PCT, the concentration of all of the following decreases except:

a) Aminoacid

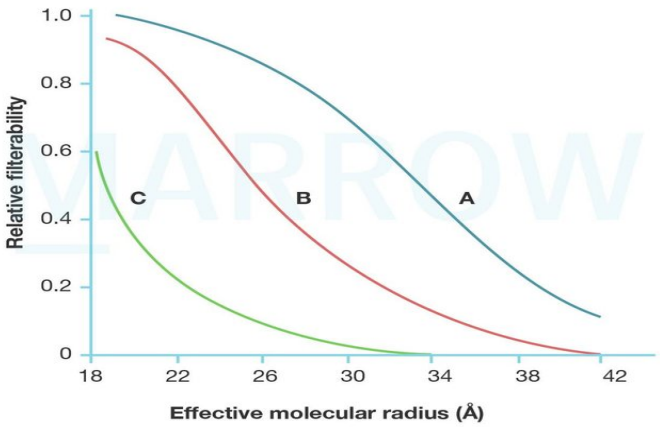
b) Glucose

c) Chloride

d) Bicarbonate

Question 16:

This is the graph depicting the filterability of dextran through the kidney, 1 representing complete filtration and 0 representing no filtration. Choose the substance A, B, C respectively.



©MARROW

a) Polycationic, Neutral, Polyanionic

b) Polyanionic, Neutral, Polycationic

c) Neutral, Polycationic, Polyanionic

d) Polyanionic, Polycationic, Neutral

Question 17:

Calculate the respiratory quotient (RQ) in a patient with 50kg body weight, if the CO2 exhaled is 200ml/min and O2 consumed is 250 ml/min.

a) 0.8

b) 1

c) 1.25

d) 1.5

Question 18:

Which of the following types of amino acids are present in the transmembranous part of the membrane receptor?

a) Amphipathic

b) Hydrophobic

c) Hydrophilic

d) None of the above

Question 19:

Which of the following is not a cause of secondary hyperparathyroidism?

a) Parathyroid adenoma

b) Lithium intake

c) Vitamin D deficiency

d) Chronic kidney disease

Question 20:

Which of the following events occur immediately when a person changes his/her posture from supine to standing?

a) Decrease in firing from baroreceptor

b) Vagal output to cardiac fibres increase

c) Mesenteric Vasoconstriction

d) Increase cardiac contractility

Question 21:

Which of the following statements is true about skeletal muscle contraction?

a) 2, 3, 4

b) 3 only

c) 1, 2, 4

d) 1, 3, 4

Question 22:

Which of the following statements are correct regarding mechanisms of depolarisation, repolarisation, and hyperpolarisation in a skeletal muscle action potential?

a) 2 and 4 are correct

b) 1, 3, and 5 are correct

c) 1, 4, and 5 are correct

d) 2, 4, and 5 are correct

Question 23:

Arrange the following events in the sequence in which they occur, after 'p wave' in ECG:

a) 1-2-3-4

b) 1-2-4-3

c) 3-1-2-4

d) 1-3-2-4

Question 24:

Which of the following increases in COPD?

a) 1 only

b) 1 and 4

c) 1 and 3

d) 1 and 2

24	d

Detailed Explanations

Solution to Question 1:

Pulse pressure increases with age due to decreased arterial wall compliance.

With advancing age, there is an increase in systolic blood pressure. Whilst diastolic blood pressure falls after 60 years of age due to increased arterial stiffness (decreased compliance). As a result of these two changes, pulse pressure increases (↑PP = ↑SBP - ↓DBP).

Solution to Question 2:

In the given image, the Orange curve represents the gamma-globin chain production. Gamma globin chain is produced in the fetal period and drops to undetectable levels 6 months postpartum which is the pattern represented by the Orange curve.

Hemoglobin in blood has different variants throughout life, in different proportions. The type of hemoglobin essentially depends on the combination of globin chains. Adult hemoglobin is made of 2 alpha and 2 beta chains, whereas fetal hemoglobin is made of 2 alpha and 2 gamma-globin chains. Other combinations of chains can be found in embryonic hemoglobin.

Here,

• Gamma chain - Orange curve

• Alpha chain - Red curve

• Beta chain - Green curve

• Epsilon chain - Black curve

• Delta chain - Blue curve

Solution to Question 3:

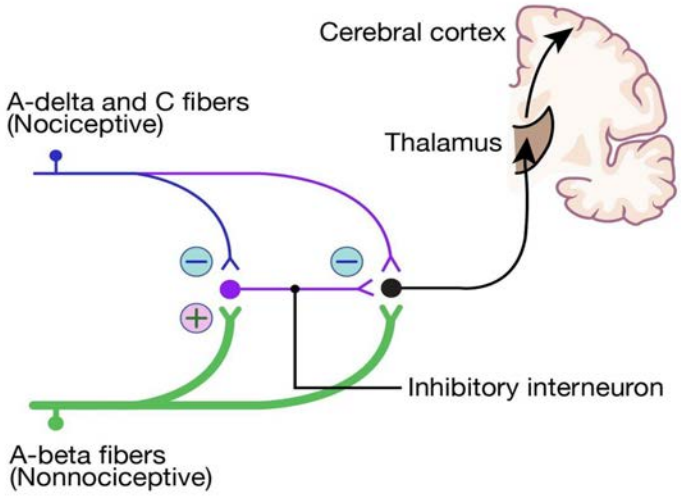
Transcutaneous electrical nerve stimulation (TENS) used for pain relief is based on the gate theory of pain. This method uses electrodes to activate Aα and Aβ fibers near the injury to relieve pain.

Gate control theory is based on the inhibition of pain pathway in the spinal cord. Various sensory inputs from a particular dermatome reach the dorsal horn of the spinal cord. The pain is transmitted via A-delta and C fibers, whereas, A-beta fibers carry tactile sensations (touch, pressure) and A-alpha fibers carry proprioception.

When these large-diameter A-beta/A-alpha fibers are stimulated, they inhibit the pain pathway in the spinal cord. This inhibition is thought to result from the local lateral inhibition of interneurons in the spinal cord.

Gate control theory operates at the substantia gelatinosa of the dorsal horn of the spinal cord.

The given image depicts the gate control theory of pain:



Solution to Question 4:

The volume of plasma passing through the kidney in 24 hours is not used in the calculation of creatinine clearance.

The parameters used to calculate creatinine clearance (CCr) are:

• Urine creatinine

• Serum creatinine

• 24hr urine output

The formula used to calculate creatinine clearance (CCr) is:

$UCr \times V / PCr$ where,

UCr - Urine creatinine(mg/dl)

PCr - Serum creatinine(mg/dl)

V - Urine volume(ml/24 hrs)

Creatinine is a metabolite of muscle metabolism and is cleared from the body mostly by glomerular filtration. Therefore, the clearance of creatinine is used to assess GFR.

Urine collection for the measurement of creatinine clearance may be subject to practical constraints. Therefore, approximate changes in GFR can be obtained by measuring the serum creatinine concentration, which is inversely proportional to GFR.

Solution to Question 5:

A single neuron receiving 400 inputs from 150 sensory neurons is an example of convergence.

Convergence means signals from multiple inputs uniting to excite a single neuron. It can be of 2 types:

• Convergence from a single source

• Convergence from multiple sources

The importance of convergence is that neurons are almost never excited by an action potential from a single input terminal. However, action potentials converging on the neuron from multiple terminals provide enough spatial summation to bring the neuron to the threshold required for discharge.

Solution to Question 6:

ECF volume of the above volunteer is calculated to be 14 L.

The ECF volume can be calculated using the formula:

Where,

• V = ECF volume

• Amount injected = 10 gm

• Amount of mannitol excreted = 10% of 10 gm = 1gm

• Plasma concentration of mannitol = 65 mg/100mL = 0.65 gm/L

Calculation:

ECF Volume = (10-1)/0.65

= 13.8 L = approximately 14 L

Mannitol cannot cross cell membranes, hence, it will be distributed in ECF but not in ICF. Thus mannitol is a marker for ECF volume and therefore calculating the volume of distribution of mannitol gives the value of ECF volume.

Solution to Question 7:

Gibbs-Donnan equilibrium is mainly due to intracellular proteins.

Donnan and Gibbs showed that "When an ion on one side of a membrane cannot diffuse through the membrane, the distribution of other ions to which the membrane is permeable is affected in a predictable way".

According to this, in the presence of intracellular proteins, which are negatively charged non-diffusable ions, the distribution of other ions to which the membrane is permeable is affected in a predictable way (Donnan Effect) so that at equilibrium their concentration ratios are equal.

Solution to Question 8:

Thyroxine hormone act by binding to intracellular nuclear receptors.

All other hormones mentioned in the options bind to receptors on the cell membrane.

Solution to Question 9:

Intercellular communication in eukaryotes is by Exosome.

In the last decade, a class of small, heterogeneous, secreted vesicles, broadly termed as extracellular vesicles have been identified.

These extracellular vesicles have been implicated as a new and important mediator of cell-cell communication that likely contributes importantly to both normal and pathologic physiology.

These vesicles are enclosed by a lipid bilayer.

They are heterogeneous in size (30-2000 nm diameter), and are generated by at least two distinct mechanisms:

• Microvesicles are generated by budding from the plasma membrane of a source cell.

• Exosomes are generated from the multivesicular body (MVB).

Note: The terms microvesicle and exosome are often lumped together as simply exosomes.

Solution to Question 10:

In skeletal muscle, dihydropyridine and ryanodine receptors show mechanical coupling involving structural interaction between the two.

Dihydropyridine receptors (DHPRs) are voltage-gated Ca^{2+} channels in the T tubule membrane.

The ryanodine receptor (RyR) is a ligand-gated Ca^{2+} channel with Ca^{2+} as its natural ligand.

Skeletal muscle excitation-contraction (E-C) coupling is thought to occur by a "mechanical coupling" mechanism involving protein-protein interactions that lead to activation of the sarcoplasmic reticulum ryanodine receptor by the voltage-sensing transverse (T-) tubule dihydropyridine receptor.

Solution to Question 11:

In negative feedback, feedback gain of infinity could be seen in blood volume control by the kidney.

When the blood volume falls below the equilibrium, the renal–body fluid mechanism causes the blood volume returns back to the equilibrium point resulting in zero error and hence the gain of kidney in its ability to regulate blood volume is infinity (∞).

The degree of effectiveness with which a regulatory system maintains constant conditions is determined by the gain of the negative feedback system.

Gain= Correction/Error

Example: If an external or internal factor led to a decrease in mean blood pressure from 100 mm Hg to 80 mm Hg. Activation of a negative feedback mechanism i.e. baroreflex leads to a correction of blood pressure to 96 mm Hg. So in this case,

• Correction = 16 mm Hg

• Error = 4 mm Hg

• Gain = Correction/Error = 16/4 = 4

Note: A gain of 0 would imply a total failure of the regulatory system and a gain of infinity (∞) would indicate complete restoration of the regulated variable.

Solution to Question 12:

The tetanizing frequency of the muscle, based on the given diagram, is 20 per second.

Tetanizing frequency = 1/contraction period. It is the frequency at which individual muscle fibres twitch that fuse and cause sustained muscle contraction, where the contraction period is the time taken from latent period to maximum force of contraction.

In this case, the time tracer was taken using a 100Hz tuning fork. Which means the tracer recorded 100 waves per second.

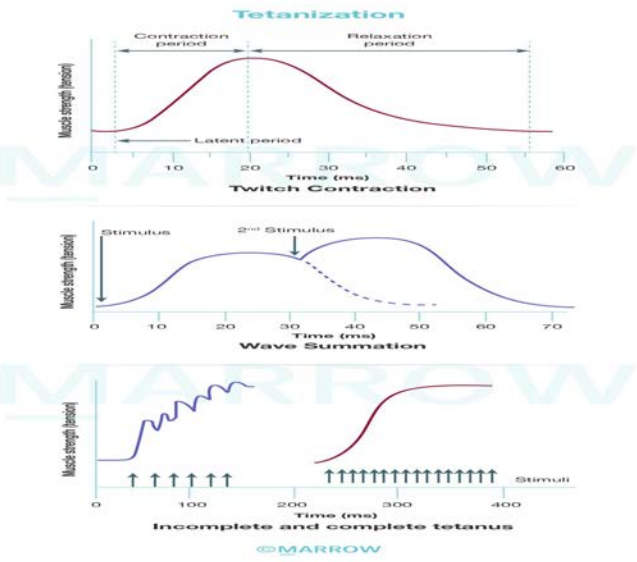
Therefore, the duration of each wave in time tracer = 0.01 seconds.

In the image given in the question, between the point B (end of latent period) to point C (maximum force of contraction), there are about 5 waves.

Hence, the duration of contraction = 5 x 0.01 = 0.05 seconds.

Substituting the value in the formula, we get:

Tetanizing frequency = 1/0.05 sec = 100/5 = 20/sec.



Tetanization:

The features of muscle contraction can be demonstrated by eliciting single muscle twitches. The adding together of individual twitch contractions to increase the intensity of overall muscle contraction is Summation. Summation occurs in two ways:

• by increasing the number of motor units contracting simultaneously, which is multiple ■ber summations.

• by increasing the frequency of contraction, which is called frequency summation and can lead to tetanization.

When the frequency of a contraction reaches a critical level, the successive contractions eventually fuse together, and the whole muscle contraction appears to be completely smooth and continuous, this is called tetanization. Beyond this point, a further increase in the frequency, will not result in increased force of contraction.

Tetanization occurs in two ways:

• Complete tetanus occurs when no relaxation occurs between stimuli.

• Incomplete tetanus when periods of incomplete relaxation take place between the summated stimuli.

Solution to Question 13:

Among the given options, the least frequency of slow waves is seen in the stomach (4/min).

The Basal electrical rhythm (BER) also called slow-wave, is a rhythmic fluctuation of membrane potential in the gastrointestinal smooth muscle. It is initiated by the interstitial cells of Cajal. The membrane potential fluctuates between -65mV and -45mV.

The BER is seen in all sites of gastrointestinal smooth muscle except in the esophagus and proximal stomach.

The rate of BER in various sites is as follows:

• Stomach: 4/min

• Duodenum: 12/min

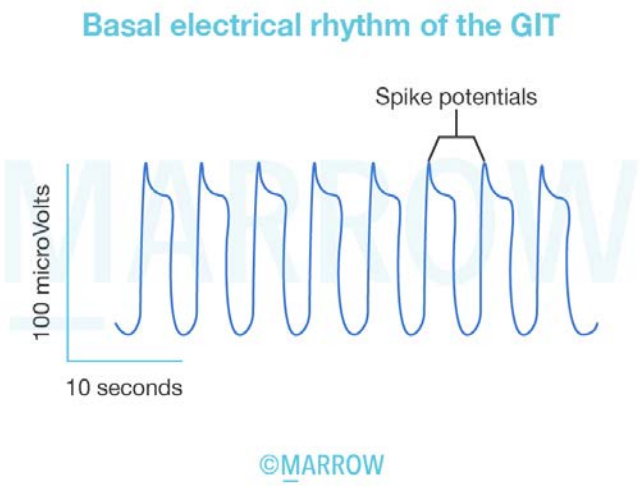
• Distal ileum: 8/min

• Cecum: 2/min

• Sigmoid colon: 6/min

The BER does not cause contraction of the smooth muscle. However, when the BER is superimposed by the spike potentials, it increases muscle tension.

Acetylcholine causes an increase in the number of spike potentials and muscle tension. Epinephrine causes a decrease in the number of spike potentials and muscle tension.

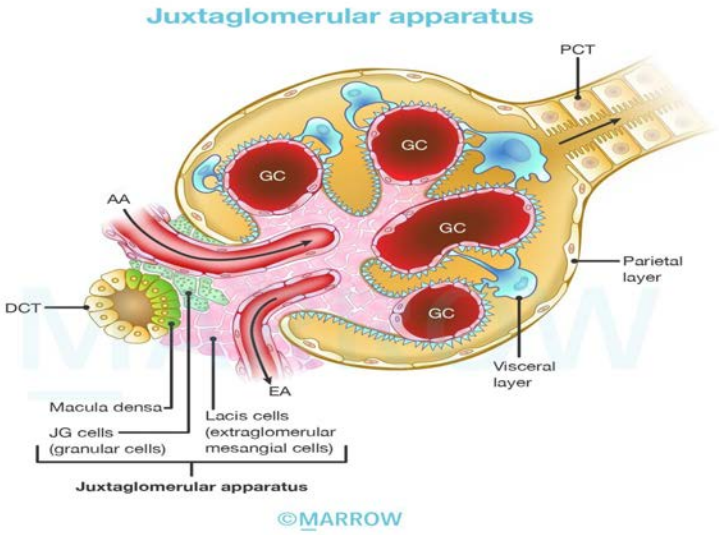


Muscle contraction can occur only when the motor stimulus is provided during the depolarisation part of the BER.

Thus, BER does not cause muscle contraction by itself, but controls the rate and organization sites of the muscle contractions, as in coordination of the peristaltic activity and setting the rhythm of segmentation.

Solution to Question 14:

Macula densa is formed by specialized tubular epithelial cells of the distal convoluted tubule.



The juxtaglomerular apparatus consists of the following parts:

• Macula densa: At the end of the thick ascending limb of Henle, and at the beginning of the distal tubule, the tubular epithelial cells are specialized to form the macula densa. They detect sodium

concentration of the fluid in the tubule (chemoreceptor). In response to elevated sodium, the macula densa cells trigger the contraction of the afferent arteriole, reducing the flow of blood to the glomerulus and the glomerular filtration rate. This happens as follows: When there is increased sodium, there is increased sodium-potassium ATPase activity which leads to increased ATP hydrolysis causing more adenosine formation. The adenosine receptors on the macula densa cells stimulate it to release more calcium, so that there is vasoconstriction of the afferent arteriole, thereby decreasing the GFR.

• Lacis cells: Extraglomerular mesangial cells situated between afferent and efferent arteriole.

• Granular cells/JG cells: Modified smooth muscle cells of the afferent arteriole, they secrete renin. Fall in pressure in afferent arteriole stimulates renin release (mechanoreceptor), which, in turn, increases blood pressure.

Solution to Question 15:

As the filtrate flows through the proximal convoluted tubule, the concentration of the chloride increases.

• The concentration of chloride in the early part of the pCT is ≈105 mEq/L.

• As the sodium is reabsorbed, it preferentially carries glucose, amino acids, and bicarbonate.

• This leaves behind the solute, that has a higher concentration of the chloride, which as it reaches the second half of the PCT is ≈140 mEq/L.

Solution to Question 16:

In the given graph, the order of filterability is A>B>C, which likely indicates that the substances are Polycationic, Neutral, Polyanionic.

The glomerular filtration barrier is negatively charged, which will repel most of the negative charged (anionic substances). Whereas, the cationic substances are easily filtered.

Hence, the order of filterability would be: Polycationic > Neutral > Polyanionic, represented by A, B, and C in the graph shown.

The glomerular filtration barrier consists of:

• Endothelium of the capillary

• Basement membrane:

• Lamina densa - electron-dense layer. It contains type IV collagen

• Lamina rara interna - contains glycosaminoglycan heparan sulfate which has a negative charge

• Lamina rara externa - contains glycosaminoglycan heparan sulfate which has a negative charge

• Layer of epithelial cells (podocytes) surrounding the outer surface of the capillary basement membrane

The capillary endothelium is perforated by thousands of small holes called fenestrae, which measure from 4 nm up to 8nm. Therefore, neutral substances with molecular diameters of less than 4 nm are freely filtered, and filtration of those with diameters of more than 8 nm approaches zero.

However, in addition to the size of the particles, the filtration also depends mainly on the charge of the particle being filtered. The glomerular capillary wall consists of highly negatively charged proteins called sialoproteins, which repel the negatively charged substances (anions). The property can be studied by using charged dextran.

When the filtration of the negatively and positively charged dextrans was studied, the results indicated that the negatively charged dextrans in the blood are repelled, with the result that filtration of anionic substances 4 nm in diameter is less than half that of neutral substances of the same size.

This explains, why albumin despite having an effective molecular diameter of approximately 7 nm, has a very low filtration rate.

Solution to Question 17:

The respiratory quotient is 0.8.

The respiratory quotient is the ratio of carbon dioxide production to oxygen utilization.

In the given question, the CO_2 production is 200mL/min, while the O_2 consumption is 250mL/min.

Therefore,

Respiratory quotient = 200/250 = 0.8

The respiratory quotient (RQ) is used for determining the metabolic utilization of various foods.

• When carbohydrates are metabolized with one molecule of oxygen, one carbon dioxide molecule is released. Therefore, the RQ of carbohydrates = 1.

• When fats are oxidized, for every 100 molecules of oxygen consumed, 70 molecules of CO_2 are released. Therefore, the RQ of fats is 0.70.

• Similarly, the respiratory quotient for proteins is 0.80.

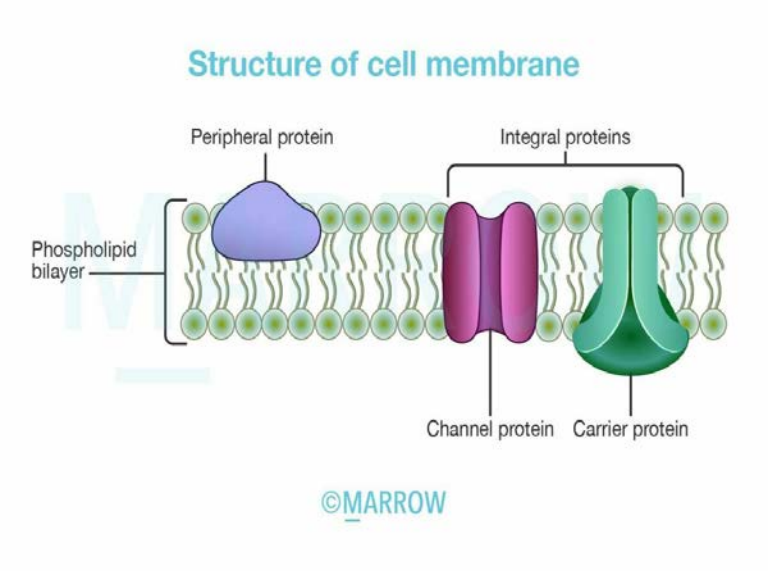
Solution to Question 18:

The transmembranous part of the membrane receptor consists of hydrophobic amino acids.

A membrane protein can be either integral protein (spans the thickness of the cell membrane) or peripheral protein (attached to the peripheral side of the membrane). The membrane-spanning segment of integral proteins are usually hydrophobic alpha-helices.

The central core of the cell membrane is hydrophobic. Integral proteins have their hydrophobic portions usually in the interior of the membrane and the hydrophilic portions towards the surfaces. The presence of these hydrophobic amino acids in the interior is a special adaptation

that allows the protein to remain stable in the hydrophobic milieu of the cell membrane.



Solution to Question 19:

Parathyroid adenoma is a benign tumor of the parathyroid gland, which causes primary hyperparathyroidism (not secondary).

Secondary hyperparathyroidism is characterized by high levels of parathyroid hormone, to compensate for the low levels of serum calcium, due to some other underlying condition.

Causes of secondary hyperparathyroidism, include:

• Chronic kidney disease: The damaged kidneys are unable to produce sufficient amounts of the active form of vitamin D, 1,25-dihydroxycholecalciferol. This further causes hypocalcemia and triggers PTH secretion.

• Vitamin D deficiency: Causes hypocalcemia, which triggers the increased secretion of PTH.

• Lithium: May cause an increased set-point of calcium for parathyroid hormone suppression, which leads to parathyroid hyperplasia.

Solution to Question 20:

There is a decreased firing from the baroreceptors.

• When a person stands up from a lying down position, it causes pooling of the blood in the legs, due to gravity. This reduces the venous return and causes a decrease in cardiac output.

• Reduced cardiac output, leads to a fall in blood pressure, which in turn causes reduced firing from baroreceptors.

• As a result, the vagal tone is suppressed leading to increased heart rate.

Solution to Question 21:

During the contraction of the skeletal muscle, the Ca2+ is released from the sarcoplasmic reticulum. Only statement 3 is correct.

Excitation contraction coupling refers to the process by which the membrane depolarization of the muscle fibre (excitation) leads to the contraction of the muscle.

The steps of excitation-contraction coupling in skeletal muscle are as follows:

• Motor-neuron discharge causes the release of acetylcholine at the motor endplate, which binds to the nicotinic acetylcholine receptors.

• This causes increased Na+ and K+ conductance in the endplate membrane, leading to the generation of end-plate potential, which is a local potential.

• When the local endplate potential reaches a threshold for the muscle fibre, and an action potential is generated.

• The generated action potential passes inward through the T tubules, leading to the spread of depolarisation.

• The depolarization of the muscle fibre causes the release of Ca2+ from terminal cisterns of sarcoplasmic reticulum and diffusion to thick and thin filaments.

• The calcium released, binds to troponin C, uncovering myosin-binding sites on actin.

• The formation of cross-linkages between actin and myosin and sliding of thin on thick filaments causes contraction of the skeletal muscle.

Steps in relaxation:

• The cytoplasmic calcium is pumped back into the sarcoplasmic reticulum, by the action of SERCA (sarcoplasmic endoplasmic reticulum calcium ATPase).

• Once the calcium concentration is lowered, the interaction between actin and myosin ceases, and the muscle relaxes.

Other options:

Statement 1: Incorrect - Extracellular calcium levels play an important role in muscle contraction. When there is a decrease in extracellular calcium as in hypocalcemia, the voltage-gated sodium channels are activated, which causes sodium influx. The increased intracellular sodium concentration causes sustained depolarization, which may lead to tetany.

Statement 2: Incorrect - Ca2+ is not released from mitochondria. It is released from the sarcoplasmic reticulum.

Statement 4: Voltage-gated calcium channels on T-tubules (part of sarcolemma) are activated by a depolarizing stimulus, which causes the release of calcium from the sarcoplasmic reticulum. The increased calcium concentration will eventually lead to muscle contraction.

Solution to Question 22:

Statements 1, 3, and 5 are correct.

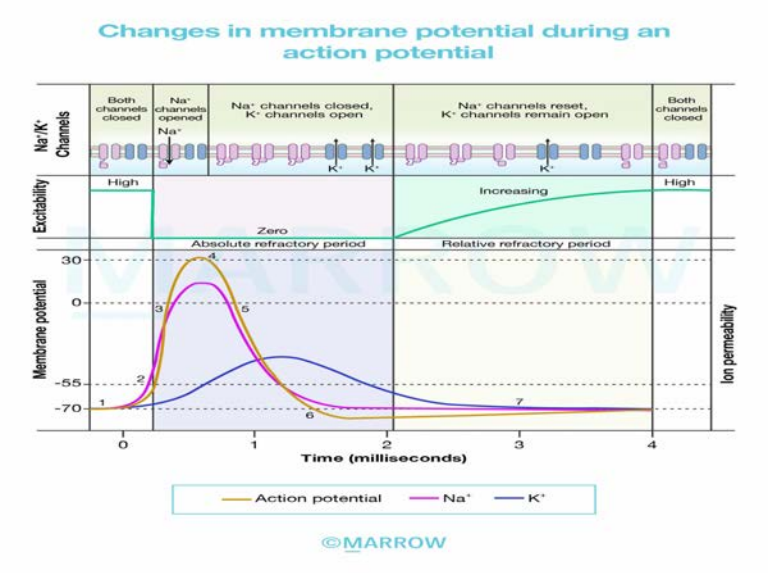
Action potential in skeletal muscle:

• Motor-neuron discharge causes end-plate potential, which when reaches to a threshold value, causes action potential in the muscle fibre.

• The depolarization of the muscle fibre is caused by the activation of the voltage-gated sodium channels, which causes the influx of sodium.

• During repolarization, the sodium channels are closed, and voltage-gated potassium channels open, which causes efflux of potassium.

• The voltage-gated potassium channels close slowly. As a result, the potassium efflux continues, leading to hyperpolarization of the membrane.



The steps in an action potential in muscle fibre and the neuron, are similar except for the quantitative differences, such as:

• RMP is -80 to -90 mV in skeletal muscle fibres, while it is about -70mV in neurons.

• The duration of the action potential in skeletal muscle is 1 to 5 msec, which is about 5 times longer than in the largest myelinated nerve fibre.

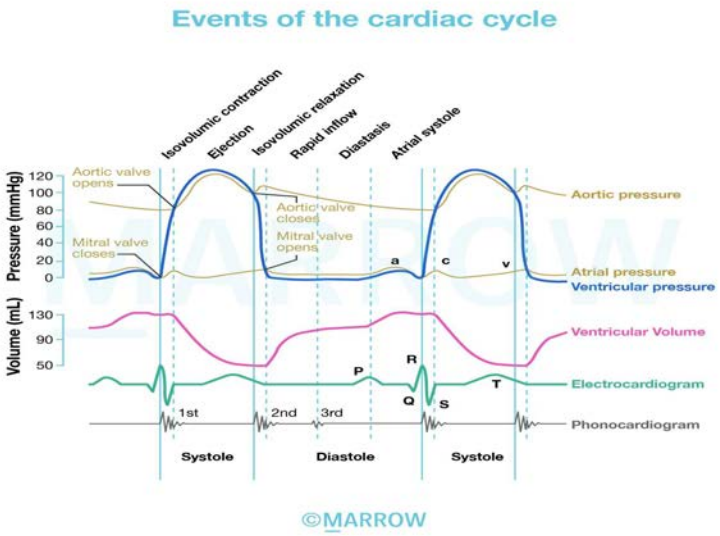
• The velocity of conduction is about 3-5m/s, which is about 1/13th of the velocity of the nerve fibre.

Solution to Question 23:

The correct sequence of events that occur after the p-wave is 1-2-4-3, ie:-

a wave in JVP → First heart sound → T wave in ECG → Rapid filling of ventricles.

The sequence of the events in this question can be better understood with the following diagram:



• The p wave in the ECG represents atrial depolarization, which causes contraction of the atria, represented by the 'a' wave in the JVP. Atrial contraction causes final filling of the ventricles (fourth phase of ventricular diastole)

• Atrial contraction is followed by the closure of the mitral valve, which causes the first-heart sound.

• This is followed by the isovolumetric contraction of the ventricle, which causes c wave in JVP, due to bulging of the tricuspid valve. This is followed by the rapid ejection phase of the ventricle.

• The T wave of ECG occurs during ventricular repolarization, which is followed by the opening of the mitral valve, followed by rapid filling phase of the ventricle (second phase of ventricular diastole).

Note: Passive rapid filling occurs as the mitral valve opens just before atrial contraction occurs.

Solution to Question 24:

In COPD, the functional residual capacity increases. Total lung capacity may be increased or normal. Hence, both 1 and 2 are correct.

• In obstructive lung diseases, both FEV1 and FVC reduces, where the decrease in FEV1 is more than the reduction in FVC. As a result, the ratio of FEV1/FVC also decreases.

• The total lung capacity is usually normal in chronic bronchitis, while increased in emphysema.

• Functional Residual Capacity (FRC) is the volume of air present in the lungs at the end of passive expiration. In COPD, FRC is increased.

Lung Capacities:

The total lung capacity can be broken down into alternative capacities that help to define functioning lungs.

• The vital lung capacity refers to the maximum amount of air expired from the fully inflated lung or maximum inspiratory level.

• The inspiratory capacity is the maximum amount of air inspired from the end-expiratory level.

• The functional residual capacity represents the volume of the air remaining in the lungs after expiration of a normal breath. Functional Residual Capacity (FRC) is expiratory reserve volume + residual volume.

Physiology NEET 2018

Question 1:

The predominant organ producing insulin-like growth factor I is

a) Liver

b) Pituitary gland

c) Pancreas

d) Adrenal glands

Question 2:

What is Prosopagnosia?

a) Impairment of consciousness

b) Being unaware of one's problems

c) Difficulty in identifying known faces

d) Failure to identify objects

Question 3:

All of the following are components responsible for the countercurrent mechanism in the kidney except _____.

a) Sodium outflow in thick ascending limb

b) Water outflow in thin descending limb

c) Sodium outflow in thin ascending limb

d) Flow of tubular fluid from PCT to DCT

Question 4:

Glucose is absorbed in intestine by?

a) Primary active transport

b) Facilitated diffusion

c) Simple diffusion

d) Secondary active transport

Question 5:

In which of the following conditions is oxygen therapy not useful?

a) Asthma

b) Acute myocardial infarction

c) Pulmonary edema

d) Central respiratory depression

Question 6:

Va/Q = infinity means _____.

a) Partial pressure of O2 becomes zero

b) No exchange of O2 & CO2

c) CO2 alone equilibrates with the venous blood

d) Partial pressure of both CO2 and O2 remain normal

Question 7:

'c' wave in JVP is seen in

a) Iso-volumetric contraction

b) Slow filling at end of diastole

c) End of systole

d) Start of diastole

Question 8:

All of the following are true regarding the actions of endothelin-1 except _____

a) Bronchodilation

b) Vasoconstriction

c) Decreased GFR

d) Has inotropic effect

Question 9:

Aldosterone secretion is maximally stimulated by_____

a) Hyperkalemia

b) ACTH

c) Hypernatremia

d) Exogenous steroid

Question 10:

cGMP is the second messenger of

a) Somatostatin

b) Angiotensin II

c) ADH

d) NO (nitric oxide)

Question 11:

Transport molecule for Fe^{2+} into the enterocytes is

a) Ferroportin 1

b) Hephaestin

c) Divalent Metal Transporter 1

d) Divalent Metal Transporter 2

Question 12:

Nuclear signalling pathways are all except

a) Caveolins

b) NF-kB

c) Importins

d) Rat proteins

Question 13:

Which of the following statements is false about Cuthbertson's metabolic ebb and flow responses to trauma?

a) The "ebb" phase is associated with a decline in body temperature and oxygen consumption.

b) The "flow" phase occurs after resuscitation from a state of shock.

c) The "ebb" phase is aimed at reducing posttraumatic energy depletion.

d) The "ebb" phase leads to activation of the innate immune system and induction of the hepatic acute-phase response.

Question 14:

Kidney responds to shock by _____.

a) Increasing renal blood flow

b) Increasing afferent arteriole resistance

c) Increasing GFR

d) Both B and C

Answer Key

Question No.	Correct Option
1	a
2	c
3	c
4	d
5	d
6	b
7	a
8	a
9	a
10	d
11	c

12	d
13	d
14	b

Detailed Explanations

Solution to Question 1:

Growth hormone acts on the liver to form small proteins called “somatomedins”

• Somatomedins increases bone growth in all aspect

• Effects are similar to insulin, hence referred to as insulin-like growth factor (IGF).

• Four types available:

• Most important is somatomedin C, specifically referred to as “insulin-like growth factor-1 (IGF-1)

• Binds to carrier protein in blood

• Hence, longer duration of action than growth hormone.

• Half-life - about 20 Hrs (compared to growth hormone - 20 mins)

• Blood concentration of IGF-1, follows the levels of growth hormone.

• Growth effects of GH are mostly attributed to somatomedin (rather than its direct effect on bones & peripheral tissues)

Solution to Question 2:

Prosopagnosia is difficulty in identifying known faces.

In humans, storage and recognition of faces is more strongly represented in the right inferior temporal lobe in right-handed individuals, though the left lobe is also active. Damage to this area can cause prosopagnosia.

Patients with this abnormality can recognize forms and reproduce them. They can recognize people by their voices, and many of them show autonomic responses when they see familiar as opposed to unfamiliar faces. However, they cannot identify the familiar faces they see. The left hemisphere is also involved, but the role of the right hemisphere is primary.

The presence of autonomic response to a familiar face in the absence of recognition has been explained by postulating the existence of a separate dorsal pathway for processing information about faces that leads to recognition at only a subconscious level.

Note:

• Autotopagnosia - inability to recognize or to orient any part of one's own body

• Simultagnosia - inability to recognize multiple elements in a visual presentation, one object or some elements of a scene can be appreciated but not the display as a whole

• Somatagnosia - inability to identify any part of the body, either one's own or another's body

• Tactile agnosia (astereognosis) - inability to recognize objects by touch, in the presence of intact cutaneous and proprioceptive hand sensation; caused by a lesion in the contralateral parietal lobe

Solution to Question 3:

Thin ascending limb is not a component of the countercurrent mechanism.

The loop of Henle function as countercurrent multipliers and vasa recta as countercurrent exchangers.

The functioning of the loop of Henle depends upon:

• High permeability of the thin descending limb to water (via aquaporin-1)

• Active transport of Na+ and Cl- from the thick ascending limb

• Inflow of tubular fluid from proximal tubule and outflow to the distal tubule.

Note: The thin ascending limbs of juxtamedullary nephrons are permeable to Na+ and Cl- and hence do contribute passively to countercurrent multiplication. However, among the options provided, Option C is the best answer as the other options are directly responsible for the countercurrent mechanism.

Solution to Question 4:

Glucose is absorbed in the intestine by secondary active transport (sodium co-transport).

The energy for glucose transport is provided indirectly, by the active transport of Na+ out of the cell. This maintains the concentration gradient across the luminal border of the cell so that more Na+ and consequently more glucose enter.

Though both secondary active transport and facilitated diffusion play a role in glucose absorption, it is the initial active transport of sodium through the basolateral membranes of the intestinal epithelial cells that provide the eventual force for moving glucose through the membranes as well. So, secondary active transport is the single best answer for this question.

Solution to Question 5:

Oxygen therapy is not beneficial in central respiratory depression.

High dose oxygen reduces the output of peripheral chemoreceptors. So, if given to patients who already have central respiratory depression, it will indirectly reduce the hypoxic drive to breathe even further, leading to a reduction in respiratory frequency and minute ventilation.

Note: In acute severe asthma, a high concentration of oxygen should be given by face mask to achieve an oxygen saturation of >90%.

Solution to Question 6:

Va /Q = infinity means No exchange of O2 & CO2.

• Va represents the ventilation in alveoli.

• Q represents the blood flow through the alveolus.

• The ratio of Va and Q explains the respiratory exchange when there is an imbalance between alveolar ventilation and alveolar blood flow.

• Ventilation-perfusion ratio is considered normal if there is an equal amount of blood flow & ventilation through alveolus.

• When Va /Q ratio is infinity,

• There is adequate ventilation but no perfusion.

• No exchange of gases through the respiratory membranes of corresponding alveoli.

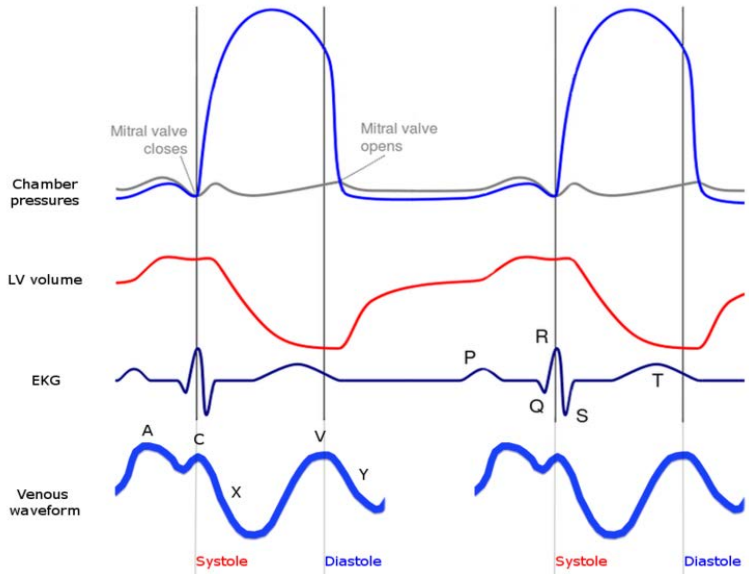
• The alveolar air equilibrates the humidified inspired air

• No exchange of oxygen and carbon-di-oxide occurs.

• Partial pressures of the O2 and CO2 are 149 mmHg & 0 mm Hg respectively

Solution to Question 7:

'c' waves are produced by bulging of the tricuspid valve into the right atrium during the Iso-volumetric contraction of the right ventricle.



Solution to Question 8:

Endothelin-1

• Potent vasoconstrictor agent.

• Produced by endothelial cells.

• They are secreted locally and act in a paracrine fashion.

Actions of Endothelin-1 (ET-1)

• Potent vasoconstrictor.

• Platelet activation.

• Inotropic effect.

• Closure of ductus arteriosus.

• Have a role in the pathogenesis of hypertension, myocardial infarction, and congestive heart failure.

• In the brain, regulate the transport of substances across blood brain barrier (BBB).

• In the kidneys, they are involved in tubuloglomerular feedback→ ↓ GFR.

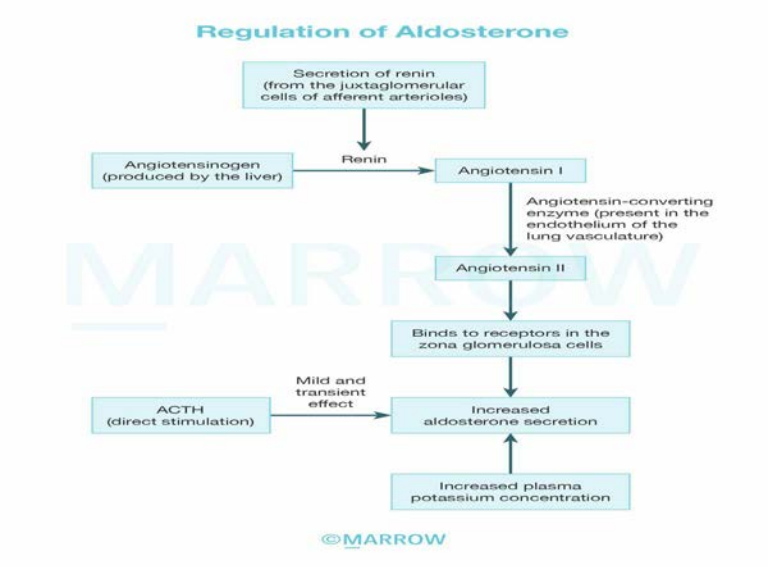
• In the lungs, it causes bronchoconstriction (mediated via ET-B receptors).

• In GIT, they are involved in the migration of myenteric plexus to distal colon (failure leads to Hirschsprung's/megacolon).

• Deletion of both alleles of ET-1 gene→craniofacial abnormalities and respiratory failure at birth.

Solution to Question 9:

Hyperkalemia and activation of renin-angiotensin system are the most potent stimulators of aldosterone secretion.



Solution to Question 10:

Vasodilatory actions of NO are mediated by cGMP.

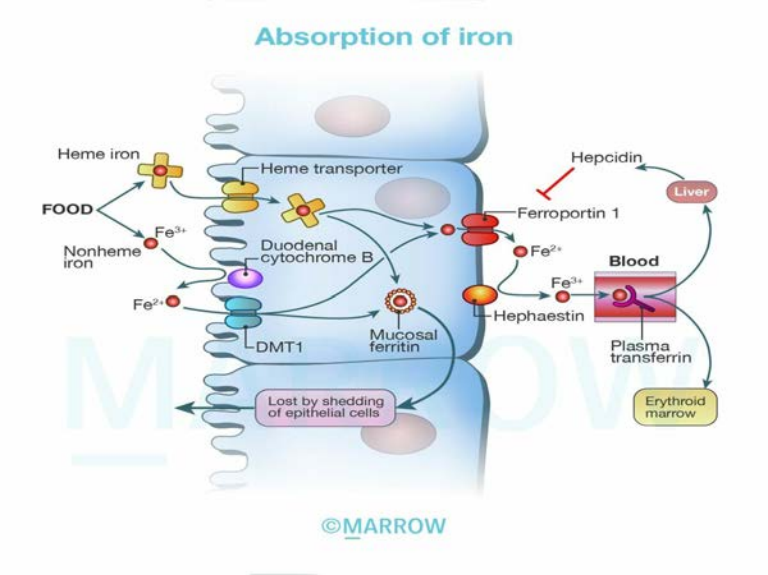
NO is a hormone derived from the amino acid arginine. It activates guanylyl cyclases in vascular smooth muscle cells resulting in the conversion of cGTP to cGMP (2nd messenger). cGMP activates cGMP dependent protein kinase, which causes blood vessels to relax.

cGMP is the second messenger for nitric oxide and atrial natriuretic factor.

Solution to Question 11:

Transport of Fe2+ into the enterocytes occurs via divalent metal transporter 1 (DMT1), through an active transport process.

Protein DMT-1 (Divalent Metal Transporter-1) is expressed on the apical surface of enterocytes in the initial part of the duodenum. DMT-1 is not specific to iron & transports other substances like zinc, copper, cobalt & manganese.



Solution to Question 12:

Rat proteins are not nuclear signalling pathways. Recombinant rat IFN- is a bioactive protein intended for use in cell culture applications.

Importin:

• Transporting protein molecules into nucleus by binding to specific recognition sequences, called Nuclear Localization Sequences (NLS).

• 2 subunits, importin α and importin β.

Caveolins:

• Family of integral membrane proteins that are principal components of caveolae membranes

• Involved in receptor-independent endocytosis.

• Acts as scaffolding proteins within caveolar membranes by compartmentalizing and concentrating signaling molecules.

NF-kB

• Part of a prototypical proinflammatory signaling pathway

• based on the role of NF-κB in the expression of proinflammatory genes including cytokines, chemokines, and adhesion molecules

Solution to Question 13:

The "flow" phase (not "ebb") leads to activation of the innate immune system and induction of the hepatic acute-phase response.

Cuthbertson's ebb and flow response to trauma:

The "ebb" phase lasts for a brief duration and is associated with a decline in body temperature and oxygen consumption, aimed at reducing post traumatic energy depletion.

The "flow" phase occurs after resuscitation from a state of shock, which leads to an increased metabolic turnover, activation of the innate immune system and induction of the hepatic acute-phase response. This hypercatabolic condition leads to a significantly increased oxygen consumption and energy expenditure.

Solution to Question 14:

Kidney responds to shock by increasing afferent arteriolar resistance.

During shock, both afferent and efferent arterioles in kidney are constricted, however, the efferent vessels are constricted much more.

The glomerular filtration rate and the plasma renal flow is decreased during shock. As plasma renal flow is decreased to a greater extent, the filtration fraction increases. (Option 1 & 3)

Physiology NEET 2019

Question 1:

According to myogenic hypothesis of renal autoregulation the afferent arterioles contract in response to stretch-induced by_____

a) NO

b) Noradrenaline

c) Opening of calcium channels

d) Adenosine

Question 2:

According to Herrington classification, the decerebrate rigidity is characterized by all except _____

a) Rigidity occurs in all the muscles of the body

b) Increase in the rate of discharge of the ■ efferent neuron

c) Increased excitability of the motor neuron pool

d) Decerebration produces no phenomenon akin to spinal shock

Question 3:

Which of the following is true for decorticate rigidity?

a) It is produced by the removal of cerebral cortex and basal ganglia

b) Flexion of lower limbs and extension of upper limbs occurs

c) Rigidity is pronounced

d) It is characterized by flexion of upper limbs and extension of lower limbs

Question 4:

Acid Citrate Dextrose (ACD), used to store blood, preserves the RBCs for a period of 21 days. The storage period when adding phosphate alone and when adding adenine and phosphate together to ACD would respectively be?

a) 35 days and 42 days

b) 21 days and 35 days

c) 28 days and 45 days

d) 35 days and 28 days

Question 5:

Functional residual capacity is:

a) Volume expired after normal inspiration

b) Volume that remains after forced expiration

c) Expiratory reserve volume + residual volume

d) Tidal volume + inspiratory reserve volume

Question 6:

Which of the following is not a dietary fiber?

a) Cellulose

b) Inulin

c) Pectin

d) Gums

Question 7:

Lesion in the medial lemniscus at the level of pons causes which of the following?

a) Pain and temperature loss in the same side

b) Pain and temperature loss in the opposite side

c) Loss of tactile and proprioception on the same side

d) Loss of tactile and proprioception on the opposite side

Question 8:

Which neurotransmitter is responsible for anterograde dilatation of the small intestine?

a) VIP

b) Acetylcholine

c) Substance P

d) Serotonin

Question 9:

Reflex responsible for tachycardia during right atrial distension is:

a) J reflex

b) Cushing reflex

c) Bezold jarisch reflex

d) Bainbridge reflex

Question 10:

Testosterone production is mainly contributed by _____

a) Leydig cells

b) Sertoli cells

c) Seminiferous tubules

d) Epidydmis

Question 11:

What is the function of tubuloglomerular feedback?

a) Regulate GFR

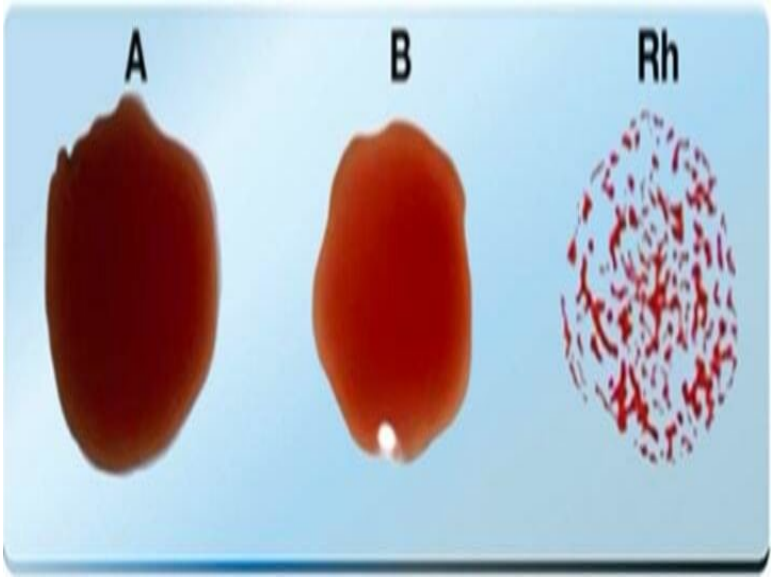
b) Decrease plasma sodium

c) Increase plasma volume

d) Decrease tubular secretion

Question 12:

Based on the agglutination test shown below, what is the blood group?



a) B positive

b) A positive

c) O positive

d) AB positive

Question 13:

Which of the following neurons predominantly fire during forceful expiration?

a) Dorsal group of neurons

b) Ventral group of neurons

c) Pneumotaxic center

d) Chemoreceptors

Question 14:

ADH acts through which aquaporin channel?

a) 1

b) 2

c) 3

d) 4

Question 15:

Which of the following has the least conduction velocity?

a) Postganglionic sympathetic fibers

b) Somatic motor fibers

c) Pre-ganglionic autonomic fibers

d) Touch and pressure fibers

Question 16:

Which part of the liver stores vitamin A?

a) Ito cells

b) Hepatocytes

c) Endothelial cells

d) Kupffer cells

Question 17:

Liver synthesizes all of the following except:

a) Albumin

b) Coagulation factors

c) Acute phase proteins

d) Immunoglobulins

Question 18:

Which of the following ions is involved in peripheral oxygen sensing chemoreceptors?

a) Potassium

b) Calcium

c) Sodium

d) Chlorine

Question 19:

Brown sequard syndrome is characterized by _____

a) Fine touch lost on the opposite side

b) Pain and temperature lost on the same side

c) Pain and temperature loss on the opposite side

d) Only pain lost on the same side

Answer Key

16	a
17	d
18	a
19	c

Detailed Explanations

Solution to Question 1:

The afferent arterioles contract in response to stretch induced by the opening of calcium channels. The mechanism is called myogenic autoregulation of renal blood flow and GFR.

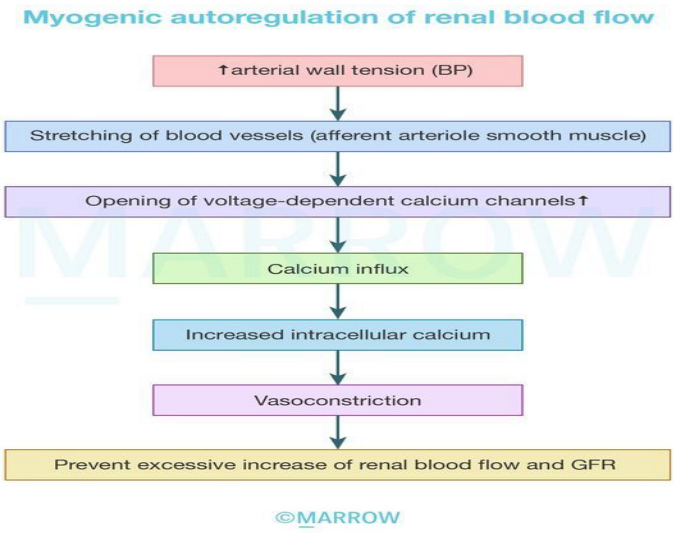
The stretch of the vascular wall allows increased movement of calcium ions from the extracellular fluid into the cells, causing them to contract. This contraction prevents excessive stretch of the vessel. This prevents excessive increase of renal blood flow and GFR by raising vascular resistance.

This mechanism may be more important in protecting the kidney from hypertension-induced injury.

Autoregulation has two main mechanisms:

• Metabolic mechanism: Tissues produce vasodilatory metabolites that regulate flow e.g. prostaglandins, NO, CO_2, H^+ and K^+

• Myogenic mechanism



Solution to Question 2:

In decerebrate rigidity, there is rigidity in extensor muscles of all the four extremities (not all muscles of the body).

Decerebration

• Complete transection of the brain stem between the superior and inferior colliculi permits the brain stem pathways to function independently of their input from higher brain structures. This is called a mid-collicular decerebration.

• This lesion interrupts all input from the cortex (corticospinal and corticobulbar tracts) and red nucleus (rubrospinal tract), primarily to distal muscles of the extremities.

• The excitatory and inhibitory reticulospinal pathways (primarily to postural extensor muscles) remain intact.

• The dominance of drive from ascending sensory pathways to the excitatory reticulospinal pathway leads to hyperactivity in extensor muscles in all four extremities which are called decerebrate rigidity.

• The excitatory input from the reticulospinal pathway activates γ-motor neurons which indirectly activate α-motor neurons (via Ia spindle afferent activity). This is called the gamma loop.

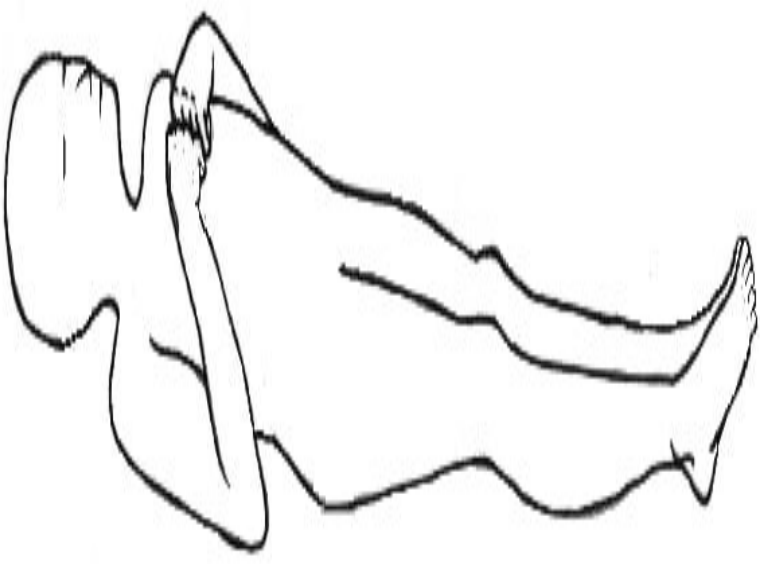
Option 4. Spinal shock is different from decebrate rigidity as it is a transient state that can occur immediately after a spinal cord injury. It is characterized by a temporary loss or depression of spinal reflexes below the level of the injury.

Solution to Question 3:

• Removal of the cerebral cortex (decortication) produces decorticate rigidity.

• Characterized by flexion of the upper extremities at the elbow and extensor hyperactivity in the lower extremities.

• The flexion can be explained by active rubrospinal excitation of flexor muscles in the upper extremities; the hyperextension of lower extremities is due to the same changes that occur after midcollicular decerebration.



Solution to Question 4:

The storage period when adding phosphate alone to ACD would be 21 days and when adding adenine and phosphate together would be 35 days.

When adding phosphate to ACD, Citrate Phosphate Dextrose (CPD) is formed – It has a storage period of 21 days. There is no change in the shelf life as phosphate only increases the 2,3 DPG levels of the stored blood.

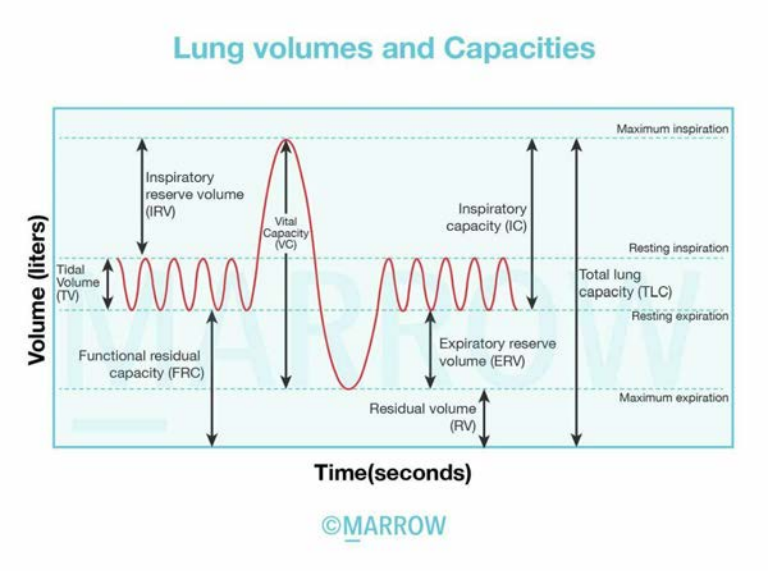
When adding both phosphate and adenine to ACD, Citrate Phosphate Dextrose Adenine (CPDA-1) is formed. It has a storage period of 35 days. It increases the shelf life by improving ATP synthesis of RBCs.

Using additive solutions containing saline, adenine, and glucose, with or without mannitol (SAGM) decreases RBC hemolysis, thus increasing the storage period to 42 days.

Solution to Question 5:

Functional Residual Capacity (FRC) is expiratory reserve volume + residual volume.

From the picture given below, (FRC = ERV + RV).



Lung Capacities:

The total lung capacity can be broken down into alternative capacities that help to define functioning lungs.

• The vital lung capacity refers to the maximum amount of air expired from the fully inflated lung or maximum inspiratory level.

• The inspiratory capacity is the maximum amount of air inspired from the end-expiratory level.

• The functional residual capacity represents the volume of the air remaining in the lungs after expiration of a normal breath.

Solution to Question 6:

Gum is the best answer among the given options. Even though all of the given options are dietary fibers, the consumption of gums through diet is very low and hence, it is the best answer.

Dietary fibers consist of both soluble and insoluble forms and include lignin, pectin, inulin, cellulose, hemicellulose, etc.

Advantages of fibers:

• Forms bulk of the stool and reduces stool transit time

• Reduces incidence of carcinoma colon, DM, CAD, diverticulitis

Solution to Question 7:

Lesion in the medial lemniscus at the level of pons causes loss of tactile and proprioception on the opposite side.

Fibers of medial lemniscus ascend ipsilaterally in the dorsal columns of the spinal cord to the medulla, where they synapse in the gracilus and cuneate nuclei.

The second-order neurons from these nuclei cross the midline and ascend in the medial lemniscus to end in the contralateral ventral posterior lateral (VPL) nucleus and related specific sensory relay nuclei of the thalamus.

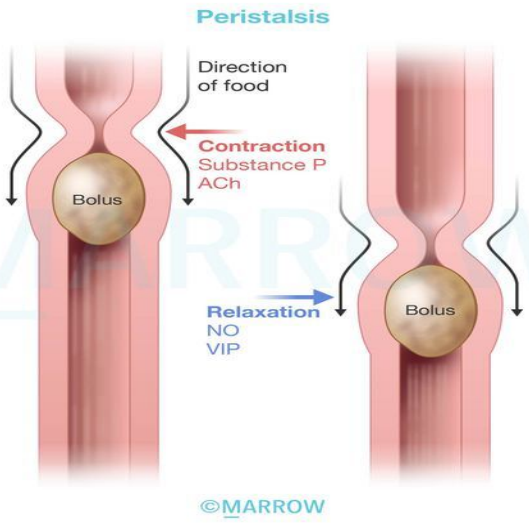
Solution to Question 8:

VIP is responsible for anterograde dilatation of the small intestine.

Peristalsis involves the contraction of a segment of intestine behind the bolus of food and relaxation of a segment of the intestine in front of the bolus of food.

Cholinergic neurons passing in anterograde direction produce NO and VIP which cause relaxation of a segment of the intestine in front of the bolus.

Cholinergic neurons passing in retrograde direction produce substance P and acetylcholine which cause contraction of a segment of the intestine behind the bolus.



Note: In achalasia cardia, there is decreased release of NO and VIP in the distal part of the esophagus.

Solution to Question 9:

Reflex responsible for tachycardia during right atrial distension is Bainbridge reflex.

Atrial Reflex Control of Heart Rate: The Bainbridge Reflex

• The stretch receptors of the atria that elicit the Bainbridge reflex transmit their afferent signals through the vagus nerves to the medulla of the brain.

• Then efferent signals are transmitted back through vagal and sympathetic nerves to increase heart rate and strength of heart contraction.

Bezold-Jarisch Reflex:

• Activation of chemosensitive vagal C fibres in the cardiopulmonary region (e.g. Juxta capillary region of alveoli, ventricles, atria, great veins, and pulmonary artery) causes profound brady-cardia, hypotension and a brief period of apnea followed by rapid shallow breathing.

Cushing Reflex:

• When ICP is increased, the blood supply to RVLM neurons is compromised.

• The local hypoxia and hypercapnia causes an increase in discharge from the neurons, producing hypertension, bradycardia and irregular respiration.

• The resultant rise in systemic arterial pressure tends to restore the blood flow to the medulla.

Solution to Question 10:

Testosterone production is mainly contributed by Leydig cells.

Testosterone is synthesized from cholesterol in the Leydig cells and also from androstenedione secreted by the adrenal cortex.

The diagnosis of testosterone deficiency should be made only on the basis of clinical signs and symptoms consistent with androgen deficiency, and consistently subnormal serum testosterone concentrations at 8 to 10 AM on three occasions.

Testosterone has been used to treat primary or secondary hypogonadism in adult men.

Solution to Question 11:

Tubuloglomerular feedback regulates glomerular filtration rate (GFR).

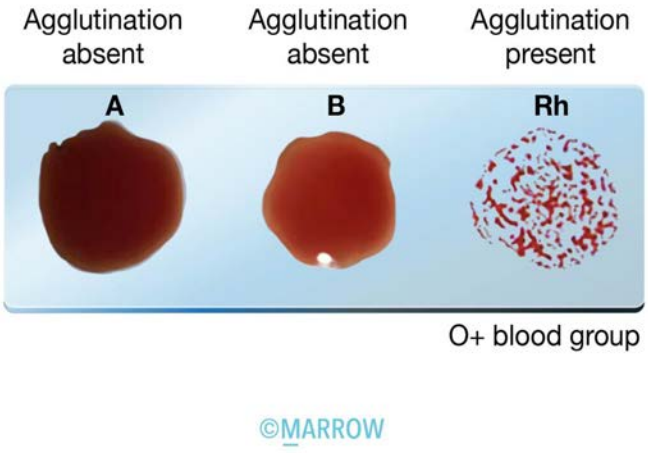
As the rate of ■ow through the ascending limb of the loop of Henle and first part of the distal tubule increases, glomerular filtration in the same nephron decreases, and, conversely, a decrease

in ■ow increases the GFR.

Solution to Question 12:

Based on the agglutination test shown in the image, the blood group is O positive.

As agglutination is present only in 'Rh' and not with 'A' and 'B' hence the blood group is O Rh positive.



Solution to Question 13:

Ventral groups of neurons fire, when forceful expiration is needed like during heavy exercise.

Dorsal group of neurons control the normal inspiration and expiration.

Pneumotaxic center limits the duration of inspiration.

Solution to Question 14:

The antidiuretic hormone acts through aquaporin channel 2.

ADH binds to V2 receptors in the late distal tubules, collecting tubules, and collecting ducts, and stimulates the movement of an intracellular protein, called aquaporin-2 (AQP-2), to the luminal side of the cell membranes.

Solution to Question 15:

Postganglionic sympathetic (type C) has the least conduction velocity among the given options.

Types of nerve fibers:

Fiber type	Function	Fiber diameter (μm)	Conduction velocity (m/s)
Aα	Proprioception, somatic motor	12-20	70-120
Aβ	Touch, pressure	5-12	30-70
Aγ	Motor to muscle spindles	3-6	15-30
Aδ	Pain, temperature	2-5	12-30
B	Preganglionic autonomic	<3	3-15
C, Dorsal root	Pain, temperature	0.4-1.2	0.5-2
C, Sympathetic	Post ganglionic sympathetic	0.3-1.3	0.7-2.3

Solution to Question 16:

Vitamin A is stored in the liver perisinusoidal stellate (Ito) cells as retinyl ester (retinol palmitate).

Kupffer cells, also known as stellate macrophages and Kupffer-Borowicz cells; are specialized macrophages located in the liver that form part of the mononuclear phagocyte system. These are present, lining the walls of the sinusoids, not the perisinusoidal space (Space of Disse).

Solution to Question 17:

Immunoglobulins are not synthesized by the liver. They are produced by plasma cells.

Plasma proteins synthesized by the liver are:

• Albumin

• Coagulation/clotting factors

• Acute-phase proteins

• Steroid binding and other hormone-binding proteins

Solution to Question 18:

Potassium is involved in peripheral oxygen sensing chemoreceptors.

Type I glomus cells (carotid and aortic body) have O2-sensitive K+ channels, whose conductance is reduced in proportion to the degree of hypoxia.

This reduces the K+ efflux, depolarizing the cell and causing Ca^{2+} in■ux.

The Ca^{2+} influx triggers action potentials and consequent excitation of the afferent nerve endings.

Solution to Question 19:

Hemisection of the spinal cord causes damage to ascending sensory (dorsal column pathway, ventrolateral spinothalamic tract) and descending motor (corticospinal tract) pathways, which is called the Brown- Séquard syndrome.

The lesion to fasciculus gracilus or fasciculus cuneatus leads to ipsilateral loss of discriminative touch, vibration, and proprioception below the level of the lesion.(fibers from the sacral cord are positioned most medially and those from the cervical cord are positioned most laterally.)

The loss of the spinothalamic tract leads to contralateral loss of pain and temperature sensation beginning one or two segments below the lesion.

Damage to the corticospinal tract produces weakness and spasticity in certain muscle groups on the same side of the body.

Physiology NEET 2020

Question 1:

A person develops headache and breathlessness on a trekking expedition following rapid ascent to over 3000 metres above the sea level. Which of the following is not used in the treatment of this condition?

a) IV digoxin

b) Descent to lower altitude

c) Administration of oxygen

d) Tablet acetazolamide

Question 2:

V/Q = infinity holds true in which of the following conditions?

a) Foreign body obstruction in the bronchus

b) Equal to dead space

c) When O_2 and CO_2 ratio is equal

d) The PO_2 of alveolar air is 159 mmHg and PCO_2 is 40 mmHg

Question 3:

Prolactin level is highest during :

a) 24 hours after ovulation

b) 24 hours after delivery

c) REM Sleep

d) After running for 1 hour

Question 4:

C wave of JVP represents:

a) Tricuspid bulge into right atrium during isovolumetric ventricular contraction

b) Contraction of right atrium

c) Passive filling of right atrium

d) Passive emptying of right atrium

Question 5:

The protein in the glomerular basement membrane responsible for charge-dependent filtration is?

a) Fibronectin

b) Heparan sulfate

c) Collagen Type IV

d) Entactin

Question 6:

Which of the following clotting factors would have decreased gamma carboxyglutamate residue in a patient on warfarin therapy?

a) Factor 2

b) Factor 11

c) Tissue factor

d) Factor 5

Question 7:

Which of the following conditions would have the highest levels of ACTH and cortisol?

a) Early morning

b) Normal individuals with dexamethasone administration

c) Addison's disease

d) Cushing's disease

Question 8:

Following complete ileal and partial jejunal resection, the patient is most likely to have

a) Folic acid deficiency

b) Vitamin B12 deficiency

c) Gastric ulcer

d) Constipation

Question 9:

Respiratory distress syndrome is due to defective

a) Type 1 pneumocytes

b) Type 2 pneumocytes

c) Alveolar capillary endothelial cells

d) Bronchial mucosal epithelial cells

Question 10:

Which of the following hormones use receptor tyrosine kinase signalling?

a) Insulin

b) TSH

c) TRH

d) MSH

Question 11:

What is the site of lesion in Wernicke's hemianopic pupil?

a) Optic nerve

b) Optic tract

c) Optic radiation

d) Optic chiasma

Question 12:

In which of the following reflexes, gastric emptying is delayed when acidic content enters the duodenum?

a) Gastrocolic

b) Enterocolic

c) Gastroileal

d) Enterogastric

Question 13:

A lady presents with vascular injury to the inferior frontal gyrus. Which functional area is likely to be affected?

a) Motor speech area

b) Wernicke's area

c) Auditory area

d) Visual area

Question 14:

A man falls into a deep sleep with one arm under his head. He finds he is not able to move this arm when he awakens. However, it tingles and pain sensation in the arm is still intact. What is the reason for the loss of motor function without loss of pain sensation is that in the nerves to his arm?

a) B fibers are more susceptible to pressure than A fibers

b) A fibers are more sensitive to pressure than C fibers

c) C fibers are more sensitive to pressure than A fibers

d) Motor nerves are more affected by sleep than sensory nerves

Question 15:

Which of the following has the highest oxygen concentration in fetal circulation?

a) Inferior vena cava

b) Right atrium

c) Superior vena cava

d) Ascending aorta

Question 16:

Respiratory distress syndrome is due to the deficiency of

a) Dipalmitoyl Phosphatidylcholine

b) Phosphatidylserine

c) Phosphatidylethanolamine

d) Phosphatidylinositol

Question 17:

What makes CPDA superior than ACD for blood storage:

a) The fall in 2, 3 DPG is less

b) Decreased release of O2

c) It has less P50

d) It is less acidic

Detailed Explanations

Solution to Question 1:

The symptoms of headache and breathlessness following rapid ascent indicate acute mountain/altitude sickness and IV digoxin is not used to treat this condition.

On ascent to high altitudes, the low partial pressure of oxygen leads to hypoxia and systemic arteriolar dilatation. Consequently, the capillary pressure rises with increased transudation of fluid into the brain tissue and the following symptoms are seen:

• Headache

• Irritation

• Insomnia

• Breathlessness

• Nausea and vomiting

Treatment involves administration of oxygen, descent to a lower altitude and administration of acetazolamide. Acetazolamide counteracts hypoxia by stimulating respiration and also reduces the formation of cerebrospinal fluid, thereby reducing intracranial tension.

Portable hyperbaric chambers are increasingly being used in the treatment of high-altitude illnesses when rapid descent is not possible. These chambers are available in armed forces hospitals in high altitude areas

Solution to Question 2:

VA /Q= infinity means that there is no exchange of O2 & CO2, which means the volume of the lung equals to dead space and the physiological effort of breathing is wasted.

VA represents the ventilation in alveoli and Q represents the blood flow through the alveolus. The ratio of VA and Q explains the respiratory exchange when there is an imbalance between alveolar ventilation and alveolar blood flow. The ventilation-perfusion ratio is considered normal if there is an equal amount of blood flow & ventilation through the alveolus.

VA /Q ratio is infinity when:

• There is adequate ventilation but no perfusion.

• No exchange of gases (O2 and CO2)through the respiratory membranes of corresponding alveoli.

• The alveolar air equilibrates the humidified inspired air.

• Partial pressures of the O2 and CO2 are 149 mmHg & 0 mm Hg respectively.

Solution to Question 3:

Among the given options, the prolactin level is highest 24 hours after delivery.

The maximum level of prolactin is seen during pregnancy and in the immediate postpartum period. During pregnancy, the secretion is increased reaching a peak at the time of delivery. After delivery, the plasma concentration falls to nonpregnant levels in a few weeks. Suckling produces surges of prolactin release.

Solution to Question 4:

'C' wave in JVP represents tricuspid bulge into right atrium during isovolumetric ventricular contraction.

Characteristics of JVP :

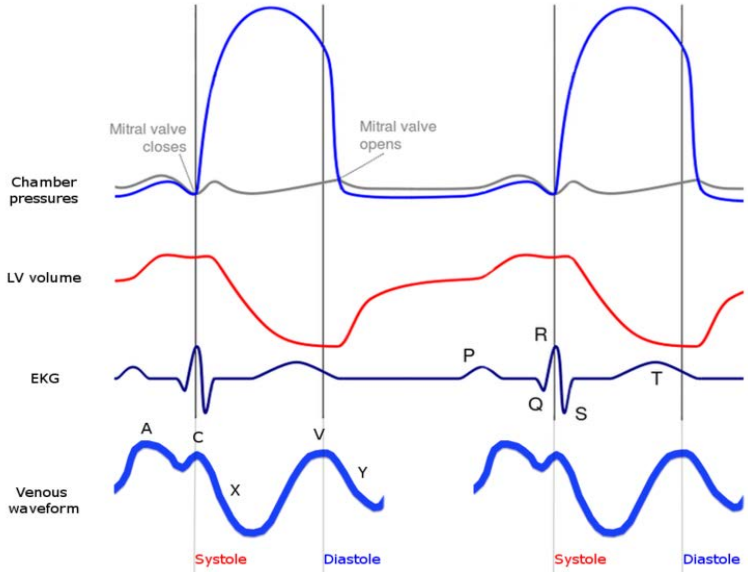
• a wave corresponds to atrial systole which causes regurgitation of some blood into the great veins.

• c wave occurs due to the increase in atrial pressure caused by bulging of the tricuspid valve into the right atrium during isovolumetric ventricular contraction.

• x descent occurs due to the fall in atrial pressure during ventricular systole due to pulling of valve leaflets.

• v wave is seen at the end of ventricular contraction and occurs due to the slow venous filling which causes an increase in atrial pressure.

• y descent occurs due to the passive emptying of the right atrium into the right ventricle.



Solution to Question 5:

The protein in the glomerular basement membrane responsible for charge-dependent filtration is heparan sulfate. It prevents filtration by repelling negatively charged proteins.

Collagen type IV, fibronectin, entactin are structural components of basement membrane.

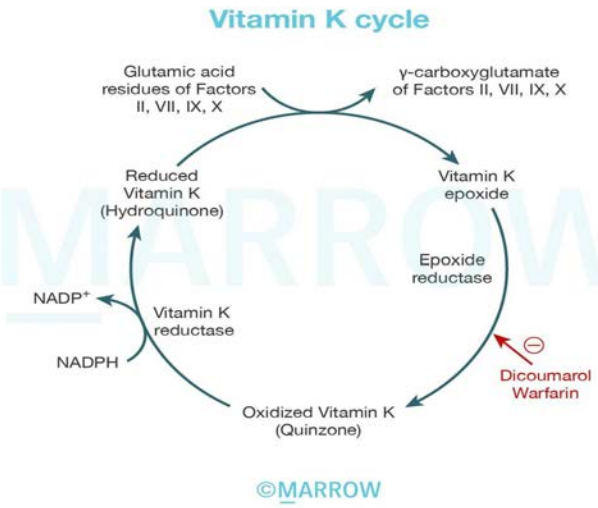
Solution to Question 6:

Factor 2 would have decreased gamma carboxyglutamate residue in a patient on warfarin therapy.

Activation of coagulation factors II, VII, IX, X is done by carboxylation of their glutamate residues. This is done by the enzyme γ-glutamyl carboxylase with the reduced form of vitamin K as a co-factor.

This reduced form of vitamin K needs to be constantly recycled back from its oxidized form for the reaction to continue. This recycling is done by the enzyme vitamin K epoxide reductase. This enzyme is inhibited by warfarin.

Hence, warfarin indirectly inhibits the γ-carboxylation of vitamin K dependent clotting factors - Factors II, VII, IX, X by directly inhibiting vitamin K epoxide reductase. Thus leading to decreased gamma carboxyglutamate residue in these factors.

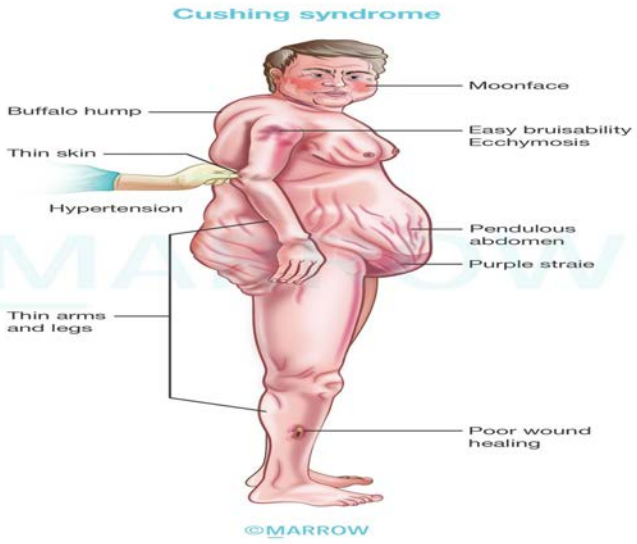


Solution to Question 7:

Among the given conditions, the levels of ACTH and cortisol will be highest in Cushing's disease.

Cushing's disease is caused by an ACTH secreting pituitary adenoma. The increased ACTH causes increased cortisol production.

Note: In normal physiologic state, ACTH levels are higher in the early morning but not as high as in Cushing's disease.



Solution to Question 8:

After complete ileal and partial jejunal resection, the patient is likely to have vitamin B12 deficiency.

Vitamin B12 is absorbed in the ileum. Vitamin B12 binds to intrinsic factor, a protein secreted by the parietal cells of the stomach, and the complex is absorbed across the ileal mucosa. Hence after ileal resection, there is impaired absorption of vitamin B12.

Solution to Question 9:

Respiratory distress syndrome is due to defective type 2 pneumocytes which produce lung surfactants. The surfactants reduce the surface tension in the alveoli. A defect in type 2 pneumocytes or surfactant deficiency can lead to respiratory distress syndrome.

The primary alveoli develop and the production of the surfactant begins by week 20-24. However, it does not reach the lungs until later. The surfactant appears in the amniotic fluid between 28 and 32 weeks of gestation. Mature levels of the pulmonary surfactant are present usually after 35 weeks of gestation.

Antenatal corticosteroids are given to increase production of surfactant.

Solution to Question 10:

Insulin uses the receptor tyrosine kinase signalling to exert its functions.

Other hormones acting in a similar fashion includes

• Growth hormone

• Growth factors like VEGF, PDGF, FGF, NGF

• Prolactin

• Leptin

Solution to Question 11:

The site of lesion in Wernicke's hemianopic pupil is optic tract.

Wernicke hemianopic pupil is the light reflex, where, illumination of the blind half of the retina shows no pupillary reaction while stimulating the normal side of the retina shows a pupillary reaction. It is seen in lesions involving the optic tract. It is also seen in cases such as TB, syphilis and tumours of the optic thalamus.

Homonymous hemianopia (HH) involves loss of vision on the same side of the visual field in both eyes. HH is characteristically seen in lesions involving the visual pathway posterior to the optic chiasma.

Solution to Question 12:

In the enterogastric reflex, gastric emptying is delayed when acidic content enters the duodenum.

When the food enters the duodenum, multiple reflexes are initiated from the duodenal wall which passes back to the stomach. These reflexes slow or stop the stomach emptying if the volume of the chyme in the duodenum becomes too much. These reflexes are called enterogastric reflexes.

This reflex can be triggered due to the following reasons:

• Presence of irritants and acids in duodenal chyme (most sensitive factor)

• Distension of duodenum due to the presence of an excessive volume of chyme

• Rapid entry of hypertonic or hypotonic fluids into the duodenum

• Presence of breakdown products of protein digestion and sometimes fat

Solution to Question 13:

Broca's motor speech area is likely to be affected in the vascular injury of the inferior frontal gyrus

A lesion in this region leads to motor/Broca's aphasia. Speech is non-fluent and interrupted by many word-finding pauses. The speech is impoverished in function words that contribute to the syntax but is enriched in meaningful nouns and verbs. However, comprehension of speech is intact and the patient knows what he wants to say.

For example, a patient with Broca's aphasia may say "walk dog" instead of "I want to take the dog for a walk".

Solution to Question 14:

The reason for the loss of motor function without loss of pain sensation is that in the nerves to his arm, A-fibers are more sensitive to pressure than C fibers.

Sleeping for a long period with the arms under the head puts pressure on a nerve. It leads to the loss of conduction in large-diameter motor, touch, and pressure fibers, while pain sensation remains relatively intact. A-fibers (includes the motor fibers) are affected.

The susceptibility of the nerve fibers to pressure is A>B>C.

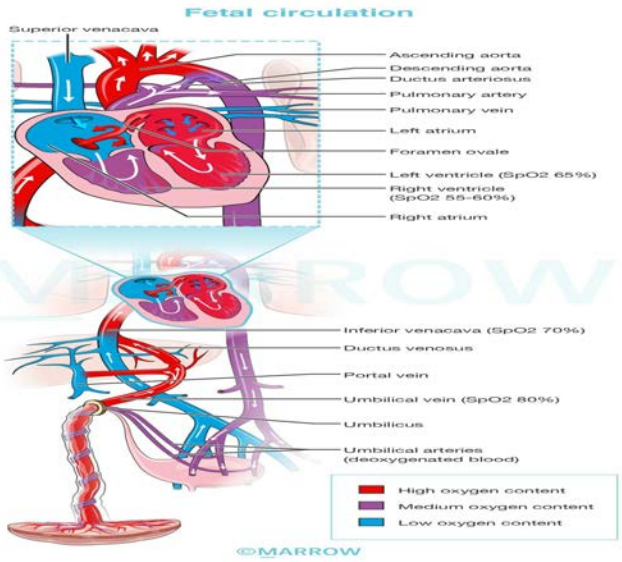
This is responsible for Saturday night or Sunday morning paralysis.

Solution to Question 15:

Inferior vena cava has the highest oxygen concentration in fetal circulation.

The blood gets oxygenated in the placenta and this passes to the umbilical vein. From the umbilical vein, 50% of the blood enters the hepatic circulation and 50% bypasses the liver to enter the inferior vena cava. From here, the blood enters the heart via the right atrium. The right atrium also receives deoxygenated blood from the superior vena cava. This mixed blood is distributed to the body via aorta.

Therefore, inferior vena cava has the highest concentration of oxygen in the fetal circulation.



Solution to Question 16:

Respiratory distress syndrome is due to the deficiency of dipalmitoyl-phosphatidyl-choline(DPPC) /dipalmitoyl lecithin. It is the major pulmonary surfactant.

Clinical relevance- Test to assess fetal lung maturity is L/S ratio - lecithin/sphingomyelin ratio. A ratio of ≥ 2 is considered normal.

Solution to Question 17:

The fall in 2, 3 DPG is less when the blood is stored in CPDA compared with ACD.

2, 3 DPG (2,3-diphosphoglycerate) binds to deoxygenated haemoglobin. Therefore, an increase in 2,3 DPG causes increased release of O2 to the tissues. The equilibrium between Hb and O2 can be understood from the following equation:

$HbO_2 + 2,3\text{-DPG} \blacksquare Hb–2,3\text{-DPG} + O_2$

In stored blood, the 2,3 DPG levels usually fall. As a result, stored blood releases less oxygen to the tissues than the normal circulating blood, thus limiting its use in hypoxic patients (Eg: anaemia).

However, such a fall in 2,3 DPG is less when it is stored in a phosphate-containing solution like CPDA (Citrate, phosphate, dextrose, adenine), rather than ACD (Acid citrate dextrose). Therefore, the blood stored in CPDA, in comparison with blood stored in ACD has:

- Higher 2,3 DPG concentration
- More amount of deoxygenated blood bound to 2,3 DPG
- Decreased affinity of Hb to the oxygen.
- Increased release of oxygen to the tissues.
- Raised P50 (PO_2 at which Hb is half saturated)
- Shift in O_2-Hb dissociation curve to the right

Physiology INI-CET 2021

Question 1:

Which of the following is not involved in renal auto-regulation?

a) Tubuloglomerular feedback

b) Myogenic reflex

c) Renin-angiotensin system

d) Renal sympathetic system fibres

Question 2:

The formula for urea clearance is U*V/P, where U is

a) Urine volume

b) Serum urea in mg /100ml

c) Urine urea in g/24h

d) Urine urea in mg /100ml

Question 3:

The relaxation of the intestinal segment distal to the segment with the bolus of food during peristalsis is because of

a) VIP

b) Substance P

c) Dopamine from adrenergic fibres

d) Acetylcholine from myenteric fibres

Question 4:

A patient presented with severe watery diarrhea resembling that of rice gruel stool. Damage of which structure is likely to have resulted in this diarrhea?

a) Zona occludens

b) Gap junction

c) Adherent junction

d) Hemidesmosomes

Question 5:

Beta hCG is structurally similar to which biochemical moiety?

a) LH

b) FSH

c) ACTH

d) Oxytocin

Question 6:

What is the duration of short term memory?

a) 3-6 Hours

b) 12-18 hours

c) 30-300 seconds

d) 3-4 seconds

Question 7:

The stroke volume depends on end-diastolic volume. This is best represented as

a) Length-force relationship

b) Length- velocity relationship

c) Length-tension relationship

d) Length-viscosity relationship

Question 8:

Which of the following ions in the thick ascending limb of the loop of Henle is responsible for the resorption of divalent ions?

a) H^+

b) HCO_3^-

c) K+

d) Na+

Question 9:

Which of the following sensory receptors are responsible for tactile discrimination?

a) Merkel disc

b) Ruffini end organ

c) Pacinian corpuscle

d) Meissner's corpuscle

Question 10:

All of the following increases gastric acid secretion except:

a) Gastrin

b) Histamine

c) Acetylcholine

d) Serotonin

Question 11:

Pacinian corpuscle is stimulated by which of the following?

a) Pain

b) Temperature

c) Touch

d) Pressure

Question 12:

Which of the following jugular venous pressure (JVP) waves corresponds to the isovolumetric contraction phase of the cardiac cycle?

a) a wave

b) c wave

c) x descent

d) y descent

Question 13:

The extracellular concentration of chloride is 100mmol/L and the intracellular concentration is 10 mmol/L. What is the equilibrium potential of chloride?

a) + 10 mV

b) - 10 mV

c) - 60 mV

d) + 60 mV

Question 14:

After reaching an equilibrium state during exercising, it was found that the body was consuming oxygen at the rate of 1500 ml/min. Calculate the MET score if the baseline oxygen consumption at rest is 250 ml/min.

a) 5

b) 6

c) 1/5

d) 1/6

Question 15:

All of the following cause a right shift of the oxygen-hemoglobin dissociation curve, except ___.

a) Increased HbF

b) Raised 2,3 BPG

c) Acidosis

d) Increased CO_2

Question 16:

The latent period, contraction period, and relaxation period of a skeletal muscle are 10 ms, 40 ms, and 50 ms respectively. Calculate the tetanizing frequency.

a) 100 per second

b) 50 per second

c) 20 per second

d) 25 per second

Question 17:

An individual is in an environment of a temperature of 47°C. What is the mechanism of heat loss?

a) Radiation

b) Conduction

c) Convection

d) Sweating

Question 18:

Which among the following has the highest airway resistance?

a) Alveolar duct

b) Bronchi

c) Respiratory bronchioles

d) Small bronchioles

Question 19:

If the contractility of the heart is decreased, which of the following is seen

a) End diastolic volume and pressure curve shifts to left without change in slope

b) Slope changes in ESV pressure curve

c) End systolic volume and pressure curve shifts to left without change in slope

d) Slope changes in EDV and pressure curve

Question 20:

A lesion in which lobe will lead to impairment of hand-eye coordination?

a) Parietal lobe

b) Frontal lobe

c) Temporal lobe

d) Occipital lobe

Question 21:

All of the following ions have decreased concentration on the luminal side of proximal convoluted tubule except :

a) Amino acids

b) Glucose

c) Chloride

d) Bicarbonate

Question 22:

Sodium iodide symporter is present in all of the following except:

a) Thyroid gland

b) Placenta

c) Salivary gland

d) Pituitary gland

Detailed Explanations

Solution to Question 1:

Renal sympathetic system fibres is not involved in the autoregulation of renal blood flow, because a denervated kidney also maintains the auto regulation of renal blood flow as that of a normal kidney.

Tubulo glomerular feedback, myogenic reflex, and renin-angiotensin system are all involved in the autoregulation of renal blood flow.

Tubulo glomerular feedback:

• When the renal artery pressure increases, the renal blood flow and glomerular filtration rate (GFR) increases

• This increased GFR results in increased delivery of solute and water to the early distal tubule, particularly the macula densa

• The macula dense, then secretes a vasoactive substance that constricts afferent arteriole via a paracrine mechanism

• This vasoconstriction then reduces renal blood flow and GFR back to normal

Myogenic reflex:

• The increase in renal arterial pressure stretches the walls of the afferent arterioles, which then contracts

• This contraction increases the afferent arteriolar resistance

• This increase in resistance then compensates for the increase in blood pressure, thereby keeping the renal blood flow constant.

Renin-angiotensin system:

• Angiotensin II is a potent vasoconstrictor of both afferent and efferent arterioles

• However efferent arterioles are more sensitive to angiotensin II than afferent arteriole

• Thus low levels of angiotensin II produce an increase in GFR by constricting efferent arterioles

• High levels of angiotensin II decreases GFR by constricting afferent and efferent arterioles, thereby decreasing the renal blood flow

Solution to Question 2:

'U' in the urea clearance stands for urine concentration of urea in mg /100ml.

The formula for renal clearance of a substance is,

Clearance (C) = U × V / P,

where

U = Urine concentration of the substance in mg / ml

V = Urine flow rate in ml/min

P = Plasma concentration of substance in mg /ml.

Renal clearance of a substance is the volume of plasma that is completely cleared of the substance by the kidneys per unit of time.

Solution to Question 3:

The relaxation of the intestinal segment distal to the segment of a bolus of food during peristalsis is due to Vasoactive Intestinal Peptide (VIP).

Peristaltic contractions in the small intestine are designed to propel the food towards the large intestine.

The food bolus in the small intestine is sensed by enterochromaffin cells of the intestinal mucosa, which release 5-hydroxytryptamine (5-HT)(serotonin). The 5-HT then binds to the receptors on intrinsic primary afferent neurons (IPANs), which when activated, initiate the peristaltic reflex in that segment of the small intestine. Behind the bolus, excitatory transmitters like acetylcholine, Substance P, neuropeptide Y are released in the circular muscle, while these pathways are inhibited in the longitudinal muscle; thus this segment of small intestine (behind the bolus) contracts and lengthens.

(Recall that contraction of circular muscle decreases the diameter of that small intestinal segment whereas contraction of the longitudinal muscle decreases the length of that segment. To prevent the conflict that would occur if circular and longitudinal are contracted at the same time, they are

reciprocally innervated)

In front of the bolus, inhibitory pathways like vasoactive intestinal peptide (VIP) and nitric oxide (NO) are activated in the circular muscle, while excitatory pathways are activated in the longitudinal muscle;thereby relaxing and shortening this segment of small intestine.

Solution to Question 4:

The given clinical picture of a patient having rice gruel stools is suggestive of the diagnosis of 'cholera'. Vibrio cholerae in addition to the cholera toxin (CT) produces some additional toxins such as,

• Zonula occludens toxin, which alters the intestinal permeability by acting on intestinal epithelial cell tight junctions (which are also called zonula occludens)

• Accessory cholera enterotoxin.

Zonula occludens:

• Also known as tight junctions

• Characteristically surround the apical margins of the cells in epithelia such as the intestinal mucosa, the walls of the renal tubules, and the choroid plexus.

• Also important to the endothelial barrier function and endothelium-dependent vasodilation.

• Made up of ridges- half from one cell and a half from another cell- which adhere so strongly that there is no space between the cells.

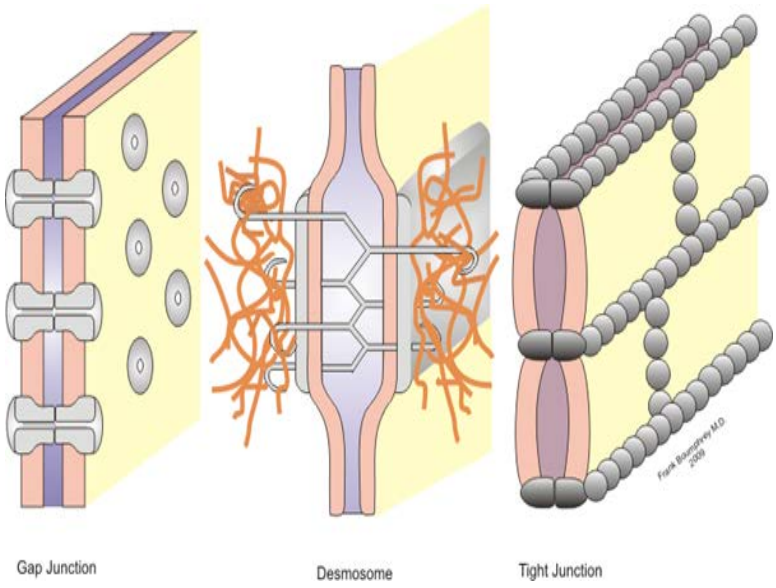
• Three families of transmembrane proteins are involved:

• Occludin

• Junctional adhesion molecule

• Claudins

• Paracellular pathway - these tight junctions permit the passage of ions, solutes, and intracellular signaling molecules in between adjacent cells.



Other options:

B) Gap junctions:

• The gap between the two cells in these types of junctions is about 4nm.

• These junctions are formed by units called connexons, which are present in the membrane of each cell.

• Each connexon is made up of six protein subunits called connexins.

• They permit substances to pass between the cells, without entering the ECF.

• The pore diameter is around 0.8 to 1.4 nm, which permits the passage of ions, sugars, amino acids, and other solutes which weigh up to 1000 Da.

• They also permit rapid propagation of electrical activity from cell to cell, as well as the exchange of various chemical messengers and intracellular signaling molecules.

C) Adherent junctions:

• Adherent junctions or Zonula adherens is a continuous structure on the basal side of the zonula occludens.

• It contains cadherins.

D) Hemidesmosomes:

• They look like half-desmosomes.

• They attach cells to the underlying basal lamina and are connected intracellularly to intermediate filaments.

• They contain integrins.

Solution to Question 5:

Beta hCG (human chorionic gonadotropin) has biological activity similar to that of luteinizing hormone (LH).

hCG is a glycoprotein produced by syncytiotrophoblasts. It is made up of α and β subunits. Though the α subunit of hCG is similar to the α subunits of LH, FSH, and TSH, the β subunit has structural similarity to LH only. Hence, LH is a better answer than FSH.

hCG is primarily luteinizing and luteotrophic. It appears to act on the same receptor as that of LH. The function of hCG is to prevent regression of the corpus luteum. It can be detected in blood as early as 6 days after conception and forms the basis of various tests used to identify pregnancy.

Its level peaks at gestational week 9 and then declines gradually but is present in lower concentration till the end of pregnancy. But hCG is not specific for pregnancy as it is secreted in a variety of gastrointestinal and genital tumors in both males and females.

Solution to Question 6:

Short-term memory lasts for seconds to minutes, hence of the given 4 options, 30-300 seconds is the most appropriate answer.

Memory is usually divided into two forms: Explicit or declarative memory which is associated with consciousness or awareness. Implicit or nondeclarative memory does not involve awareness and its retention does not usually involve processing in the hippocampus.

Explicit and many forms of implicit memory involve

• Short-term memory and

• Long-term memory.

Short-term memory:

It lasts seconds to minutes; the encoding process for short-term explicit memory involves the hippocampus. It lasts only till the person continues to think about the number or facts.

Working memory is a form of short-term memory that keeps information available, usually for very short periods of time, until the individual plans action based on it.

Long-term memory:

It stores memories that can be recollected after years or even for a lifetime. These memories are stored in various parts of the neocortex. The various parts of the memories such as, visual, auditory, olfactory, etc., are localised to the cortical regions concerned with these functions. All these parts of the memories are brought together by long-term changes in the strength of transmission at relevant synaptic junctions so that all the components are brought to consciousness when that particular memory is recalled.

Neural basis of memory:

The basis of memory is the alteration in the strength of the selected synaptic connections. Second messenger systems contribute to the changes in the neural circuits which are required for learning and memory. Alterations in the cellular membrane channels also contribute to it.

Solution to Question 7:

The relationship between end-diastolic volume and stroke volume is best represented by length-tension relationship.

This is explained by the 'Frank-Starling law of heart' which states that ' the volume of blood ejected by the ventricle depends on the volume present in the ventricle at the end of the diastole'. The length of the myocytes depend on the volume (and hence tension) present at the end of the diastole, which in turn, depends on the volume returned to the heart, or the venous return.

• The Frank-Starling law governs the normal ventricular function and ensures that the cardiac output equals venous return, within physiological limits.

• There is a curvilinear relationship between stroke volume or cardiac output and the ventricular end-diastolic volume.

• Agents that increase the contractility of the cardiac muscle have a positive inotropic effect and produce increased stroke volume and thereby increased cardiac output for a given end-diastolic volume. (Eg: Digoxin)

• Agents that decrease the contractility of the cardiac muscle have a negative inotropic effect and produce decreased stroke volume (and cardiac output) for a given end-diastolic volume.

Solution to Question 8:

Potassium (K+) in the thick ascending limb of loop of Henle is responsible for the resorption of divalent ions such as, calcium, magnesium, etc.

This resorption is driven by the lumen-positive potential difference across the cells of the thick ascending limb, created by the potassium leak into the lumen.

Mechanism of resorption in thick ascending limb:

• The luminal membrane contains a Na+-K+-2Cl- cotransporter.

• There is net resorption of Na+, K+ and Cl- in the thick ascending limb as follows:

• All three ions are transported into the cell on the cotransporter.

• Na+ is extruded from the cell by the Na+-K+ ATPase in the basolateral membrane.

• K+ and Cl- diffuse through channels in the basolateral membrane, down their respective electrochemical gradients.

• Most of the K+ leaves the cell across the basolateral membrane; the remaining portion of K+ however diffuses back into the lumen.

• This K+ leak into the lumen generates a positive electrochemical potential difference in the lumen.

• This lumen-positive potential difference drives the resorption of ions such as sodium(Na+), magnesium (Mg2+), calcium (Ca+),etc.,

Solution to Question 9:

Meissner's Corpuscles are responsible for discriminative touch.

Meissner's corpuscles are encapsulated receptors found in the dermis of the non-hairy skin, most commonly on the fingertips, lips, and other locations where tactile discrimination is very good. Their field of reception is very small and hence used for two-point discrimination. These are rapidly adapting receptors that encode

• Point discrimination

• Precise location

• Tapping

• Flutter

Solution to Question 10:

All of the above increase gastric acid secretion except serotonin.

Serotonin is localized in the enterochromaffin cells of the gastrointestinal (GI) mucosa and within neurons of the GI tract. Serotonin inhibits gastric acid secretion. It stimulates the production and release of gastric and colonic mucus. Serotonin acts as an enteric neurotransmitter and increases intestinal motility.

The main factors that stimulate gastric secretion are acetylcholine, gastrin, and histamine. Parasympathetic stimulation releases Ach which stimulates the secretion of

• pepsinogen by peptic cells

• hydrochloric acid by parietal cells

• mucus by mucous cells.

Both gastrin and histamine strongly stimulate acid secretion by parietal cells but have little effect on other cells.

The stomach mucosa has two important types of tubular glands:

• The oxyntic (gastric) glands secrete hydrochloric acid, pepsinogen, intrinsic factor, and mucus.

• The pyloric glands secrete mainly mucus for protection of the pyloric mucosa from the stomach acid. They also secrete the hormone gastrin.

Note- Serotonin released from the small intestine triggers vomiting by stimulation of 5HT3 receptors. Therefore, 5HT3 antagonists like ondansetron are used as antiemetics.

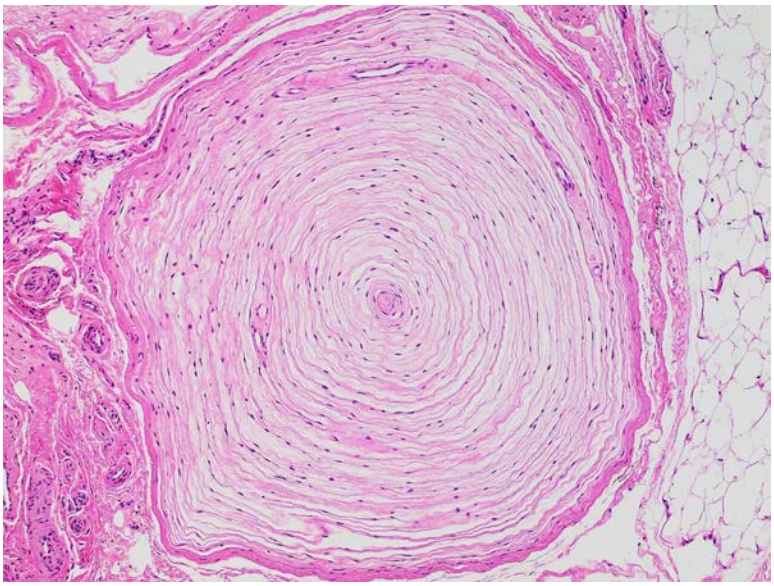
Solution to Question 11:

Pacinian corpuscle is stimulated by pressure.

Pacinian corpuscles are the largest cutaneous mechanoreceptors. They are present in the dermis of glabrous and hairy skin. They are composed of a nerve ending which is encapsulated by

concentric layers of connective tissue that give it an onion-like appearance. These receptors respond to fast vibration and deep pressure and adapt very rapidly. The sensory nerves from cutaneous mechanoreceptors are myelinated Aα and Aβ fibers.

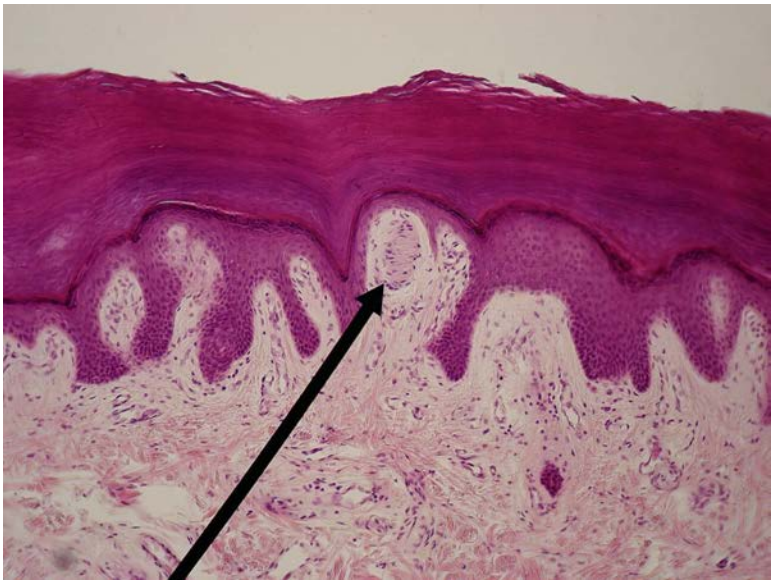
Image shows histology of Pacinian corpuscle.



Other mechanoreceptors:

• Meissner's corpuscles are present mainly in the dermis of non-hairy skin particularly in the fingertips, lips, and other locations where tactile discrimination is well developed. They have small receptive fields and can be used for two point discrimination. Meissner corpuscles are rapidly adapting receptors that sense point discrimination, precise location, tapping, and flutter. These are encapsulated nerve endings of a large myelinated sensory nerve (Aβ type).

The image shows the histology of Meissner's corpuscle in the dermis.



• Merkel discs are seen in the epidermis of glabrous skin. They are slowly adapting receptors and have very small receptive fields. These receptors detect vertical indentations of the skin. They

are expanded dendritic endings.

• Ruffini corpuscles are capsulated, enlarged, dendritic endings. They are located in the dermis of glabrous and hairy skin, and in joint capsules. They are slowly adapting receptors. Ruffini corpuscles detect stretch and joint rotation.

Pain and temperature sensations arise from receptors located on unmyelinated sensory neurons present throughout the glabrous skin, hairy skin, and deep tissue. Impulses from nociceptors are transmitted via thinly myelinated Aδ fibers and unmyelinated C fibers.

Activation of Aδ fibers is responsible for first pain (also called fast pain). It is a rapid response and helps in the discrimination of pain or the ability to localize the site and intensity of the noxious stimulus. It is mediated by the release of glutamate. An example is pinprick.

Activation of C fibers is responsible for delayed second pain(also called slow pain). It is a dull, intense, diffuse, and unpleasant feeling associated with a noxious stimulus. . Second pain is mediated by the release of a combination of glutamate and substance P. Example is visceral pain.

Types of nociceptors :

• Mechanical nociceptors respond to strong pressure (eg, from a sharp object).

• Thermal nociceptors are activated by skin temperatures above 45°C or by severe cold (<20°C).

• Chemically sensitive nociceptors respond to chemicals such as bradykinin, histamine, high acidity, and environmental irritants.

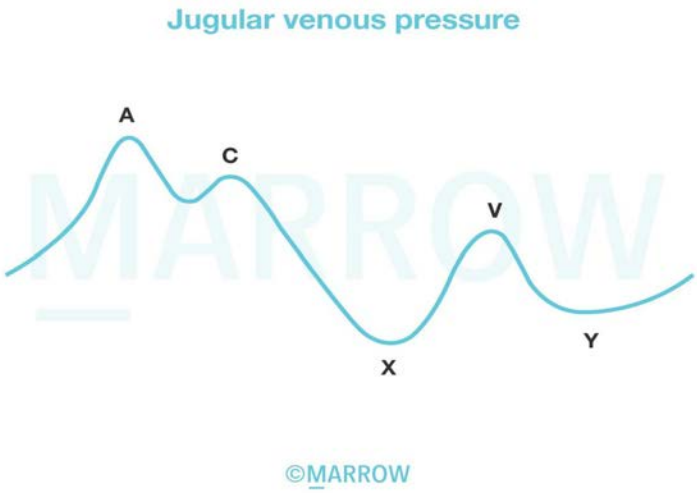
• Polymodal nociceptors respond to combinations of these stimuli.

Solution to Question 12:

The c wave of jugular venous pressure wave corresponds to the isovolumetric contraction phase in the cardiac cycle.

During isovolumetric contraction, the ventricles start contracting with valves closed. This leads to bulging of the tricuspid valve. This bulging increases pressure in the right atrium which is transmitted to the right internal jugular vein. This appears as a c wave in jugular venous pressure (JVP) tracing.

JVP measured in the internal jugular vein (IJV) is a reflection of the right atrial pressure. IJV is preferred because it is not valved and is in direct line with superior vena cava and right atrium.



The waveforms seen in a normal JVP are:

• a wave corresponds to atrial contraction and occurs just after the P wave (on ECG) and just before the first heart sound.

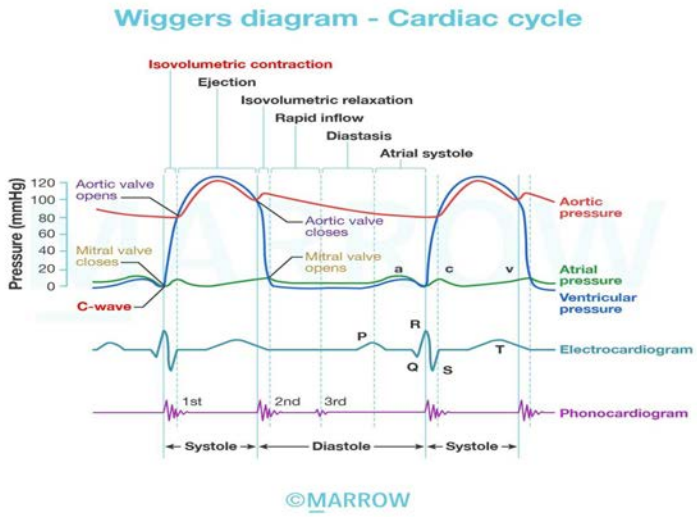
• c wave represents the bulging of the tricuspid valve into the right atrium during ventricular systole.

• x descent corresponds to the atrial relaxation during atrial diastole.

• v wave represents atrial filling during ventricular systole and peaks at the second heart sound.

• y descent represents passive emptying of the right atrium into the right ventricle after tricuspid valve opening.

The Wiggers diagram given below correlates JVP with other aspects of cardiac cycle.



Solution to Question 13:

The equilibrium potential of chloride in the given question is -60 mV.

Solution to Question 14:

The MET score in the given scenario is 6.

One metabolic equivalent (MET) is defined as the amount of oxygen consumed while sitting at rest.

Normally, one MET= 3.5 ml O2 /kg body weight/min

In the above question, the baseline O2 consumption at rest is given as 250 ml/min. According to the definition of one MET, we can deduce that the given 250ml/min is one MET.

O2 consumption at reaching equilibrium during exercise= 1500ml/min

MET score= O2 consumption during exercise/ one MET

= 1500/250

= 6

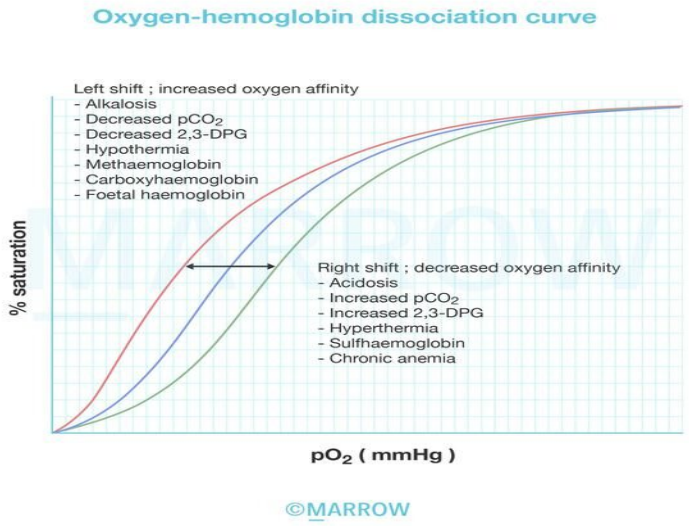
The MET concept represents a simple, practical, and easily understandable procedure for expressing the energy cost of physical activities as a multiple of the resting metabolic rate. If the MET score is low, it means that the activity requires less oxygen compared to an activity that has a higher MET score. Eg. Gardening requires around 3-7 METS compared to that jogging that may need around 9-11 METS. We can classify activities as light, moderate or heavy, depending on MET scores. It can also be used to identify the functional capacity of a patient.

Solution to Question 15:

Increased HbF (fetal hemoglobin) causes a left shift of the oxygen-hemoglobin dissociation curve.

Oxygen-hemoglobin dissociation curve:

This is a plot of the partial pressure of O2 and the percentage saturation of Hb with O2. It is normally sigmoid in shape. If the oxygen-hemoglobin dissociation curve is shifted to the right, it means that the affinity of Hb for O2 has become less, which favors O2 delivery. This means a higher P50, which implies that a higher PO2 is required to maintain 50% saturation (R - Right shift Releases oxygen). If the curve is shifted to the left, it means that affinity has increased for O2 (which favors O2 binding) i.e. lower P50 value (L-Left shift Leashes oxygen).



Causes of the right shift of the oxygen-hemoglobin dissociation curve:

• Hypoxia and Hypercarbia - metabolically active tissues utilize O2 and tissues produce CO2

• ↓ pH - Secondary to increased CO2 production

• ↑ in temperature

• ↑ in 2,3-DPG - increased anaerobic glycolysis

• Growth hormone, thyroid hormone, androgen - by increasing 2,3 DPG

• Sickle cell anemia - reduced affinity for O2

• Exercise

Causes of the left shift of oxygen-hemoglobin dissociation curve:

• ↑ pH (alkalosis)

• ↓ PCO2

• ↓ 2,3-DPG

• ↓ Temperature

• HbF

• Carboxyhemoglobin

Bohr's effect- The decrease in the O2 affinity of hemoglobin when the pH of the blood falls

Solution to Question 16:

The tetanizing frequency of the given skeletal muscle is 25 per second.

In the question, it is given that the contraction period is 40 msec (40 msec is 0.04 seconds)

Tetanizing frequency = 1/contraction period

Therefore, tetanizing frequency = 1/40 millisecond = 1/0.04 per second = 1000/40 per second = 25 per second.

When there is a repeated stimulus to a muscle fiber before relaxation, it produces an additional contraction of the muscle. The second contraction adds to the first contraction and the total strength of contraction increases. This phenomenon is known as a summation of contractions.

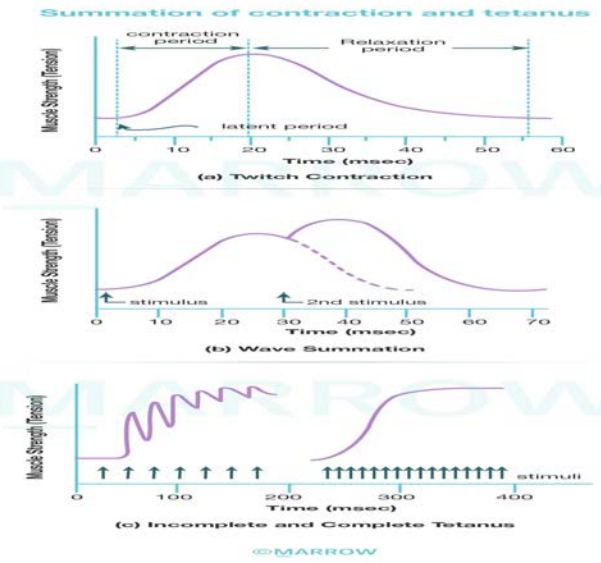
With repeated stimulation, contraction occurs repeatedly before any relaxation has occurred. This causes the individual responses to fuse into one continuous contraction. Such a response is called tetanus (tetanic contraction). ■■■

Tetanizing frequency is the minimum frequency required for producing tetanus.

Tetanus is of two types.

• Complete tetanus- when no relaxation occurs between stimuli

• Incomplete tetanus- when periods of incomplete relaxation occur between the summated stimuli.



Solution to Question 17:

The mechanism of heat loss in the given case where the surrounding temperatures are higher than the body temperature is sweating.

Different methods of heat loss:

• Radiation is heat loss in the form of infrared rays.

• Conduction is heat loss that occurs by direct contact with an object.

• Convection is heat loss resulting from air movement.

When the temperature of the surroundings is more than that of the skin, the body gains heat by both radiation and conduction. Under these conditions, the heat can be lost from the body only by evaporation or sweating.

When the body temperature is greater than the temperature of the surroundings, heat can be lost by radiation and conduction.

Solution to Question 18:

Among the given options, bronchi (medium-sized airway) offer maximum resistance.

The best answer here is bronchi, as all the other options suggest smaller airways, while bronchi are the only medium-sized airway.

Airflow can be derived from Poiseuille-Hagen formula:

$Q = \pi \Delta P r^4 / 8\eta L$

Where

• Q is the flow rate

• π is pie symbol

• ΔP is the pressure difference

• r is radius

• η is viscosity

• L is length

Also,

Flow rate (Q) = pressure difference (ΔP)/ resistance (R).

Therefore, substituting this in Poiseuille- Hagen formula,

$\Delta P / R = \pi \Delta P r^4 / 8\eta l$

$1/R = \pi r^4 / 8\eta l$

$R = 8\eta l / \pi r^4$

Therefore it can be derived that airway resistance is inversely proportional to the radius by the power of four.

With Poiseuille- Hagen formula we might feel that the smallest airways are the major site of resistance. However, the contribution by the smallest airways is very little to the overall total resistance. This is because, the airway branches in each generation exist in parallel rather than in series. As the parallel branching increases, the resistance decreases. (Total cross-sectional diameter of small airways put together is high). Thus the overall resistance of the small airways is very small. Also, airflow velocity decreases substantially as the effective cross-sectional area increases (i.e., the flow becomes laminar).

Other factors affecting airway resistance :

• Lung volume, as lung volume increases the resistance decreases and vice versa. Lung volume increases the transairway pressure thus increasing the caliber of the airway.

• Airway mucus, edema, and contraction of bronchial smooth muscle increase the airway resistance. Its clinical application is seen in asthma, bronchitis, and emphysema

• The density and viscosity of inspired gas also contribute to airway resistance. A gas with more density imparts more resistance.

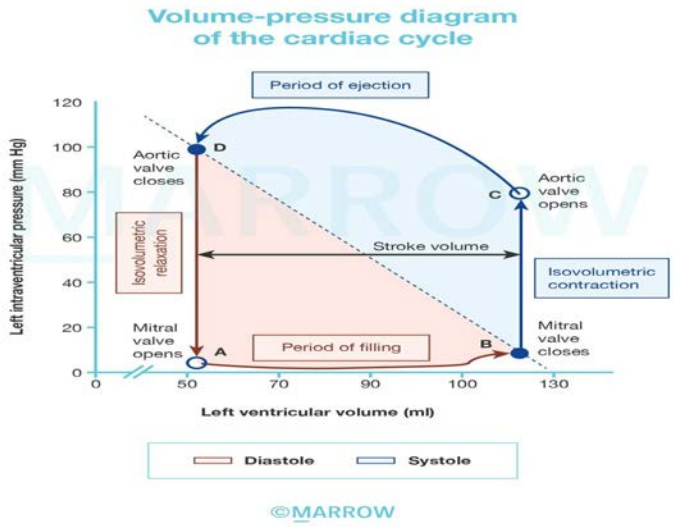
Solution to Question 19:

If the contractility of the heart is decreased, slope changes in the ESV pressure curve are seen.

To answer this question, we will first understand the volume-pressure diagram and the end-systolic pressure-volume relationship (ESPVR) during cardiac cycle.

Volume-pressure diagram during the cardiac cycle

The volume pressure diagram plots the changes in the pressure and volume in the left ventricle that occurs during the cardiac cycle. The x-axis shows the changes in ventricular volume, while the y-axis shows the changes in ventricular pressure.



It has the following phases.

Phase I- This phase is called the period of filling and extends between points A and B. Point A is at the end of systole when the ventricular volume is about 50 mL. This volume is called end-systolic volume. The pressure at this point is about 2 to 3 mm Hg. These volume and pressure go on increasing as the blood from the atrium flows to the ventricle during diastole. At the end of diastole, marked by point B, the ventricle will have a volume of around 120 mL. This volume is called end-diastolic volume. The pressure is slightly raised to 5-7mm Hg.

Phase II- It is the phase of isovolumetric contraction, and extends between points B and C. At the end of diastole (point B), a slight increase in the ventricular pressure closes the mitral valve, and contraction starts. The ventricle contracts while both mitral and aortic valves are closed. Therefore, the pressure within the ventricle slowly rises without any changes in the volume.

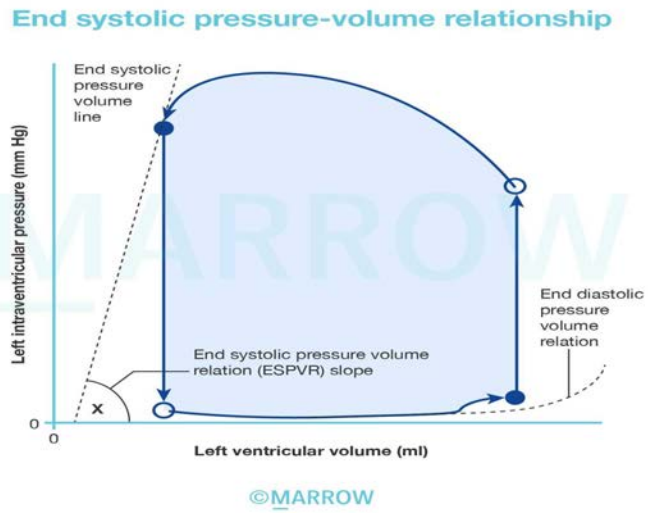
Phase III- It is the phase of ejection and extends between point C and point D. Point C is the place where the aortic valve opens. The pressure within the left ventricle rises slowly during isovolumetric contraction until it is sufficient to open the aortic valve. Once the aortic valve opens, blood within the left ventricle is ejected into the aorta. This decreases the volume of the left

ventricle, while increasing the pressure within the ventricle.

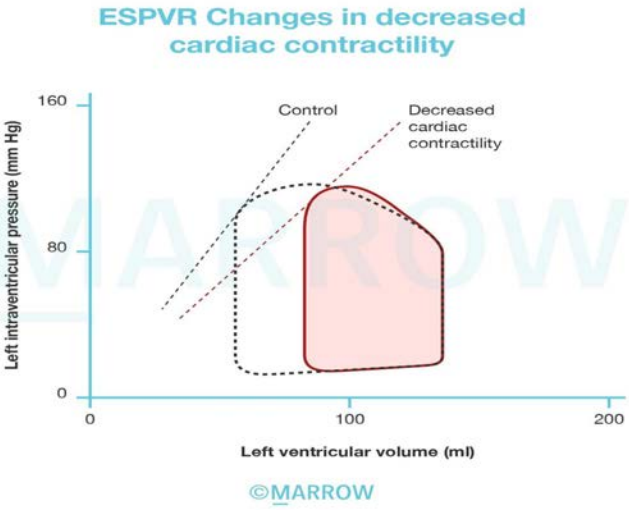
Phase IV- It is the period of isovolumetric relaxation. It extends between points D and A. At the end of the ejection (Point D), the aortic valve closes. However, the ventricular relaxation continues despite closed aortic and mitral valves. Therefore, the ventricular pressure continues to fall while the volume remains the same. The ventricle returns to its starting point, with about 50 ml of blood left in the ventricle and pressure of about 2 to 3 mm Hg

End-systolic pressure-volume relationship (ESPVR)

ESPVR is the maximum pressure that can be developed by the ventricle at the end-systolic volume. It is determined by the line intersecting the upper left corners of the loops. This line can be extended down to the x-axis. The slope of this line is called as ESPVR slope.



Now coming to the question, when the contractility of the heart is decreased, the force of ejection decreases leading to decreased stroke volume, and increased end-systolic volume. Therefore, the volume-pressure diagram shifts to the right. If the diagram shifts to the right, then ESPVR also changes, leading to a change in the slope of the ESPVR curve.



Other options:

Options A and D- End diastolic volume and pressure curve (EDPVR) mainly assesses the compliance of the ventricle, rather than contractility. The slope of this curve increases when the compliance decreases, and vice versa.

Option C- ESPVR shifts to right with change in slope.

Solution to Question 20:

A lesion in the parietal lobe will lead to impairment of hand-eye coordination.

The somatic sensory area and related parts of the posterior parietal lobe project to the premotor cortex. Some of these neurons are concerned with aiming and manipulating the hands at an object, whereas other neurons are concerned with hand-eye coordination. Neurons in this posterior parietal cortex contribute to the descending pathways involved in motor control.

There are two parietal lobes, the dominant side, and the non-dominant side.

• The functions of the dominant side of the parietal lobe are calculation, language, planned movement, appreciation of size, shape, weight, and texture. A lesion here causes dyscalculia, dysphasia, dyslexia, apraxia, agnosia, homonymous hemianopia.

• The function of the non-dominant side is spatial orientation and constructional skills. Its lesion causes spatial disorientation, constructional apraxia, neglect of the non-dominant side, dressing apraxia, and homonymous hemianopia.

Other options:

Option B: The frontal lobe is responsible for personality, emotional response, social behavior. Any lesion in the frontal lobe causes disinhibition, antisocial behavior, impaired memory, incontinence, anosmia.

Option C: The temporal lobe has two lobes and is divided as dominant and non-dominant.

• The dominant temporal lobe has important functions like auditory perception, speech, language, verbal memory, smell. Lesions lead to dysphasia, dyslexia, poor memory, complex hallucinations (smell, sound, vision), impaired face recognition (Prosopagnosia) and homonymous hemianopia.

• The nondominant temporal lobe auditory perception, music, tone sequences, non-verbal memory (faces, shapes, music). Lesions here leads to poor non-verbal memory, loss of musical skills, complex hallucinations, and homonymous hemianopia.

Option D: The occipital lobe is responsible for the analysis of vision. A lesion in occipital lobe mainly affects vision leading to homonymous hemianopia, visual agnosia, impaired face recognition (prosopagnosia), visual hallucinations (lights, lines and zigzags).

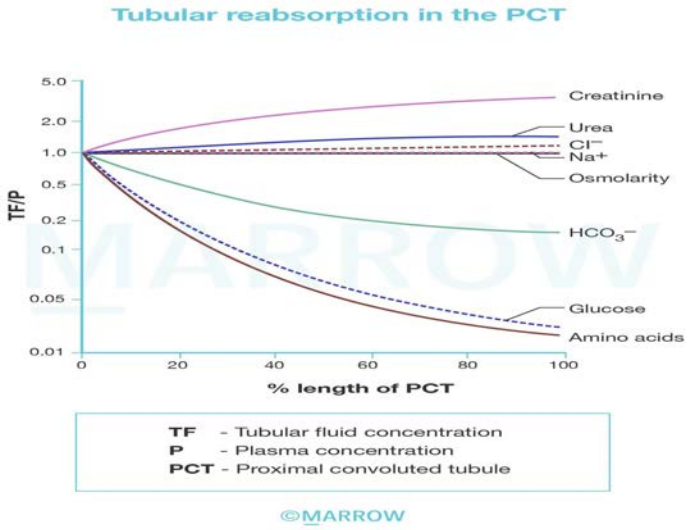
Solution to Question 21:

The concentration of chloride on the luminal side is more when compared to sodium, glucose, and amino acids.

In the first half of the proximal tubule, sodium is reabsorbed by co-transport along with glucose, amino acids, and other solutes. As sodium is reabsorbed in the proximal tubule, it preferentially carries glucose, amino acids, bicarbonate along with it. Thus, their concentrations decrease markedly along the length of the proximal tubule, and a solution having a higher concentration of chloride is left behind. The concentration of chloride here is around 105 mEq/L.

In the second half of the proximal tubule, sodium gets re-absorbed along with chloride since there is only a little glucose and amino acids yet to be re-absorbed. The second half of the proximal tubule has a concentration of chloride ≈140 mEq/L. This higher chloride concentration favors its own diffusion from the lumen into the renal interstitial fluid.

Although the amount of sodium in the tubular fluid decreases markedly along the proximal tubule, the concentration of sodium and the total osmolarity remain relatively constant. This is because the proximal tubule is highly permeable to water and water reabsorption increases to keep pace with the sodium reabsorption.



Solution to Question 22:

Sodium iodide symporter is present in all of the options given above except the pituitary gland.

Sodium iodide symporter is expressed mainly in the thyroid gland and is responsible for iodine uptake in the follicular cells of the thyroid gland.

Sodium iodide symporter (NIS)

The NIS is mainly present in the basolateral membranes of the thyrocytes. The NIS transports two Na+ ions and one I- ion into the cell against the concentration gradient. The energy for this transport is derived from the Na+-K+ ATPase pump. Na+-K+ ATPase pumps sodium outside the cell and causes low intracellular sodium concentration. This causes sodium to enter the cell by facilitated diffusion. Along with sodium, iodide ions also enter the cell. Since the energy to

transport sodium and iodide ions in NIS is derived from Na+-K+ ATPase pump, this is called secondary active transport.

The NIS is also expressed in:

• Salivary glands

• Gastric mucosa

• Placenta

• Ciliary body of the eye

• Choroid plexus

• Mammary glands

• Certain cancers are derived from these tissues.

The significance of these extrathyroidal NIS is not known.

Physiology NEET 2021

Question 1:

A 30-year-old man weighing 70 kg had a sodium level of 120 mEq/L. Calculate the sodium deficit.

a) 280 mEq

b) 480 mEq

c) 840 mEq

d) 1400 mEq

Question 2:

Beta 2 receptor action leading to hyperglycemia/ hypoglycemia is mediated by which of the following enzymes?

a) Adenylyl cyclase

b) Guanylyl cyclase

c) Phospholipase C

d) Phospholipase A2

Question 3:

A body fluid sample is being studied and has Na: 10 mEq/L, K: 140 mEq/L, CI: 4 mEq/L. Identify the compartment from which the sample has been obtained.

a) Interstitial

b) Intracellular fluid

c) Extracellular fluid

d) Plasma

Question 4:

A middle-aged female patient presented with slowly progressive motor weakness, nuchal rigidity, and difficulty in swallowing and carrying out day-to-day activities. A provisional

diagnosis of multiple sclerosis is suspected. Which of the following cells are affected in multiple sclerosis?

a) Microglia

b) Oligodendrocytes

c) Astrocytes

d) Ependymal cells

Question 5:

A child with loose stools for one day presented to your OPD. On examination, signs of dehydration were present and the child was given ORS. It facilitates glucose absorption through which of the following receptors?

a) SGLT1

b) SGLT2

c) GLUT4

d) Na- Ca transporter

Answer Key

Question No.	Correct Option
1	c
2	a
3	b
4	b
5	a

Detailed Explanations

Solution to Question 1:

The sodium deficit in the given scenario is 840 mEq.

Sodium deficit is calculated as 0.6 x body weight x (target plasma sodium concentration - starting plasma sodium concentration).

Substituting the given values in the formula :

Sodium deficit = 0.6 x 70 x (140 - 120) = 840 mEq.

Solution to Question 2:

Beta 2 receptor action leading to hypoglycemia/ hyperglycemia is mediated by adenylyl cyclase. Catecholamines act through beta 2 receptors and they use adenylyl cyclase - cAMP second messenger system to stimulate the target tissues.

Other hormones that use adenylyl cyclase - cAMP second messenger system are :

- Adrenocorticotropic hormone
- Angiotensin II
- Corticotropin-releasing hormone
- Calcitonin
- Follicle-stimulating hormone
- Glucagon
- Growth hormone-releasing hormone
- Human chorionic gonadotropin
- Luteinizing hormone
- Parathyroid hormone
- Secretin
- Somatostatin
- Thyroid-stimulating hormone
- Vasopressin

Hormones exert their actions by stimulating cAMP production within the cells. When the hormone binds to the membrane receptor, the receptor is coupled to the G protein. This G protein can either stimulate (Gs protein) or inhibit (Gi protein) adenylyl cyclase that controls the conversion of cytoplasmic adenosine triphosphate to adenosine monophosphate (cAMP). The protein kinases dependent on cAMP are thus activated. This leads to a series of biochemical reactions enabling the hormone to exert its actions.

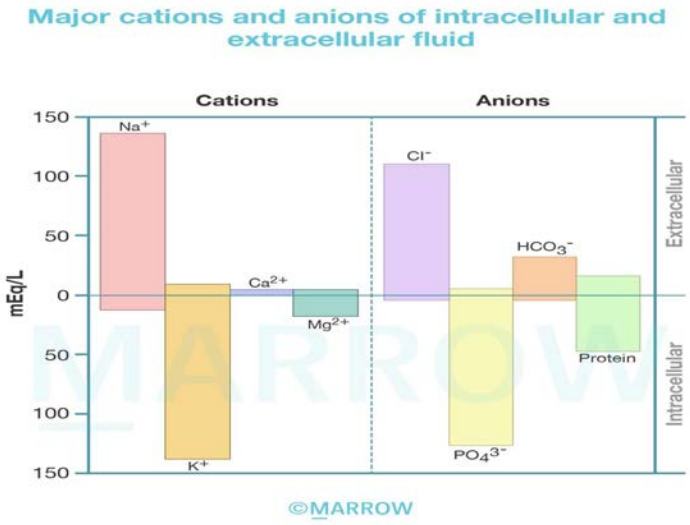
Guanylyl cyclase is the enzyme that catalyzes the formation of cGMP.

Solution to Question 3:

The sample obtained is from the intracellular fluid (ICF) compartment. The ICF contains large quantities of potassium (K+) ions - 140 mEq/L . The ICF also has lesser amounts of sodium (Na+) and Chloride (Cl-) ions.

The extracellular fluid (ECF) compartment includes interstitial fluids and plasma. In contrast to the ICF, the ECF has an abundance of sodium, chloride, calcium and bicarbonate ions, and lesser amounts of potassium, phosphate and magnesium ions.

The image below depicts the proportion of the important anions and cations present in the intracellular and extracellular fluids.



Solution to Question 4:

Oligodendrocytes are affected in multiple sclerosis.

In multiple sclerosis, there is patchy destruction of myelin in the central nervous system and the axons are demyelinated. This causes loss of conduction or delayed conduction in the demyelinated axons. Oligodendrocytes and Schwann cells are involved in the formation of myelin. Hence, they are affected by multiple sclerosis.

Other options

Option A: Microglia are a part of the immune system. Microglia are scavenger cells that aid in the removal of cellular debris formed due to various diseases. They originate from macrophages outside of the nervous system and are unrelated to the neural cell types.

Option C: There are three types of macroglia - astrocytes, oligodendrocytes, and Schwann cells. Astrocytes are found throughout the brain and they induce capillaries to form the blood-brain barrier. The astrocytes may be fibrous or protoplasmic.

Option D: Ependymal cells line the ventricular system. They are in contact with the cerebrospinal fluid and play a role in fluid homeostasis.

Solution to Question 5:

ORS facilitates glucose absorption through SGLT 1 (Sodium-dependent glucose co-transporter - 1). In a child with diarrhea, when oral rehydration solution is given, there is coupled absorption of sodium and glucose through SGLT -1.

Glucose transport may be active or passive.

Active transport of glucose takes place through Sodium dependent glucose transporter (SGLT 1 and 2). SGLT 1 helps in glucose absorption in the small intestine and renal tubules. SGLT 2 primarily facilitates glucose absorption in the renal tubules.

Passive absorption of glucose occurs through facilitated diffusion. This is carried out by Glucose transporters (GLUT) 1 -7.

Physiology INI-CET 2022

Question 1:

Which physiological adaptation does not happen at high altitudes?

a) Pulmonary vasoconstriction

b) Polycythemia

c) Respiratory acidosis

d) Hypoxia

Question 2:

Countercurrent mechanism is present in which of the following parts of the body?

a) 1 and 2 are correct

b) 1,2,3 are correct

c) 1,2,3,4,5 are correct

d) 2,3,4,5 are correct

Question 3:

Match the following molecules with their carriers in plasma:

a) 1-b, 2-c, 3-d, 4-a

b) 1-a, 2-b, 3-c 4-d

c) 1-a, 2-d, 3-b 4-c

d) 1-b, 2-c, 3-a, 4-d

Question 4:

Myosin ceases to be in contact with actin filaments as a result of:

a) Dissociation of ADP and Pi

b) Cessation of calcium release from sarcoplasm

c) Conformational change in Troponin T

d) Attachment of ATP to myosin head

Question 5:

Transport of iron into enterocytes is done by which of the following proteins:

a) Transferrin

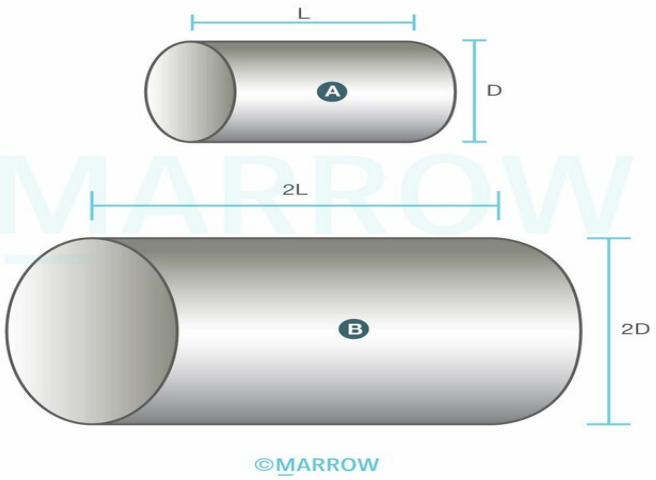
b) Ferroportin

c) Hepcidin

d) Divalent metal transporter - 1

Question 6:

Vessel A has a length of L and diameter of D and vessel B has 2L and 2D. Considering the flow is laminar through both the cylinders, the flow through B is how many times as much as the flow through A?



a) 4 times

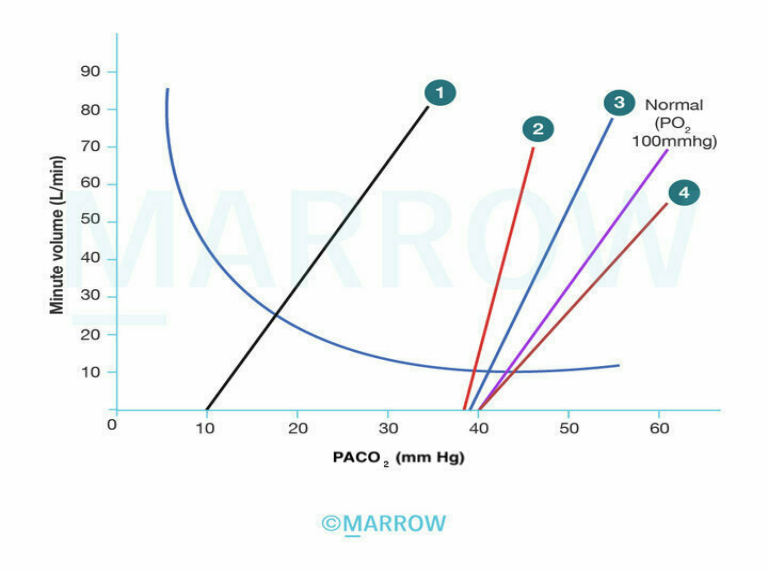
b) 8 times

c) 16 times

d) 32 times

Question 7:

If the pH is reduced from 7.4 to 7.3 with the PO2 being constant at 100 mmHg, which line would PCO2 follow?



a) 1

b) 2

c) 3

d) 4

Question 8:

Substances and the type of transport across a membrane are given below, choose the correct combination:

a) 1 and 2 are correct

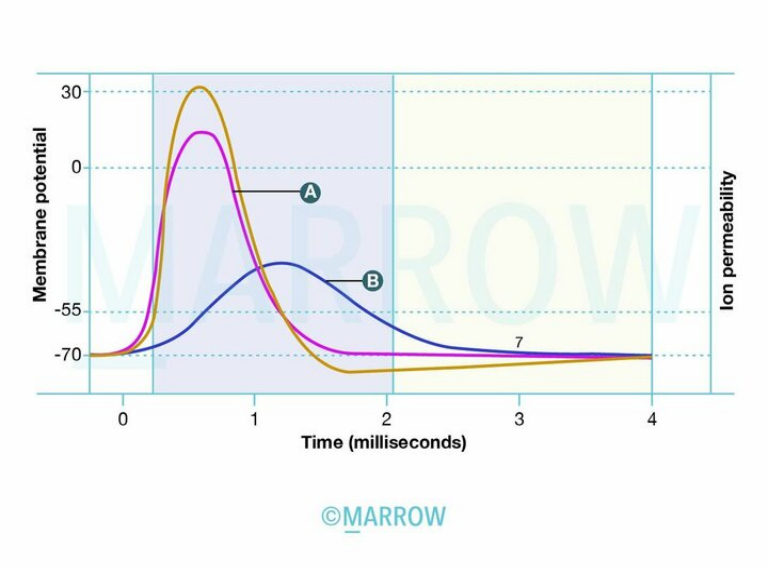
b) 1, 2, and 4 are correct

c) 1, 2, 3, 4, and 5 are correct

d) 1, 2, and 5 are correct

Question 9:

A and B in the graph below represent which of the following ions, in terms of permeability for action potential generation?



a) A is Na+, B is K+

b) A is Na+, B is Ca2+

c) A is K+, B is Ca2+

d) A is Ca2+, B is K+

Question 10:

Transcutaneous electrical nerve stimulation (TENS) is used to relieve pain. What is the mechanism behind it?

a) Gate control theory

b) Conditioned pain modulation

c) Descending inhibition

d) Central inhibition

Question 11:

The parents notice that their child is tired and that he has shortness of breath on climbing stairs and while lying down. What is the first investigation that you would do?

a) Echocardiogram

b) Chest x-ray

c) Spirometry

d) MRI to rule out enlarged heart

Question 12:

Match the following molecules with their carriers in plasma:

a) 1-b, 2-c, 3-d, 4-a

b) 1-a, 2-b, 3-c 4-d

c) 1-a, 2-d, 3-b 4-c

d) 1-b, 2-c, 3-a, 4-d

Question 13:

Arrange the following steps of ventricular action potential in the correct order.

a) B, A, C, D

b) D, C, B, A

c) C, D, A, B

d) A, B, C, D

Question 14:

What does the zero pressure indicate in the pressure-volume curve?

a) Residual volume

b) Functional residual capacity

c) Tidal volume

d) Inspiratory reserve volume

Question 15:

How is cerebral perfusion pressure calculated?

a) Systolic blood pressure + Intracranial pressure

b) Systolic blood pressure - intracranial pressure

c) Mean arterial pressure/intracranial pressure

d) Mean arterial pressure - intracranial pressure

Question 16:

Fluid leaving the proximal convoluted tubule in the absence of antidiuretic hormone is:

a) Isotonic

b) Hypotonic

c) Hypertonic

d) Depends on fluid intake

Question 17:

2,3-BPG causes the unloading of oxygen to tissues by _____.

a) Increasing ATP production

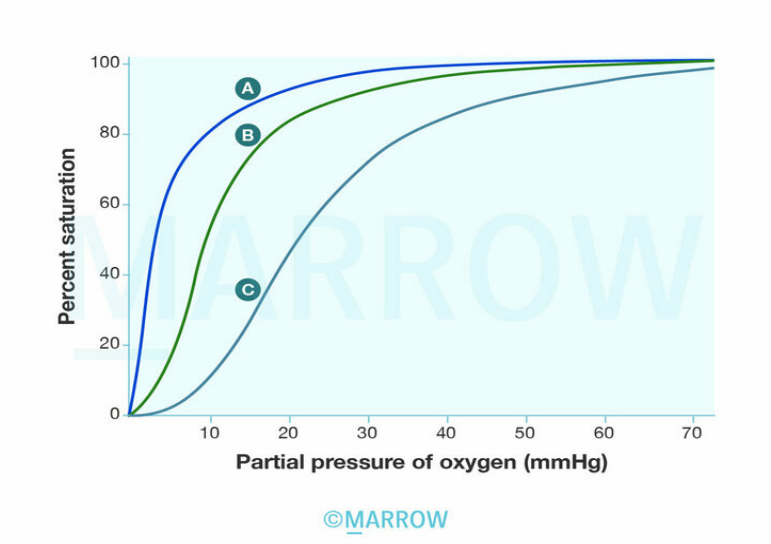
b) Binding to beta subunit of Hb

c) Inhibiting taut structure

d) Decreasing ATP production

Question 18:

The graph below shows oxygen dissociation curves. What does the curve marked as 'A' indicate?



a) Myoglobin

b) Carboxyhemoglobinemia

c) Methemoglobin

d) Fetal hemoglobin

Question 19:

Which among the following organs has the least arteriovenous oxygen difference?

a) Brain

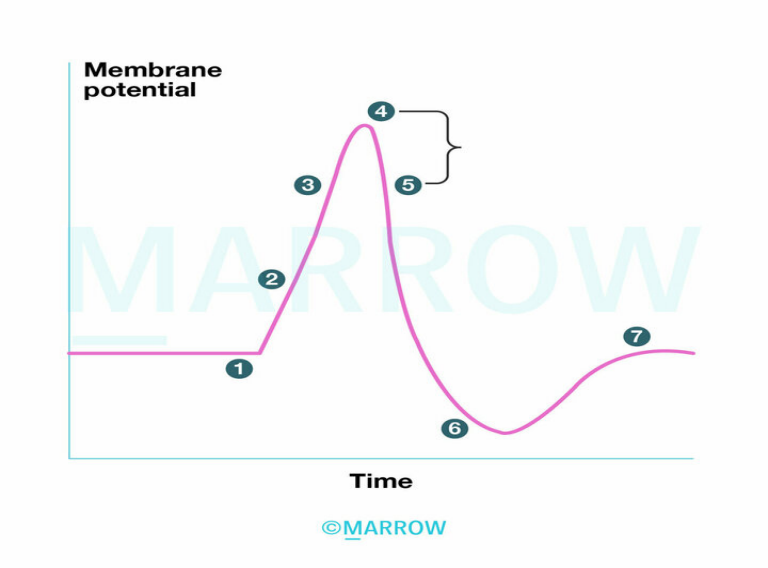
b) Kidney

c) Skin

d) Liver

Question 20:

The image shows changes in membrane potential during an action potential. The region marked between 4 to 5 is due to _____.



a) Influx of Na+

b) Efflux of Na+

c) Influx of K+

d) Efflux of K+

Question 21:

What is the value of normal tissue oncotic pressure?

a) 12 mmHg

b) 25 mmHg

c) 32 mmHg

d) 54 mmHg

Question 22:

Where is the signaling sequence in a type 2 membrane protein located?

a) Inside the membrane at the N-terminal end

b) Inside the membrane at the C-terminal end

c) Outside the membrane at the N-terminal end

d) Outside the membrane at the C-terminal end

Question 23:

Which of the following primary second messengers is involved in the contraction of ciliary muscles while focusing on near objects?

a) cAMP

b) cGMP

c) Na+ inflow through a channel

d) IP3

Question 24:

Which of the following tissues are dependent on insulin for glucose uptake?

a) Brain

b) Adipose tissue

c) Pancreas

d) Muscle

Question 25:

The second phase of saliva secretion involves:

a) Active Na+ reabsorption, passive Cl- reabsorption, passive K+ secretion, active secretion of HCO_3^-

b) Passive Na+ reabsorption, active Cl- reabsorption, passive K+ secretion, active secretion of HCO_3^-

c) Passive Na+ secretion, active Cl- reabsorption, active K+ secretion, passive secretion of HCO_3^-

d) Active Na+ reabsorption, passive Cl- reabsorption, active K+ secretion, passive secretion of HCO_3^-

Question 26:

Macula densa is made of specialized cells located at:

a) Junction of thick descending limb and DCT

b) Junction of thick descending limb and PCT

c) Junction of thick ascending limb and DCT

d) Junction of DCT and collecting duct

Question 27:

Which of the following can be used to calculate the cardiac output?

a) A, B, C, D

b) A, D

c) B, C, D

d) A, C, D

Question 28:

Match the given cellular components with their respective marker enzymes.

a) 1-D, 2-A, 3-C, 4-B

b) 1-D,2-A,3-B,4-C

c) 1-C, 2-B, 3-A, 4-D

d) 1-B, 2-C, 3-D, 4-A

Question 29:

Consider the following statements about sympathetic, parasympathetic, and motor nerves. Which of the following statements are true?

a) 1,3

b) 1,4

c) 2,3

d) 2,4

Question 30:

What is the normal insensible water loss?

a) 100 mL/hour

b) 150 mL/hour

c) 50 mL/hour

d) 200 mL/hour

Question 31:

A woman has vomiting whenever she eats spicy food. Arrange the sequence of events during vomiting.

a) 6, 4, 2, 5, 1, 3

b) 6, 4, 2, 3, 1, 5

c) 4, 6, 2, 1, 3, 5

d) 4, 6, 2, 5, 3, 1

Answer Key

Question No.	Correct Option
1	c
2	d
3	a
4	d

5	d

31	b

Detailed Explanations

Solution to Question 1:

The physiological adaptation that does not happen at high altitudes is respiratory acidosis. Respiratory alkalosis is the physiological adaptation seen at high altitudes due to hyperventilation. It is a method of acclimatization. Compensatory mechanisms that are carried out to increase altitude tolerance are called acclimatization.

Following are the physiological changes that occur during acclimatization:

• Hyperventilation leads to respiratory alkalosis and shift of the oxygen–hemoglobin dissociation curve to the left (and shifts to right after aclimitization).

• Increased erythropoietin secretion, leading to an increase in circulating red blood cells

• Increased number of mitochondria

• Increased myoglobin to facilitate the movement of O2 into the tissues.

• Increased tissue cytochrome oxidase

• Increased sympathetic tone

• Renal suppression of carbonic anhydrase and excretion of dilute alkaline urine brings the pH of the blood to normal.

• Decreased maximal exercise capacity (by ~1% for every 100 meters gained above 1500 meters)

Other options:

Option A- In response to the high altitude hypoxia, pulmonary vasoconstriction occurs due to which blood flow is distributed where it is most effective, leading to distribution of blood flow to the pulmonary areas in proportion to their alveolar O2 pressures.

Option B- Polycythemia - Erythropoietin secretion increases on the ascent to high altitude which results in polycythemia

Option D- Hypoxia - Total barometric pressure decreases as altitude increases, resulting in decreased Po2 (partial pressure of oxygen) leading to hypoxic hypoxia.

Solution to Question 2:

The countercurrent mechanism is present in the testis, kidney, gut, and lungs. When the inflow runs parallel to, counter to, and in close proximity to the outflow for some distance it is called as the counter current mechanism.

Spermatogenesis requires a temperature considerably lower than that of the interior of the body. The testes are kept cool by heat exchange in a countercurrent manner between the spermatic arteries and veins.

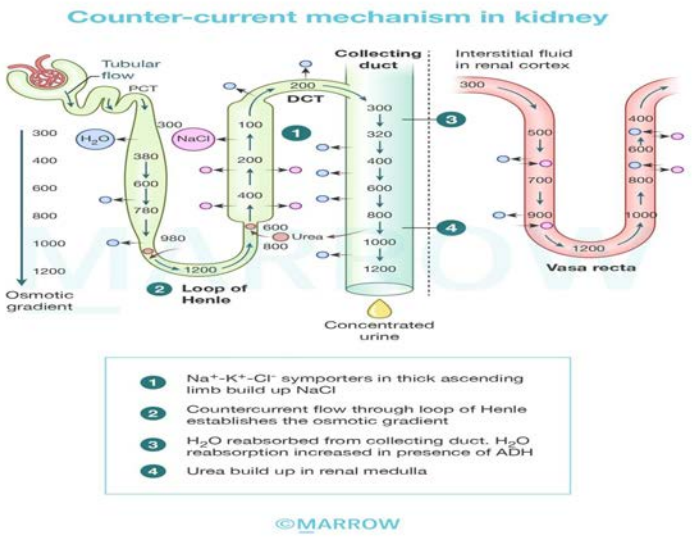
The concentration of the urine by the kidney requires an osmolality gradient. This gradient is produced by the loop of Henle as counter-current multipliers and maintained by vasa recta as counter-current exchangers.

The functioning of the loop of Henle depends upon:

• The high permeability of the thin descending limb to water (via aquaporin-1)

• Active transport of Na+ and Cl- from the thick ascending limb, thereby diluting the tubular fluid.

• The inflow of tubular fluid from proximal tubule and outflow to the distal tubule.



The countercurrent mechanism is used in the villi to decrease the oxygen availability for local metabolic reactions of the gut. Hence this will increase the blood flow in the intestine during gastrointestinal activity.

Countercurrent exchange of oxygen is seen in the lungs as well.

Solution to Question 3:

Plasma contains various components like ions, inorganic and organic molecules which help in the transport of substances across various parts of the body. Albumin, globulin, and fibrinogen fractions are important plasma proteins. Some of the plasma proteins act as antibodies and are also concerned with blood clotting. Where some others are non-specific carriers of hormones, drugs, and other solutes. Majority of plasma proteins are synthesized in the liver. The above table shows some of the proteins synthesized by the liver and the molecules they carry.

Thyroxine is carried by thyroid-binding pre-albumin which is also known as transthyretin.

Albumin is a carrier protein as well as an osmotic regulator which carries hormones, amino acids, vitamins, and steroids too.

Hemopexin binds with heme, particularly for heme recycling.

Haptoglobin binds to free hemoglobin and prevents its excretion in urine.Hence, haptoglobin levels decrease in the presence of free hemoglobin as seen in hemolytic anemia.

Molecules	Carriers
Thyroxine	Prealbumin
Free fatty acid	Albumin

Molecules	Carriers
Hemoglobin	Haptoglobin
Heme	Hemopexin

Solution to Question 4:

Myosin ceases to be in contact with actin filaments as a result of the attachment of ATP to the myosin head.

Muscle contraction occurs by sliding of thin filament over thick filament. The sequence of events are as follows:

• Troponin I is bound to actin and tropomyosin and covers the sites where actin interacts with myosin heads in a resting muscle. The myosin head contains tightly bound adenosine phosphate (ADP) and inorganic phosphate (Pi).

• Following an action potential, cytosolic Ca^{2+} is increased due to the Ca^{2+} released from the sarcoplasmic reticulum. Simultaneously Ca^{2+} influx happens through voltage-gated Ca^{2+} channels too.

• The free Ca^{2+} binds with troponin C. This binding will weaken the troponin I interaction with actin and exposes the actin-binding site for myosin.

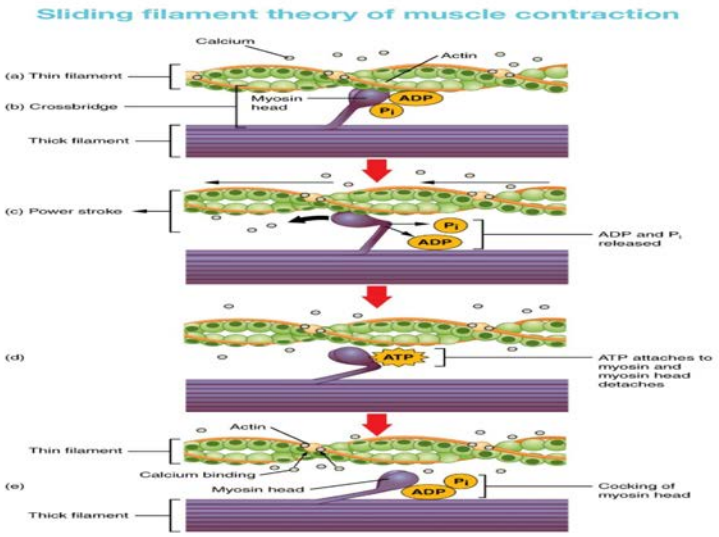
• This results in the formation of myosin-actin cross-bridges.

• The cross-bridge between the head of the myosin and the active site of the actin causes a conformational change in the head and the power stroke occurs, moving the thin filament relative to the thick filament.

• Once the head of the cross-bridge tilts, the ADP and phosphate ion that were previously attached to the head are released and a new ATP molecule can bind in that place.

• The binding of the new ATP molecule to the free site on the myosin causes detachment of the head of the myosin from the actin.

• ATP is hydrolyzed and Pi released, causing a re-cocking of the myosin head and completing the cycle.



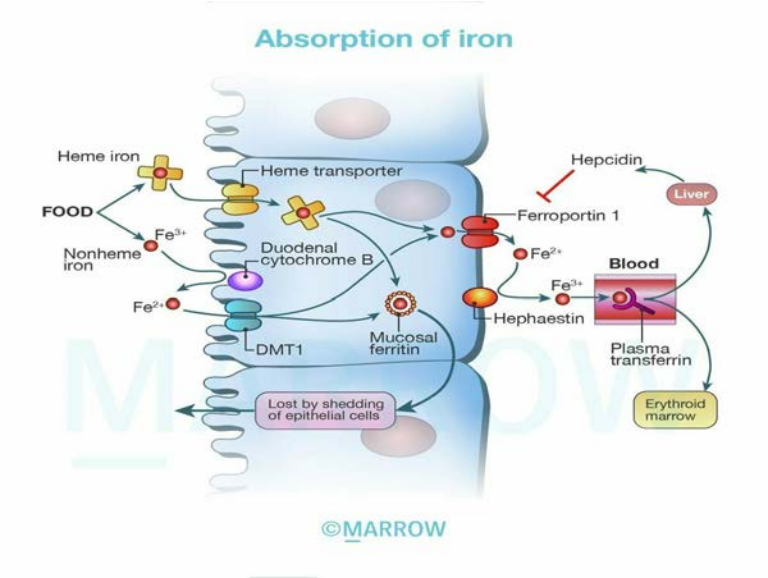
Solution to Question 5:

Transport of iron into enterocytes is done by divalent metal transporter-1 protein.

Iron absorption occurs in the duodenum. Iron in our gut exists in 2 forms, they are nonheme and heme iron.

Luminal nonheme iron is mostly in the Fe3+ (ferric) state and is reduced to Fe2+ (ferrous) iron by ferrireductases. Fe2+ iron is then transported across the apical membrane by divalent metal transporter 1 (DMT1).

Given below is an image of iron absorption that shows divalent metal transporter-1 protein in intestinal mucosal cells.



Heme iron is moved across the apical membrane into the cytoplasm through heme transporters.

In the duodenal cells, Fe^{2+} iron can follow one of two pathways: transport to the blood or storage as mucosal iron. The nonstorage form of Fe^{2+} iron is transported from the cytoplasm into circulation by the protein ferroportin (Option B).

Once in circulation, Fe^{2+} is again oxidized back to Fe^{3+} iron by hephaestin and ceruloplasmin. The newly absorbed Fe^{3+} iron binds rapidly to transferrin (Option A), which delivers iron to red cell progenitors in the marrow.

Hepcidin (Option C), is a protein secreted from the liver that plays a major role in the regulation of iron absorption. When the body's iron stores are adequate, it downregulates the expression of ferroportin and thereby decreases iron absorption.

Solution to Question 6:

Flow through B will be 8 times more than the flow through A.

According to Poiseuille Hagen formula,

$F = \Delta P \times \pi/8 \times 1/n \times r4/L$

F = flow

ΔP = pressure difference between two ends of the tube

η = viscosity

r = radius of the tube

L = length of the tube

Hence flow directly varies to the 4th power of radius and inversely varies to length.

Flow through B = $(2r)4/2L$ = 8 times

Solution to Question 7:

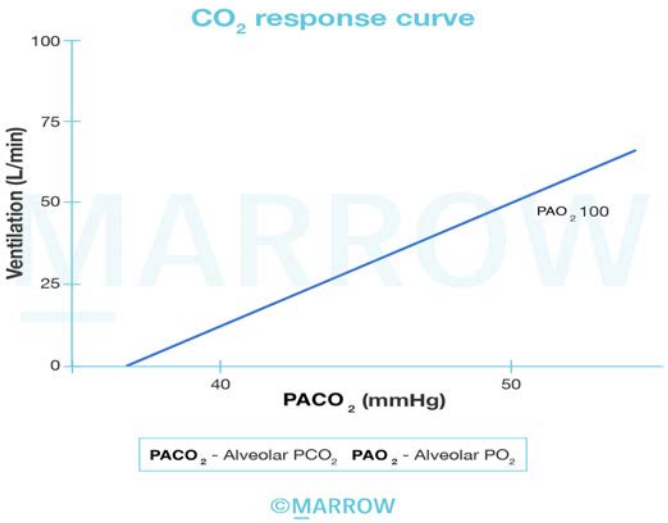
If the pH is reduced from 7.4 to 7.3 with the alveolar PO_2 being constant at 100 mmHg, PCO_2 would follow line 1.

This concept can be understood in three steps.

Step 1- Effect of CO_2 on ventilation, when the alveolar PO_2 is kept constant.

When the alveolar PO_2 (PaO_2) is kept constant, an increased amount of inspired CO_2 leads to increase in the ventilation. The relation is a straight line.

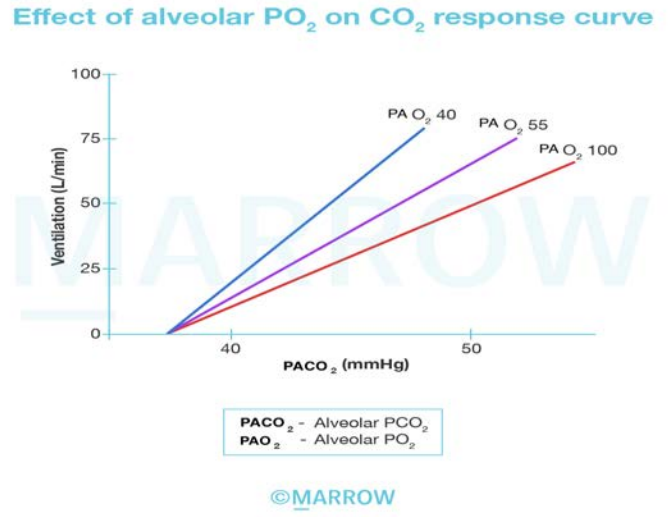
The below graph shows the effect of CO_2 on ventilation when alveolar PaO_2 is kept constant at 100mm Hg.



Step 2. The shift of the above graph when PO2 changes.

When PO2 changes, the relation between the amount of CO2 inhaled and ventilation still remains in a straight line. However, the slopes of the lines change. The slope increases when alveolar PO2 decreases and vice versa. In other words, the lines move towards the left when PO2 decreases. However, the point of intersection of all these lines remains the same.

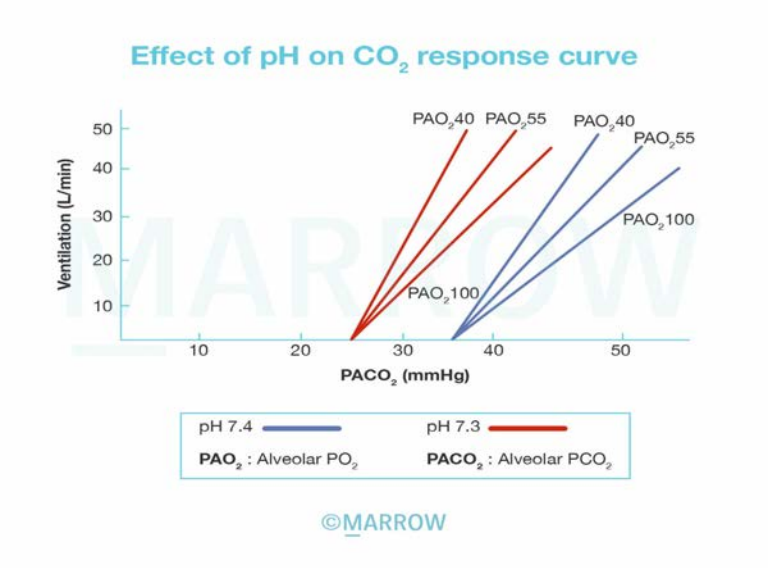
The below graph shows the relation between inspired CO2 and ventilation when alveolar PO2 is maintained at 40mm Hg, 55mm Hg, and 100 mm Hg. As the alveolar PO2 has decreased, the lines have shifted to the left. But they are all intersecting at the same point on the x-axis.



Step 3. The shift of the above graph when pH changes.

When pH decreases, as in acidosis, the CO2 response curve is similar to the above. The only difference is they are shifted to the left and have different points on the intersection on x- axis.

The below graphs show CO2 response curves when pH is 7.4, 7.3, and PO2 is 40mm Hg, 55mm Hg, and 100mm Hg. The lines have shifted to the left and have a different point of intersection.



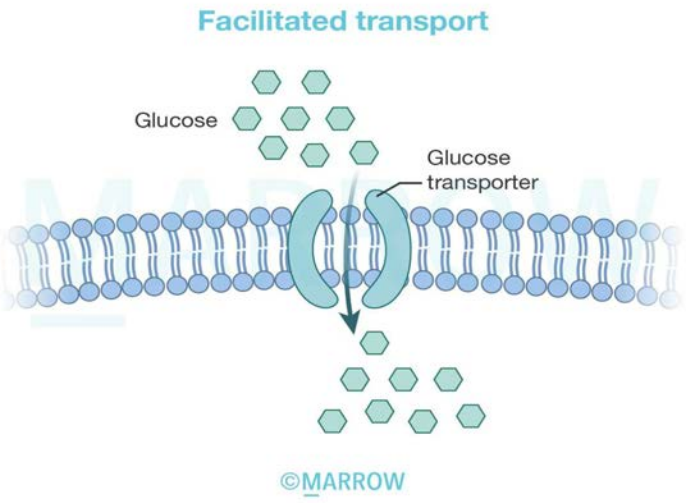
In the question image, only line 1 has been shifted to the left and has a different point of intersection on x-axis compared to other lines. Therefore, line 1 is the answer.

Solution to Question 8:

All the given combinations 1, 2, 3, 4, and 5 are correct.

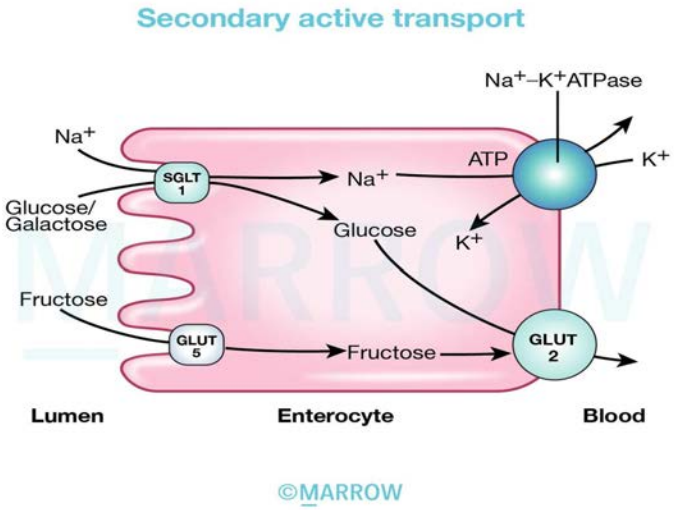
1) Oxygen is a non-polar molecule and hence can diffuse across the lipid membrane of the cells.

2) Facilitated diffusion - Transporting the molecule from one side of the cell membrane to the other is done with the help of transport proteins called carriers. Molecules move from areas of high concentration to areas of low concentration. No energy input is required when carrier proteins move substances in the direction of their gradients. Glucose transport by the glucose transporter is an example, which moves glucose down its concentration gradient from the ECF to the cytoplasm of the cell.



3) Voltage-gated channels are simple ion channels acting as transport proteins, gated by membrane potential alterations. Sodium transported via voltage-gated channels is an example.

4) Transporting more than one substance together using a single transport protein against the gradient is known as secondary active transport. An example is SGLT 1, the cotransporter of sodium and glucose from the intestinal lumen into mucosal cells.



5)Active transport - Transporting of substances against the gradients, and requires energy. Ca2+ ATPase that pumps out calcium out of the cells is an example.

Solution to Question 9:

In the given graph, showing action potential generation in terms of ion permeability, wave A represents Na+ and B represents K+.

The sequence of events during the action potential occurs in 7 steps as described below.

1. Resting-state - Both channels are closed

2. Na+ channels open in response to depolarizing stimulus. Sodium enters the cell. The membrane reaches threshold potential.

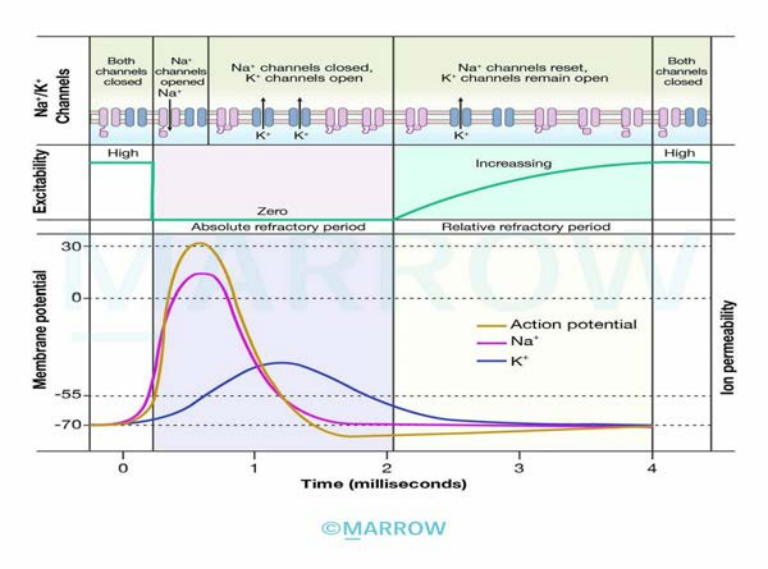
3. The sodium influx causes the opening of more Na+ channels through a positive feedback mechanism. Rapid depolarization occurs.

4. Sodium conductance decreases.

5. Na+ channels close and K+ channels open. Repolarization occurs.

6. Sodium channels are reset, and are ready to respond to another depolarizing stimulus (relative refractory period). During this phase, the potassium channels remain open and slowly return to closed state causing after-hyperpolarization.

7. Both channels are closed. The membrane returns to RMP.

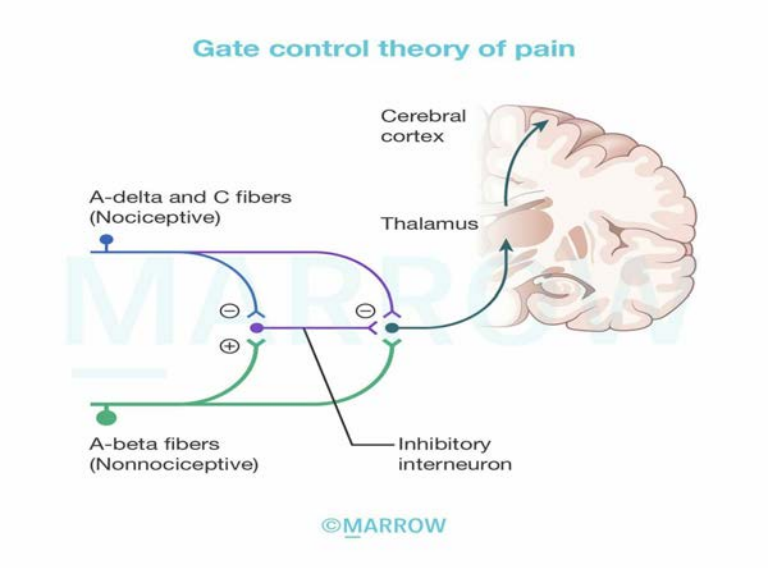


Solution to Question 10:

Gate theory of pain is the mechanism behind transcutaneous electrical nerve stimulation (TENS). This method uses electrodes to activate Aα and Aβ fibres near the injury to relieve pain.

At the site of sensory afferent termination, transmission in nociceptive pathways can be interrupted. This is done by the actions within the dorsal horn of the spinal cord. Pain subsiding when the site of injury is rubbed or shook is an example. Afferents of innocuous cutaneous mechanoreceptors emit collaterals that terminate in the dorsal horn. The responsiveness of dorsal horn neurons to their input from nociceptive afferent terminals is reduced by these afferents This is called the gate-control mechanism of pain modulation.

The given image depicts the gate control theory of pain:



Solution to Question 11:

The first investigation to be done for a child who feels shortness of breath on climbing stairs and in the supine position is a chest x-ray.

The child having shortness of breath on climbing stairs is known as dyspnea on exertion. The most common cause is congestive heart failure. The child feeling shortness of breath in the supine position is orthopnea. It is relieved on sitting or standing.

Respiratory causes include asthma, chronic obstructive pulmonary disorder (COPD), pneumonia, and pulmonary embolism. Cardiovascular causes include congestive heart failure(CHF), pulmonary edema, valvular heart defect, and pulmonary hypertension.

Evaluation begins with assessing the airway, breathing, and circulation of the patient. Oxygen saturation can appear normal at rest, and hence oxygen saturation during physical activity should

be obtained. A chest x-ray is the first diagnostic test which can show pulmonary pathology or pumonary edema and other signs of CHF that could help in identifying the cause and further evaluation.

Other options:

Option A: An echocardiogram can be done if the chest X-ray is abnormal. It is done to evaluate cardiac function, valvular function, and pericardial space.

Option C: Spirometry is done when the chest x-ray is normal. It is done to determine lung function. Abnormal spirometry can indicate either an obstructive pathology such as asthma, or COPD or a restrictive disease such as interstitial fibrosis.

Option D: Cardiac MRI (Magnetic resonance imaging) is an emerging modality done to look for cardiomegaly. It is for the accurate evaluation of left and right ventricular mass, size, and function. It is also used for localizing ischemic and non-ischemic causes such as myocarditis.

Solution to Question 12:

The correct pairs are as follows:

1. Thyroxine - B. Pre-albumin

2. Vitamin B12 - C. Transcobalamin

3. Hemoglobin - D. Haptoglobin

4. Heme - A. Hemopexin

Thyroxine is carried by thyroid-binding prealbumin, which is also known as transthyretin.

Vitamin B12 binds to transcobalamin II in the ileal cells and is secreted into the plasma. Transcobalamin II delivers vitamin B12 to the liver and other cells of the body, including rapidly proliferating cells in the bone marrow and the gastrointestinal tract.

Hemopexin binds to porphyrins, particularly heme, for heme recycling.

Haptoglobin binds to free hemoglobin and prevents its excretion in urine.

Solution to Question 13:

The correct sequence for ventricular action potential is as follows:

C. Opening of voltage-gated sodium channels

D. Transient outward flow of potassium

A. Opening of voltage-gated calcium channels

B. Repolarizing K+ currents

The events of action potential occur in the following sequence:

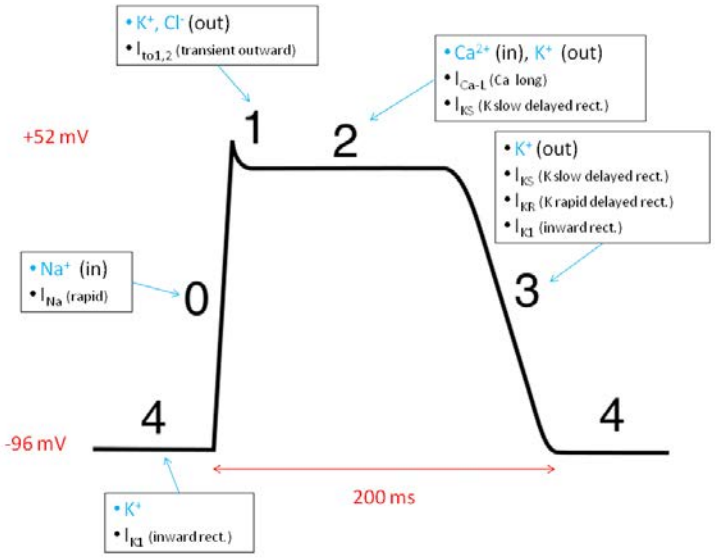
• Phase 0: Voltage-gated Na+ channels open in response to depolarizing stimulus (rapid depolarization phase)

• Phase 1: Inactivation of voltage-gated Na+ channels and transient outward flow of K+ causes rapid repolarization (rapid repolarization phase)

• Phase 2: Opening of slow voltage-gated Ca²■ channels causes the influx of calcium into the cells and results in the plateau phase (plateau phase)

• Phase 3: Opening of various K+ channels results in the efflux of K+ from the cells and results in slow repolarization (slow repolarization phase).

• Phase 4: Return to resting membrane potential



Solution to Question 14:

The zero pressure in the pressure-volume curve indicates the functional residual capacity.

The pressure-volume relationship is basic to the understanding of the fundamental relationship between the compliance of the lungs and the chest wall. It is measured by a spirometer.

The functional residual capacity is the volume of the air that remains in the lungs after normal expiration. The normal value is about 2.5 liters.

Other options:

Option A: Residual volume is the air left in the lungs after a maximal expiratory effort.

Option C: Tidal volume is the amount of air that moves in during each inspiration or the amount of air that moves out with each expiration, during quiet breathing. The normal tidal volume is 500–750 mL.

Option D: Inspiratory reserve volume is the air inspired with a maximal inspiratory effort in addition to the tidal volume.

Solution to Question 15:

Cerebral perfusion pressure (CPP) is calculated as mean arterial pressure (MAP) - intracranial pressure (ICP).

However, ICP values are not readily available. In this case, CPP may be calculated as MAP - central venous pressure (CVP), and if CVP > ICP.

The brain depends on continuous perfusion for oxygen and glucose delivery, thus its survival. The blood flow to the brain is normally about 55 mL per 100 g of brain tissue. If the cerebral flow reduces to less than 20 mL per minute, the brain undergoes ischemia.

Blood flow depends on cerebral perfusion pressure (CPP). Normally the CPP is 75-105 mmHg, MAP is 90-110 mmHg and ICP is 5-15 mmHg.

According to Monro Kellie doctrine, the cranium is a rigid box containing a nearly incompressible brain. In cases of head trauma, there is an expansion of cranial content, in the form of hematomas and brain swelling. This increase in cranial pressure is accommodated initially by the exclusion of fluid components, venous blood, and cerebrospinal fluid. Further increase in the cranial pressure leads to an uncontrolled rise in ICP resulting in a compromise in cerebral perfusion and eventually cerebral herniation.

Acute rise in ICP causes Cushing reflex, a triad of widened pulse pressure (increasing systolic, decreasing diastolic) bradycardia, and irregular respirations.

Thus, in cases of head injury with intracranial bleeding, cranial decompression is performed to avoid further complications due to the raised ICP.

Solution to Question 16:

Fluid leaving the proximal convoluted tubule (PCT) in the absence of antidiuretic hormone (ADH) is isotonic.

The PCT is the site of maximum water reabsorption under normal physiological conditions. It reabsorbs around 60% of the filtered NaCl and water and other nutrients such as glucose and amino acids. Isosmotic reabsorption occurs in the PCT, so the amount of solute and water reabsorbed are coupled and proportional to each other. Here, sodium is reabsorbed along with the water. The large amounts of sodium and water reabsorption are essential in maintaining the ECF volume.

In addition to the isosmotic reabsorption, the water reabsorption in the PCT also occurs through aquaporin-1 which are active water channels. Reabsorption of sodium and water in PCT is not affected by ADH levels. Thus even in the absence of ADH, fluid is isotonic in PCT.

Solution to Question 17:

2,3-Bisphosphoglycerate (BPG) causes the unloading of oxygen to tissues by binding to the beta subunit of Hb.

2,3 BPG is formed from glycolysis. It is found in high amounts in red blood cells and in trace amounts in most other cells. 2,3 BPG facilitates increased oxygen delivery by reducing the affinity of hemoglobin for oxygen.

Hemoglobin exists in 2 forms in the blood. The deoxyhemoglobin form is called the taut or T form. This hemoglobin has a low affinity for oxygen. The oxyhemoglobin form is called the relaxed or R form. This hemoglobin has a high affinity for oxygen.

2,3 BPG binds more selectively to deoxyhemoglobin and stabilizes the taut conformation of hemoglobin (Option C).

Other options:

Options A and D: The process of unloading oxygen by 2,3 BPG is independent of ATP production.

Solution to Question 18:

The curve 'A' shows a hyperbolic curve that is characteristic of oxygen dissociation in myoglobin.

Myoglobin is an iron-containing component of the skeletal muscle. Myoglobin can bind only to one oxygen molecule and hence lacks co-operative binding. It has a higher affinity to oxygen than hemoglobin and hence releases oxygen only at low PO_2 values. This leads to a leftward shift in the myoglobin oxygen dissociation curve.

Myoglobin is present in large quantities in muscles that are commonly used for sustained contraction. During such contractions, muscle blood supply is decreased due to compression. Myoglobin facilitates oxygen supply in these conditions.

Other options:

Option B: Carbon monoxide (CO) reacts with hemoglobin to form carbon monoxyhemoglobin (carboxyhemoglobin or COHb). The affinity of hemoglobin for CO is 210 times its affinity for O_2, and COHb liberates CO very slowly. An additional difficulty is that when COHb is present, the dissociation curve of the remaining HbO_2 shifts to the left, decreasing the amount of O_2 released.

Option C: Hemoglobin normally has ferrous ion. When it is oxidized to ferric iron, it is called methemoglobin. It causes dark-coloured blood.

Option D: Fetal hemoglobin (HbF) is structurally similar to hemoglobin A except for the gamma chains. It binds less avidly to 2,3 bisphosphoglycerate and hence has higher affinity for oxygen leading to left ward shift in the dissociation curve.

Solution to Question 19:

The organ with the least arteriovenous oxygen difference is the kidney.

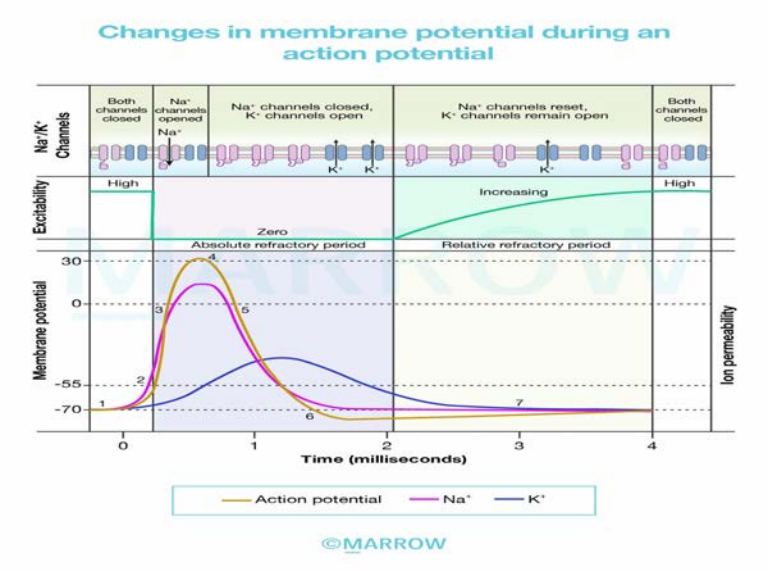
The arteriovenous oxygen difference is the amount of oxygen the tissues take up from the blood. If the amount of oxygen utilized by the tissues is more, the greater the arteriovenous oxygen difference.

The renal cortical blood flow is comparatively greater as the main function is to filter large volumes of blood through the glomeruli. Here, the oxygen extracted from the blood is relatively less. The arteriovenous oxygen difference for the kidney is only 14 mL/L of blood, which is very less when compared to the brain and heart.

Organs	Arteriovenous Oxygen Difference (mL/L)
Brain	62
Kidney	14
Skin	25
Liver	34
Heart muscles	114

Solution to Question 20:

The region marked between 4 and 5 in the action potential curve indicates repolarization due to the efflux of K+ ions across the cell membrane.



The sequence of events during the action potential occurs in the following sequence.

1. Resting state: Both channels are closed.

2. Na+ channels open in response to depolarizing stimulus. Sodium enters the cell. The membrane reaches threshold potential.

3. The sodium influx causes the opening of more Na+ channels through a positive feedback mechanism. Rapid depolarization occurs.

4. Sodium conductance decreases.

5. Na+ channels close and K+ channels open. Due to K+ efflux, repolarization occurs.

6. Na+ channels are reset and are ready to respond to another depolarizing stimulus (relative refractory period). During this phase, the K+ channels remain open and slowly return to the closed state causing after-hyperpolarization.

7. Both channels are closed. The membrane returns to RMP.

Solution to Question 21:

The value of normal tissue oncotic pressure is 12 mmHg. It refers to the interstitial osmotic pressure.

The interstitial oncotic pressure, while very small, is the pressure exerted by a small amount of protein present in the interstitium that tends to pull fluids out of the capillaries. It is different for each organ based on the level of protein components. It is mostly negligible, but sometimes can be as high as 6 mmHg in the brain. The values are also positive in the liver and kidneys.

The colloid osmotic pressure or oncotic pressure is the osmotic pressure exerted due to the presence of colloidal proteins like albumin and globulin within the plasma. The colloidal proteins are impermeable to the semi-permeable cell membrane and cannot cross the membrane. Thus, it exerts osmotic pressure, which pulls fluid into the capillaries.

The lowest number in the given options is 12 mmHg and, hence, is the best possible answer to this question.

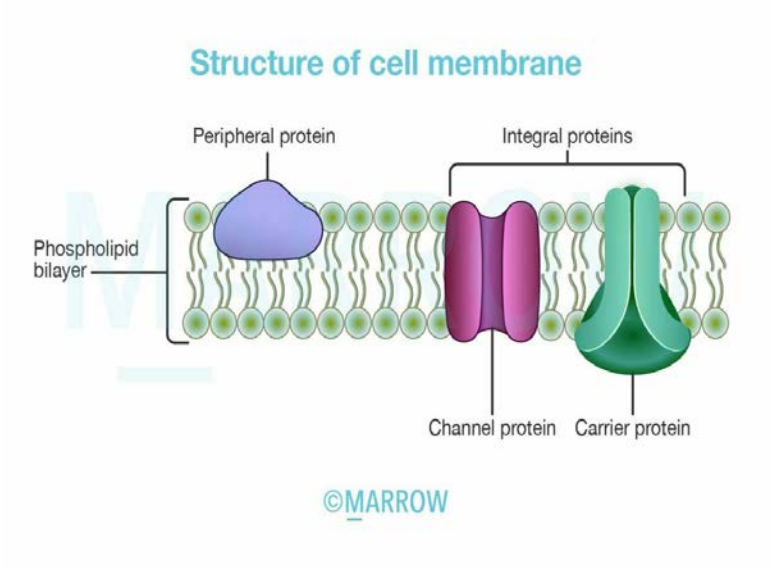
Solution to Question 22:

The signaling sequence in a type 2 membrane protein is located inside the membrane (transmembrane region).

A membrane protein can be either integral protein (spans the thickness of the cell membrane) or peripheral protein (attached to the peripheral side of the membrane).

Integral membrane proteins or transmembrane proteins are embedded in the cell membrane, spanning through the entire thickness. They are anchored by hydrophobic interactions and require the use of detergent for solubility. Examples are ligand-binding receptors for hormones or neurotransmitters, transport proteins like Na+-K+ ATPase, pores, ion channels, cell adhesion molecules, and GTP-binding proteins (G proteins).

Peripheral proteins are attached only to one surface of the cell membrane and do not penetrate all the way through. They are often attached to integral proteins. Examples are cell surface receptors, enzymes, ankyrin.



Signaling sequences are 16 to 30 amino acid residues in length and located at the N-terminal extension of the membrane proteins. After an appropriate trigger, they are either cleaved (and bind to MHC class I of the endoplasmic reticulum) or act as a membrane anchor (transporting proteins across the membrane).

Integral proteins can be divided into:

• Type I integral proteins have a cleavable N-terminal signal sequence (towards the cytosol). Examples include histocompatibility antigens, glycophorin, and membrane immunoglobulin.

• Type II integral proteins have a non-cleavable N terminal combined signal/anchor sequence. Examples include transferrin receptors and glycosyl transferases.

Solution to Question 23:

IP3 is the primary second messenger involved in the contraction of ciliary muscles to focus on a near object.

On focusing on a near object, stimulation of the parasympathetic nerve fibers leads to the contraction of the bilateral ciliary muscle, via short ciliary nerves, which relaxes the lens ligaments. The lens becomes thicker and the increase in the refractive index allows the eye to focus on the near object. This is known as the accommodation reflex.

In the ciliary muscles of the eye, contraction is mediated via M3 > M2 receptors, while relaxation is mediated via the β2 receptor.

M3 receptors act via the formation of inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG), leading to an increase in intracellular Ca2+ and activation of protein kinase C, respectively. The increase in intracellular Ca2+ sets up a chain reaction which eventually leads to contraction of the ciliary smooth muscle of the eye.

Thus, in the contraction of the ciliary muscle during focusing on a near object, the second messenger involved is the IP3-DAG pathway.

Solution to Question 24:

Adipose tissue is dependent on insulin for glucose uptake.

The uptake of glucose in skeletal muscles is also dependent on insulin but may be mediated via non-insulin-dependent mechanisms as well (such as muscle contractions). Therefore the best answer out of the given options is adipose tissue.

Glucose uptake by skeletal muscle, cardiac muscle, and adipose tissues is via GLUT-4 which is insulin-dependent. In the presence of insulin, GLUT-4 receptors translocate to the cell membrane and hence, glucose uptake by the cell occurs.

Most of the other GLUT transporters are not insulin sensitive and are constitutively expressed in the cell membrane. Ex: GLUT-1 in RBCs, brain and kidneys. (GLUT-3 is also present in the brain and kidneys)

Solution to Question 25:

During the second phase of salivary secretion, Na+ is actively reabsorbed, Cl- is reabsorbed passively, K+ is secreted actively and HCO3- is secreted passively (part of the secretion may be active as well, but among the given options, option D is the most accurate with respect to all the ions).

Salivary secretion occurs in two stages:

The first stage involves acini, which secrete ptyalin and/or mucin together with some ions. The composition of the ions is similar to that of the extra-cellular fluid.

The second stage involves the ducts. As the primary salivary secretion flows through the ducts, two active transport processes occur:

• Na+ is actively re-absorbed and K+ is actively secreted, in exchange for Na+.

• HCO3- is secreted by the ductal epithelium into the lumen of the salivary ducts. Some of this secretion occurs by passive bicarbonate exchange for Cl- and partly active secretion.

As a result, the Na+ and Cl- concentrations are lower than that of plasma, while K+ and HCO3- concentrations are higher than that of plasma.

Composition of ions:

• Under resting conditions, the Na+ and Cl- concentrations in saliva are about 15 mEq/L each, which is 1/7th to 1/10th of the plasma concentrations.

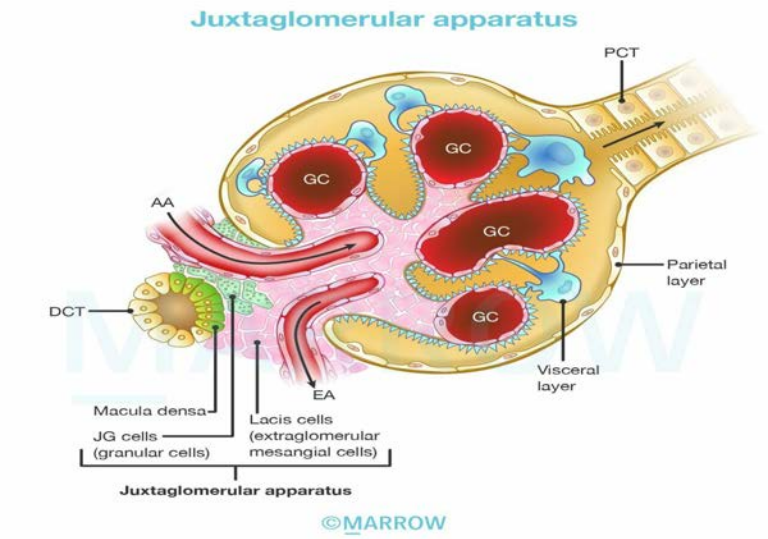
• K+ concentration is about 30 mEq/L, which is seven times higher than that of plasma.

• HCO3- concentration is 50 to 70 mEq/L, which is two to three times higher than that of the plasma.

Solution to Question 26:

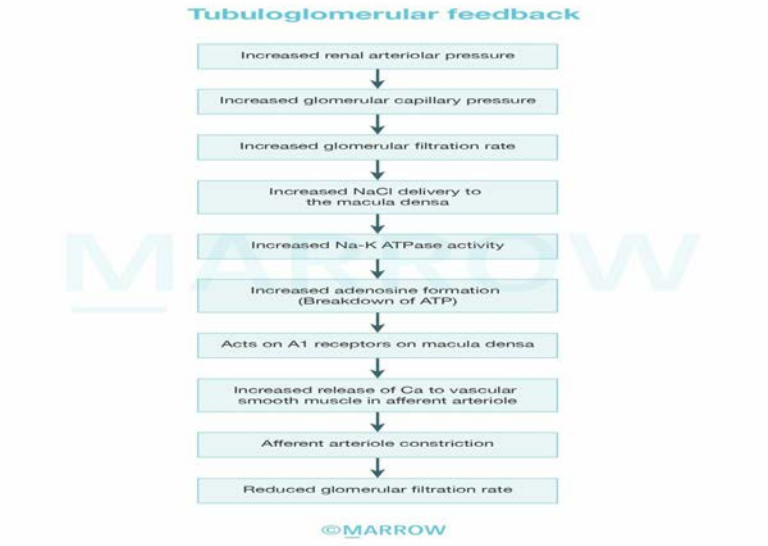
Macula densa are the specialized cells present at the distal end of the thick ascending loop of Henle, where it reaches the glomerulus. Distal convoluted tubule starts from macula densa.

Macula forms the part of the juxtaglomerular apparatus.



Signals from the renal tubules affect filtration in its glomerulus. As the rate of flow through the ascending limb of the loop of Henle and the first part of the distal tubule increases, glomerular filtration in the same nephron decreases, and vice versa. This is known as tubuloglomerular feedback which maintains the constancy of the load delivered to the distal tubule.

The sensor is the macula densa. The Na+ and Cl– in the fluid enter the macula densa cells via theNa+–K–2Cl– cotransporter in their apical membranes. The increased Na+ increases the Na+-K+ ATPase activity causing ATP hydrolysis and the formation of adenosine. This acts on adenosine A1 receptors on the macula densa cells, causing the release of Ca2+ into the vascular smooth muscle in the afferent arterioles, leading to vasoconstriction and decreased GFR.



Solution to Question 27:

Fick principle, thermodilution, and ECHO can be used to measure cardiac output.

Cardiac output is the amount of blood pumped by the heart into the aorta every minute. The average cardiac output is 5L/min and can be measured by various indirect methods.

Fick's principle uses the total amount of oxygen absorbed from the air by the lungs and the arteriovenous oxygen difference of blood to calculate the cardiac output using the following formula:

Cardiac output (L/min) = (O_2 absorbed per minute by the lungs (mL/min)) / (Arterio-venous O_2 difference(mL/L of blood))

Thermodilution method employs cold saline which is infused into the right atrium through a double-lumen Swan–Ganz thermodilution catheter and the temperature change is measured at the pulmonary artery using a thermistor at the end of the catheter. The mean decrease in the temperature of blood is inversely proportional to the cardiac output.

An ECHO uses ultrasound waves from a transducer placed on the chest wall to measure the velocity of blood flowing from the left ventricle into the aorta. Stroke volume can be calculated from this. Cardiac Output = Heart Rate X Stroke Volume.

The other methods that can be used to measure cardiac output include impedance cardiography a.k.a. thoracic electrical bioimpedance, electromagnetic or ultrasonic flowmeter,and indicator dilution method.

Ventilation-perfusion scan is not a method of cardiac output measurement. It is used to assess pulmonary circulation.

Solution to Question 28:

The correctly matched answer is 1-D,2-A,3-B,4-C.

Each organelle has some specific enzymes are called marker enzymes. After centrifugation, the separated organelles are identified by the detection of marker enzymes in the sample.

Cellular components	Marker enzymes
1. Mitochondria	D. ATP synthase
2. Peroxisomes	A. Catalase
3. Golgi complex	B. Galactosyl transferase
4. Endoplasmic reticulum	C. Glucose-6-phosphatase

Solution to Question 29:

The true statements are 1,4.

Sympathetic efferents are distributed extensively all over the body whereas parasympathetic distribution is limited to head, neck, and trunk regions.

Sympathetic fibers travel short distances to the sympathetic ganglionic chain, before finally synapsing and then have a long course to supply the target organs. Parasympathetic fibers travel a longer distance to their respective ganglia which are located close to the target organs.

Motor neurons are located in the ventral horn of the spinal cord from where the axons come out and divide into several branches, each of which supplies an individual muscle fiber. A motor unit comprises a motor neuron and a group of skeletal muscle fibers it innervates.

Solution to Question 30:

The normal insensible water loss is 50 mL/hour.

In human beings, there is a loss of water through vaporization from the respiratory tract (300–400 mL) and diffusion from the skin (300–400 mL). This is called insensible water loss. It is about 50 mL/hour. This insensible water loss via the skin is independent of sweating and occurs in people without sweat glands as well.

Solution to Question 31:

The correct sequence of vomiting is 6, 4, 2, 3, 1, 5.

6. Reverse peristalsis in the small intestine.

4. Relaxation of the pyloric sphincter.

2. Strong contractions in the stomach.

3. Inspiration against a closed glottis.

1. LES is open and UES is closed.

5. LES opens and UES opens.

The sensory signals that initiate vomiting are located in the pharynx, esophagus, stomach, and upper portions of the small intestines. Excessive distention or irritation of the duodenum provides a strong stimulus for vomiting. Area postrema constitutes the vomiting centre.

In the early stage, reverse peristalsis begins often minutes before vomiting. It begins far down in the ileum and travels up the intestine. This process pushes a large share of lower small intestine contents to the duodenum and stomach. Relaxation of the pyloric sphincter occurs during this process.

At the onset of vomiting, strong intrinsic contractions are seen in the duodenum and stomach. Once the vomiting centre has been stimulated, inspiration occurs against the closed glottis. It prevents the flow of vomitus into the lungs. The lower esophageal sphincter (LES) is open and

the upper esophageal sphincter (UES) is closed at this stage.

The muscles of the abdominal wall contract, building intra-gastric pressure. Finally LES relaxes completely and UES also relaxes allowing the expulsion of the gastric contents.

Note: The esophageal smooth muscle functions as LES at the gastro-esophageal junction. It normally remains tonically constricted. Receptive relaxation of LES occurs when the peristaltic wave passes down the esophagus.

Physiology NEET 2022

Question 1:

A person after sleeping overnight with the arm under his head now experiences paresis but no numbness in the morning. Which of the following is the best explanation for it?

a) C fibers are more sensitive to pressure than A fibers.

b) A fibers are more sensitive to hypoxia than B fibers.

c) A fibers are more susceptible to pressure changes than C fibers.

d) A fibers are more susceptible to hypoxia than C fibers.

Question 2:

Which of the following mechanisms is seen in the baroreceptor reflex?

a) Feedforward

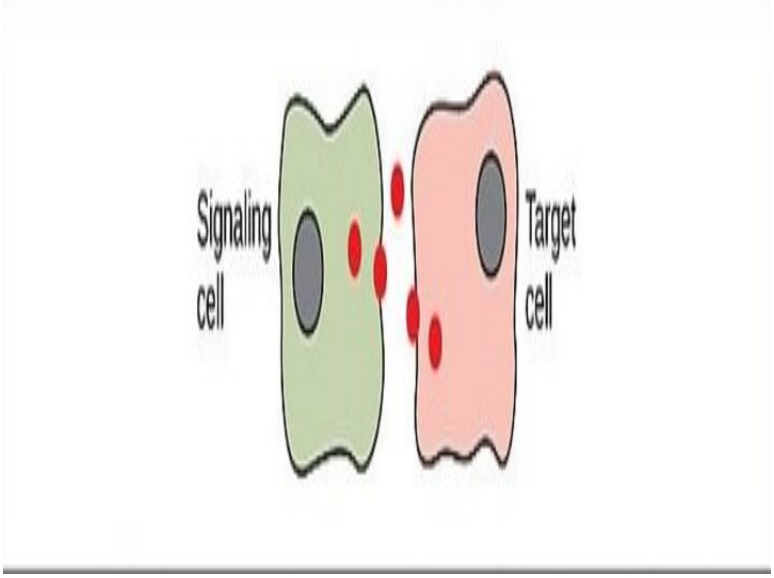
b) Positive feedback

c) Negative feedback

d) Adaptive control regulation

Question 3:

The image below depicts which of the following types of cell-to-cell signaling?



a) Paracrine

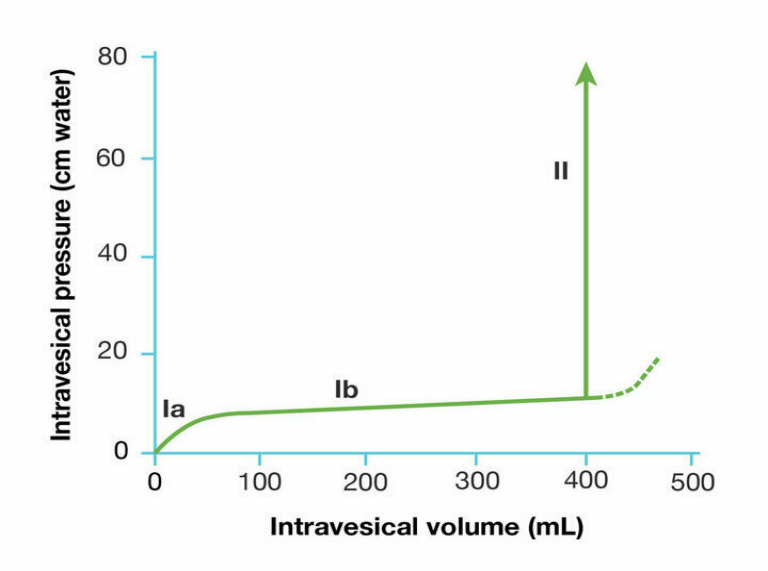
b) Autocrine

c) Endocrine

d) Merocrine

Question 4:

Which of the following statements is true regarding the given cystometrogram?



a) Segment Ia is due to residual urine

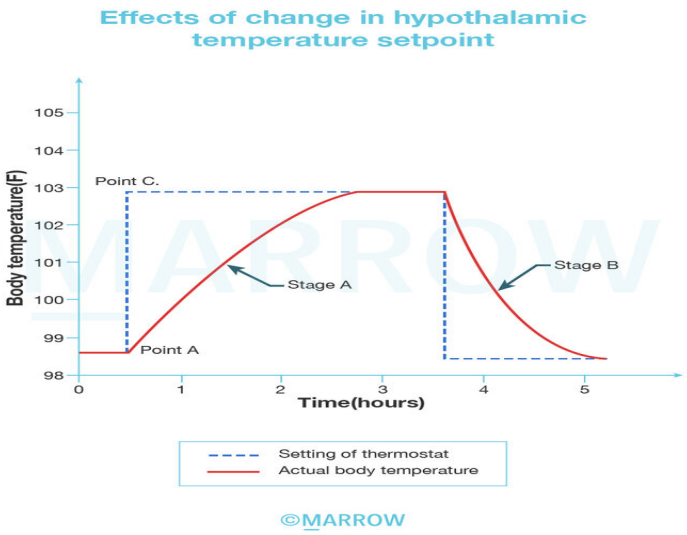
b) Segment Ib is due to Laplace law

c) Micturition fails to happen in segment II

d) The dotted line represents that micturition has occurred

Question 5:

In a patient, the hypothalamic thermostat was reset from point A to point C as shown below. Which of the following happens in stage A compared to stage B?



a) Shivering

b) Sweating

c) Increased blood flow to skin

d) Inhibition of chemical thermogenesis

Question 6:

A 65-year-old man suffered from a stroke 2 days ago. He now presents with involuntary, violent, and flinging movements of the limbs on one side. What is the likely site of lesion in this patient?

a) Subthalamic nuclei

b) Globus pallidus

c) Putamen

d) Caudate nucleus

Answer Key

Question No.	Correct Option
1	c
2	c
3	a

4	b
5	a
6	a

Detailed Explanations

Solution to Question 1:

In the above scenario, the patient has developed paresis (partial paralysis) but the pain sensation is intact (no numbness). This is because A fibers that carry motor, touch, and pressure sensations are more susceptible to pressure changes/compression than C fibers that carry pain sensations.

The compression of a large diameter nerve fiber leads to a reversible physiologic conduction block or neuropraxia.

The relative susceptibility of nerve fibers to conduction blocks produced by various agents:

Susceptibility	Most susceptible	Intermediate	Least susceptible
Local anesthetic	C	B	A
Hypoxia	B	A	C
Pressure	A	B	C

Solution to Question 2:

The negative feedback mechanism is seen in the baroreceptor reflex. If the activity of a particular system is increased, the controller system initiates the negative feedback mechanism, which prevents overactivity and ensures normal homeostasis.

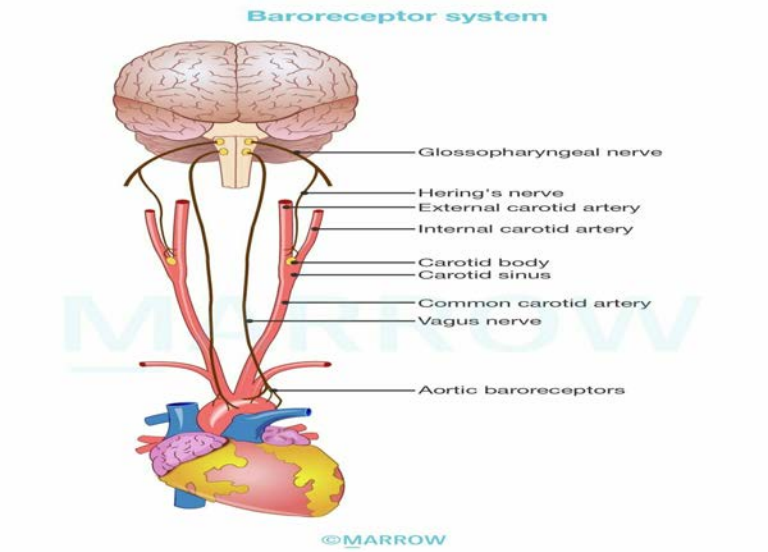
Baroreceptors are stretch receptors located in the heart and the adventitia of the blood vessels. They are stimulated by the stretching of the walls of the blood vessels when there is an increased volume or blood pressure in the vessel. They are important in the immediate management of blood pressure. They are of two types: carotid sinus and aortic arch receptors (high-pressure regions) and cardiopulmonary receptors (low-pressure regions).

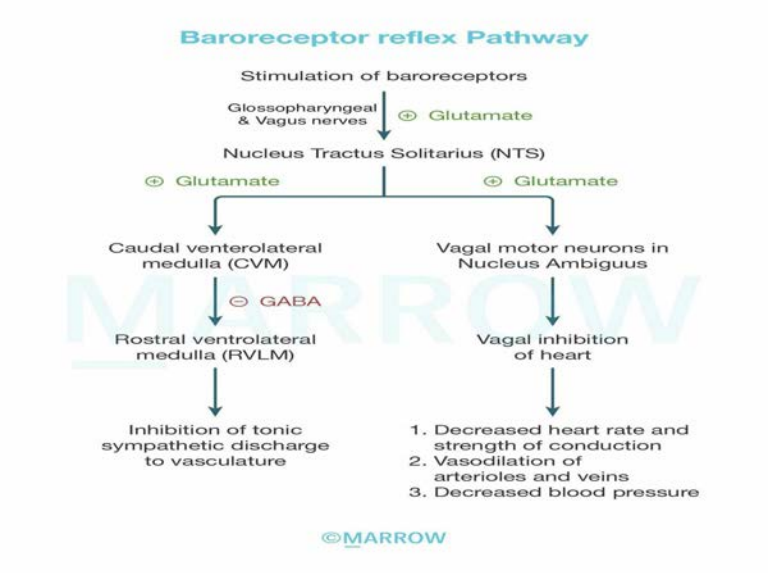
An increase in blood pressure stimulates the baroreceptors. These signals are transmitted through small Hering's nerves to the glossopharyngeal nerves and then to the nucleus tractus solitarius (NTS) in the medulla. These signals release glutamate and activate the caudal ventrolateral medulla (CVLM). This in turn inhibits the rostral ventrolateral medulla (RVLM) considered the vasoconstrictor center for the brain and the heart.

Simultaneously, this pathway also excites the vagal parasympathetic center. The stimulation of the vagus results in a slowing of impulse generation in the SA node and

a slowing of conduction velocity in the AV node.

These neural changes produce vasodilation, venodilation, hypotension, bradycardia, and a decrease in cardiac output.





Other options:

Option A: The feedforward mechanism responds to the anticipation of a change in a regulated variable. For example, when a meal is in the digestive tract, a feedforward mechanism increases the secretion of insulin that promotes the cellular uptake and storage of ingested nutrients.

Option B: Positive feedback mechanism refers to the enhancement or amplification of the output so that it moves in the direction of the initial change. An example is seen in the luteinizing hormone (LH) surge where the estrogen positively regulates the further secretion of LH.

Option D: The adaptive control mechanism refers to the delayed type of negative feedback mechanism. When the feedforward mechanism has an error, the correction is made by a retrospective feedback mechanism called the adaptive control mechanism.

Solution to Question 3:

The given image shows the paracrine cell-to-cell signaling mechanism. In paracrine signaling, the signaling molecules released by a cell only affect target cells in close proximity to it.

An example of paracrine signaling is the release of endothelin-1, a potent vasoconstrictor released by the endothelial cells.

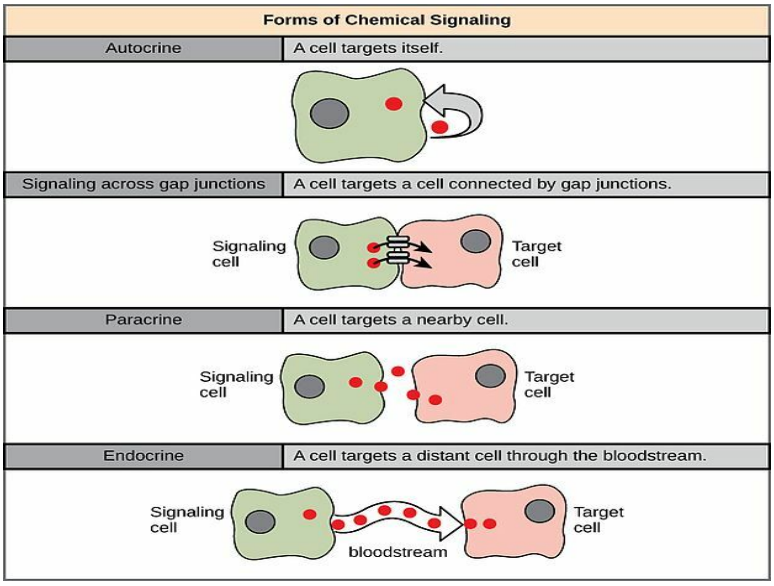
Synaptic signaling is a special case of paracrine signaling (for chemical synapses) between neurons and target cells.

Other options:

Option B: In the autocrine signaling mechanism, the cells respond to the signaling molecules that are released by themselves, which is the site of release and action within the same cell. Note that the signaling molecules are first secreted out of the cell and then act on the same cell through receptors. An example is the proliferation of activated T-cells by IL-2 released by the same cell after it interacts with antigen-presenting cells.

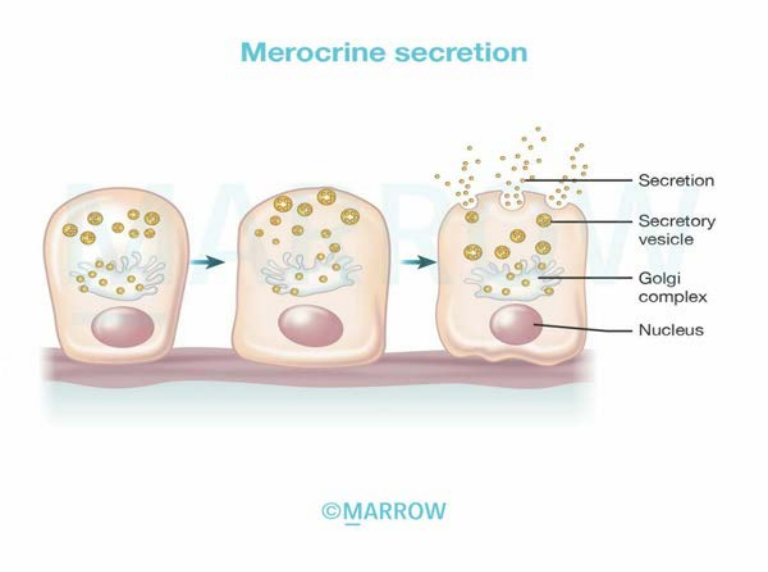
Option C: In endocrine signaling, a signaling molecule, a hormone (for example insulin, FSH, LH), is usually carried by the blood from its site of release to act on its target at a distance.

The below image shows the different types of extracellular cell-to-cell communication mechanisms.



Option D: Merocrine is a type of glandular secretion and not an extracellular signaling mechanism. In this, the secretions are poured out by exocytosis and the cell remains intact. An example of the merocrine gland is the goblet cell and eccrine sweat gland.

An illustration depicting this mechanism is given below.



Solution to Question 4:

The true statement regarding the given cystometrogram is that segment Ib is due to Laplace law.

Cystometrogram is a plot of intravesical pressure against the volume of fluid in the bladder. The curve shows three segments:

• Ia- initial slight rise in pressure when the first increments in the volume are produced

• Ib- long, nearly flat segment as further increments are produced

• II- sudden, sharp rise in pressure as the micturition reflex is triggered (not failure).

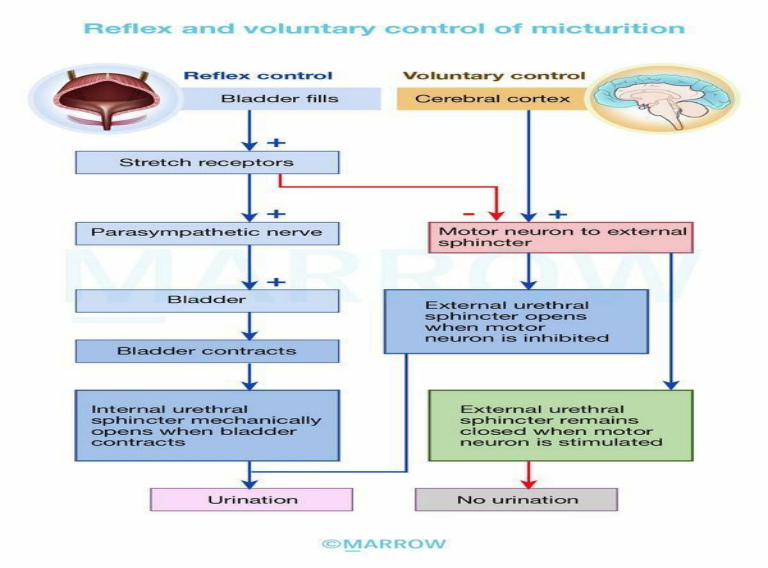
• The dotted line- pressure-volume relation if the micturition had not occurred.

The flatness of segment Ib is a demonstration of the law of Laplace. The law of Laplace states that the pressure (P) in a spherical viscus is equal to twice the wall tension (T) divided by the radius (R). This is expressed as P= 2T/R. In the bladder, the tension increases as the bladder get filled. Since the radius also increases there is only a slight increase in pressure until the bladder is relatively full.

The first urge to void is felt at a bladder volume of about 150 mL. A marked sense of fullness is felt at a bladder volume of 400ml.

Micturition reflex is the result of sensory signals from the stretch receptors in the bladder wall, which are conducted to the sacral segments of the cord through the pelvic nerves and then efferent signals conducts back again to the bladder through the parasympathetic nerve fibers.

The micturition reflex pathway is given below.



Solution to Question 5:

In the above scenario, the patient's hypothalamic thermostat has been reset from point A to a higher temperature (point C). The body responds to this change by using certain measures in stage A such as shivering.

In stage A the body activates various heat gain mechanisms to match the hypothalamic temperature setpoint. These include:

• Shivering- the shivering center is located in the posterior hypothalamus. It is normally inhibited by signals from the heat center in the anterior hypothalamic-preoptic area but is excited by cold signals from the skin and spinal cord. ■A sudden increase in heat setpoint results in the activation of this center. It then transmits non-rhythmic signals through bilateral tracts through the lateral columns of the spinal cord, and finally to the anterior motor neurons. They increase the tone of the skeletal muscles throughout the body. As the tone rises above a certain critical level, shivering begins. During maximum shivering, body heat production can rise to four to five times normal.

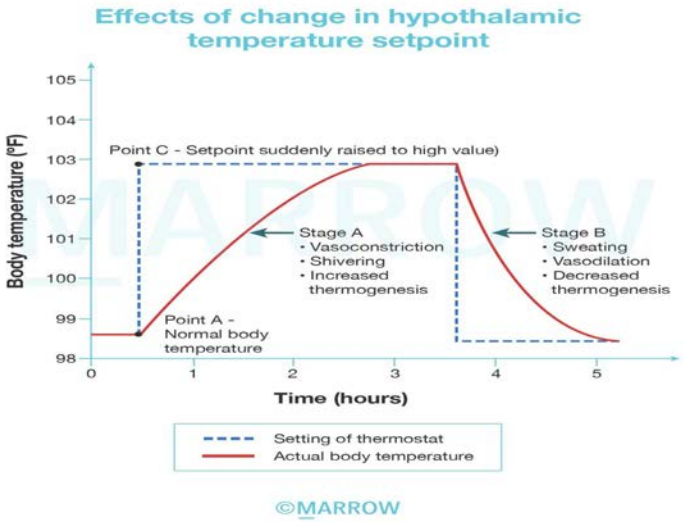
• Vasoconstriction (decreased blood flow to skin) is mediated by increased sympathetic drive by the activation of the posterior hypothalamic sympathetic center.

• An increase in chemical thermogenesis in which heat production takes place in the brown fat by the mechanism of uncoupling of oxidative phosphorylation. This is the predominant mechanism seen in neonates.

In stage B, the hypothalamic temperature setpoint is lower than the normal body temperature. Hence body activates various heat loss mechanisms to match the hypothalamic temperature setpoint. It includes vasodilatation of the skin blood vessel, sweating, and decreased thermogenesis.

The temperature of the body is regulated majorly by a nervous feedback mechanism that operates through temperature-regulating centers located in the hypothalamus. Minor regulation is done by the thermal receptors in the skin and the deep thermal receptors present in the spinal

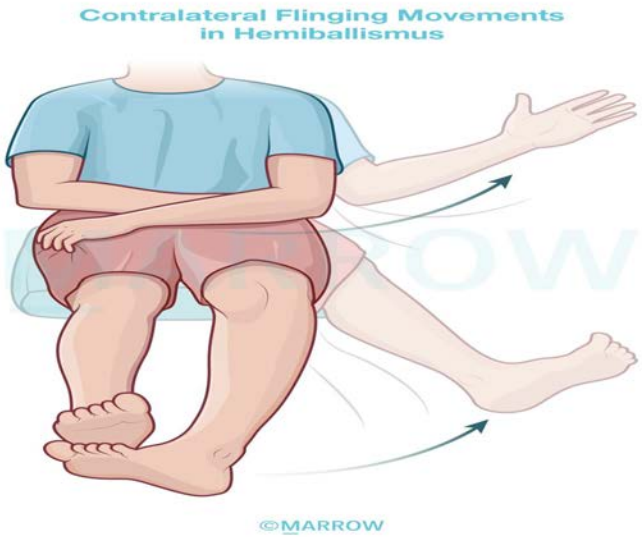
cord and abdominal viscera.



Solution to Question 6:

The above clinical scenario is suggestive of hemiballismus. A lesion in subthalamic nuclei is responsible for this condition.

A lesion in the subthalamic nucleus causes sudden, violent, involuntary, and flinging movements confined to one side of the body, commonly affecting the proximal muscles of the limbs, a condition called hemiballismus. The movements are seen contralateral to the side of the lesion, i.e., involuntary movements of the right arm and leg are seen in the lesion of the left subthalamic nucleus and vice versa.



Basal ganglia circuits have both direct and indirect pathways. The direct pathway stimulates the cortex to produce movement, whereas the indirect pathway inhibits it. The striatal activity in the direct pathway is mediated by D1 dopamine receptors and in the indirect pathway by D2 dopamine receptors.

The subthalamic nucleus is a part of the indirect pathway. Hence, a lesion at subthalamic nuclei leads to loss of inhibitory effect of the indirect pathway resulting in dopaminergic overactivity. This is responsible for features of hemiballismus.

This movement disorder is usually self-limiting and tends to resolve spontaneously after weeks or months. Dopamine antagonistic agents can be given to manage it as well.

Other options:

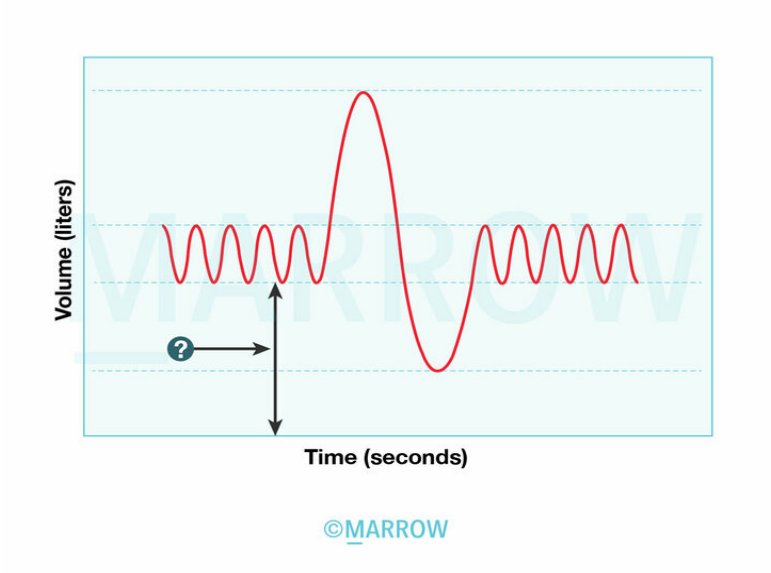
Option B: A lesion in the globus pallidus can give rise to athetosis. This involves spontaneous and continuous writhing movements of the hand, arm, neck, or face.

Options C and D: A lesion in the putamen and caudate nucleus can give rise to chorea. Chorea is defined as rapid, semi-purposeful, graceful, dance-like nonpatterned involuntary movements involving distal or proximal muscle groups.

Physiology NEET 2023

Question 1:

Identify the marked region in the given spirometry.



a) Functional residual capacity

b) Tidal volume

c) Expiratory reserve volume

d) Expiratory capacity

Question 2:

A man was brought to the emergency after he suddenly became unconscious while working in the field. On examination, his temperature was 105 degrees Fahrenheit and his skin turgor was decreased. Which of the following would not be seen in the patient?

a) Tachypnea

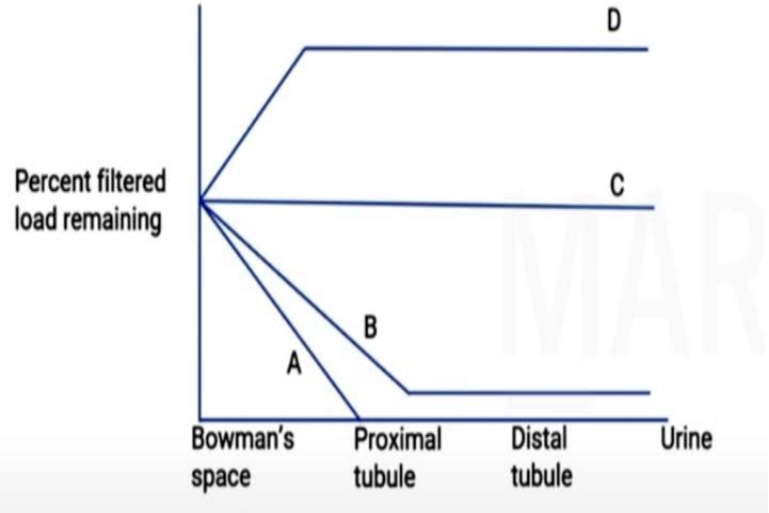
b) Hypotension

c) Sweating

d) Red hot skin

Question 3:

Identify the correctly matched pair of substances with their renal clearance from the graph given below.



a) A - Glucose, B - PAH, C - Bicarbonate and D - Inulin

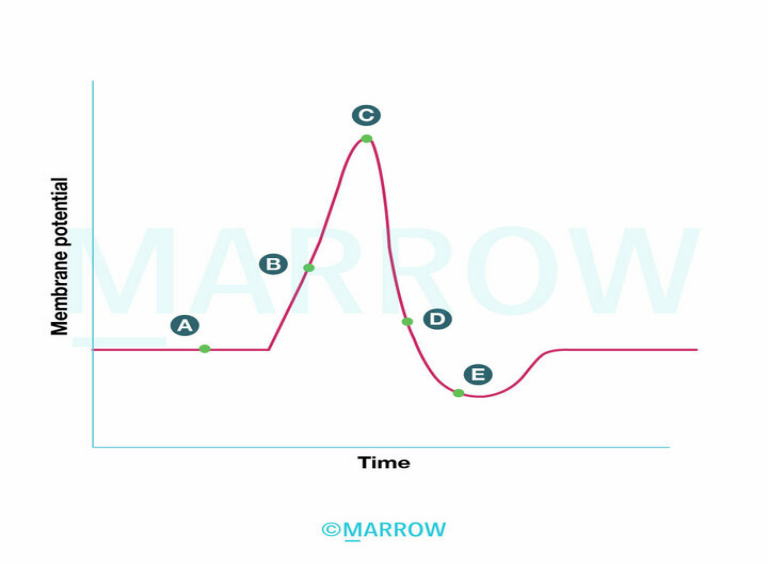
b) A - Glucose, B - Bicarbonate, C - Inulin and D - PAH

c) A - PAH, B - Inulin, C - Glucose and D - Bicarbonate

d) A - Inulin, B - Glucose, C - Bicarbonate and D - PAH

Question 4:

Identify the true statement regarding the given nerve action potential curve.



a) Threshold point is at A

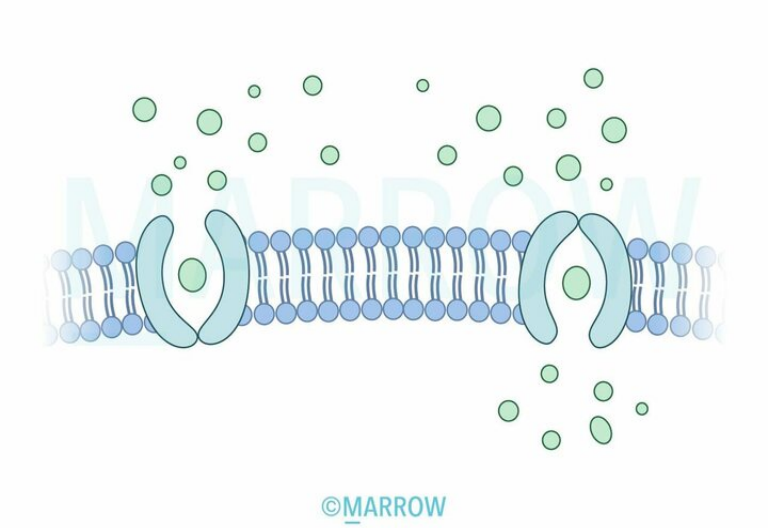
b) At point E, the nerve is more excitable

c) Point C to D is due to opening of Na+ and closure of K+ channels

d) Point B to D is refractory period

Question 5:

Identify the type of transport across the cell membrane given below.



a) Simple diffusion

b) Facilitated diffusion

c) Primary active transport

d) Secondary active transport

Question 6:

A preterm baby who was delivered at 28 weeks developed respiratory distress syndrome. Which of the following is true about surface tension and compliance in this baby?

a) Surface tension - decreased; Compliance - increased

b) Surface tension - increased; Compliance - decreased

c) Both surface tension and compliance decreased

d) Both surface tension and compliance increased

Question 7:

A patient came to the hospital after a road traffic accident. He had severe muscle injury and his serum K+ level was found to be 5.5 mEq/L. What will happen to the resting membrane potential in this patient?

a) No change

b) Becomes more negative

c) Becomes more positive

d) First becomes more positive then negative

Question 8:

A patient met with a road traffic accident and developed a cervical spine injury. The fracture fragment had pierced the lateral aspect of the dorsal column tract. Which of the following findings is seen in this patient?

a) Absence of ipsilateral lower limb proprioception

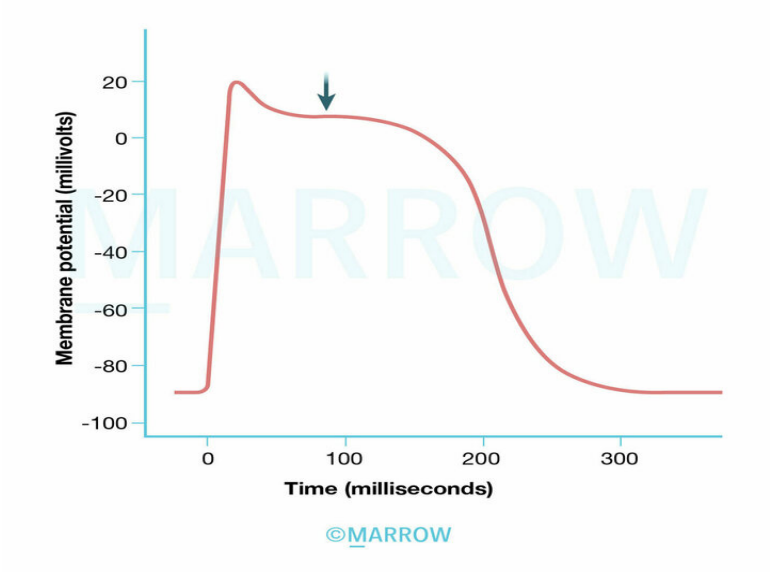
b) Absence of fine motor movement of fingers

c) Absence of ipsilateral arm proprioception

d) Absence of contralateral lower limb proprioception

Question 9:

Identify the true statement regarding the point marked on the myocardial action potential curve.



a) Due to opening of Na+ and closure of fast K+ channels

b) Due to slow but prolonged opening of Ca2+ channels

c) Due to closure of Na+ and opening of slow K+ channel

d) Due to Na+/K+ ATPase

Answer Key

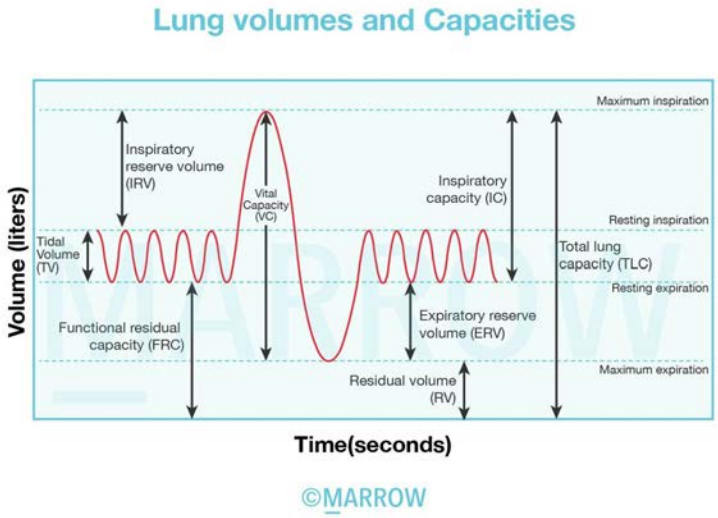
Question No.	Correct Option
1	a
2	c
3	b
4	d
5	b
6	b
7	c
8	c
9	b

Detailed Explanations

Solution to Question 1:

The marked area in the spirometry shows the total amount of air present in the lung after normal expiration. This is called functional residual capacity.

The various volumes and capacities in a spirometry are shown below.



Solution to Question 2:

The given clinical vignette in a patient with signs of dehydration and a body temperature of 105°F is highly suggestive of heatstroke. Sweating would not be seen in a patient with heatstroke.

The body has various mechanisms to maintain body temperature within a range of 36–37°C. When the body temperature is elevated by exposure to high environmental temperatures or physical exertion, the central control area in the medial preoptic and anterior hypothalamic nuclei is activated. This engages the autonomic pathways that promote sweating and cutaneous vasodilation, causing the heat to dissipate and bring the body to normal temperature.

Heatstroke occurs due to the failure of the heat regulation center of the hypothalamus. The person fails to lose heat by cutaneous circulation and sweating. It is likely to develop when the body temperature rises to a range of 105°F to 108°F. The predisposing factors include high temperature, increased humidity, minor infections, old age, and physical activity.

It is a medical emergency that leads to homeostatic imbalance. The symptoms include dizziness, abdominal distress, vomiting, delirium, and eventually leading to loss of consciousness. On examination, the skin is dry, hot, and flushed, with a complete absence of sweating (anhidrosis). Other signs seen in heat stroke are tachycardia, Kussmaul-type rapid deep breathing (tachypnea), hypotension, cardiac failure, dizziness, muscle cramping, confusion, and seizures.

Heatstroke can cause damage to multiple organ systems, including the brain, kidneys, and liver, which can lead to life-threatening complications. It is essential to initiate rapid cooling and supportive care measures to prevent permanent injury or death. The cooling methods used to treat heatstroke include:

• Cold water immersion: The patient is immersed in a tub of cold water, which is the most effective way to lower body temperature.

• Evaporative cooling: The patient's body is sprayed with water while fans blow air over the body to help facilitate evaporation and cooling.

• Applying cold packs: Applying ice packs to the neck, armpits, and groin can help cool the body by targeting areas where large blood vessels are located close to the skin surface.

• Misting and fanning: Spraying the patient with cool water and using a fan to circulate air can help promote evaporative cooling.

Preventive measures for heatstroke include staying hydrated, taking regular breaks in shaded areas, and avoiding strenuous activities during the hottest part of the day.

Other Options

• Option A: Tachypnea - Rapid, deep breathing (Kussmaul breathing) can be seen in heatstroke as the body tries to eliminate excess heat through increased respiratory rate.

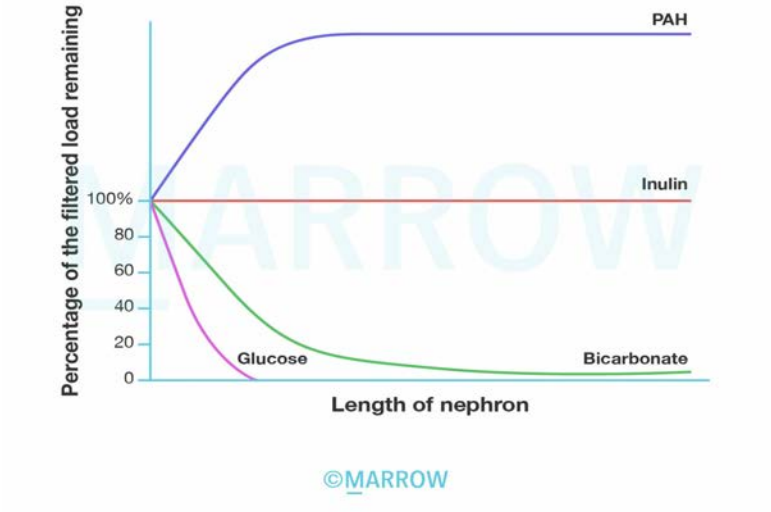
• Option B: Hypotension - Dehydration and vasodilation in an attempt to dissipate heat can result in hypotension in heatstroke patients.

• Option D: Red hot skin - Heatstroke patients often present with hot, flushed skin as a result of increased blood flow to the skin surface and the body's inability to dissipate heat effectively.

Solution to Question 3:

The correctly matched pair of substances and their renal clearance is A - Glucose, B - Bicarbonate, C - Inulin and D - PAH.

The concentration of the substance changes as it passes through the tubules. The tubular cells may remove the substance from the filtrate (tubular reabsorption) or add more of the substance to the filtrate (tubular secretion) or both. The amount of the substance finally excreted equals the amount filtered plus the net amount transferred out by the tubules.



PAH is filtered by the glomeruli and secreted by the tubular cells. Its concentration increases on moving through the length of the nephron due to secretion into tubules. It is represented by curve D.

Inulin is freely filtered by glomeruli and does not undergo any reabsorption or secretion. Hence, its concentration does not change throughout the length of the nephron and its excretion is constant and equal to the glomerular filtration rate. It is represented by curve C.

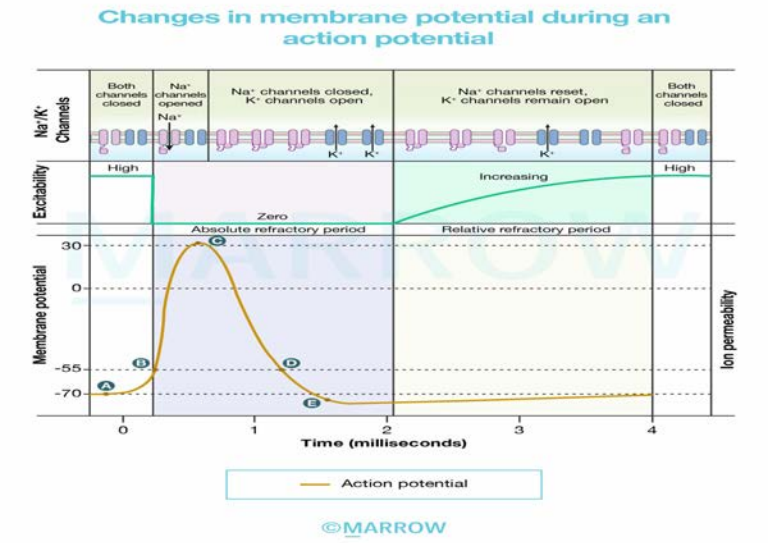
The majority of bicarbonate reabsorption occurs in the proximal tubule and a small amount of it flows into the distal tubules and collecting ducts. Its reabsorption occurs in all parts of the tubules, except the descending and ascending thin limbs of the loop of Henle. It is represented by curve B.

Substances like amino acids or glucose are reabsorbed along with sodium in the early portion of the proximal tubule. They have a graph that is sloping down as shown in curve A.

Solution to Question 4:

The correct statement regarding the given nerve action potential curve is point B to D is the refractory period.

The sequence of events occurring during an action potential is shown below



• Point A represents the resting state where both channels are closed.

• Na+ channels open in response to depolarizing stimulus and sodium enters the cell. The initiation of action potential occurs only after a certain potential is reached, which is called the threshold potential represented by point B. (Option A)

• After this, the sodium influx causes the opening of more Na+ channels through a positive feedback mechanism. Rapid depolarization occurs to reach point C.

• At point C, Na+ channels close and K+ channels open, causing repolarization due to K+ efflux. (Option C)

• Point D represents continued repolarization due to potassium efflux.

• At point E, Na+ channels are reset and are ready to respond to another depolarizing stimulus. During this phase, the K+ channels remain open and slowly return to the closed state, causing after-hyperpolarization. As a stronger stimulus is required to reach the threshold potential, the excitability of nerve fiber is reduced at point E. (Option B)

• As both channels close, the membrane returns to resting membrane potential back to point A.

Point B-D is a part of the refractory period. During this period, the application of even a stronger stimulus will not elicit an action potential.

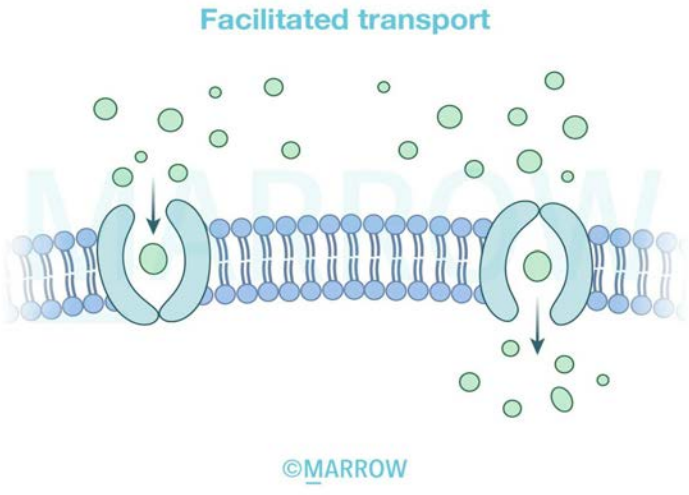
The refractory period is divided into an absolute refractory period and a relative refractory period. During the absolute refractory period, the nerve will not be excited no matter how strong a stimulus is given. However, during the relative refractory period, stronger than normal stimuli can cause excitation.

Solution to Question 5:

The given image shows the transport of a molecule across a membrane with the help of a carrier protein. This form of transport is called facilitated diffusion.

When carrier proteins help in the movement of substances in the direction of their chemical or electrical gradients (downhill movement), no energy input is required and the process is called facilitated diffusion.

Glucose transporters or GLUTs are examples of transport proteins in the cell membrane responsible for the transfer of glucose into the cells by facilitated diffusion. Facilitated diffusion involves the passage of molecules or ions inside the cell membrane by binding to a carrier/ transport protein.



Other options -

Option A. Simple diffusion - It is along the concentration gradient but is not carrier-mediated. In the cell, examples of molecules that can use simple diffusion to travel in and out of the cell membrane are water, oxygen, carbon dioxide, and nitrogen. They pass directly through the cell membrane along the concentration gradient, without the use of energy.

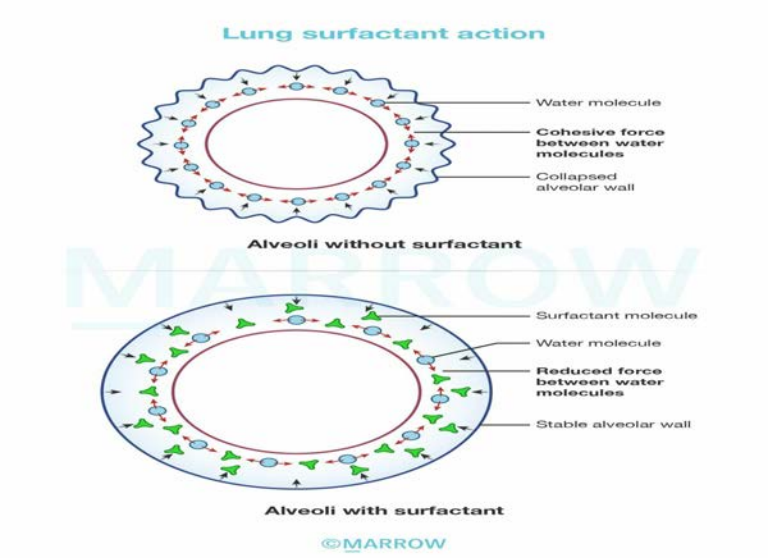
Option C. Primary active transport - It is a form of cellular transport requiring energy in the form of hydrolysis of ATP to ship and transfer molecules against gradient differences. The important examples of primary active transport include sodium-potassium ATPase, proton pump, and calcium ATPase.

Option D. Secondary active transport - In this form of transport, two or more substances are transported together across the membrane with help of a carrier molecule. As one of the substances (e.g., sodium) diffuses down its electrochemical gradient, the energy released is used to drive another substance (e.g., glucose) against the gradient. It does not require energy directly from ATP.

Solution to Question 6:

This preterm baby who developed respiratory distress syndrome has surfactant deficiency. In case of surfactant deficiency, the surface tension increases and compliance decreases.

Surfactant is secreted by the type 2 pneumocytes in the alveoli. Dipalmitoyl lecithin/dipalmitoylphosphatidylcholine (DPPC) is a major component of lung surfactant. It reduces surface tension inside the alveoli, as shown below.



Compliance is defined as the extent of lung expansion for each unit increase in pressure. An important factor that affects lung compliance is surface tension. As surface tension increases, the pressure required to keep the alveoli open also increases. As more pressure is required to expand the alveoli, lung compliance will be reduced.

Solution to Question 7:

In the given clinical scenario, the patient has hyperkalemia. It would result in the resting membrane potential becoming more positive.

The resting membrane potential represents an equilibrium situation where the concentration gradient of ions across the membrane is equal and opposite to the electrical gradients. At a normal potassium concentration of 3.5–5.0 mEq/L, the equilibrium potential for potassium is –90 mV. This is close to the resting membrane potential of neurons, which is about –70 mV.

A decrease in the extracellular sodium concentration reduces the size of the action potential but has little effect on the resting membrane potential. However, the intracellular and extracellular potassium (K+) concentrations are the major determinants of the RMP.

This is because

• At rest, there are more open K+ channels compared to Na+ channels; therefore, the membrane permeability of K+ is greater.

• The RMP is close to the equilibrium potential of K+.

In hyperkalemia, the extracellular level of K+ is increased. Thus, the RMP moves closer to the threshold to elicit an action potential, leading to a more excitable nerve. This means the RMP has become more positive.

In hypokalemia, the extracellular level of K+ is reduced. Thus, the RMP is reduced or becomes more negative and the nerve is hyperpolarized.

Hyperkalemia can lead to various clinical manifestations depending on the severity of the condition. Mild to moderate hyperkalemia may be asymptomatic or cause nonspecific symptoms such as fatigue, muscle weakness, and paresthesias. Severe hyperkalemia can lead to life-threatening complications such as cardiac arrhythmias and paralysis. The management of hyperkalemia includes treating the underlying cause, administering medications to stabilize the cardiac membrane (e.g., calcium gluconate), promoting the movement of potassium into cells (e.g., insulin and glucose, beta-agonists), and enhancing the removal of potassium from the body (e.g., diuretics, ion-exchange resins, or hemodialysis).

Solution to Question 8:

The above clinical scenario of transection of the spinal cord in the lateral aspect of the dorsal column would affect the fasciculus cuneatus. This lesion would result in absence of ipsilateral proprioception of the arm.

The fibers in the dorsal column are organized in such a way that the sacral segments are positioned most medially and those from the cervical segments are positioned most laterally.

These are called

• Fasciculus gracilis - carrying sensations from the ipsilateral lower limb

• Fasciculus cuneatus - carrying sensations from the ipsilateral upper limb.

This patient with an injury to the lateral part of the cervical cord's dorsal column tract will have damaged fasciculus cuneatus. This would result in loss of touch, vibration, and proprioception in

the arm of the same side of the lesion.

The extent of neurological deficits resulting from a spinal cord injury depends on the level of the injury and the severity of the damage. Injuries may be classified as complete or incomplete, depending on whether there is a total or partial loss of sensory and motor function below the level of injury. The key to solving this question lies in recognizing that the question mentions that the damage is to the lateral aspect of the dorsal column tract.

Other options:

Option A: Absence of ipsilateral lower limb proprioception - This would be seen if the fasciculus gracilis was affected, which is responsible for carrying sensations from the ipsilateral lower limb. However, in this case, the injury is to the lateral part of the dorsal column, affecting the fasciculus cuneatus.

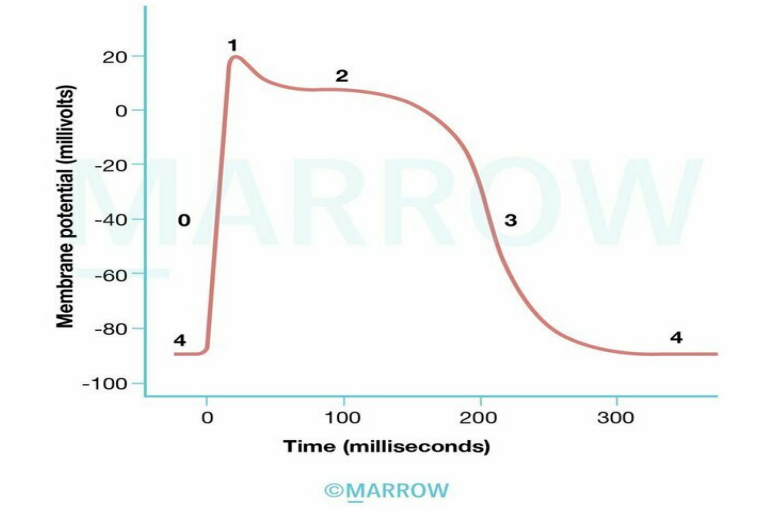
Option B: Absence of fine motor movement of fingers - This would be a result of damage to the corticospinal tract, which carries motor information. The question is specifically focused on the dorsal column tract, which is responsible for carrying sensory information.

Option D: Absence of contralateral lower limb proprioception - Proprioception is carried by the dorsal column pathway, and it is affected ipsilaterally. Damage to the lateral part of the dorsal column would not result in contralateral loss of proprioception.

Solution to Question 9:

The myocardial action potential curve marked above represents the plateau phase, which is due to the slower and prolonged opening of calcium channels.

Two types of voltage-gated Ca2+ channels (T- and L-types) are present in myocardial cells. The opening of the slower L-type Ca2+ channels is mostly responsible for changes in the action potential. The action potential curve of cardiac muscles consists of 5 phases, as shown below.



Phase 0: Depolarization - Opening of voltage-gated sodium channels (fast sodium channels) leads to sodium influx.

Phase 1: Initial repolarization - Closure of Na+ channels and opening up of K+ channels leads to potassium efflux.

Phase 2: Plateau - Slower but prolonged opening of voltage-gated Ca2+ channels, leading to calcium influx and reduced permeability of K+ channels, causes the graph to plateau

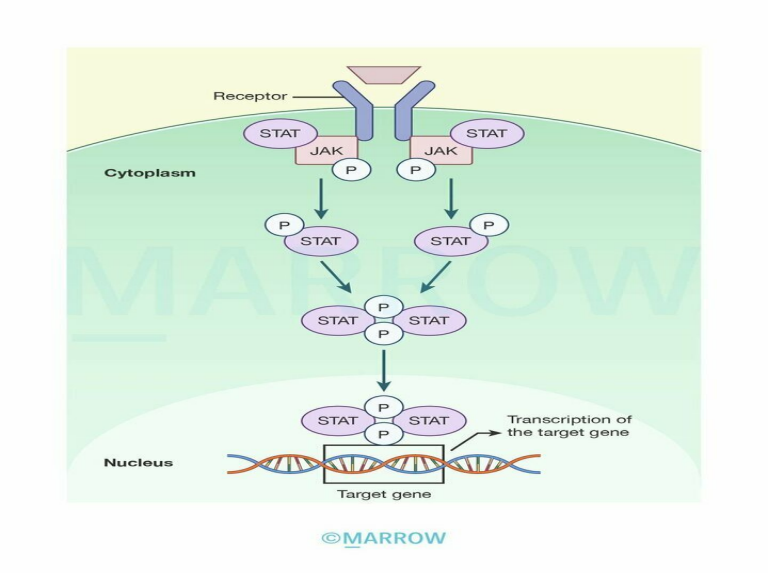
Phase 3: Rapid Repolarization - The closure of Ca2+ channels and opening of K+ at the end of the plateau phase causes repolarization.

Phase 4: Resting membrane potential - Is reached at the end of phase 3

Physiology INI-CET 2023

Question 1:

Which of the following hormone acts via this pathway?



a) Leptin

b) Calcitonin

c) Vasopressin

d) Aldosterone

Question 2:

Which of the following options is false regarding the measurement of temperature in a febrile patient?

a) Rectal temperature is ideal for measuring the core body temperature

b) Rectal temperature is lower than axillary temperature

c) Tympanic membrane temperature is lower than rectal temperature

d) Rectal temperature is higher than oral temperature.

Question 3:

Which of the following statements is/are true about skeletal muscle?

a) Only 2

b) Only 3

c) 3, 4

d) 1, 4

Question 4:

Cells with prolific smooth endoplasmic reticulum secrete_____

a) Eicosanoid hormones

b) Steroid hormones

c) Amine hormones

d) Peptide hormones

Question 5:

At which volume or capacity, pressure measured at the upper airway becomes zero?

a) Residual volume

b) Functional residual capacity

c) Total lung capacity

d) Inspiratory capacity

Question 6:

Arrange the following bands in the sarcomere from the periphery to the center.

a) 1,2,3,4

b) 2,3,4,1

c) 1,3,4,2

d) 1,4,2,3

Question 7:

Which of the following are incorrectly paired?

a) Gastrin - G cells, Antrum

b) Secretin - S cells, Duodenum

c) CCK - I cells, Duodenum and jejunum

d) Motilin - M cells, Duodenum and Jejunum

Question 8:

Which of the following is responsible for fetal heart acceleration?

a) Carotid body chemoreceptors

b) Aortic baroreceptors

c) Autonomic brain stem regulation

d) ANP

Question 9:

Our body was built to identify toxic substance by the recognition of bitter taste. Which of the following substances is responsible for the bitter taste?

a) Amino acids

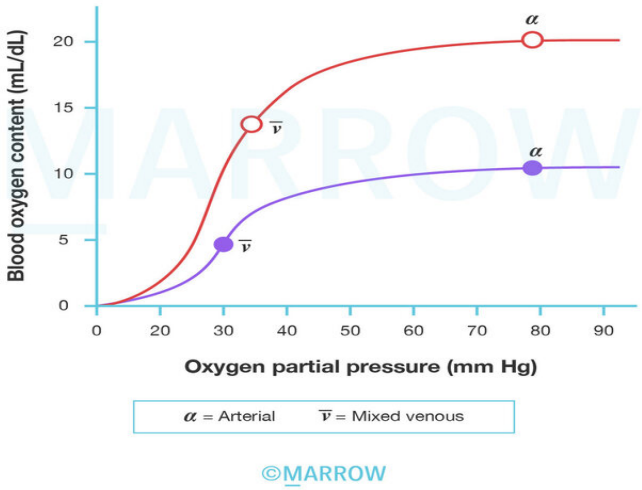
b) Alkalaoids

c) Hydrogen ions

d) Aldehydes

Question 10:

The type of hypoxia based on the graph is_____ (Consider the plot in red as normal)



a) Stagnant hypoxia

b) Histotoxic hypoxia

c) Hypoxic hypoxia

d) Anemic hypoxia

Question 11:

Assertion: RMP is dependent on proteins and phosphate ions. Reason: Diffusion potential can be calculated using Nernst Equation.

a) The assertion is independently a true statement, but the reasons is independently a false statement.

b) The assertion is independently a false statement, but the reasons is independently a true statement.

c) Both assertion and reason are independently true and the reason is not the correct explanation for the assertion

d) Both assertion and reason are independently true and the reason is the correct explanation for the assertion

Question 12:

Windkessel effect is shown by all except _____

a) Radial artery

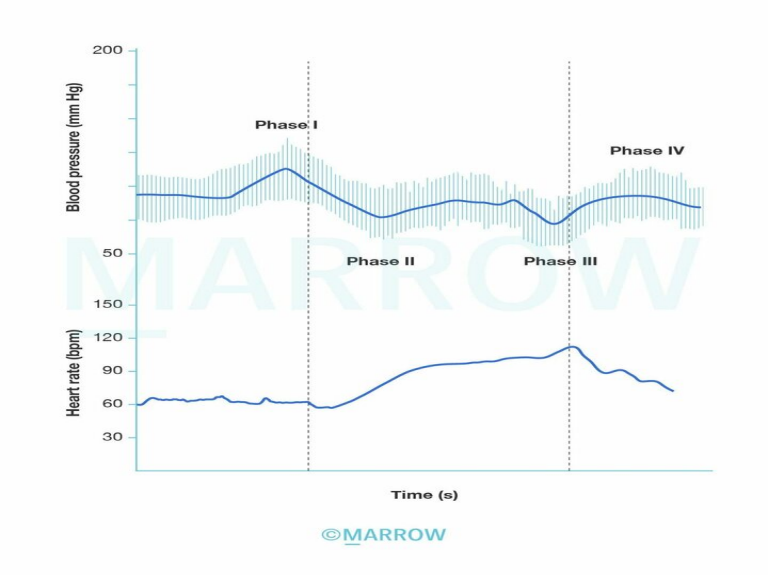
b) Renal Artery

c) Aorta

d) Carotid artery

Question 13:

Increase in blood pressure at the beginning of Valsalva maneuver is due to_____



a) Increase in intrathoracic pressure adding to left ventricular pressure

b) Increase in intrathoracic pressure adding to aortic pressure

c) Increase in left atrial pressure

d) Increase in left ventricular volume

Question 14:

Which of the following statements is false about male sexual development?

a) At eight weeks the embryo is bipotent.

b) Wolffian duct develops into epidymis and vas deferens on either side of the body.

c) Mullerian inhibiting substance inhibits mullerian duct.

d) Dihydrotestosterone leads to the development of secondary sexual characters and external genitalia.

Question 15:

The upstroke of action potential (phase 0) in the sinoatrial node is due to _____ ?

a) Sodium influx via voltage gated sodium channels

b) Calcium currents only

c) Potassium efflux

d) Influx of both sodium and calcium

Question 16:

Which of the following types of pain stimulus is associated with the Carrageenan-induced experimental pain model?

a) Inflammatory stimulus

b) Acute noxious stimulus

c) Deep boring stimulus

d) Neuropathic stimulus

Question 17:

Insulin-independent glucose transporter is present in all of the following except?

a) Brain

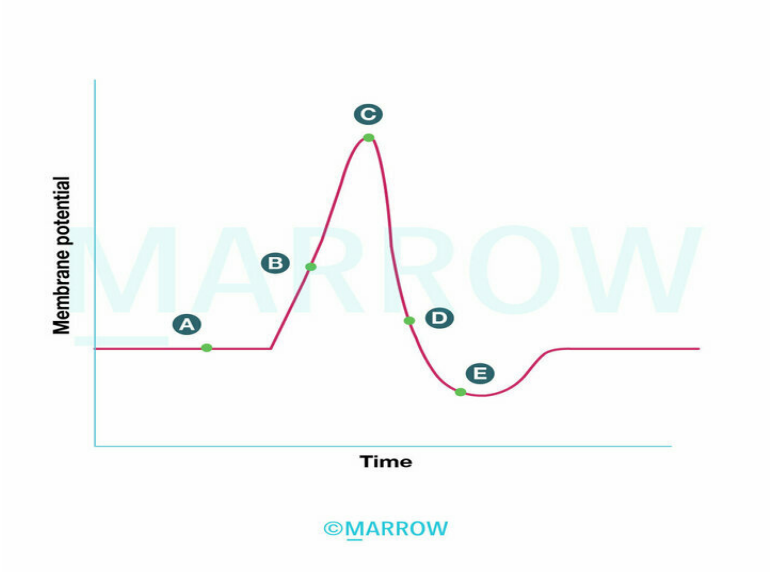
b) Adipose tissue

c) RBC

d) Pancreas

Question 18:

Which of the following is responsible for the phase marked C to D in the given nerve action potential?



a) Na+ influx

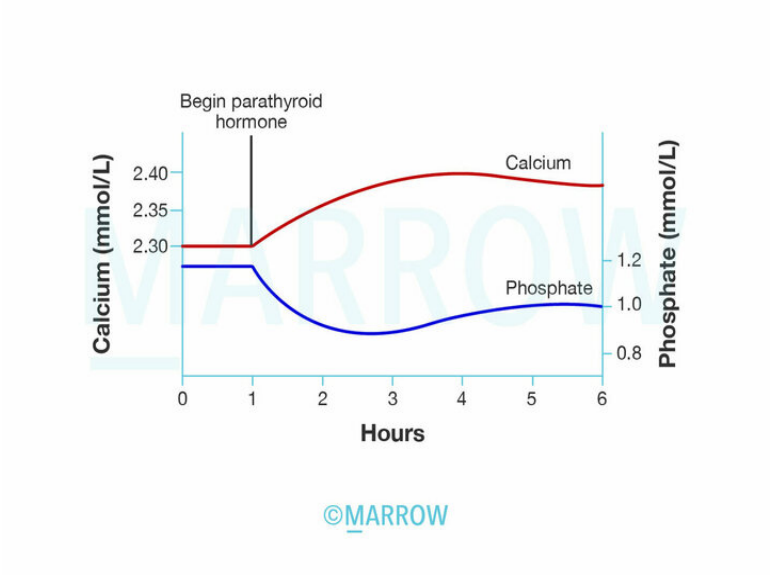
b) K+ influx

c) Na+ efflux

d) K+ efflux

Question 19:

The given graph shows the effect of PTH on blood calcium and phosphate levels in an experimental animal. How does PTH increase plasma calcium levels?



a) By increasing osetoclastic activity

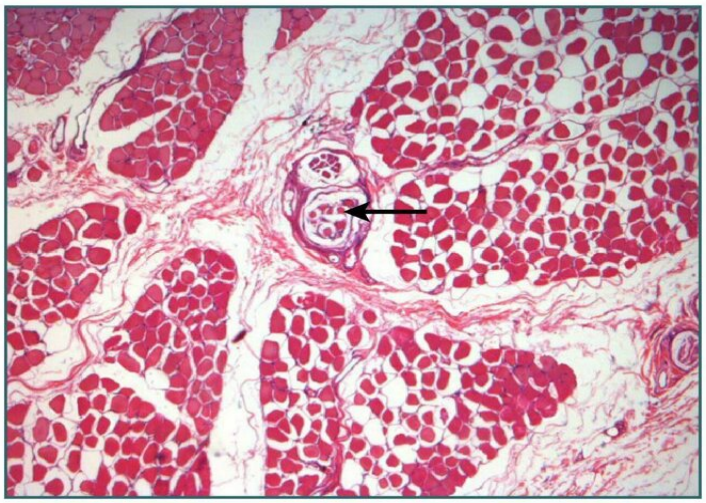
b) By decreasing renal excretion of calcium

c) By increasing osteoblastic activity

d) By increasing osteoclastic activity and decreasing renal excretion of calcium

Question 20:

In the given cross-section of a muscle spindle, the structure marked below is innervated by which of the following motor nerve fibres?



a) Gamma

b) Alpha

c) Beta

d) Delta

Question 21:

Which of the following is responsible for pneumoperitoneal bradycardia following CO_2 insufflation during laparoscopic surgery?

a) Decreased afterload

b) Vascular injury

c) Air embolism

d) Peritoneal stretching

Question 22:

Which of the following sodium transporters are present maximally in the early part of the PCT?

a) 2,3,4

b) 2,4

c) 1, 2, 3

d) 1,4

Question 23:

Which of the following statements is incorrect with respect to the baroreceptors present in the carotid sinus?

a) They need the support of electromechanical transducers

b) They are located in the deep smooth muscle layer

c) Afferent fibres pass via cranial nerve IX

d) They express several non-selective cation channels

Answer Key

Question No.	Correct Option
1	a
2	b
3	b
4	b
5	b
6	c
7	d
8	a
9	b
10	d

22	c
23	b

Detailed Explanations

Solution to Question 1:

The given image shows the JAK-STAT signaling pathway, which is associated with tyrosine kinase receptors. Among the given hormones leptin acts via this pathway.

Hormones that use receptor tyrosine kinase/ JAK-STAT signaling include the following:

• Growth hormone

• Fibroblast growth factor

• Hepatocyte growth factor

• Insulin

• Insulin-like growth factor-1

• Leptin

• Prolactin

• Vascular endothelial growth factor

Leptin is a hormone that is secreted by fat cells. The physiological effects of leptin are regulating appetite and energy balance. The leptin receptor acts via tyrosine kinase of the Janus kinase (JAK) family, JAK2. Leptin binds to the extracellular part of the leptin receptor, which causes phosphorylation (P) and activation of the intracellular JAK2. This causes phosphorylation of signal transducer and activation of transcription (STAT) proteins, which results in the transcription of target genes and the synthesis of proteins.

Phosphorylation of JAK2 also results in the activation of other intracellular enzyme pathways such as mitogen-activated protein kinases (MAPK) and phosphatidylinositol 3-kinase (PI3K).

Other options:

Hormones such as adrenal (Aldosterone)and gonadal steroid hormones, thyroid hormones, retinoid hormones, and vitamin D, bind with protein receptors inside the cell rather than on the

cell surface. These hormones are lipid soluble and they readily cross the cell membrane and interact with receptors in the cytoplasm or nucleus.

Vasopressin in the epithelial cells acts via V2 receptor. They use adenylyl cyclase as their second messenger system. Vasopressin in the vascular smooth muscles acts via V1 receptor that uses phospholipase C as the second messenger system.

Solution to Question 2:

With regards to the measurement of temperature in a febrile patient, rectal temperature is higher than axillary temperature.

For humans, the conventional normal value for oral temperature is 37°C (98.6°F).

Rectal temperature represents the core body temperature and is less affected by changes in environmental temperature. It remains relatively constant. In comparison, oral temperature is typically 0.5°C lower than rectal temperature. However, the oral temperature can be influenced by various factors such as consuming hot or cold fluids, chewing gum, smoking, and breathing through the mouth.

Tympanic membrane thermometers measure radiant heat emitted by the tympanic membrane and the nearby ear canal, providing an absolute value of temperature. Tympanic membrane readings are generally 0.8°C (1.6°F) lower than rectal temperatures. The axillary temperature measured is lower than the rectal temperature.

Solution to Question 3:

The true statement about skeletal muscle is that the calcium is released from sarcoplasmic reticulum.

Excitation-contraction coupling refers to the process by which the membrane depolarization of the muscle fiber (excitation) leads to the contraction of the muscle.

For the maximum contraction of the skeletal muscle, the current has to penetrate deeply into the muscle fiber to the vicinity of the separate myofibrils. This penetration of current is achieved by transmission of action potentials along transverse tubules (T tubules). The T tubules penetrate through the muscle fiber, from one side of the fiber to the other.

Sarcoplasmic reticulum contains calcium ions in high concentration within its vesicular tubules. These ions are released from each vesicle when an action potential occurs in the adjacent T tubule. (Statement 3)

This action potential when it reaches the T tubule, it is sensed by the dihydropyridine receptors linked to calcium release channels. Actvation of this receptor leads to the opening of calcium release channels that releases the calcium ions into the sarcoplasm surrounding the myofibrils and causing contraction. (Statement 4)

In skeletal muscles, extracellular calcium supply partially contributes for the maintenance of skeletal muscle contraction.(Statement 1)

Solution to Question 4:

Cells with prolific smooth endoplasmic reticulum secrete steroid hormones.

The endoplasmic reticulum contains a complex series of tubules in the cytoplasm of the cell.

• Ribosomes are attached to the cytoplasmic side of the membrane in the rough(granular) endoplasmic reticulum. Protein synthesis and the initial folding of polypeptide chains with the formation of disulfide bonds are the functions of rough ER.

• Ribosomes are absent in the smooth (agranular) endoplasmic reticulum. Free ribosomes are found in the cytoplasm. It is the site of steroid synthesis in steroid-secreting cells and the site of detoxification processes in other cells.

The sarcoplasmic reticulum is a modified endoplasmic reticulum, that functions as an intracellular calcium store, which releases calcium into the cytoplasm stimulating cell contraction, proliferation, and migration.

Solution to Question 5:

Pressure measured at the upper airway becomes zero at functional residual capacity.

The curve of airway pressure obtained is plotted against the volume, which is the pressure-volume curve of the total respiratory system. This curve is used in understanding the fundamental relationship between the compliance of the lungs and the chest wall. It is measured by a spirometer.

The functional residual capacity is the volume of the air that remains in the lungs after normal expiration. The normal value is about 2.5 liters. At the lung volume of functional residual capacity (FRC), which is the relaxed state of the lungs, the pressure inside the lungs is effectively zero.

Other options:

Option A: Residual volume is the air left in the lungs after a maximal expiratory effort.

Option C: Total lung capacity is the sum of tidal volume, inspiratory reserve volume, expiratory reserve volume, and residual volume.

Option D: Inspiratory capacity is the maximum amount of air inspired from the end-expiratory level. It is the sum of tidal volume and inspiratory reserve volume.

Solution to Question 6:

The correct sequence of bands in the sarcomere from the periphery to the centre is: Z line→ A band→ H zone→ M line.

The sarcomere is the contractile unit of the skeletal muscle fibre.

• Z line provides attachment to actin filaments. The area between two adjacent Z lines is called the sarcomere. It is composed of thick and thin filaments:

• Thick filament: Myosin

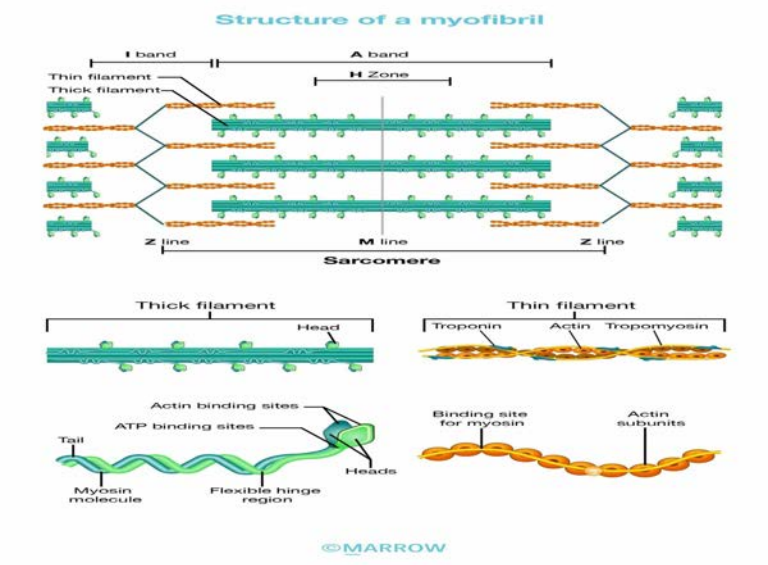
• Thin filaments: Actin, tropomyosin and troponin

• I band is isotropic to light. It contains only actin filaments.

• A band is anisotropic to light. It contains myosin plus overlapped actin.

• H bands are the lighter areas in the centre of the A band. These are the areas where the the thick filaments do not overlap the thin filaments, when the muscle is relaxed.

• M line is present in the centre of H band. There are slender cross-connections that hold the thick filaments in proper array.



Solution to Question 7:

Motilin is secreted by the Mo cells(not M cells) in the stomach, small intestine, and colon

Motilin is a gastrointestinal hormones that is secreted by enterochromaffin cells and Mo cells in the stomach, small intestine, and colon. It mediates its action via G-protein-coupled receptors on enteric neurons in the duodenum and colon. It produces contraction of smooth muscle in the stomach and intestines in the period between meals.

M cells are microfold cells are located in the epithelium covering mucosa-associated lymphoid tissues of the small intestine such as the Peyer's patches (PPs). Their function is to transport luminal antigens to the underlying lymphoid follicles to initiate an immune response.

Gastrin is secreted by G cells of the antrum, duodenum, and jejunum. It stimulates gastric acid secretion and mucosal growth.

Secretin is secreted by the S cells of the duodenum. Its primary function is to promote the secretion of bicarbonate-rich pancreatic juice by the ductal cells of the pancreas and duodenum. This secretion is poor in enzymes.

Cholecystokinin (CCK) is secreted by I cells of the duodenum, jejunum, and ileum. It stimulates pancreatic enzyme secretion, pancreatic bicarbonate secretion, gallbladder contraction, and growth of the exocrine pancreas. It also inhibits gastric emptying.

Solution to Question 8:

Amongst the given options, the best answer for the site responsible for Fetal heart acceleration is Carotid body chemoreceptors>Aortic baroreceptors>Autonomic brain stem regulation.

Though the brainstem is critical to mediating this reflex, the primary stimulus for initiating the changes in the heart rate is initiated by the carotid chemo and baro receptors, especially the chemoreceptor which is highly sensitive to the changes in O2 levels in the blood. It plays a permissive role on fetal heart rate acceleration.

Arterial chemoreceptors in the carotid arteries>aortic arch, respond to low pH levels and decreased oxygen saturation. These chemoreceptors detect instances of significant fall in blood oxygen levels, setting off the peripheral chemoreflex and heightening both parasympathetic and sympathetic neural activities. The activation of the parasympathetic branch leads to a swift decline in Fetal Heart Rate (FHR), a clinical manifestation identified as intrapartum decelerations. Concurrently, the sympathetic branch prompts significant peripheral vasoconstriction across a range of vascular territories, which results in the elevation of arterial blood pressure, ensuring continuous perfusion to essential organs.

The permissive action on the FHR acceleration comes in instances of alleviated hypoxemia, detected by the chemoreceptors in the carotid body and aortic arch, suppressing the peripheral chemoreflex, leading to a reduction in parasympathetic and sympathetic neural activities. Deactivation of the parasympathetic branch results in a swift increase in Fetal Heart Rate (FHR), typically seen clinically as an increase in intrapartum accelerations.

Solution to Question 9:

Alkaloids cause an intensely bitter taste, that causes the rejection of the food.

Bitter taste sensations are caused by two particular classes of substances:

• Long-chain organic substances that contain nitrogen.

• Alkaloids

Alkaloids cause an intensely bitter taste, leading to the rejection of certain foods. They are found in many medicinal drugs such as quinine, caffeine, strychnine, and nicotine. The bitter taste sensation in many deadly toxins found in poisonous plants is often caused by alkaloids. This helps the person or animal to reject the food.

Sweet taste is caused by chemicals such as sugars, glycols, alcohols, aldehydes, ketones, amides, esters, some amino acids, some small proteins, sulfonic acids, halogenated acids, and inorganic salts of lead and beryllium.

Sour taste is caused by acids (Hydrogen ion concentration). The sour taste is directly proportional to the strength of the acid.

Solution to Question 10:

The graph represents the oxygen-hemoglobin dissociation curve that would be seen in anemic hypoxia and normal. The X-axis represents the partial pressure of oxygen(PO_2). The Y-axis represents the percentage saturation between the hemoglobin and the oxygen.

The graph indicates two lines: a red line representing normal hemoglobin and a purple line representing reduced hemoglobin levels. The red line corresponds to an arterial blood oxygen content of approximately 19 mL/dL, and venous blood oxygen content of 14 mL/dL. On the other hand, the purple line represents an arterial blood oxygen content of 9 mL/dL and venous blood oxygen content of 4 mL/dL.

This scenario demonstrates a 50% decrease in oxygen saturation of hemoglobin, while the partial pressure of oxygen (PO_2) remains within the normal range. This condition is characterized as anemic hypoxia.

In anemic hypoxia, the blood oxygen content is decreased. The patients might not experience any difficulty during rest because 2,3-DPG increases in the red blood cells. However, they may have difficulty during exercise because of a limited ability to increase O_2 delivery to the active tissues.

Conditions that cause a right shift in the oxygen hemoglobin curve are: (Conditions with the increased requirement of O_2 - metabolically active tissues)

- Hypoxia
- Hypercarbia
- Decreased pH
- Increased temperature
- Increased 2,3-biphosphoglycerate

Conditions that cause a left shift in the oxygen hemoglobin curve

- Increased oxygen
- Decreased carbon dioxide
- Increased pH
- Decreased temperature
- Decreased 2,3-biphosphoglycerate
- Fetal hemoglobin.

Solution to Question 11:

Both assertion and reason are independently true and the reason is not the correct explanation for the assertion.

Resting membrane potential (RMP) is the difference in the electrical potentials between the cytoplasm of the cell and the extracellular space. It represents an equilibrium situation where

the concentration gradient of ions across the membrane is equal and opposite to the electrical gradients.

Resting membrane potential is primarily influenced by sodium (Na+) and potassium (K+) ions, along with negatively charged intracellular proteins and organic phosphates. In neurons, the concentration of potassium is higher inside the cell, while sodium ions exhibit the opposite distribution. The establishment of this concentration difference is facilitated by the Na, K ATPase pump. Potassium ions passively move out of the cell, while sodium ions move into the cell.

The Goldman-Hodgkin-Katz equation is utilized to calculate the resting membrane potential since multiple ions are involved. Among these ions, potassium, which has the greatest conductance across the membrane at rest, becomes the primary contributor to the resting membrane potential.

Goldman-Hodgkin-Katz equation

$$EMF\,(millivolts) = -61 \times \log \frac{C_{Na_i^+} P_{Na^+} + C_{K_i^+} P_{K^+} + C_{Cl_o^-} P_{Cl^-}}{C_{Na_o^+} P_{Na^+} + C_{K_o^+} P_{K^+} + C_{Cl_i^-} P_{Cl^-}}$$

The Nernst equation establishes a connection between the diffusion potential and the ion concentration difference across a membrane. The magnitude of the Nernst potential is determined by the ratio of the ion concentrations on the two sides of the membrane.

Nernst equation :

EMF(millivolts) = [61/z] X log [Co / Ci]

• EMF = electromotive force (Nernst potential)

• z = charge of ion

• Co = concentration outside

• Ci = concentration inside

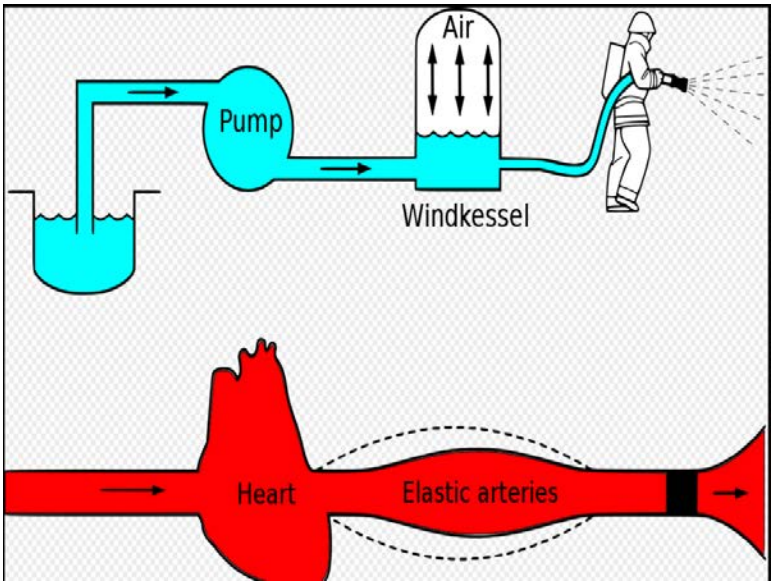
Solution to Question 12:

Windkessel effect is shown by all except the radial artery.

The windkessel effect is seen in the large elastic arteries like the aorta, carotid, and renal artery. The elasticity or windkessel effect is the exclusive property of large and elastic vessels. These vessels when stretched undergo elastic recoil.

The aorta is stretched during systole. This expansion causes temporary storage of blood, allowing more blood to enter the aorta. This buffer stock of blood is released during diastole, to maintain organ perfusion even during diastole.

The image given below shows the windkessel effect seen in the aorta.



Several methods can be used to evaluate the elastic properties of the aortic Windkessel in living humans. One simple approach is to measure the pulse wave velocity along the aorta, where a higher velocity indicates increased stiffness and elastic resistance. Alternative methods involve assessing the ratio between pulse pressure and changes in aortic volume (delta P/delta V). These methods can be noninvasively performed using ultrasound or tomographic techniques.

Solution to Question 13:

Increase in blood pressure at the beginning of the Valsalva maneuver is due to increase in intrathoracic pressure adding to aortic pressure.

Valsalva maneuver involves the performance of forced expiration against a closed glottis. It occurs during coughing, defecation, and heavy lifting. At the onset of straining, the blood pressure is raised because the increase in intrathoracic pressure is added to the pressure of the blood in the aorta. The pressure then falls as the high intrathoracic pressure compresses the veins and decreases the cardiac output.

When the glottis is opened and intrathoracic pressure returns to its normal state, cardiac output is regained, but there is constriction in the peripheral vessels. As a result, blood pressure elevates beyond the normal range, which triggers the baroreceptors, leading to bradycardia and a subsequent decrease in pressure back to normal levels.

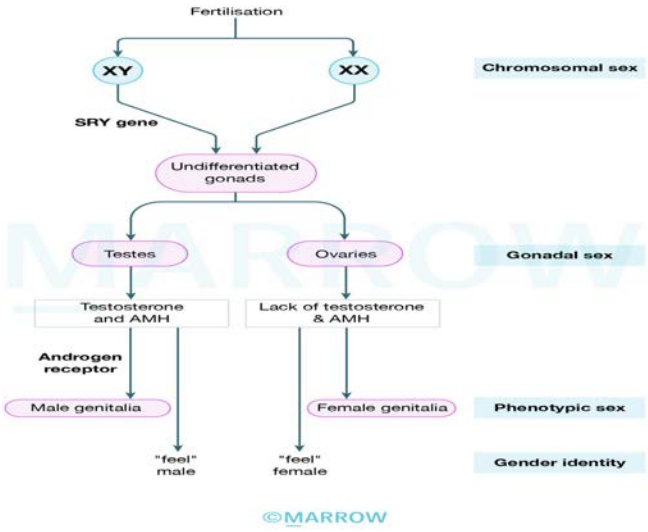
Solution to Question 14:

The embryo is bipotent till seven weeks of gestation, not eight.

At the seventh week, the embryo contains both male and female primordial genital ducts. In the case of a female fetus, uterine tubes and the uterus develops from the Mullerian duct. In case of a male fetus, the wolffian duct system on each side develops into the epididymis and vas deferens.

Testosterone is secreted by the Leydig cells of the fetal testis and MIS (Mullerian inhibiting substance) is secreted by the Sertoli cells. MIS is an amino acid that belongs to the family of transforming growth factor β (TGF-β). MIS causes apoptosis of the Mullerian ducts on the side on which it is secreted.

Dihydrotestosterone, a metabolite of testosterone is responsible for the formation of male external genitalia and male secondary sex characteristics. Development of the vas deferens, epididymis, and other structures from the wolffian ducts is due to the action of testosterone.



Solution to Question 15:

The upstroke of action potential (phase 0) in the sinoatrial node is due to calcium currents only. It occurs due to the influx of Ca2+ ions by the opening of voltage-gated L-type channels.

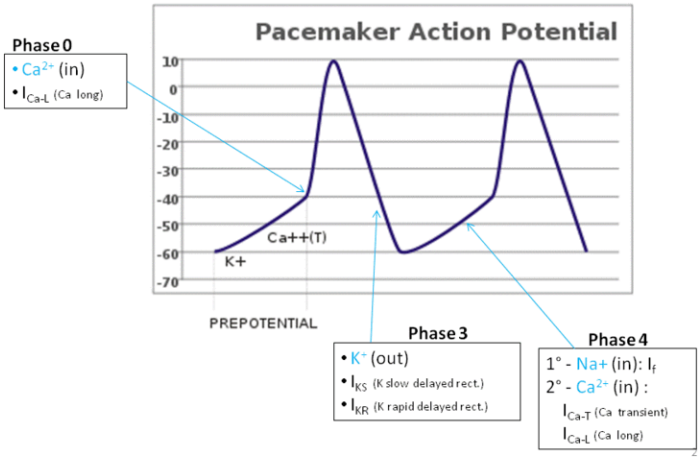
The action potential of the SA node differs from that of the atria, ventricles, and Purkinje fibres in the following ways: (1) In the absence of neural input, the SA node demonstrates automaticity and the ability to produce its own action potentials. (2) It has an unstable resting membrane potential. (3) It has no sustained plateau.

The resting membrane potential (RMP) of the SA node is -55 to -60 millivolts. Phases of this potential are:

• Phase 0 (Upstroke wave)- This is due to the influx of Ca2+ ions by the opening of voltage-gated L-type channels.

• Phase 3 (Downstroke wave)- This is due to the efflux of K+ leading to repolarization. (Option C)

• Phase 4 (Prepotential)- Because of ongoing K+ efflux, hyperpolarization sets in. This makes the channel more permeable to Na+ ions and since these Na+ channels are activated during hyperpolarization they are referred to as funny currents (Ih/ If). They form the first half of the pre-potential. The second half of the prepotential is completed by the opening of the voltage-gated T-(transient) type Ca2+ channel. The slope of Phase 4 in the SA node determines the heart rate.



Solution to Question 16:

The Carrageenan-induced pain model also called the Carrageenan-Induced Paw Edema model is a well-known model of acute inflammation.

It is employed to evaluate the anti-inflammatory properties of a variety of synthetic and natural substances. A non-antigenic phlogistic polysaccharide derived from red seaweed, carrageenan is frequently added to processed foods as a thickening, stabilising, gelling, and emulsifying agent. The activation of the complement system and inflammatory mediators is caused by the sulphated sugars found in carrageenan.

Carrageenan is injected subcutaneously into the plantar surface of the rat paw to cause inflammation. This process results in temporary inflammation and acute swelling, which peaks 3 to 5 hours after injection and subsides in 24 hours.

Postcapillary venules dilate due to the action of carrageenan, causing inflammatory cells and fluid to exude. During this process, a number of proinflammatory mediators are released. The cyclooxygenase pathway's activation is commonly associated with the carrageenan model. A biphasic curve represents the edema caused by carrageenan.

Part of the initial phase of inflammation caused by carrageenan is attributed to injection trauma and the release of acute phase mediators, particularly bradykinin, histamine, and serotonin. The second phase of carrageenan-induced inflammation, which happens about three hours after carrageenan is added, is mostly caused by prostaglandins.

Solution to Question 17:

Insulin-dependent (not independent) glucose transporter is found in the adipose tissue.

Glucose uptake by skeletal muscle, cardiac muscle and adipose tissues is via GLUT-4 which is insulin-dependent.

In the cytoplasm of insulin-sensitive cells, the vesicles contain a pool of GLUT-4 molecules. When the insulin receptors of these cells are activated, the vesicles move rapidly to the cell membrane and fuse with it, inserting the transporters into the cell membrane.

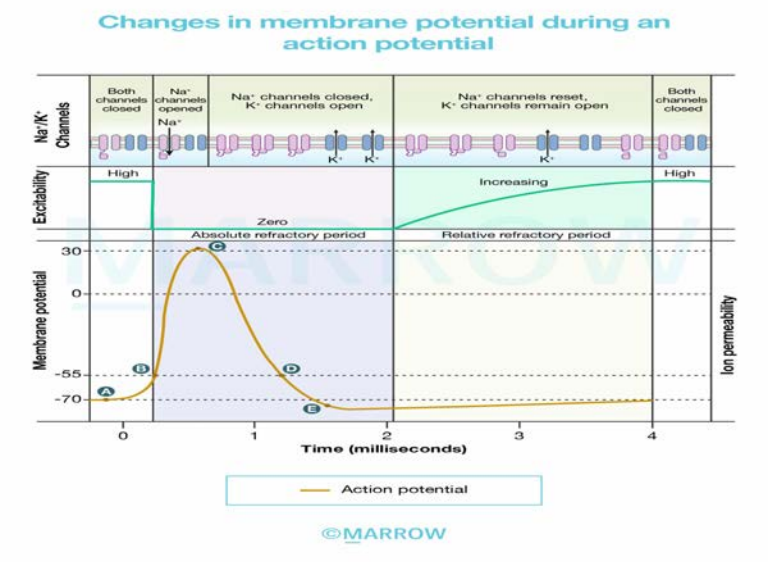
The membrane patches containing transporters are endocytosed when insulin action stops, preparing the vesicles for subsequent insulin exposure. Phosphoinositol 3-kinase is activated by the insulin receptor, which causes the vesicles to migrate to the cell membrane

Most of the other GLUT transporters are not insulin-sensitive and are constitutively expressed in the cell membrane. Ex: GLUT-1 in RBC's and brain, GLUT-2 in the beta cells of the pancreas and GLUT-3 present in the brain and kidneys.

Solution to Question 18:

The phase C to D in the given nerve action potential is caused by K+ efflux as a result of the opening of the K+ channels, resulting in repolarization.

The sequence of events occurring during an action potential is shown below



• Point A represents the resting state where both channels are closed.

• Na+ channels open in response to depolarizing stimulus resulting in Na+ influx (option A). The initiation of action potential occurs only after a certain potential is reached, which is called the threshold potential represented by point B.

• After this, the sodium influx causes the opening of more Na+ channels through a positive feedback mechanism. Rapid depolarization occurs to reach point C.

• At point C, Na+ channels close and K+ channels open, causing repolarization due to K+ efflux.

• Point D represents continued depolarization due to K+ efflux.

• At point E, Na+ channels are reset and are ready to respond to another depolarizing stimulus. During this phase, the K+ channels remain open and slowly return to the closed state, causing after-hyperpolarization. As a stronger stimulus is required to reach the threshold potential, the excitability of nerve fibre is reduced at point E.

• As both channels close, the membrane returns to resting membrane potential back to point A.

Point B-D is a part of the refractory period. During this period, the application of even a stronger stimulus will not elicit an action potential.

The refractory period is divided into an absolute refractory period and a relative refractory period. During the absolute refractory period, the nerve will not be excited no matter how strong a stimulus is given. However, during the relative refractory period, stronger than normal stimuli can cause excitation.

Solution to Question 19:

The parathyroid hormone increases the plasma calcium levels by increasing osteoclastic activity and decreasing renal excretion of calcium.

By regulating intestinal reabsorption, renal excretion, and the exchange of these ions between the extracellular fluid and bone, PTH offers a potent mechanism for controlling the concentrations of calcium and phosphate in extracellular fluid.

The parathormone (PTH) increases Ca+2 concentration by:

• Increased reabsorption of Ca+2 by renal tubules, decreasing the urinary Ca+2 excretion

• Increasing bone resorption, leading to Ca+2 release into the ECF

• Decreased phosphate reabsorption by the renal tubules, increasing the urinary excretion of phosphate

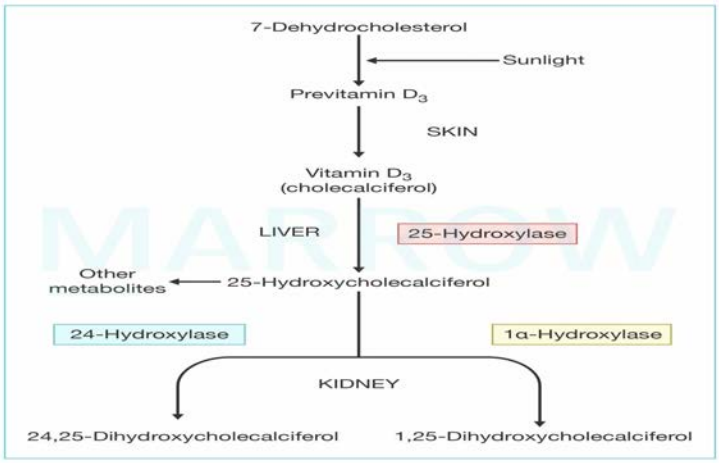
• Conversion of 25-hydroxycholecalciferol to 1,25-dihydroxycholecalciferol which increases intestinal Ca2+ absorption

Activation of the osteoclasts occurs due to activated osteoblasts and osteocytes that send secondary signals to the osteoclasts. Preosteoclast cells become mature osteoclasts when their receptors are activated by RANKL, a significant secondary signal. Activation of the osteoclastic system occurs in two stages: (1) immediate activation of the osteoclasts that are already formed and (2) formation of new osteoclasts.

PTH administration decreases proximal tubular reabsorption of phosphate ions, which results in a rapid loss of phosphate in the urine. At the same time that PTH reduces phosphate reabsorption, it also increases calcium reabsorption through renal tubules. This ultimately leads to a decrease in the renal excretion of calcium.

Furthermore, it increases the reabsorption of hydrogen and magnesium ions while decreasing the reabsorption of ions from amino acids, potassium, and sodium in a manner similar to how it affects phosphate. Distal tubules and the thick ascending loop of the Henle are the primary sites

of the increased calcium reabsorption.



Various steps in formation and hydroxylation of Vitamin D3

Solution to Question 20:

In the given cross-section of a muscle spindle, the structure marked shows intrafusal muscle fibres, which are innervated by gamma(γ) motor neurons.

Each muscle spindle is 3 to 10 mm long and consists of 3 to 12 tiny intrafusal muscle fibers that are pointed at their ends and attached to the glycocalyx of the surrounding large extrafusal muscle fibers. There are two kinds of sensory endings in each spindle, a single primary (group Ia) ending and up to eight secondary (group II) endings.

Intrafusal fibers are of 2 types: (1) nuclear bag fibers - subdivided as dynamic and static nuclear bag fibers and (2) nuclear chain fibers.

Each intrafusal muscle fiber is a tiny skeletal muscle fiber. Since there are either few or no actin and myosin filaments in the centre of each of these fibres, the centre does not contract when the ends do. It performs the role of a sensory receptor instead. The end portions that do contract are excited by small gamma(γ) motor nerve fibers which help control basic muscle tone.

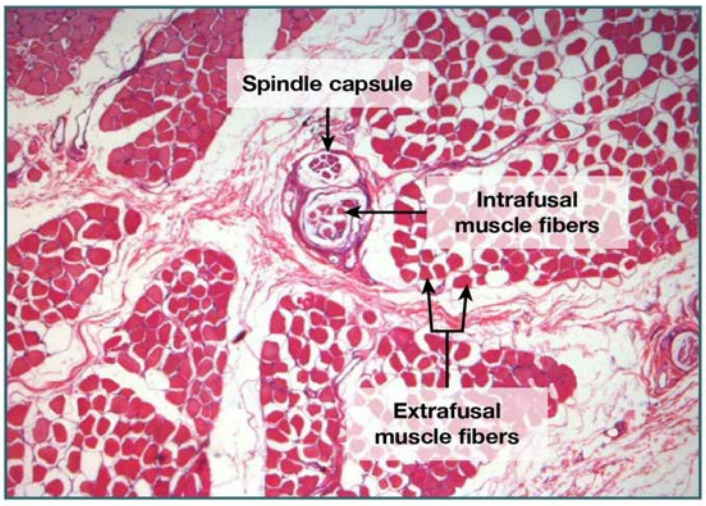
There are two types of γ motor neurons- (a) dynamic that supplies dynamic nuclear bag fibers and (b) static that supply static nuclear bag fibers and nuclear chain fibers.

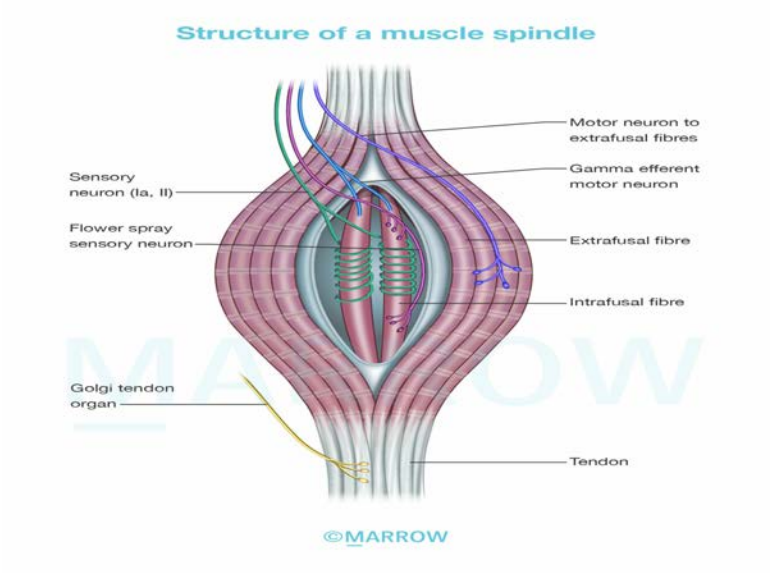
Other options:

Option B: Alpha (α) motor fibers supply the extrafusal muscle fibers which are the regular contractile units of the muscle. They are on an average 14 micrometers in diameter and these fibers branch many times after they enter the muscle and innervate the large skeletal muscle fibers at the motor endplate. A single alpha nerve fibre can stimulate anywhere between three to several hundred skeletal muscle fibres, which are collectively called the motor unit.

Option C: Beta (β) motor fibers are for touch and pressure.

Option D: Delta (δ) motor fibers are for pain and temperature.





Solution to Question 21:

Vagal stimulation due to peritoneal stretching is responsible for bradycardia following CO_2 insufflation during laparoscopic surgery.

Carbon dioxide (CO_2) and nitrous oxide (N_2O) are used in pneumoperitoneum, a technique that enhances laparoscopic surgery by distending the abdominal cavity and splitting up its contents.

The physiologic effects of CO_2 pneumoperitoneum can be divided into local and systemic effects:

CO_2 pneumoperitoneum is associated with the risk of pathophysiological cardiovascular changes such as severe bradycardia, arrhythmia, and cardiac arrest requiring cardiopulmonary resuscitation. These changes are known to be associated with vagal-mediated cardiovascular reflexes triggered by rapid peritoneum distension due to insufflation.

This can be managed by desufflation of the abdomen, the use of vagolytic medications (such as atropine), and sufficient volume replacement.

Most people can tolerate the hemodynamic and metabolic effects of pneumoperitoneum for a brief duration, and most healthy people can tolerate them for a longer period of time. Long laparoscopic procedures can be challenging for patients whose cardiovascular systems are compromised.

In such cases, alternative gases like helium, neon and argon can be used. They do not cause any metabolic effects, but if they get direct access to the venous system, they can cause gas emboli because they are not as soluble in blood as CO_2 and N_2O.

Gas embolism is treated by positioning the patient in a left lateral decubitus position, head down, to trap the gas in the right ventricle's apex. The gas can then be aspirated out of the right ventricle using a rapidly placed central venous catheter.

Limiting intra-abdominal pressure (IAP) below 12-15 mmHg during insufflation is also effective in preventing pathophysiological changes of pneumoperitoneum.

Local Effects	Systemic effects
Peritoneal distention	Hypercarbia
Vagal reaction	Acidosis
Elevated diaphragm	Increased afterload
Altered venous return	Increased catecholamines

Solution to Question 22:

The sodium transporters present in the early part of PCT are Na-K-ATPase, Na+-glucose cotransporter (SGLT) and Na+-H+ antiporter.

Reabsorption of sodium in different parts of the nephron are:

• Proximal convoluted tubule (PCT):

• Nearly 60% of the filtered sodium is reabsorbed in the PCT. Solutes mainly absorbed in the proximal tubule are sodium, chloride, bicarbonate, phosphate, lactate, glucose, amino acids etc.

• Na^+ is actively pumped from these cells into the interstitial space by Na-K ATPase in the basolateral membrane after travelling by cotransport or exchange via the tubular lumen into the tubular epithelial cells along its concentration and electrical gradients. It extrudes three Na^+ in exchange for two K^+ that are pumped into the cell.

• In early PCT, the main sodium channels used for reabsorption are Na+-glucose cotransporter (SGLT), Na+-H+ antiporter, Na+-amino acid cotransporter, Na+-phosphate cotransporter, etc.

• In distal PCT, due to high chloride concentration in the lumen, it favours NaCl reabsorption, driven by Cl^- gradient.

• The total solute and water reabsorption are proportional to each other. Thus, the entire proximal tubule also reabsorbs nearly 60% of the filtered water (isosmotic reabsorption).

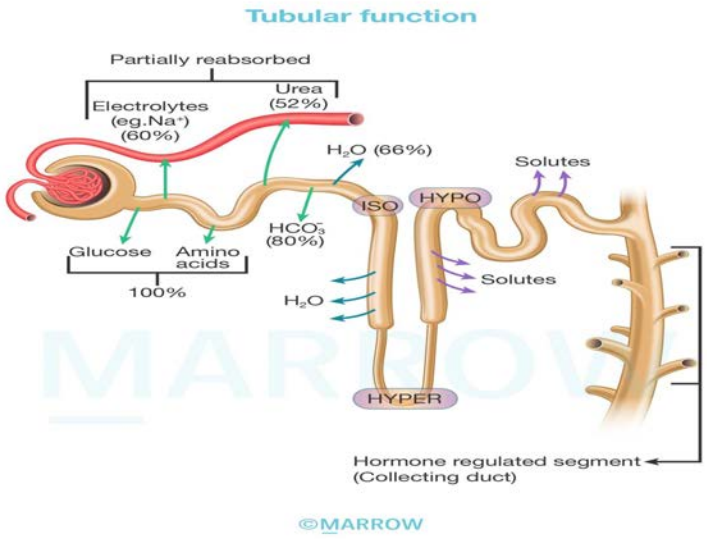
• Loop of Henle:

• The thin descending limb has no active transport of Na+ outside the lumen but the loop is permeable to water, making the tubular fluid hypertonic.

• A thick ascending limb reabsorbs nearly 30% of the Na+ by Na–2Cl–K cotransporter, an example of secondary active transport. This loop is impermeable to water. Since some of the solutes are reabsorbed and water is not reabsorbed, it dilutes the tubular fluid.

• Distal convoluted tubule: Approximately 7% of the filtered load of sodium chloride is reabsorbed in the early distal tubule. This occurs due to the presence of sodium chloride co-transporter. Even this segment dilutes the tubular fluid as it is impermeable to water.

• Cortical collecting tubule: The remaining 3% of the filtered Na+ is absorbed via ENaCs (epithelial sodium channels) in this duct. This portion is regulated by aldosterone to maintain homeostasis in Na+ balance.



Solution to Question 23:

Baroreceptors are not located in the deep smooth muscle layer. They are located in the adventitia layer.

Baroreceptors are mechanoreceptors which respond to stretch stimuli. They are located in the heart and adventitia of the blood vessels. There are two types of baroreceptors: high-pressure arterial baroreceptors and low-pressure volume receptors. Arterial baroreceptors are located within the carotid sinuses and the aortic arch.

The carotid sinus is a small dilation of the internal carotid artery just above the bifurcation of the common carotid into external and internal carotid branches. The afferent nerve fibres from the carotid sinus form a distinct branch of the glossopharyngeal nerve (CN IX), the carotid sinus nerve.

Afferent signals from both the aortic and carotid sinus baroreceptors are sent to the nucleus tractus solitarius (NTS) and they create a negative feedback loop that keeps arterial blood pressure within normal limits.

By stimulating these arterial baroreceptors in response to vascular distension, elevated arterial blood pressure can be reflexively brought back to normal levels by decreasing peripheral sympathetic outflow and activating peripheral parasympathetic outflow.

Three subsequent functional processes must take place in order to convert a mechanical change in the arterial vasculature into an excitatory signal:

• Vascular distension and the deformation of arterial baroreceptor terminals

• Mechanoelectrical transduction converts the mechanical deformation of arterial baroreceptor nerve terminals into baroreceptor membrane depolarization. Mechanosensitive ion channels such as the epithelial Na+ channels (ENaCs), acid-sensing ion channels (ASICs) and transient receptor potential (TRP) ion channels are responsible for mechanoelectrical transduction in arterial baroreceptor nerve terminals.

• Translation of membrane depolarization into action potentials via voltage-gated ion channels (Na+, Ca2+ and K+).

Physiology INI-CET 2024

Question 1:

Which of the following are properties of ventricular cardiac muscle?

a) 1,2

b) 1,2,3

c) 1,2,4

d) 1,2,3,4

Question 2:

Which of the following may lead to a decrease in GFR?

a) Increase in renal blood flow

b) Decrease in glomerular oncotic pressure

c) Increase in glomerular hydrostatic pressure

d) Decrease in bowman capsule oncotic pressure

Question 3:

Which is the most potent naturally occurring estrogen?

a) Estradiol

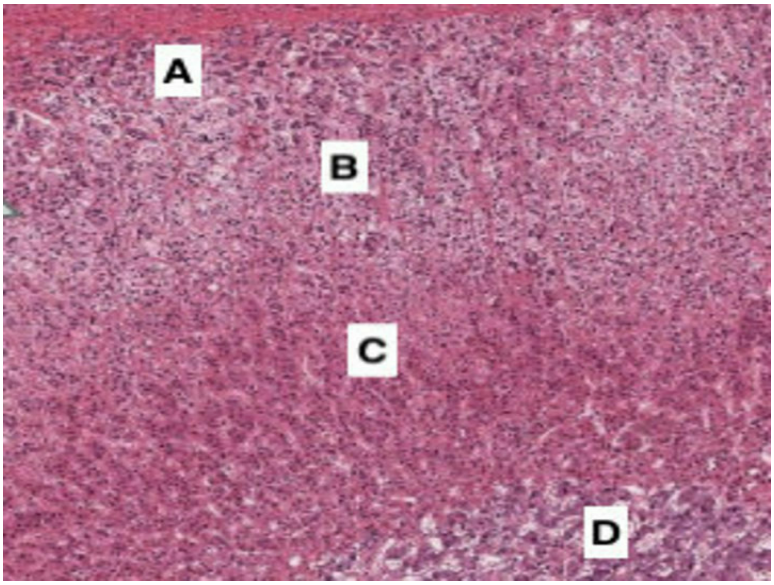
b) Estriol

c) Estrone

d) Conjugated Estrogen

Question 4:

Which hormones are produced from the zones labelled in the image given?



a) A-cortisol, B-aldosterone, C-androgens, D-epinephrine

b) A-epinephrine, B-cortisol, C-aldosterone, D-androgens

c) A-aldosterone, B-epinephrine, C-androgens, D-cortisol

d) A-aldosterone, B-cortisol, C-androgens, D-epinephrine

Question 5:

Erythropoietin is produced by:

a) 1 only

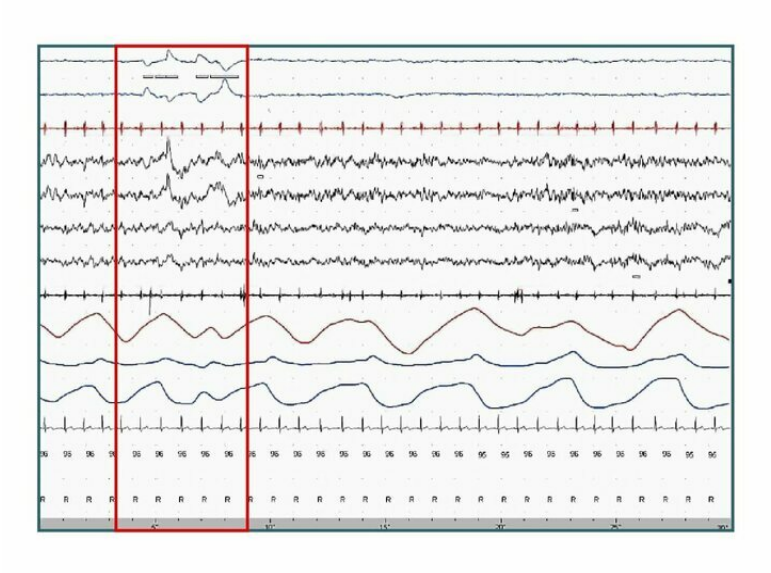
b) 2 only

c) 1,2

d) 1,2,3,4

Question 6:

EOG, EEG, and EMG of a patient are given respectively from above downwards. Which stage of sleep does the marked area represent?



a) NREM I sleep

b) NREM II sleep

c) REM sleep

d) NREM III sleep

Question 7:

Which of the following statements is incorrect regarding ABO blood grouping?

a) Antibodies are naturally present since birth

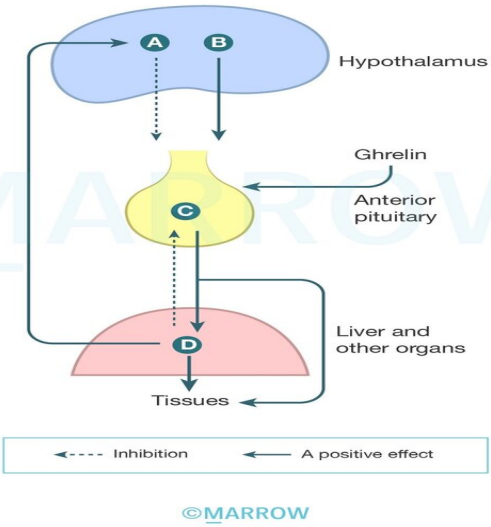
b) The antigens are carbohydrate in nature

c) The antibodies are predominantly IgM

d) Antibodies are present only if antigens are absent

Question 8:

Identify the hormones marked in the image given



a) A-Somatostatin, B-GHRH, C-GH, D-IGF-1

b) A-GHRH, B-GH, C-IGF-1, D-Somatostatin

c) A-GHRH, B-Somatostatin, C-GH, D-IGF-1

d) A-GH, B-GHRH, C-IGF-1, D-Somatostatin

Question 9:

Identify the correct sequence.

a) Protein kinase A » Adenylyl cyclase » cAMP

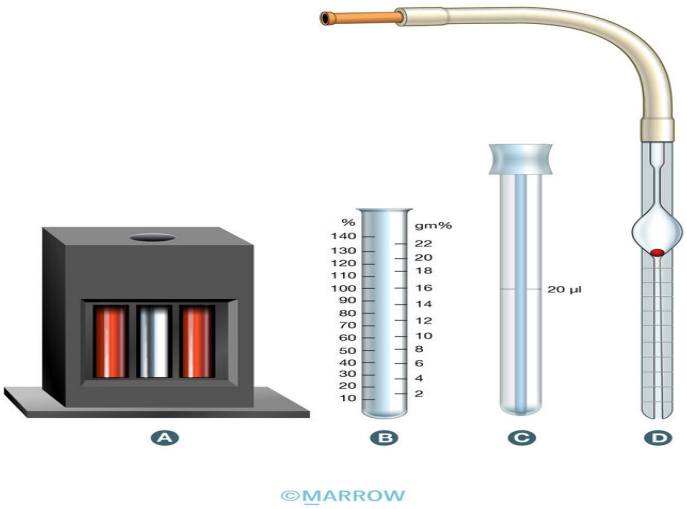
b) cAMP » Adenylyl cyclase » Protein kinase A

c) Adenylyl cyclase » cAMP » Protein kinase A

d) Protein kinase A » cAMP » Adenylyl cyclase

Question 10:

Which among the following instruments is not used in the Sahli's method of hemoglobin estimation?



a) A

b) B

c) C

d) D

Question 11:

Which neurotransmitter is secreted by the SA node in response to increased blood pressure?

a) Acetylcholine

b) Epinephrine

c) Norepinephrine

d) Dopamine

Question 12:

Match the following hormones with their receptors.

a) A-1, B-2, C-3, D-4

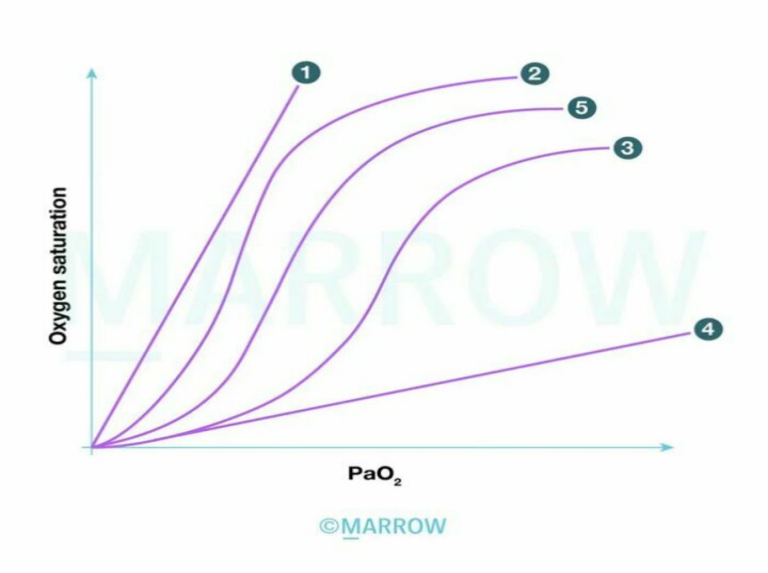
b) A-1, B-3, C-2, D-4

c) A-3, B-4, C-1, D-2

d) A-4, B-2, C-3, D-1

Question 13:

The O2 saturation with respect to PO2 is shown by the curve marked as 5. What happens to the oxygen Hb dissociation curve on transfusion of stored RBCs?



a) 2

b) 3

c) 4

d) 1

Question 14:

Not seen in decompression sickness

a) Vision loss

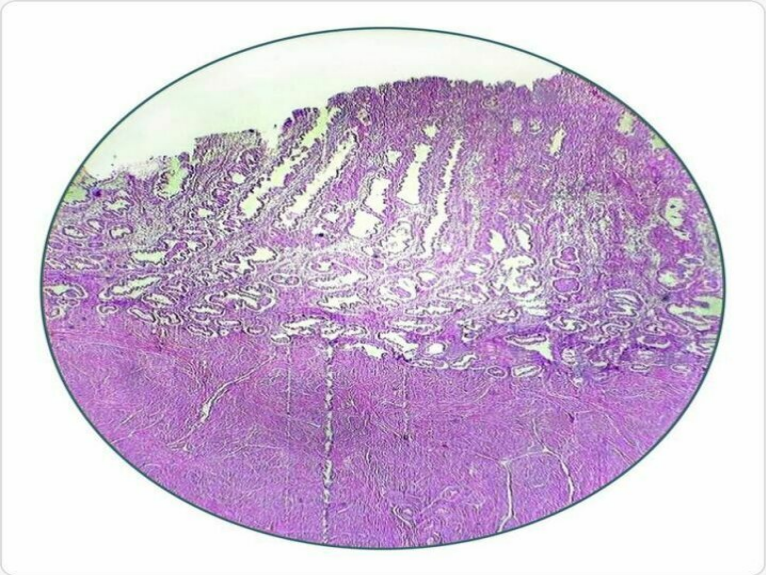
b) Hearing loss

c) Hemodilution

d) Coagulopathy

Question 15:

Which of the following ovarian structures is responsible for the following finding?



a) Secondary follicle

b) Theca interna

c) Granulosa cell

d) Corpus luteum

Question 16:

Which of the following does not form the inner component of photoreceptors?

a) Mitochondria

b) Membranous disc

c) Golgi apparatus

d) Endoplasmic reticulum

Question 17:

Which of the following does not stimulate catecholamine synthesis?

a) Hyperglycemia

b) Smoking

c) Standing posture

d) Exercise

Question 18:

While collecting a blood sample for serum calcium, which is easily alterable, which of the following should be prevented to measure it accurately?

a) If a tourniquet is needed, tie and release as soon as the sample is collected.

b) Collecting after exercise.

c) Making a fist is not recommended.

d) Not collecting samples from patients immobilized for long periods of time

Question 19:

Which receptor contributes to static 2 point discrimination?

a) Merkel cell

b) Meissner corpuscle

c) Pacinian corpuscle

d) All of them

Question 20:

Mitochondrial sheaths are found in which part of the sperm?

a) Tail

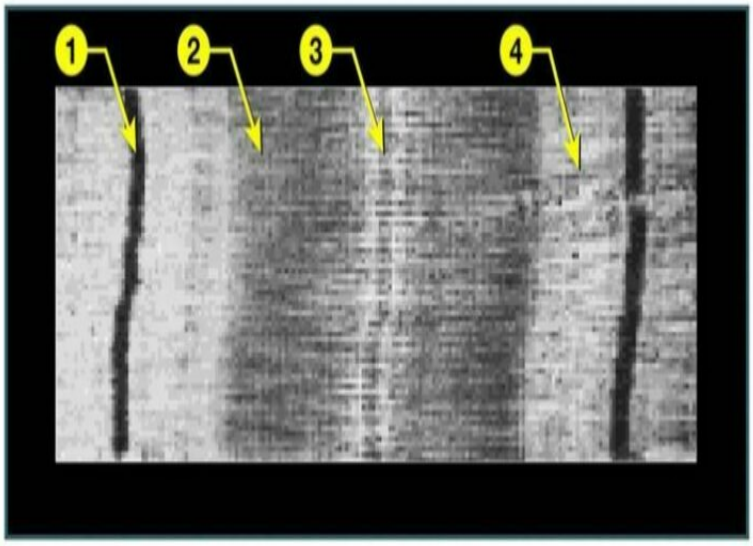
b) Middle piece

c) Principal piece

d) Connecting piece

Question 21:

Identify the correct option



a) 1-Z line, 2-A band, 3-H zone, 4-I band

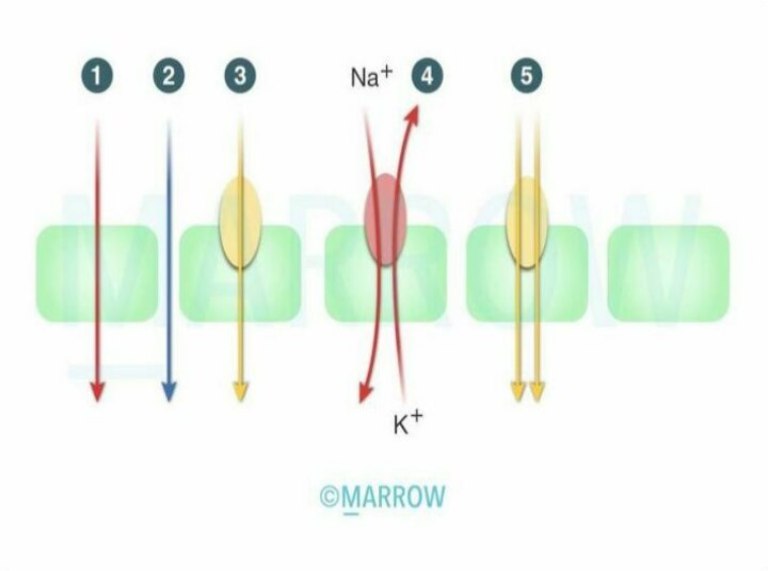
b) 1-A band, 2-Z line, 3-H zone, 4-I band

c) 1-T tubule, 2-I band, 3-H zone, 4-A band

d) 1-T tubule, 2- A band, 3-I band, 4-H zone

Question 22:

Which of these drug transport systems do not require ATP?



a) 1,2,3

b) 2,3,4

c) 3,4,5

d) 1,2,5

Question 23:

Choose the correct options from the given statements of the enteric nervous system-

a) 1,2,3

b) 1,4

c) 1,3

d) 2

Question 24:

What causes decrease in GFR?

a) Decrease in glomerular coefficient

b) Decrease in glomerular oncotic pressure

c) Increase in glomerular hydrostatic pressure

d) Decrease of Bowman's hydrostatic pressure

Question 25:

A 70-year-old man with a BP of 170/100mmHg. What is the reason for the increased pulse pressure in this patient?

a) Decreased arterial compliance

b) Increased cardiac output

c) Increased sympathetic outflow

d) Increased myocardial contractility

Question 26:

Physiological dead space :

a) Can be measured by spirometry

b) Is lesser than anatomical dead space

c) Represents inadequately ventilated alveoli

d) Represents inadequately perfused alveoli

Question 27:

What contributes to the latent period of muscle twitch?

a) 1,2,4

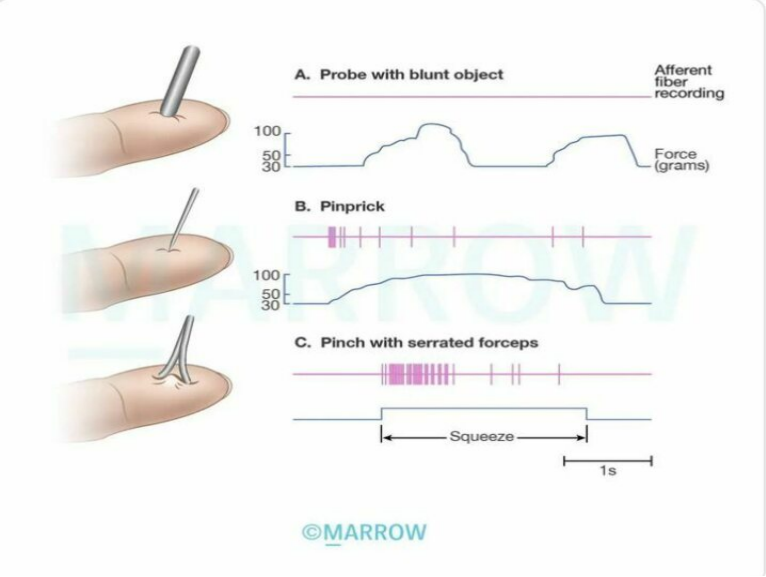
b) 1,2,3

c) 3,4

d) 2,3

Question 28:

Mechanical nociceptors and their response to a probe with a blunt object, pinprick, and toothed forceps with serrations are recorded as an output of a force transducer coupled to the stimulator. What could be inferred from this?



a) There are no responses from the nociceptors when stimulated by blunt forceps

b) Pinching with toothed forceps causes stimulation of mechano-nociceptors, but no pain

c) Pricking with a needle does not stimulate nociceptors

d) Sharp pain sensation is carried by C fibres

Question 29:

Peripheral chemoreceptors are most sensitive to?

a) Hypercapnia

b) Hypoxia

c) Acidosis

d) Alkalosis

Question 30:

Identify the marked structure.

a) Intercalated disc

b) Connective tissue

c) Cytoskeletal condensation

d) Nerve fibre

Question 31:

Which blood component is not separated by centrifugation in the blood bank?

a) Red blood cells

b) Platelets

c) Cryoprecipitate

d) Albumin

Answer Key

Question No.	Correct Option
1	b
2	d

28	a
29	b
30	a
31	d

Detailed Explanations

Solution to Question 1:

All or none phenomenon, length tension relationship and long refractory period applies to cardiac muscles. Cardiac muscle cannot be tetanized due to long refractory period.

In cardiac myocytes, depolarization proceeds rapidly and an overshoot of the zero potential is present. This is followed by a plateau before the membrane potential reaches the RMP (-90mV). This plateau phase lasts for 200 msec or more. Repolarization is therefore not complete until contraction is 50% completed.

Phases of cardiac action potential

• 0→ Depolarisation and overshoot-Due to opening of voltage-gated Na+ channels

• 1→ Initial rapid repolarization-Due to closure of Na+ channels and opening up of K+ channels

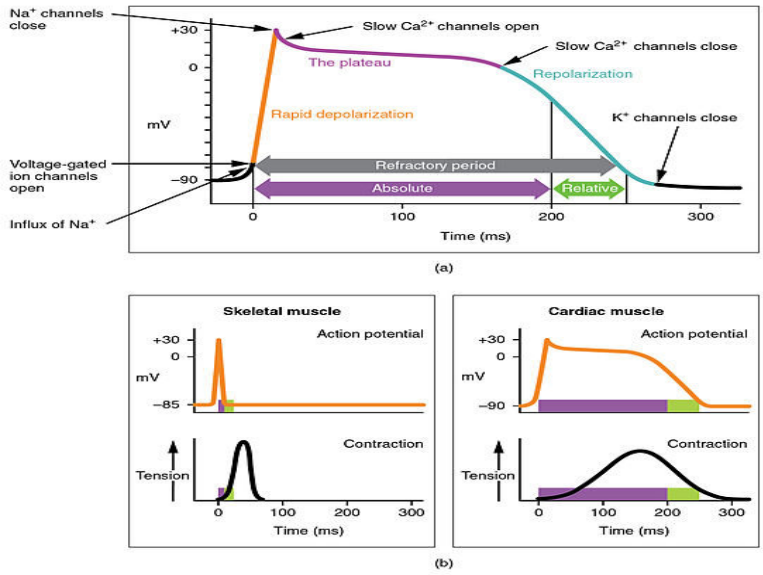
• 2→ Plateau phase - Due to slow but prolonged opening of Ca2+ channels

• 3→ Late rapid repolarization

• 4→ Baseline (RMP)

Phases 3 and 4 are due closure of Ca2+ channels and a slow, delayed increase of K+ efflux through K+ channels.

During phases 0 to 2 and about half of phase 3 of cardiac action potential, cardiac muscle cannot be excited again, that is, it is in its absolute refractory period. It remains relatively refractory until phase 4. Thus, cardiac muscle cannot be tetanized.



Solution to Question 2:

A decrease in bowman's capsule oncotic pressure would lead to a decrease in GFR.

Glomerular filtration rate (GFR) is the volume of fluid filtered from the renal glomerular capillaries into the Bowman's capsule per unit time.

The GFR is determined by sum of the hydrostatic and colloid osmotic forces across the glomerular membrane, which gives the net filtration pressure. It is dependant on Glomerular Kf (glomerular ultrafiltration coefficient) also.

Mathematically, it can be expressed as follows:

GFR= Kf [PG + πB -PB- πG]

Forces favoring Filtration

• PG: Glomerular hydrostatic pressure

• πB: Bowman's capsule oncotic pressure

Forces opposing Filtration

• PB: Bowman's capsule hydrostatic pressure

• πG: Glomerular capillary oncotic pressure

Factors that can increase the GFR are as follows:

• Increase in glomerular capillary filtration coefficient Kf: This coefficient depends on the hydraulic conductivity and surface area of the glomerular capillaries.

• Decrease in Bowman's capsule hydrostatic pressure: Conditions with urinary tract obstruction can lead to an increase in this pressure and a fall in GFR.

• Decrease in glomerular colloid osmotic pressure: Accumulation of plasma proteins that are not filtered from the blood contributes to this pressure and an increase reduces the further filtration and GFR. It is directly proportional to the following factors:Arterial plasma colloid osmotic pressure

• Filtration fraction

Solution to Question 3:

Estradiol is the most potent naturally occurring estrogen.

Classic estrogens are C18 steroid compounds containing a phenolic ring. Only three estrogens are present in significant quantities in the plasma of the human female—β-estradiol, estrone, and estriol.

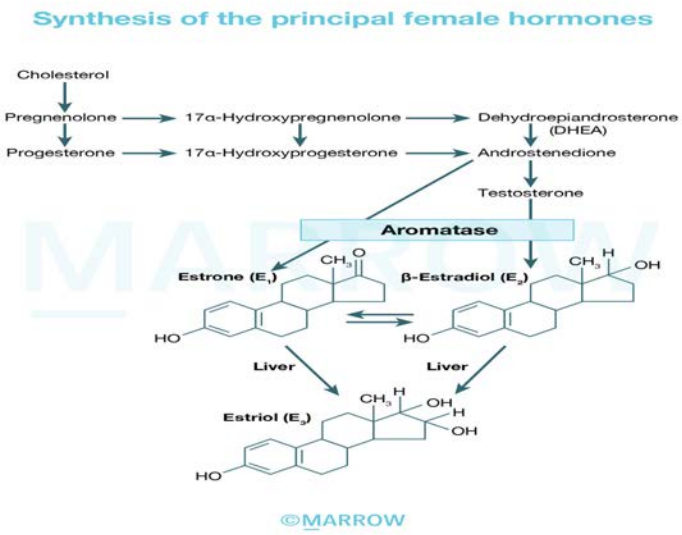
The principal estrogen secreted by the ovaries is β-estradiol.

Small amounts of estrone are also secreted, but most of this is formed in peripheral tissues from androgens secreted by the adrenal cortices and by ovarian thecal cells.

Estriol is a weak estrogen; it is an oxidative product derived from both estradiol and estrone, with the conversion occurring mainly in the liver.

The estrogenic potency of β-estradiol is 12 times that of estrone and 80 times that of estriol. Hence, estradiol is the most potent natural form of estrogen.

In the liver, estradiol, estrone, and estriol are converted to inactive glucuronide and sulfate conjugates. All these compounds, along with other metabolites, are excreted in the urine.



Solution to Question 4:

Option D is the correct option. This is a section through an adrenal gland showing both the medulla and the zones of the cortex. Following are the zones of the cortex and medulla, and the hormones they secrete.

A – Zona Glomerulosa – secretes mineralocorticoids (aldosterone)

B – Zona Fasciculata – secretes glucocorticoids (cortisol, corticosterone)

C – Zona Reticularis – secretes androgens (dehydroepiandrosterone)

D – Adrenal Medulla – Produces Catecholamines: Norepinephrine, Epinephrine, and Dopamine

On histological examination, the different layers are identified as:

• Outer zona glomerulosa - small, compact cells

• Central zona fasciculata - larger lipid-rich cells arranged in radial columns

• Inner zona reticularis - pigmented, compact cells

• Adrenal medulla - thin layer of large chromaffin cells

Solution to Question 5:

Erythropoietin is produced mainly by kidney and liver.

In adults, approximately 85% of erythropoietin is produced by the kidneys, while 15% is synthesized by the liver. Both of these organs possess the mRNA necessary for erythropoietin production. Although erythropoietin can be found in the spleen and salivary glands, these tissues

lack the mRNA required for its synthesis, indicating that they do not produce the hormone.

Erythropoietin is secreted by interstitial cells in the peri-tubular capillary bed of the kidneys and by perivenous hepatocytes in the liver. It is also generated in the brain, where it provides a safeguarding effect against excitotoxic harm caused by hypoxia; and in the uterus and oviducts, where it is stimulated by estrogen and seems to facilitate estrogen-driven angiogenesis.

Solution to Question 6:

REM sleep is represented by the marked area in the given polysomnography.

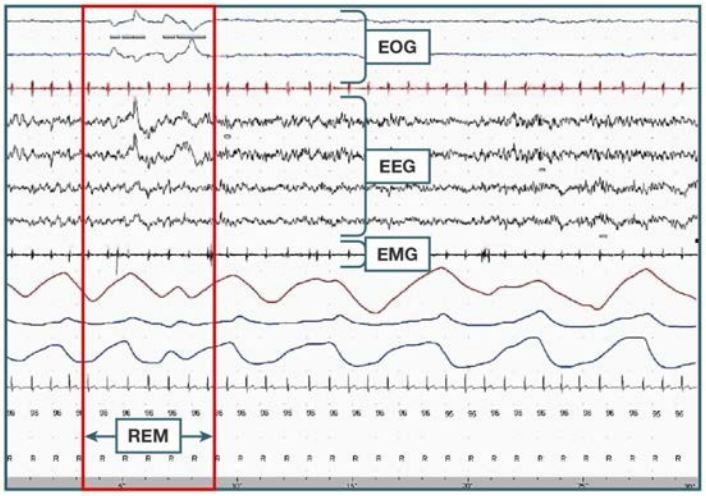
The three zones in the given image represent EOG, EEG, and EMG, respectively. In the marked area,

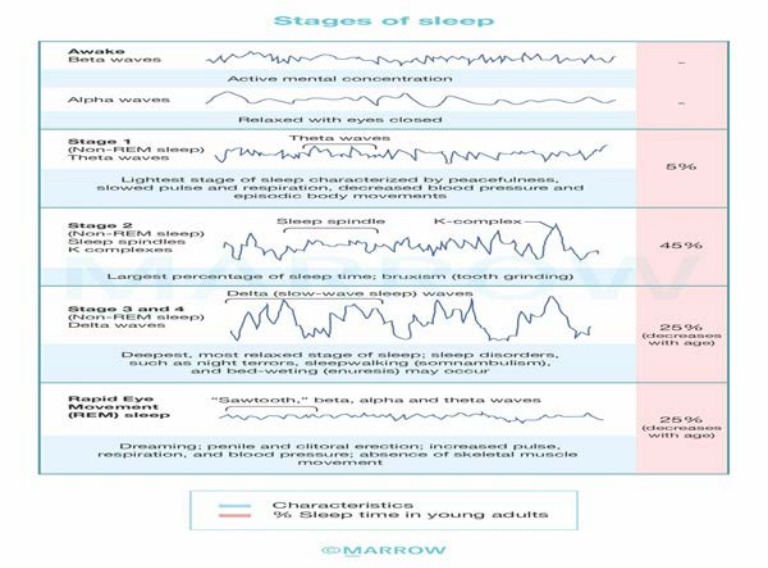
• EOG shows Positive activity

• EEG shows Mixed waves

• EMG shows Minimal activity

This is characteristic of REM sleep.





Solution to Question 7:

Antibodies are not present since birth. At 2 to 8 months after birth, an infant begins to produce agglutinins (antibodies).

In the absence of type A agglutinogen(antigen) in an individual's RBCs, antibodies called anti-A agglutinins form in the plasma. Similarly, when type B agglutinogen is lacking in the RBCs, antibodies referred to as anti-B agglutinins develop in the plasma. Type A blood carries type A agglutinogens and anti-B agglutinins, while type B blood contains type B agglutinogens and anti-A agglutinins. Type AB blood possesses both A and B agglutinogens but no agglutinins. On the other hand, type O blood, which lacks agglutinogens, does have both anti-A and anti-B agglutinins.

The A and B antigens are complex oligosaccharides that differ in their terminal sugar. The agglutinins are gamma globulins produced by the bone marrow and lymph gland cells. Most of them are IgM and IgG immunoglobulin molecules.

Solution to Question 8:

In the given image, A: Somatostatin, B: GHRH, C: GH, D: IGF-1

• Growth hormone-releasing hormone (GHRH) secreted from the hypothalamus acts on the anterior pituitary to release growth hormone.

• Growth hormone (GH) increases the circulating levels of IGF -1 which exerts its effect on the tissues.

• Ghrelin promotes the secretion of growth hormone from the anterior pituitary.

• Somatostatin secreted from the hypothalamus is an inhibitory effect on the GH secretion from the anterior pituitary.

• Similarly, IGF -1 exerts negative feedback on GH secretion and positive feedback on somatostatin secretion, which in turn inhibits GH secretion.

Solution to Question 9:

The correct sequence in Gs is adenylyl cyclase » cAMP » Protein kinase A.

G protein-coupled receptors (GPCRs) are cell membrane receptors that span across the membrane 7 times. They also serve as receptors for various peptide hormones, neurotransmitters and amino acids. Subtypes of GPCRs are distinguished by their alpha subunits. The important subtypes of GPCRs are Gs, Gi, and Gq.

When hormones bind to the receptor, it enables the receptor to connect with a G protein. If the G protein activates the adenylyl cyclase-cAMP system, it is referred to as a Gs protein, indicating a stimulatory G protein. The Gs protein stimulates adenylyl cyclase, an enzyme located in the cell membrane, which then converts a small amount of cytoplasmic adenosine triphosphate into cAMP. This cAMP activates cAMP-dependent protein kinase, which phosphorylates specific proteins within the cell, initiating biochemical reactions that ultimately result in the cell's response to the hormone.

Solution to Question 10:

Option D is RBC pipette, it is not used in Sahli's method of hemoglobin estimation. The instruments used are comparator with brown glass standard(Option A), graduated hemoglobin tube(Option B), Sahli's pipette (Option C)and stirrer.

Sahli's method of estimation of hemoglobin is based on colorimetric measurement of the intensity of color developed on the addition of dilute hydrochloric acid (N/10 HCl) reagent to the blood.

In Sahli's method, hemoglobin is converted to acid hematin with the action of dilute hydrochloric acid (N/10 HCl). The brown color of the acid hematin is matched to its intensity with a standard brown glass comparator in a visual colorimeter called Sahli's colorimeter. It can be used to estimate oxyHb and reduced Hb.

Sahli's method is a simple bedside test and is cost-effective. However, it has some disadvantages, which include visual errors, the inability to measure other forms of hemoglobin like carboxyhemoglobin, methemoglobin, and sulfhemoglobin, fading of the comparator over time, and the color of acid hematin fading quickly.

The visual error can be reduced by taking the average of three readings; first, when the color is slightly darker than the standard; second, when the color exactly matches the standard; and third, when the color is slightly lighter than the standard.

Solution to Question 11:

Acetylcholine is released in response to increased blood pressure.

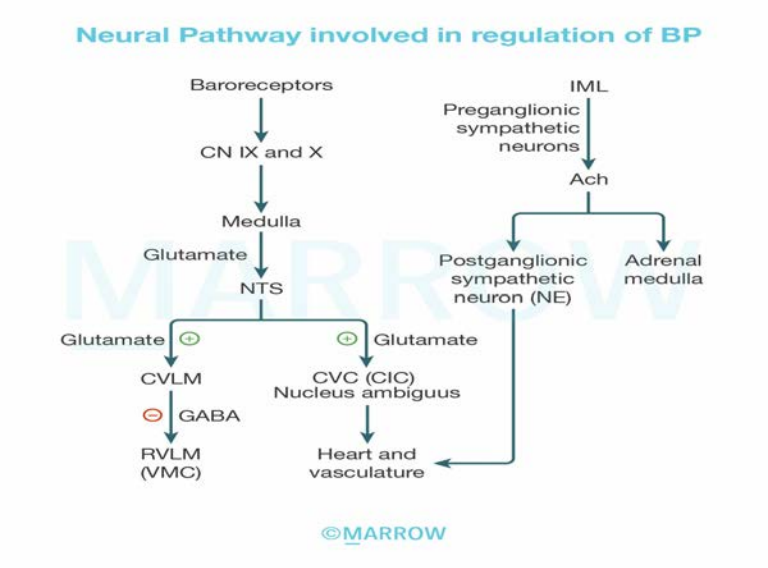
In response to raised BP, there is inhibition of sympathetic system and activation of parasympathetic system. Acetylcholine is the universal neurotransmitter of PNS.

Baroreceptors are stretch receptors located in the heart and the adventitia of the blood vessels. They are stimulated by the stretching of the walls of the blood vessels when there is an increased volume or blood pressure in the vessel. They are important in the immediate management of blood pressure. They are of two types: carotid sinus and aortic arch receptors (high-pressure regions) and cardiopulmonary receptors (low-pressure regions).

An increase in blood pressure stimulates the baroreceptors. These signals are transmitted through small Hering's nerves to the glossopharyngeal nerves and then to the nucleus tractus solitarius (NTS) in the medulla. These signals release glutamate and activate the caudal ventrolateral medulla (CVLM). This in turn inhibits the rostral ventrolateral medulla (RVLM) considered the vasoconstrictor center for the brain and the heart.

Simultaneously, this pathway also excites the vagal parasympathetic center. The stimulation of the vagus results in a slowing of impulse generation in the SA node and a slowing of conduction velocity in the AV node.

These neural changes produce vasodilation, venodilation, hypotension, bradycardia, and a decrease in cardiac output.



- NTS: Nucleus Tractus Solitarius
- CVLM: Caudal Ventrolateral Medulla
- RVLM : Rostral Ventrolateral Medulla (Vasomotor center)
- CVC : Cardiovagal center (Cardioinhibitory center)
- IML: intermediolateral nucleus

Solution to Question 12:

The correct answer is A-3, B-4, C-1, D-2.

Insulin binds to a receptor that has intrinsic tyrosine kinase activity. Upon activation, the receptor phosphorylates itself and downstream signaling proteins. (A-3)

Acetylcholine acts on nicotinic receptors, which are ligand-gated ion channels. Binding of acetylcholine opens the channel, allowing ion flow (e.g., Na■ or K■). (B-4)

Growth hormone binds to its receptor, which lacks intrinsic kinase activity but recruits Janus Kinase (JAK) to phosphorylate downstream proteins and activate the STAT (Signal Transducer and Activator of Transcription) pathway. (C-1)

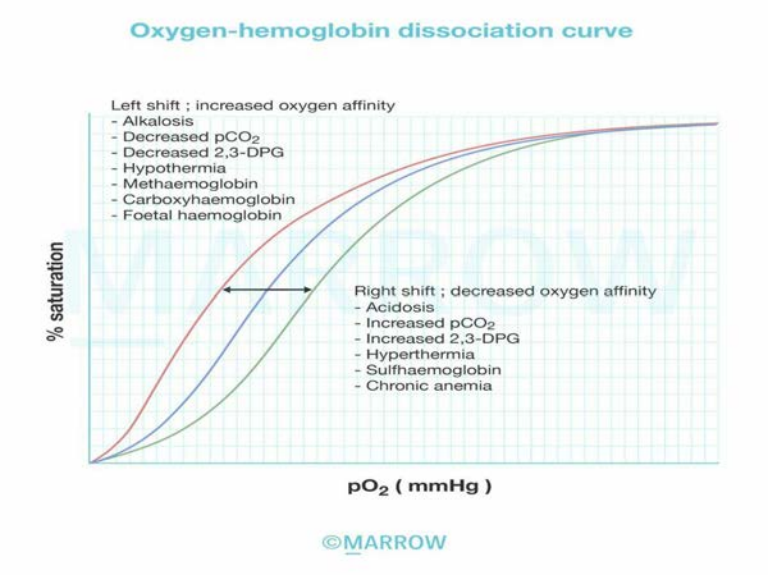
Thyroxine (and its active form, T3) binds to intracellular nuclear receptors. These hormone-receptor complexes act as transcription factors, regulating gene expression directly in the nucleus. (D-2)

Hormone	Receptor
A.Insulin	3. Tyrosine Kinase
B.Acetylcholine	4. Ligand gated

Hormone	Receptor
C.Growth Hormone	1. JAK/STAT
D.Thyroxine	2. Nuclear Receptor

Solution to Question 13:

When stored RBCs are transfused, the oxygen-hemoglobin dissociation curve typically shifts to the left but still retains its sigmoid shape as represented by the curve marked as 2.



This is due to reduced levels of 2,3-bisphosphoglycerate (2,3-BPG) in stored red blood cells. 2,3-BPG is a metabolite in RBCs that binds to hemoglobin and reduces its affinity for oxygen.

During storage, metabolic processes in RBCs slow down, leading to a depletion of 2,3-BPG. Lower 2,3-BPG levels make hemoglobin hold onto oxygen more tightly, impairing oxygen delivery to tissues. Hence, this increases hemoglobin's affinity for oxygen, shifting the curve to the left.

Other Options:

Option B and C: show a right shift to the oxygen-hemoglobin dissociation curve.↑ in 2,3-BPG seen in increased anaerobic glycolysis leads to the right shift of the curve. Storage of blood causes depletion of 2,3-BPG, hence leading to left shift instead of right.

Solution to Question 14:

Hemodilution is not seen in decompression sickness. Instead, hemoconcentration is seen in decompression sickness.

Hemodilution refers to the dilution of blood, usually due to excessive fluid intake or other medical conditions, but it is not a feature of decompression sickness.

Decompression sickness (DCS) is a condition that occurs when a person ascends too quickly after being exposed to high-pressure environments (such as deep-sea diving), causing nitrogen bubbles to form in the bloodstream and tissues.

Other options

Option A: Vision changes or loss can occur in DCS due to gas bubbles affecting the optic nerve or retinal circulation, leading to temporary or permanent vision impairment.

Option B: Gas bubbles in DCS can also affect the auditory system, leading to hearing loss or tinnitus, a common feature of the condition.

Option D: Decompression sickness can lead to coagulopathy, which refers to abnormal blood clotting due to the formation of nitrogen bubbles that disrupt the vascular system, potentially causing bleeding or clotting disorders.

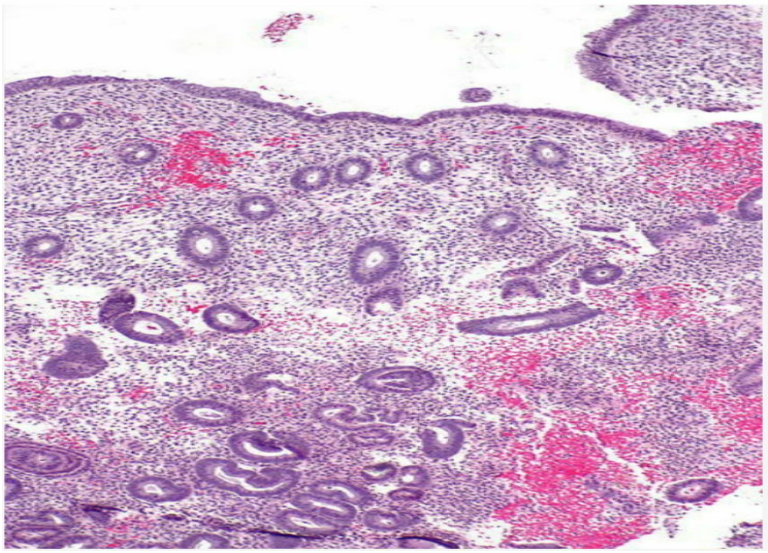
Solution to Question 15:

The ovarian structure responsible for the following finding is the corpus luteum.

The histological image shows a corkscrew appearance of the glands, and this is characteristic of the secretory phase of the endometrium in the menstrual cycle. This phase is stimulated by progesterone, which is secreted by the corpus luteum.

Endometrial Biopsy of the various stages of the ovarian cycle:

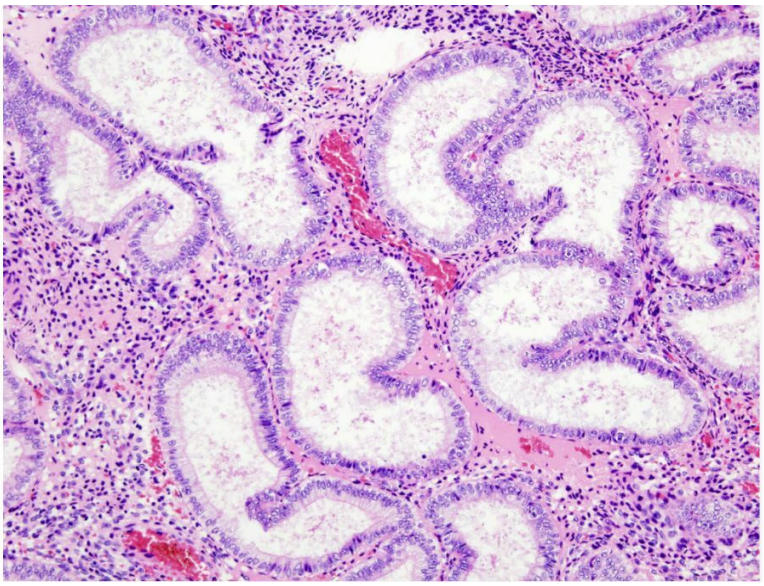
1. Proliferative phase: The glands are simple, straight, and tubular glands. The lining of the glands shows pseudostratified columnar epithelium with mitotic figures, indicating active cell proliferation. The stroma is dense and compact, with numerous cells undergoing mitosis.



2. Early secretory phase: The initially straight glands begin to coil as the endometrium transitions into the secretory phase. Subnuclear Vacuolation is seen in the epithelial cells of the endometrial

glands, caused by the accumulation of glycogen at the base of the cells.

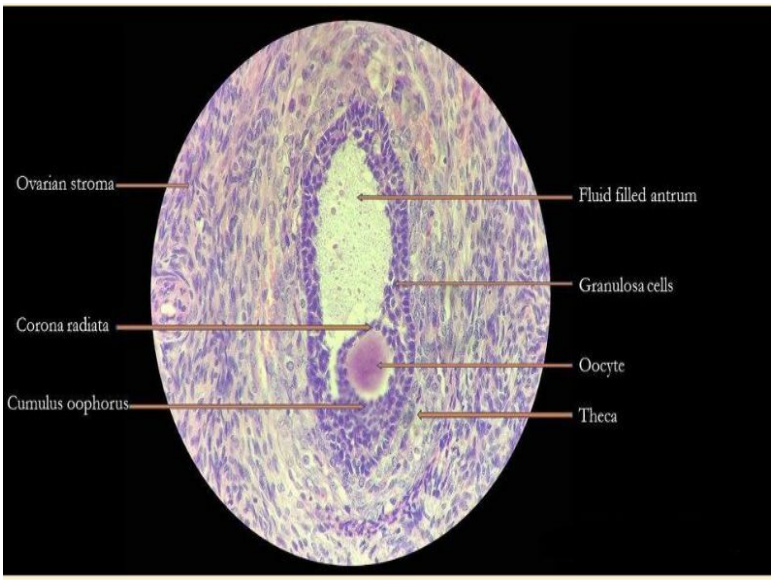
3. Late secretory phase: The glands become maximally tortuous and assume a distinctive "saw-tooth" appearance due to extreme coiling. They are filled with secretions rich in glycogen and glycoproteins, essential for supporting a potential embryo. The stroma is edematous.



Other Options:

Option A: Secondary follicle

The secondary follicle is a more advanced stage of follicular development following the primary follicle. It contains a fluid-filled cavity (antrum) surrounded by two layers: theca interna and theca externa.

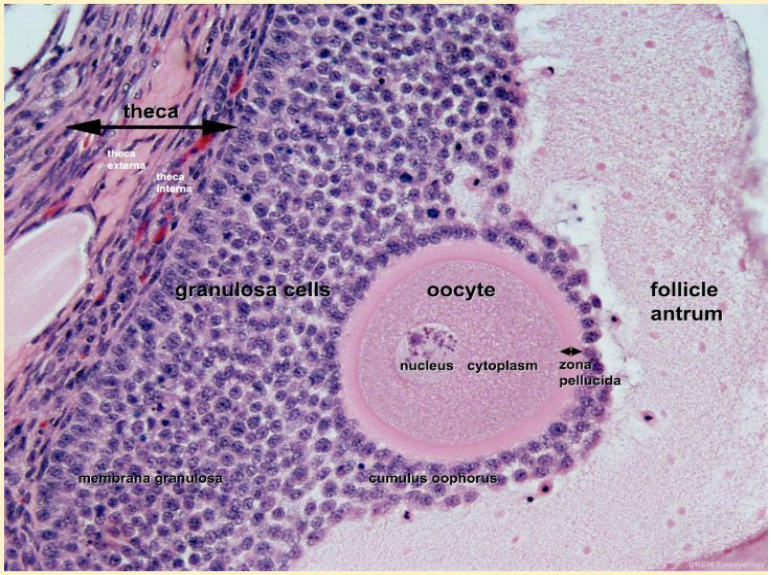


Option B and C: Theca interna and Granulosa cell

The theca interna is a layer of stromal cells just outside the basal lamina of the granulosa cells. They are composed of cuboidal endocrine cells with lipid droplets and abundant smooth

endoplasmic reticulum, reflecting its role in steroidogenesis.

Granulosa cells line the interior of the follicle. Cells are organized in layers, initially single-layered in primary follicles and multilayered in secondary follicles.



Solution to Question 16:

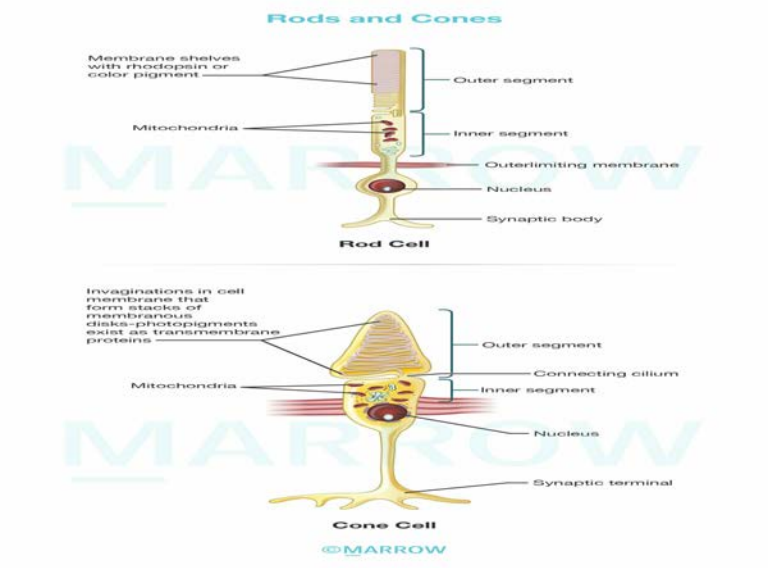
Among the given options, the membranous disc does not form the inner component of photoreceptors but instead forms the outer component.

The other three options i.e., mitochondria, Golgi apparatus, and endoplasmic reticulum form the inner component of photoreceptors.

Photoreceptors (rods and cones) are specialized neurons in the retina with distinct structural components:

• Outer segment: Contains membranous discs that have photopigments (like rhodopsin in rods and photopsins in cones) essential for light detection.

• Inner segment: Contains cellular organelles responsible for metabolism and protein synthesis, such as mitochondria, Golgi apparatus, and endoplasmic reticulum.



Solution to Question 17:

Hyperglycemia does not stimulate catecholamine synthesis. Instead, hypoglycemia stimulates catecholamine synthesis.

Catecholamine synthesis is primarily stimulated by various physiological stressors and factors that activate the sympathetic nervous system, such as physical exertion(exercise), changes in posture, or certain external stimuli like smoking.

Other options:

Option B: Smoking stimulates catecholamine release through the activation of the sympathetic nervous system, which increases catecholamines like adrenaline and norepinephrine.

Option C: When a person stands up, it can lead to orthostatic hypotension, which triggers the release of catecholamines to help increase blood pressure and maintain adequate perfusion.

Option D: Exercise stimulates the sympathetic nervous system and increases catecholamine production to support increased heart rate, blood pressure, and metabolic demands.

Solution to Question 18:

Blood collection after exercise should be prevented to measure serum calcium accurately.

Option A: A prolonged tourniquet is usually avoided while drawing blood for calcium measurements since hemoconcentration also leads to an increase in serum calcium levels. Hence, the tourniquet should be released as soon as the sample is collected.

Option C: Fist-clenching or forearm exercise can lead to falsely elevated ionized (free) calcium levels. Hence, making a fist while blood collection is not recommended.

Option D: Staying immobilised for long periods of time increases bone resorption and increases calcium levels. Hence, do not collect blood samples for serum calcium estimation in patients who are immobilised for long periods.

Solution to Question 19:

Merkel cell contributes to static 2 point discrimination.

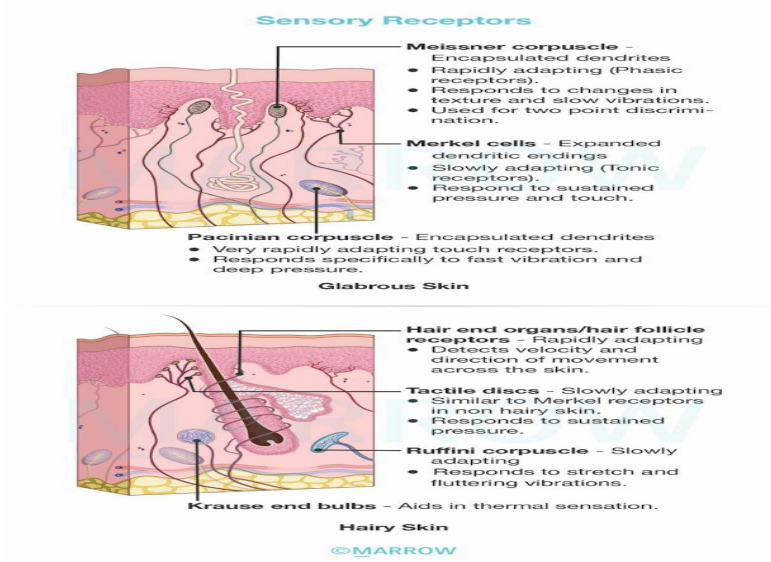
Merkel cells are responsible for static two-point discrimination. These cells are specialized for detecting pressure and texture and are involved in the detection of fine touch. They provide information about the spatial resolution of tactile stimuli, which is essential for static two-point discrimination, where the ability to differentiate between two distinct points of touch is tested.

Merkel cells are expanded dendritic endings in the epidermis of glabrous (non-hairy) skin. They respond to sustained pressure and touch. They are slowly adapting receptors.

Static vs. Dynamic Two-Point Discrimination

Static: Measures the ability to distinguish stationary points; mediated by Merkel cells (slow-adapting receptors).

Dynamic: Measures the ability to distinguish moving points; mediated by Meissner corpuscles (fast-adapting receptors).



Other options:

Option B: Meissner corpuscle: Meissner corpuscles are dendrites encapsulated in the connective tissue beneath the epidermis of glabrous (non-hairy) skin. They respond to tap and flutter (low-frequency vibration - 5-40Hz). They are rapidly adapting receptors.

Option C: Pacinian corpuscle: Pacinian corpuscles are the largest cutaneous mechanoreceptor. They are present in the dermis of glabrous (non-hairy) and hairy skin. A Pacinian corpuscle consists of a nerve ending encapsulated by concentric layers of connective tissue, giving it an onion-like appearance. They respond to fast vibration (60-500Hz) and deep pressure. They are

rapidly adapting receptors.

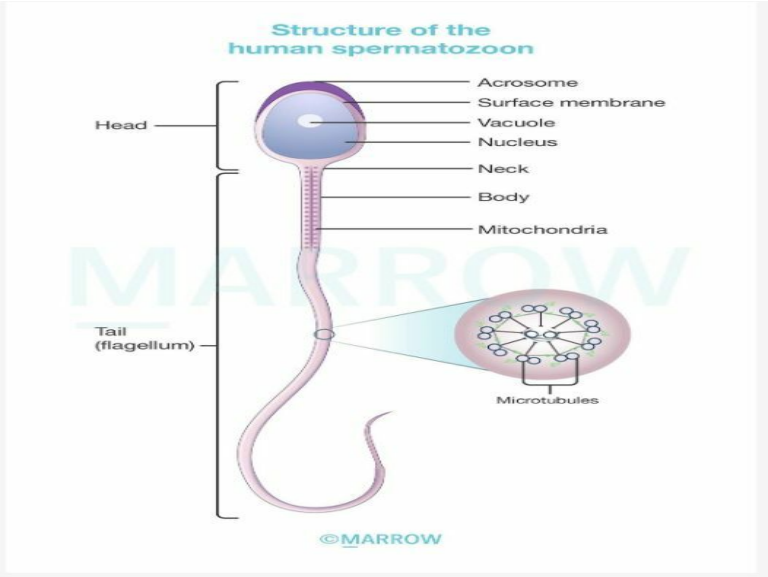
Solution to Question 20:

Mitochondrial sheaths are found in the middle piece of the sperm.

The middle piece is the segment of the sperm located just behind the head and neck.

It contains a spiral arrangement of mitochondria, forming the mitochondrial sheath around the central axoneme.

These mitochondria generate ATP, which provides the energy required for the flagellar movement of the sperm, enabling motility.



Other options:

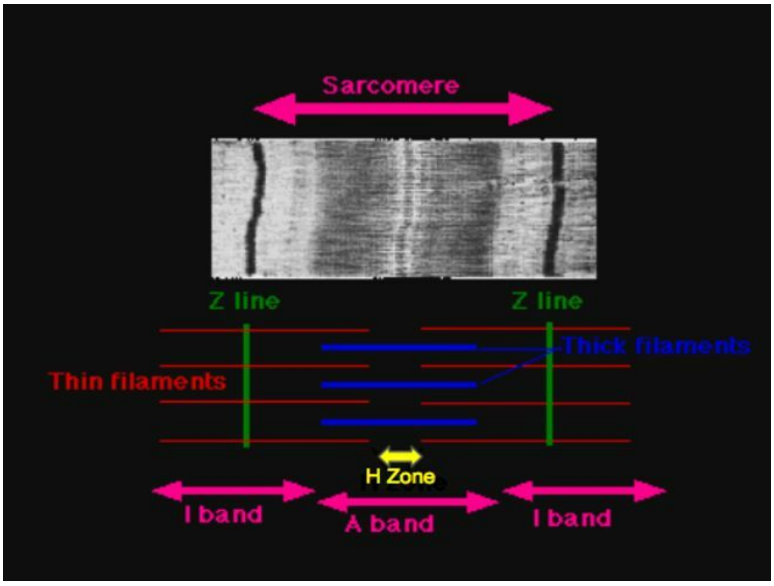
Option A: Tail: Comprises the middle piece, principal piece, and end piece and is primarily responsible for motility.

Option C: Principle piece: Longest part of the tail which contains fibrous sheaths around the axoneme but lacks mitochondria.

Option D: Connecting piece: Links the head of the sperm to the tail (neck region). Does not contain mitochondrial sheaths.

Solution to Question 21:

The correct marking is 1-Z line, 2-A band, 3-H zone, 4-I band.



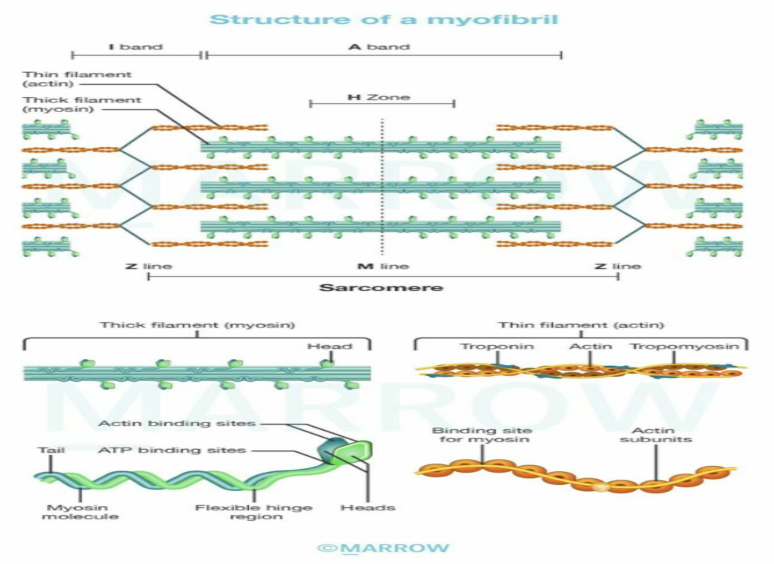
H zone or H band denotes the less refractile region in the centre of A band.

• A band – Anisotropic / Dark band: Formed by thick filaments - Myosin

• I band – Isotropic / Light band: Formed by thin filaments – Actin, Troponin, Tropomyosin

• M line – Seen in the centre of H band: Due to central bulge of A band

• Z line – Seen in the centre of each I band: Narrow line with high refractile material appearing dark.



Solution to Question 22:

Paracellular transport, Simple Diffusion and Facilitated diffusion do not require ATP as they are all passive transport mechanisms.

1: Simple diffusion : Simple diffusion is a passive transport mechanism where molecules (water, carbon dioxide, nitrogen) move from an area of high concentration to an area of low concentration and is not carrier mediated.

2: Paracellular : Paracellular transport involves movement of molecules through tight junctions between cells without the need for energy (ATP).

3: Facilitated diffusion : This also occurs along a concentration gradient, but involves carrier proteins to help move the drug across the membrane. No ATP is used because the process is still passive (driven by the concentration gradient).

4: Antiport (Na/K ATPase): Antiport transport system actively moves ions (Na+, K+) against their concentration gradient using ATP in the opposite direction. It is a form of primary active transport.

5: Symport : Two substances are transported in the same direction across a membrane. ATP is required to move substances against their gradients, often via a secondary active transport mechanism.

Solution to Question 23:

The enteric nervous system functions independently of the brain and spinal Cord. (Statement 2)

Statement 2: Functions independent of brain and spinal cord: The enteric nervous system is often referred to as the "second brain" because it can function independently of the central nervous system (CNS). It has its own reflex circuits and can control gut motility, secretion, and blood flow without input from the brain or spinal cord, although it can be influenced by them.

Statement 1: The vagus is the only afferent from the gut: While the vagus nerve does provide significant afferent (sensory) input from the gut, other nerves, such as those from the pelvic splanchnic nerves, also contribute to afferent pathways. Therefore, the vagus is not the only afferent nerve.

Statement 3: ■Myenteric plexus in the lamina propria: The myenteric plexus is located between the circular and longitudinal muscle layers of the gut, not in the lamina propria (which is part of the mucosal layer of the gut).

Statement 4: Exclusively under the influence of nerves: The enteric nervous system is influenced by nerves, but it also responds to hormonal and immune system signals. Therefore, it is not exclusively under neural influence.

Statement 5: Only parasympathetic connects enteric to CNS: Both parasympathetic and sympathetic connect the enteric nervous system to the central nervous system. Not just the parasympathetic.

The enteric nervous system consists of submucosal and myenteric plexi. This Plexi can function independently and is often referred to as the ‘little brain’. The enteric nervous system regulates gastrointestinal (GI) function and is connected to the central nervous system by parasympathetic and sympathetic fibers.

The myenteric (Auerbach’s) plexus is present between the longitudinal and circular muscle layers. It innervates both these layers along the entire length of the GI tract. It primarily controls GI motility. On stimulation, it has the following effects:

• Increased tone of the GI wall

• Increased intensity and rate of rhythmic contractions

• Increased velocity of excitatory wave conduction

Some of the myenteric plexus neurons primarily release vasoactive inhibitory peptide (VIP), which causes the relaxation of the GI sphincters.

The submucosal (Meissner's) plexus is found between the mucosa and the circular muscle layers. It innervates the GI glands, endocrine cells, and submucosal blood vessels. It primarily controls GI secretions, absorption, and local blood flow.

The parasympathetic innervation of the plexi is from the vagus and pelvic nerves. They release either acetylcholine or substance P. It generally increases GI motility and secretion.

The sympathetic innervation is from the celiac, superior mesenteric, inferior mesenteric, and hypogastric sympathetic ganglia. It generally inhibits GI motility and stimulates sphincteric contraction.

Solution to Question 24:

Decrease in glomerular coefficient causes decrease in GFR.

The glomerular filtration coefficient (Kf) is a measure of how efficiently the glomerulus filters blood into the kidney tubules. It depends on two key factors:

• Surface Area for Filtration: Greater surface area means higher filtration.

• Permeability of the Glomerular Membrane: Higher permeability leads to greater filtration.

Glomerular filtration rate (GFR) is the volume of fluid filtered from the renal glomerular capillaries into the Bowman's capsule per unit time.

The GFR is determined by the sum of the hydrostatic and colloid osmotic forces across the glomerular membrane, which gives the net filtration pressure. It is dependent on Glomerular Kf (glomerular ultrafiltration coefficient) also.

Mathematically, it can be expressed as follows:

$GFR = Kf [PG + \pi B - PB - \pi G]$

Forces favoring Filtration

• PG: Glomerular hydrostatic pressure (Option C)

• πB: Bowman's capsule oncotic pressure

Forces opposing Filtration

• PB: Bowman's capsule hydrostatic pressure (Option D)

• πG: Glomerular capillary oncotic pressure (Option B)

The formula for glomerular filtration rate (GFR) incorporates Kf:

• A high Kf means efficient filtration (e.g., in healthy kidneys)-indicates high GFR

• A low Kf {occurs when the surface area is reduced (e.g., due to glomerular damage) or the membrane becomes less permeable (e.g., in diabetic nephropathy)}- indicates low GFR.

Kf is essential for maintaining proper kidney function, as it directly affects how well the kidneys filter blood to form urine.

Solution to Question 25:

Pulse pressure increases with age due to decreased arterial wall compliance.

Diastolic blood pressure falls after 60 years of age due to increased arterial stiffness and decreased compliance, often associated with arteriosclerosis. As the left ventricle contracts against stiffer, less compliant arteries, systolic blood pressure also increases.

As a result of these two changes, pulse pressure increases (↑PP = ↑SBP - ↓DBP)

The factors that affect the pulse pressure:

• the stroke volume output of the heart

• the compliance or total distensibility of the arterial walls

• the character of ejection from the heart during systole (less important)

Pulse pressure = Stroke volume/ arterial compliance

Widened pulse pressure (> 40 mm Hg) occurs with several diseases such as:

• Aortic regurgitation

• Aortic sclerosis

• Severe iron deficiency anaemia

• Arteriosclerosis

• Hyperthyroidism

In the majority of these cases, systolic pressures increase while diastolic pressures remain near normal.

Solution to Question 26:

Physiological dead space represents inadequately perfused alveoli.

Physiological dead space is the part of the respiratory system where no gas exchange occurs. It includes:

• Anatomic dead space: Air in the conducting airways (nose, trachea, bronchi) that doesn't reach the alveoli.

• Alveolar dead space: Air in alveoli that are ventilated but not perfused by blood.

Together, it represents the total volume of air that doesn't participate in oxygen and carbon dioxide exchange.(Option B)

Anatomical dead space refers to the volume of all the space of the respiratory system other than the alveoli that do not participate in gas exchange. The anatomical dead space is not altered with a change in ventilation.

In healthy individuals:

• Anatomical dead space = 150 mL.

• Alveolar dead space is usually zero (increased in diseased conditions).

Alveolar Dead space represents inadequately perfused alveoli (wasted ventilation). (Option C)

In normal individuals, physiological dead space remains unaltered and is equal to the anatomical dead space (volume of all the space of the respiratory system other than the alveoli that do not participate in gas exchange).

Dead space cannot be measured using spirometry. (Option A)

Solution to Question 27:

Neuromuscular transmission, Excitation contraction coupling and transmission impulse from nerve coupling contribute to latent period of muscle twitch.

The latent period of a muscle twitch is the brief delay between the application of a stimulus (such as a nerve impulse) and the onset of muscle contraction. During this period, several physiological processes occur, but neuromuscular transmission and excitation-contraction coupling primarily contribute to this delay.

Neuromuscular transmission: The action potential travels down the motor neuron to the neuromuscular junction. Acetylcholine (ACh) is released into the synaptic cleft and binds to receptors on the muscle fiber's sarcolemma, triggering an action potential in the muscle fiber. (Statement 1)

Excitation-contraction coupling: The action potential propagates along the sarcolemma and into the transverse (T) tubules. This triggers the release of calcium ions from the sarcoplasmic reticulum into the cytosol. Calcium binds to troponin, initiating the interaction of actin and myosin filaments. (Statement 2)

Reuptake of calcium back into the sarcoplasmic reticulum: This occurs during the relaxation phase, not the latent period. (Statement 3)

Transmission of impulse from nerve: This is a part of neuromuscular transmission and is involved in the latent period. (Statement 4)

Solution to Question 28:

There are no responses from the nociceptors when stimulated by blunt forceps.

Mechanical nociceptors typically respond to noxious mechanical stimuli, such as sharp pressure or intense stretch. A blunt object, such as blunt forceps, may not provide a strong enough stimulus to activate these nociceptors, leading to no response.

The sharp painful sensation felt immediately upon injury is known as fast pain. The poorly localized dull aching pain is characteristic of slow pain. The nerve fibers carrying fast pain and slow pain are Aδ and C respectively.

Nociceptors are innervated by both Aδ and C fibers. Aδ fibers are myelinated and larger in diameter with a faster conduction velocity. C fibers are unmyelinated and conduct impulses at a slower rate. When nociceptors are activated by a noxious stimulus, activated Aδ fibers release glutamate and mediate fast pain. It is a rapid response that is responsible for localizing the noxious stimulus.

Other Options:

Option B: Pinching with toothed forceps causes stimulation of mechanonociceptors, but no pain: Pinching with toothed forceps typically applies more localized pressure, which can activate mechanical nociceptors. However, it may still cause a painful sensation, not just a mechanical response. It is more likely that pain is perceived, even if the response is primarily mechanical.

Option C: Pricking with a needle does not stimulate nociceptors: A needle prick is a sharp stimulus that activates nociceptors, particularly mechanical nociceptors in response to tissue damage.

Option D: Sharp pain sensation is carried by C fibers: Sharp pain (due to a needle prick) is typically carried by A-delta fibers, which transmit fast, localized pain sensations. C fibers are responsible for carrying dull, burning pain that occurs later after the initial sharp pain.

Solution to Question 29:

Peripheral chemoreceptors are most sensitive to hypoxia.

Peripheral Chemoreceptors are located in the carotid bodies (at the bifurcation of the common carotid arteries) and aortic bodies (near the aortic arch). They are sensitive to changes in pO2, pCO2, and pH of the blood. In response to changes in these parameters, they send impulses to the medullary respiratory centers and modify the duration and frequency of respiratory cycles.

Peripheral chemoreceptors are most sensitive to a drop in partial pressure of oxygen (PaO■) in arterial blood.

Mechanism:

Type I glomus cells in the carotid and aortic bodies have O2-sensitive K+ channels, which are inactivated in response to hypoxia. This reduces the K+ efflux, depolarizing the cell and causing Ca2+ in■ux, via L-type voltage-gated calcium channels. The Ca2+ influx triggers action potentials and consequent excitation of the afferent nerve endings in the peripheral chemoreceptors.

Hypoxia (PaO■ < 60 mmHg) strongly stimulates these receptors, leading to an increase in respiratory rate and depth to improve oxygenation.

Other Options:

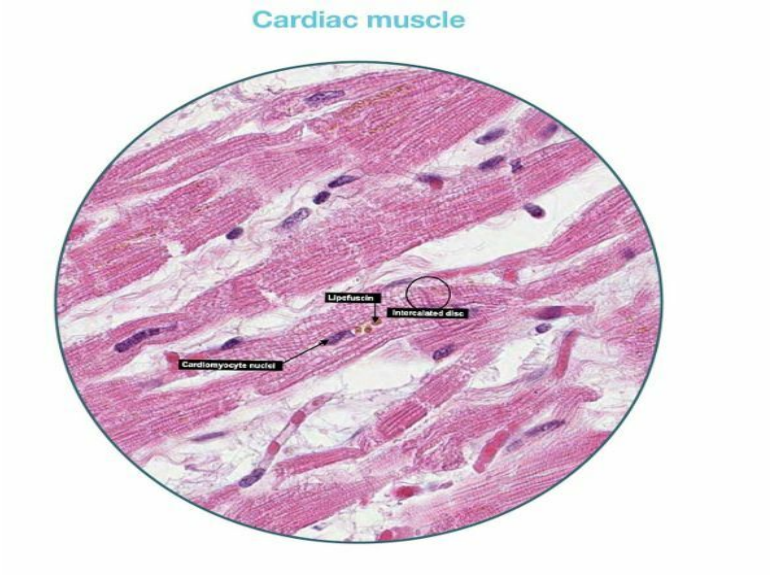
Peripheral chemoreceptors also respond to hypercapnia (Option A) and acidosis (Option C). However, these are primarily detected by central chemoreceptors, located in the medulla, which monitor CO■ levels in cerebrospinal fluid.

Alkalosis (Option D) causes a weaker response from peripheral chemoreceptors compared to hypoxia.

Solution to Question 30:

The given section shows cardiac muscle and the marked structure is an intercalated disc.

Intercalated discs are specialized structures unique to cardiac muscle tissue. They are critical for the coordinated contraction of cardiac muscle cells. They are found at the junctions between adjacent cardiac muscle cells. They appear as dark, zigzagging lines under a microscope. They facilitate the rhythmic and coordinated contraction of the heart by ensuring efficient electrical and mechanical connections.



On microscopy, cardiac muscle can be identified by:

• Presence of striations similar to the skeletal muscle.

• Presence of single and centrally placed nucleus. A perinuclear halo may be seen surrounding the nucleus.

• The junctions between adjoining cardiac myocytes are seen as dark staining transverse lines running across the muscle fibre. These lines are called intercalated discs.

• Cells within one fibre branch and join the cells in adjacent fibres.

Other Options:

Option B: Connective Tissue: Found surrounding the cardiac muscle cells, providing structural support, but not at the cell junctions.

Option C: Cytoskeletal condensation: Refers to cytoskeletal organization within a cell and is not visible as distinct structures in cardiac muscle histology.

Option D: Nerve Fibre: Present in cardiac tissue to innervate the heart but appears as separate structures and not within cardiac muscle fibers.

Solution to Question 31:

Albumin is not separated by centrifugation in the blood bank.

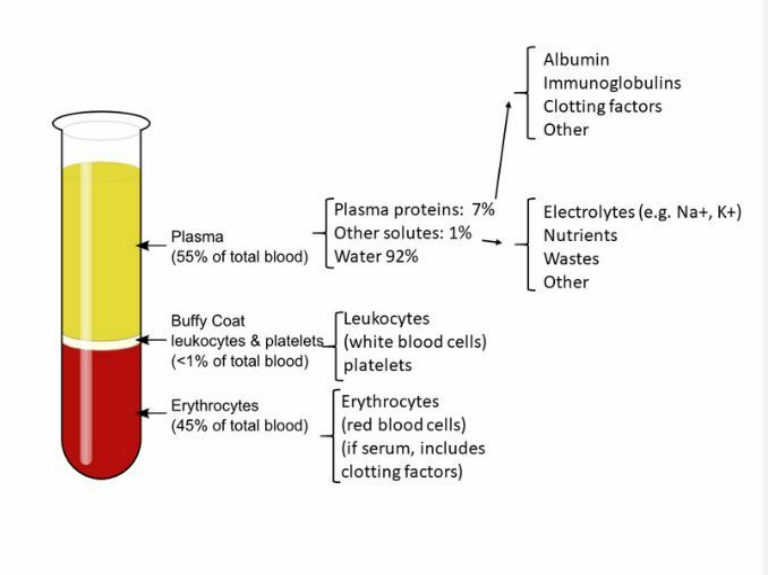
In blood banks, centrifugation is used to separate the main components of blood into distinct layers for storage and transfusion purposes. These components include:

• Red Blood Cells (RBCs): Separated by centrifugation and stored for patients with anemia or significant blood loss. (Option A)

• Platelets: Isolated through centrifugation of plasma-rich blood for use in patients with bleeding disorders. (Option B)

• Cryoprecipitate: Derived from plasma by controlled freezing and thawing, which allows the collection of clotting factors (e.g., Factor VIII, fibrinogen, von Willebrand factor). (Option C)

Albumin is a plasma protein that is extracted through a process called fractionation, not simple centrifugation. This involves the use of chemical, temperature, and pH adjustments to isolate albumin from plasma.



Physiology NEET 2024

Question 1:

What are the effects of posterior lesions in a Brodmann's area 22 in a stroke patient?

a) Auditory function

b) Receptive Speech Function

c) Expressive Speech Function

d) Visual functions

Question 2:

A 30-year-old female went on vacation and fell asleep while sitting on a beach. After some time she woke with sunburn. Later when she went back home, she experienced pain while taking a warm bath (40°C). Which of the following receptors is responsible for the pain?

a) Innocuos thermal receptor - allodynia

b) Innocuos thermal receptor - hyperalgesia

c) Thermal receptor - allodynia

d) Thermal receptor - hyperalgesia

Question 3:

To prevent polyspermy, which reaction occurs in the zona pellucida of the oocyte after fertilization?

a) Acrosomal reaction

b) Increased membrane potential of the oocyte

c) Cortical reaction

d) Decreased membrane potential of the oocyte

Question 4:

A 60-year-old patient came with a puncture wound on the left chest wall. Radiological investigations confirmed pneumothorax. Which of the following is correct regarding this

condition?

a) Lung volume increases, thoracic volume increases

b) Lung volume decreases, thoracic volume increases

c) Lung volume increases, thoracic volume decreases

d) lung volume decreases, thoracic volume decreases

Question 5:

Sour taste is mediated by which of the following receptors?

a) T1R1 GPCR

b) TRPV1 channel

c) T1R3 GPCR

d) Metabolic receptor

Question 6:

A patient who underwent right limb amputation 2 years back, now presents with severe pain in the limb (Phantom limb pain). On radiological investigations, What is the finding seen?

a) Projection of adjacent fibres to overlap the right somatosensory cortex

b) Expansion of left somatosensory cortex

c) Projection of adjacent fibres to overlap the left somatosensory cortex

d) Expansion of right somatosensory cortex

Question 7:

In a type 2 diabetes mellitus patient, serum insulin levels are found to be raised. He is advised to exercise to improve insulin resistance. Which of the following GLUT will help to improve insulin resistance after exercise ?

a) GLUT 1

b) GLUT 2

c) GLUT 5

d) GLUT 4

Question 8:

Which of the following is incorrect about iron absorption?

a) Ferrireductase convert Fe2+ to Fe 3+

b) RBC protophyrin is increased in deficiency

c) Iron excretion is only through skin, gut and urothelial cells

d) Body cannot compensate if more than 10 RBC/HPF per day is lost in urine

Question 9:

A 50-year-old patient presents with a chronic tingling sensation in the forearm. A neurological examination is done and appears to be normal. Which of the following receptors are correctly matched?

a) Merkel cells-slow vibration

b) Meissner's corpuscles-stretch

c) Pacinian corpuscles-fast vibration

d) Ruffini corpuscles-sustained pressure

Question 10:

The patient presented with alcoholic gait, and abnormal eye movements (nystagmus) after RTA. Which lobe of the cerebellum is likely affected?

a) Flocculonodular Lobe

b) Dentate nucleus

c) Anterior lobe

d) Interposed nucleus

Question 11:

Renal compensation in metabolic acidosis takes time because:

a) Initially the pH of tubular fluid increases

b) Low pH normally decreases bicarbonate excretion

c) It takes hours to days for kidney to synthesize enzymes that produce NH_4^+

d) Other ions in the tubule interfere with buffer action

Question 12:

The functioning of the thyroid involves the transport of iodine from the blood to the thyroid follicle. Iodine is transported from the follicle to the colloid. Which pump or channel is for transport of iodine from the follicle to the colloid?

a) Sodium iodine symporter

b) Calmodulin

c) Claudin

d) Pendrin

Question 13:

The resting membrane potential(RMP) of the nerve is -70mV. Increased permeability of which ion is responsible for the RMP?

a) Calcium

b) Sodium

c) Potassium

d) Chloride

Question 14:

Arrange the sequence of steps involved at neuromuscular junction endplate potential.

a) Acetylcholine release - Calcium entry- Na+ entry

b) Calcium entry- Acetylcholine release- Na+ entry

c) Na+ entry - Calcium entry - Acetylcholine release

d) Na+ entry - Acetylcholine release - Calcium entry

Answer Key

Question No.	Correct Option
1	b

2	a
3	c
4	b
5	b
6	c
7	d
8	a
9	c
10	a
11	c
12	d
13	c
14	b

Detailed Explanations

Solution to Question 1:

A posterior lesion in Brodmann's area 22, which is located in the superior temporal gyrus, typically affects receptive speech function. It is the sensory speech area.

The patient will most likely have Wernicke’s aphasia due to the damage to Wernicke’s area - area 22.

In Wernicke's aphasia, there is difficulty in finding words leading to poorly understood content for the listener. These patients also find it difficult to repeat sentences and name things properly. It is a type of fluent aphasia in which the speech is easy and fluent but there are difficulties related to the output of language like paraphasia (substitution of similar-sounding, non-words, or incorrect words). The speech is full of jargon and neologisms (non-existent words) that make little sense.

Other options:

Option A: Auditory Function is primarily mediated by Brodmann area 41, which is located in the primary auditory cortex within the superior temporal gyrus.

Option C: Expressive Speech Function is associated with Brodmann areas 44 and 45 (Broca's area), which are involved in language production and speech articulation. Lesions here can cause difficulty in producing coherent speech (Broca's aphasia).

Option D: Visual function primarily associated with Brodmann areas 17, 18, and 19 (the primary and secondary visual cortices).

Solution to Question 2:

The receptors responsible for this are innocuous thermal receptors which have perceived ordinarily non-noxious stimulus (i.e., warm bath) as severe pain also known as allodynia.

In this case, the warm bath at 40°C (typically not painful) causes pain due to sunburn, which sensitizes the skin. After sunburn, the skin becomes more sensitive, and thermal receptors that usually detect warmth now trigger pain signals in response to non-painful thermal stimuli, leading to allodynia.

Innocuous thermoreceptors, which detect non-harmful temperature changes(cold and warm), are specialized nerve endings found on the skin. Cold receptors are located on the dendritic endings of Aδ and C fibers, while warm receptors are situated on C fibers. The specific thermosensitive molecular channels mediating innocuous heat stimuli is transient receptor potential (TRP) cation channel TRPV1 and TRPM8 cation channel for innocuous cold stimuli.

Thermal hyperalgesia(increased response to noxious stimulation) is mediated by activation of NMDA receptors. After tissue or nerve injury, C-fibers discharges release glutamate and neurokinins from primary afferent terminals, leading to the release of peptides (e.g., substance P; calcitonin gene-related peptide, CGRP). As a result, a voltage-dependent magnesium block on NMDA receptors is removed allowing for an influx of calcium that triggers a cascade of intracellular events leading to the development and maintenance of hyperalgesia.(Option D)

Solution to Question 3:

To prevent polyspermy, the reaction in the zona pellucida of the oocyte after fertilisation is the cortical reaction.

The chronological steps of fertilisation:

Acrosomal reaction: After a sperm reaches the oocyte and binds to the zona pellucida, the acrosome reaction occurs. The acrosome, an enzyme-rich organelle in the anterior of the sperm head, fuses at many points with the plasma membrane of the oocyte. Then those fused membranes are sloughed off from the head, exposing the acrosomal enzymes. The enzymes digest a path through the zona pellucida, enabling the sperm to advance.

Eventually, the sperm meets and fuses with the secondary oocyte plasma membrane.

This contact results in weak membrane depolarisation(decreased membrane potential) and a calcium wave.

Cortical reaction: The calcium wave triggers the release of lysosomal enzymes from the cortical granules lining the oolemma. These enzymes hydrolyse the ZP3 receptor on the zona pellucida. Digestion of ZP3 and alteration of zona pellucida (zona reaction) prevents other sperms from binding, thus creating a block to polyspermy.

Solution to Question 4:

In pneumothorax, lung volume is decreased and thoracic volume is increased.

Both lungs and the chest wall (thoracic cage) are elastic structures. Under normal conditions, the elastic tendency of the lungs to collapse is exactly balanced by the elastic tendency of the chest

wall to expand.

In pneumothorax, air is introduced into the pleural space, so the pleural pressure, which is normally subatmospheric, becomes equal to atmospheric pressure. The chest wall springs outward and the lungs collapse. This increases the thoracic volume and decreases the lung volume.

Solution to Question 5:

Sour taste is mediated by the TRPV1 channel. The TRPV1 (Transient Receptor Potential Vanilloid 1) channel is involved in detecting the acidity of foods, which contributes to the perception of sour taste.

It is a cation channel that allows the influx of various cations, including sodium (Na^{+}), calcium (Ca^{2+}), and magnesium (Mg^{2+}), in response to changes in temperature and the presence of acidic conditions or capsaicin

Taste Receptors

• Humans have five established basic tastes: sweet, salt, sour, bitter and umami.

• The taste receptors for these five basic tastes are of two major types:

• Ligand-gated channels (ionotropic receptors): for salt and sour taste

• G-Protein Coupled Receptors (metabotropic receptors): for sweet, bitter and umami

• Salt and sour taste are mediated through epithelial sodium channels (ENaC)

• Na+ movement through ENaC → salt taste

• H+ movement through ENaC → sour taste

• Sweet, bitter, and umami are sensed via GPCRs

• T1R2 and T1R3 families→ sweet taste

• T2R family → bitter taste

• T1R1, T1R3, and Metabotropic glutamate receptor (mGluR4) → Umami (Option A and C)

Solution to Question 6:

In the given scenario of phantom limb pain, on the radiological investigation of the brain projection of adjacent fibres to overlap the left somatosensory cortex can be seen. This pain is based on cortical plasticity.

Cortical structures are capable of reorganization after the loss of a body part. The cortical representation of the neighbouring parts spreads into the cortical area that was formerly occupied by the representation of the amputated part. This is called cortical plasticity leads to the phenomenon of phantom limb pain. The sensory cortical area occupied by the right limb is the left somatosensory cortex.

Cortical plasticity / Phantom limb: It is the sensation that an amputated or missing limb is still attached. Plasticity is the ability of the brain to adapt to such a condition by reorganization of thalamic and cortical structures.

The converse also holds true: if the cortical area representing a limb is removed, the somatosensory map of the limb moves to the surrounding cortex.

Diagnosis and Management :

• PET scan is used to document these plastic changes in cortex.

• Use of epidural analgesia during amputation surgery decreases incidence of phantom pain.

• Spinal cord stimulation also helps in reducing phantom pain. (interferes with ascending impulses to brain)

Solution to Question 7:

There is an increase in the number of GLUT 4 receptors in response to exercise. This increases the insulin dependent glucose uptake into the cells, contributing to a decrease in insulin resistance.

GLUT-4 is an insulin-dependent GLUT. Other GLUTs are not insulin-sensitive and are constitutively expressed in the cell membrane.

Insulin resistance is a condition in which the cells in muscles, fat, and liver are less responsive to insulin and have difficulty absorbing glucose from the blood. The pancreas then produces more insulin to facilitate the entry of glucose into the cells.

An arbitrary but clinically useful benchmark considers patients insulin resistant if they require greater than 1 unit/kilogram/day of exogenous insulin to maintain glycemic control. Patients requiring greater than 200 units of exogenous insulin per day are considered severely insulin resistant.

Other options

Option A: GLUT 1 receptors are present in the red blood cell, brain, kidney, colon, retina, and placenta. It is responsible for glucose uptake.

Option B: GLUT-2 is found in the liver, pancreatic β cell, small intestine, and kidney. Its function is the rapid uptake or release of glucose.

Option C: GLUT-5 is present in the small intestine and is involved in the absorption of fructose.

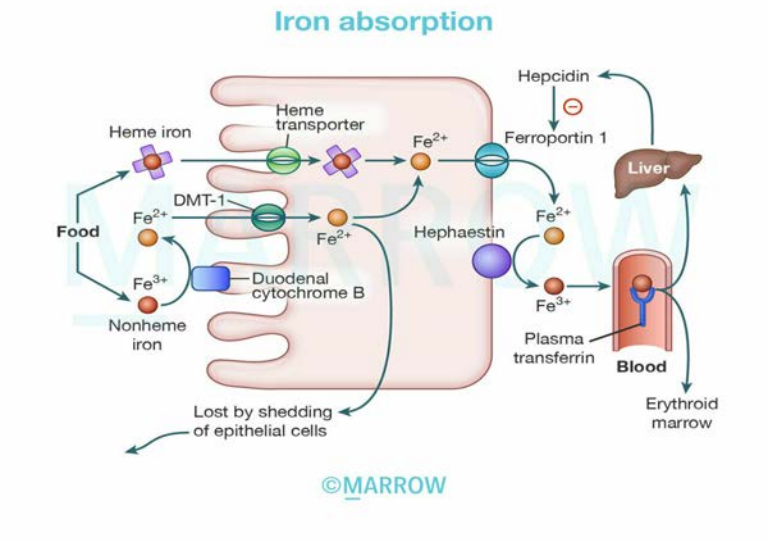
Solution to Question 8:

Ferrireductase is an enzyme that converts Fe^{3+} (ferric iron) to Fe^{2+} (ferrous iron), not the other way around. Ferrous is the form of iron that is more readily absorbed in the gut.

Almost all the iron absorption occurs in the duodenum.

Most of the iron in the diet is in the ferric (Fe^{3+}) form, whereas it is the ferrous (Fe^{2+}) form that is absorbed.

Body iron stores are controlled by intestinal absorption as there is no exit to iron from the body. Divalent metal transporter 1 (DMT1) transports non-heme iron into the enterocyte. Iron absorption in the duodenum is regulated by hepcidin release from the liver in response to increases in intrahepatic iron levels. It binds to ferroportin leading to endocytosis and degradation within the enterocyte. This prevents the transfer of iron from enterocyte to plasma resulting in iron trapping within duodenal cells in the form of mucosal ferritin. The trapped iron is lost as these cells are sloughed. The iron transported by ferroportin into the plasma is transferred to other parts with the help of transferrin and stored as serum ferritin and hemosiderin. The image depicting iron absorption and storage is given below:



Other options:

Option B: RBC protoporphyrin is increased in deficiency, increased protoporphyrin levels in red blood cells can indicate iron deficiency or disorders of heme synthesis.

Option C: Iron is primarily excreted through the gut, skin, and urinary tract, but the body generally has very limited mechanisms for iron excretion compared to iron absorption and recycling.

Option D: The body's iron homeostasis is finely tuned, and a significant loss of red blood cells, such as more than 10 ml per day, can overwhelm the body's ability to compensate and maintain iron balance.

Solution to Question 9:

Pacinian corpuscles are responsible for sensing fast vibration. The chronic tingling sensation is mediated by pressure-sensitive Aβ fibers and low-conduction velocity C fibers.

Pacinian corpuscles are the most sensitive mechanoreceptors in the somatosensory system. They are responsive to high-frequency (30–500 Hz) vibratory stimuli and deep pressure. They are also examples of rapidly adapting receptors.

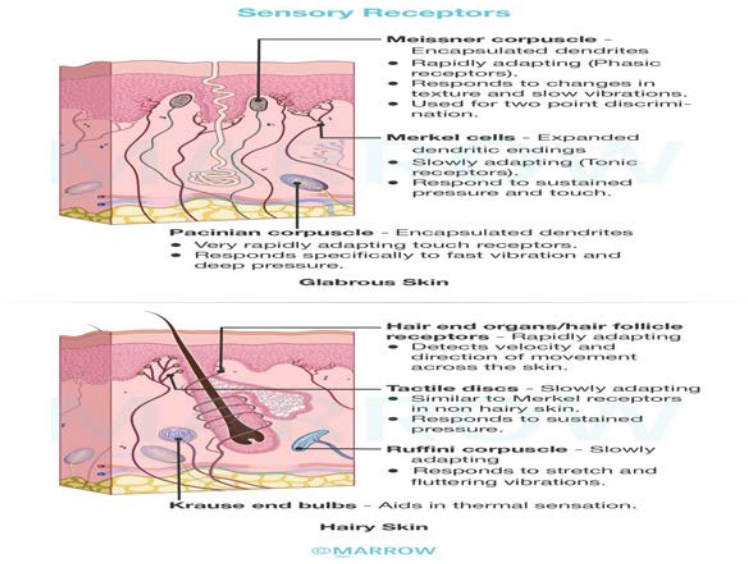
Chronic tingling causing conditions include Diabetes, carpal tunnel syndrome, ulnar nerve palsy, radial nerve palsy, tarsal tunnel syndrome, sciatica, vitamin B1,B6,B12 deficiencies, and alcoholism.

Other options

Option A: The Merkel cells are expanded dendritic endings in the epidermis of glabrous skin and respond to sustained pressure and touch.

Option B: Meissner's corpuscle senses tap and flutter. They are present in dermal papillae. They are rapidly adapting receptors.

Option D: Ruffini's corpuscles are enlarged dendritic endings with elongated capsules in the dermis of glabrous and hairy skin. They respond to stretch and fluttering vibrations. They are slowly adapting receptors.



Solution to Question 10:

The flocculonodular lobe is involved in this patient with an alcoholic gait and abnormal eye movements (nystagmus) following an RTA.

The cerebellum has three parts based on function.

• Vestibulocerebellum (or flocculonodular lobe): The oldest part of the cerebellum which contains nodulus in the vermis and the flanking flocculus. It has vestibular connections and is concerned with equilibrium and gait. Loss of it can cause disturbance of equilibrium and postural movements, especially during rapid movements.

• Spinocerebellum: The region that receives proprioceptive input from the body as well as a copy of the “motor plan” from the motor cortex. By comparing the plan with performance, it smooths and coordinates movements that are ongoing. The superior vermis is a part of the spinocerebellum. Loss of it can cause problems with coordination.

• Cerebrocerebellum: They are the newest from a phylogenetic point of view, reaching their greatest development in humans. They interact with the motor cortex in planning and

programming movements.

Other options:

Option B: The Dentate nucleus(largest) is one of the 4 deep cerebellar nuclei others being, Emoliform, Globose, and Fastigial nuclei. These receive input from climbing fibers and are the only motor output from the cerebellar cortex.

Option C: Anterior lobe is a part of the Paleo/Spinocerebellum responsible for the coordination of movement and regulation of muscle tone whose lesion results in hypotonia.

Option D: Interposed nuclei / Nucleus interpositus is the term used to describe the cerebellar nuclei, Emboliform, and Globose.

Solution to Question 11:

Compensation in metabolic acidosis happens late in the kidney because it takes hours to days for it to synthesize enzymes that produce NH4+(ammonium ions).

Acid-base balance equation: CO2 + H2O -----> H2CO3 -----> H+(acid) and HCO3-(base)

• First line of defence (in seconds): Buffers (phosphate and ammonium)

• Second line of defence (in Minutes): Lungs

• Third line of defence (in hours - days): Kidney

The kidneys regulate the acid-base balance by two major mechanisms: the reabsorption of bicarbonate and the generation of new bicarbonate via ammonia production and distal nephron acid secretion. Urinary NH4+ is produced primarily in the proximal tubule cells by converting glutamine to glutamate.

Renal failure leads to a buildup of acids due to loss of excretory function of the kidney. The decreased glomerular filtration rate also leads to diminished excretion of the renal buffers phosphate and ammonium. Thus, bicarbonate reabsorption decreases, resulting in metabolic acidosis.

Solution to Question 12:

The channel needed for the transport of iodine from the follicle to the colloid is Pendrin.

Steps in synthesis and secretion of thyroid hormone:

• Iodide uptake: The basolateral sodium-iodide symporter (NIS) actively takes up I-(iodide) from the circulation into the follicular cells. It is then transported into the colloid through a pendrin (chloride-iodide) transporter

• Thyroglobulin synthesis: Thyroglobulin (Tg), is a large glycoprotein rich in tyrosine residues. It is synthesized by follicular cells.

• Iodination of Tg: This is regulated by the thyroid peroxidase (TPO) enzyme. TPO has three functions:

• Oxidation: TPO oxidizes I- to I2 (iodine) in the presence of H2O2

• Organification: TPO links tyrosine residues of thyroglobulin with iodine (I2) to form monoiodotyrosine (MIT), diiodotyrosine (DIT)

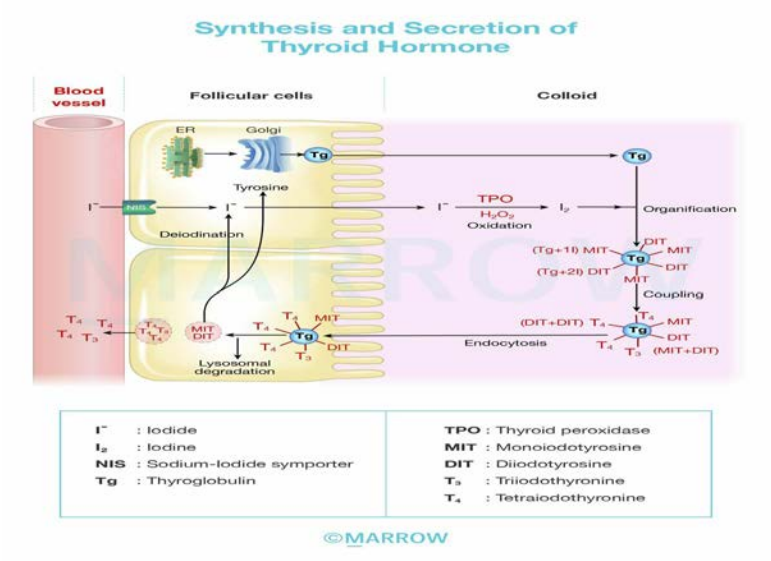
• Coupling reactions: TPO combines iodinated tyrosine residues to make MIT + DIT = T3 (triiodothyronine), DIT + DIT = T4 (tetraiodothyronine)

• Storage: Thyroid hormones are bound to thyroglobulin and stored in the follicular lumen as colloids. The colloid has hormone reserves for 2-3 months

• Release: Iodinated thyroglobulin is taken up by the thyroid follicles via endocytosis and fuses with lysosomes. It is cleaved by lysosomal proteolytic enzymes into MIT, DIT, T3, and T4. T4 (80%) and T3 (20%) are released into the blood

• Peripheral T3 conversion: T4 undergoes deiodination in extrathyroidal tissue to form T3, which is the active form of the hormone.

Pendred syndrome: Pendrin is present in the thyroid gland and inner ear. The mutation causes goiter and sensorineural hearing loss.



Other options

Option A: Sodium-iodide symporter (NIS) is responsible for transporting iodine from the bloodstream into the thyroid follicular cell, not into the colloid. It works by bringing in iodine along with sodium from the bloodstream into the follicle.

Option B: Calmodulin is structurally and functionally related to troponin. In place of troponin, smooth muscle cells contain a large amount of the regulatory protein calmodulin; it is different in the manner in which it initiates contraction. Calmodulin initiates contraction by activating the myosin light chain kinase.

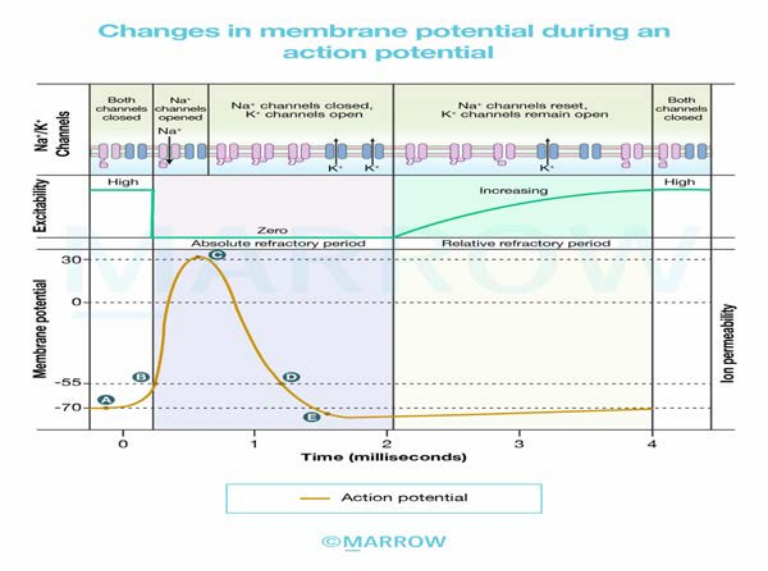
Option C: Claudin is a transmembrane protein involved in the formation of tight junctions.

Solution to Question 13:

Increased permeability of potassium ions(K+) is responsible for the RMP of a nerve as there are more K+ channels open at rest, facilitating the flow of potassium ions across the membrane.

Resting membrane potential (RMP) is the difference in the electrical potentials between the cytoplasm of the cell and the extracellular space.

At rest, there are more open K+ channels compared to Na+ channels, thus the membrane permeability of K+ is greater. As a result of this, the intracellular and extracellular K+ concentrations are the major determinants of the RMP. Furthermore, the RMP is close to the equilibrium potential of K+ in general.



Clinical Significance: In hyperkalemia, the extracellular level of K+ is increased. Thus the RMP moves closer to the threshold to elicit an action potential leading to a more excitable nerve. The excitable nerve, stimulates the muscle repeatedly causing fasciculations, exhaustion of muscle, and weakness. In hypokalemia, the extracellular level of K+ is reduced. Thus the RMP is reduced and the neuron is hyperpolarized.

Solution to Question 14:

The sequence of steps involved at neuromuscular junction endplate potential is Calcium entry-Acetylcholine release- Na+ entry.

Events occurring at the Chemical Synapse:

The action potential arriving at the end of the motor neuron increases the permeability of its endings to Ca2+

↓

Ca2+ enters the endings and triggers a marked increase in exocytosis of the acetylcholine-containing synaptic vesicles

↓

The binding of acetylcholine to nicotinic receptors increases the Na+ and K+ conductance

↓

The resultant influx of Na+ produces a local depolarizing potential, the endplate potential

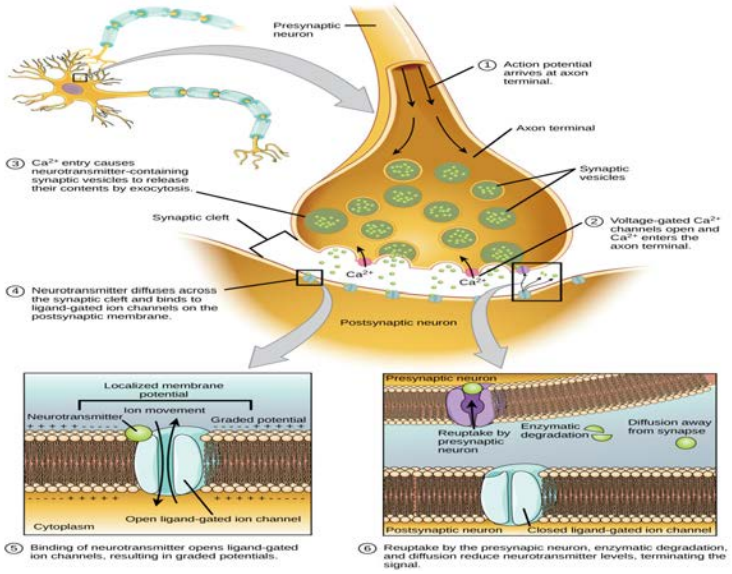
↓

The current created by this local potential depolarizes the adjacent muscle membrane to its firing level

↓

Action potentials are generated on either side of the endplate and are conducted away from the endplate in both directions along the muscle fiber. This muscle action potential, in turn, initiates muscle contraction.

Acetylcholine is then removed from the synaptic cleft by acetylcholinesterase, which is present in high concentration at the neuromuscular junction.



Biochemistry AIIMS 2017

Question 1:

Identify the anaplerotic reaction among the following?

a) Conversion of pyruvate to Acetyl CoA

b) Conversion of pyruvate to Oxaloacetate

c) Conversion of pyruvate to Acetaldehyde

d) Conversion of pyruvate to Lactic acid

Question 2:

True regarding mitochondrial DNA is:

a) One set from each parents

b) It has a higher mutation rate than nuclear DNA

c) It codes for more than 25% of oxidative phosphorylation proteins

d) It has 3 X 10^9 base pairs

Question 3:

Which of the following is Thermogenic food

a) High fat diet

b) It does not depend on the macronutrients

c) High protein diet

d) High carbohydrate diet

Question 4:

Klenow fragment lacks the activity of

a) 3'→5' Exonuclease

b) 5'→3' Exonuclease

c) 5'→3' DNA polymerase

d) 3'→5' DNA polymerase

Question 5:

In SCID, what type of DNA repair is defective:

a) Base excision repair

b) Nucleotide excision repair

c) Mismatch Repair

d) Non-homologous end joining repair

Question 6:

A 10-year-old boy rapidly develops hypoglycemia after moderate activity. Blood examination reveals raised levels of ketone bodies, lactic acid, and triglycerides. On examination, the liver and kidneys are found to be enlarged. Histopathology of the liver shows deposits of glycogen in an excess amount. What is the diagnosis?

a) von Gierke's disease

b) Pompe's disease

c) McArdle's disease

d) Cori's disease

Question 7:

Which one of the following is not involved in iron metabolism:

a) Ceruloplasmin

b) Hepcidin

c) Transthyretin

d) Transferrin

Question 8:

Which of the following amino acids is not formed after post-translational modification?

a) Selenocysteine

b) Triiodothyronine

c) Hydroxy proline

d) Hydroxylysine

Question 9:

Which test will be positive in starvation state in urine?

a) Benedict test and heat coagulation test

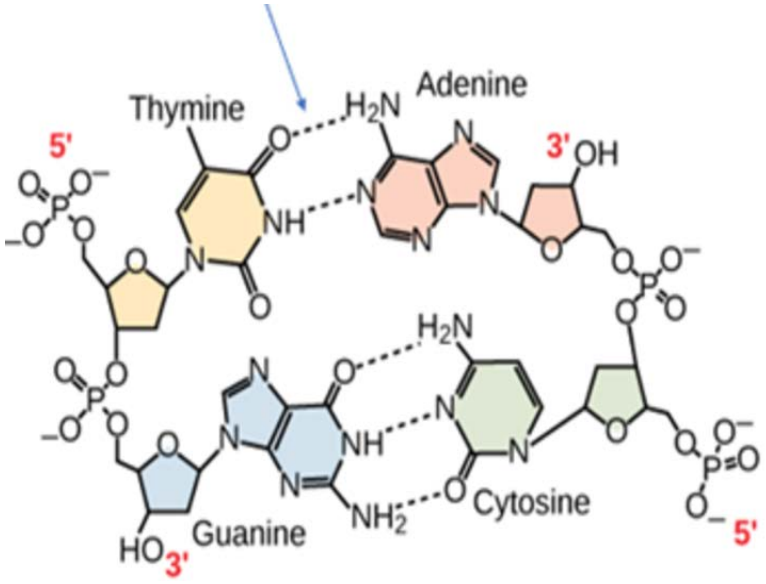
b) Heat coagulation test

c) Rothera's test

d) Heat coagulation test and Rothera's test

Question 10:

Identify the marked bond:



a) Ionic bond

b) Covalent bond

c) Hydrogen bond

d) Phosphodiester Bond

Question 11:

Which among the following serves as cofactor for Glycogen phosphorylase:

a) Thiamine

b) Niacin

c) Pyridoxal Phosphate

d) Biotin

Question 12:

Glucosamines are used in which of the following conditions:

a) Arthritis

b) Niemann Pick disease

c) Alzheimer's disease

d) Cancer

Question 13:

Which of the following site does the restriction enzyme act when RFLP is used in-order to identify the five different species of staphylococci in a surgical ICU?

a) ATGGAC-TACGTG

b) GATATC- CTATAG

c) TAGATA-ATCTCT

d) AATATA-TATAAT

Question 14:

Thiamine deficiency results in decreased■ energy production, because TPP _____

a) Interferes with alcohol metabolism

b) Interferes with transketolase activity

c) Is coenzyme for pyruvate and alpha ketoglutarate dehydrogenase

d) Interferes with energy production from amino acids

Question 15:

A young patient came with complaints of acute abdominal pain on and off and tingling sensation of limbs and at times weakness of limbs. She had a history of eating paint from the

wall of a newly built house. Which of the following enzyme defect will be the cause of her condition?

a) ALA synthase

b) ALA dehydratase

c) Heme synthase

d) Coproporphyrinogen oxidase

Question 16:

Under anaerobic metabolism which of the following substrates yields 3 molecules of ATP?

a) Glycogen

b) Amino acid

c) Glucose

d) Galactose

Question 17:

Which of the following is the reason for using phenylbutyrate in urea cycle disorders?

a) It maintains renal output

b) It scavenges nitrogen

c) It maintains energy production

d) It activates enzymes

Question 18:

Which of the following can alter the gene expression by methylation and acetylation but not change the gene sequence?

a) Mutation

b) Epigenetics

c) Translocation

d) Inversion

Question 19:

Which of the following is not seen in low insulin-glucagon ratio?

a) Glycogen breakdown

b) Ketogenesis

c) Glycogen storage

d) Gluconeogenesis

Answer Key

Question No.	Correct Option
1	b
2	b
3	c
4	b
5	d
6	a
7	c
8	a
9	c
10	c
11	c

14	c
15	b
16	a
17	b
18	b
19	c

Detailed Explanations

Solution to Question 1:

The conversion of pyruvate to oxaloacetate is an anaplerotic reaction. It is catalyzed by pyruvate carboxylase.

Anaplerotic reactions are chemical reactions that form intermediates of a metabolic pathway. The above reaction is important in maintaining an adequate concentration of oxaloacetate for the condensation reaction with acetyl-CoA. If acetyl-CoA accumulates, it acts as an activator of pyruvate carboxylase and an inhibitor of pyruvate dehydrogenase, thereby ensuring an adequate supply of oxaloacetate.

Other anaplerotic reactions are:

• Compounds that are metabolized to yield propionyl CoA, which can be then carboxylated and isomerized to succinyl CoA.

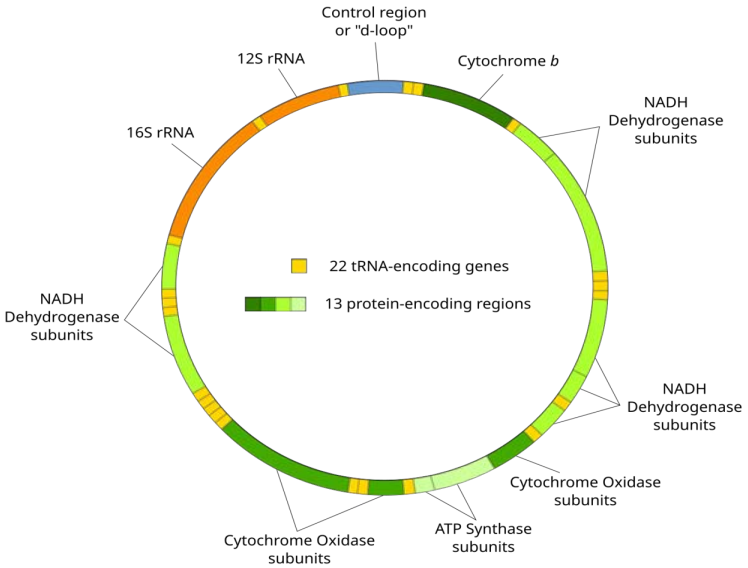
• Glutamate and glutamine are important anaplerotic substrates because they yield α-ketoglutarate as a result of the reactions catalyzed by glutaminase and glutamate dehydrogenase.

• Transamination of aspartate leads directly to the formation of oxaloacetate.

Solution to Question 2:

The true statement is that mitochondrial DNA has a high mutation rate.

Mitochondrial DNA is circular and double-stranded. It has 16,569 bp (that makes up approximately 1% of total cellular DNA) while nuclear DNA has 3.3 billion bp. It has 37 genes that encode 13 protein subunits of the respiratory chain (out of a total of 67 proteins) i.e. about 20%. It mutates at a rate 5-10 times that of nuclear DNA. Mitochondrial DNA is transmitted by maternal non-mendelian inheritance.



Solution to Question 3:

A high intake of protein results in a higher rate of protein turnover, which explains the increased diet-induced thermogenesis seen in people consuming a high protein diet.

The state of protein nutrition can be determined by measuring the difference between intake and output of nitrogenous compounds which are known as nitrogen balance.

• In a healthy adult, nitrogen balance is in equilibrium, when intake equals output, and there is no change in the total body content of protein.

• In a growing child, a pregnant woman, the excretion of nitrogenous compounds is less than the dietary intake of nitrogen in the body as protein— positive nitrogen balance.

• In response to trauma or infection, or if the intake of protein is inadequate to meet requirements, there is the net loss of protein nitrogen from the body—negative nitrogen balance.

A high intake of protein does not lead to positive nitrogen balance; although it increases the rate of protein synthesis, it also increases the rate of protein catabolism, so that nitrogen equilibrium is maintained with a higher rate of protein turnover.

Both protein synthesis and catabolism are ATP expensive, hence the increased diet-induced thermogenesis seen in people consuming a high protein diet.

Solution to Question 4:

Klenow fragment lacks 5’ → 3’ exonuclease activity.

DNA polymerase I is an enzyme involved in DNA replication. It has polymerase activity along with both 3' → 5' and 5' → 3' exonuclease activity. When the 5' → 3' exonuclease domain is removed, the remaining fragment is called Klenow fragment. It retains the polymerization and proofreading activities of DNA polymerase I.

Solution to Question 5:

SCID is due to defective non-homologous end joining repair.

Defects in DNA Repair:

Non-Homologous End Joining Repair	Severe combined immunodeficiency disease (SCID)
Homologous Repair	Bloom syndrome Werner syndrome Breast cancer susceptibility
Nucleotide Excision Repair	Xeroderma pigmentosum
Mismatch Repair	Hereditary nonpolyposis colorectal cancer (HNPCC)
Base Excision Repair	MUTYH-associated polyposis (MAP)

Solution to Question 6:

The given features are consistent with von Gierke's disease. It is the most common glycogen storage disease.

Enzyme deficient in this condition is glucose-6-phosphatase (common to both glycogenolysis and gluconeogenesis). Inheritance is autosomal recessive.

Von Gierke disease (type I glycogen storage disorder) occurs due to the deficiency of glucose-6-phosphatase enzyme in the liver, kidney, and intestinal mucosa. Patients present commonly by 3-4 months of age with hypoglycemia (leading to seizures), lactic acidosis, and hepatomegaly. Affected children often have a doll-like face with fat cheeks, relatively thin extremities, short stature, and a protuberant abdomen due to massive hepatomegaly. The kidneys are also enlarged, whereas the spleen and heart are not involved. Laboratory findings include hypoglycemia, lactic acidosis, hyperuricemia, and hyperlipidemia.

A definitive diagnosis is made using a liver biopsy. Fructose and galactose restriction in the diet is advised.

Solution to Question 7:

• Hepcidin, ceruloplasmin, and transferrin are involved in iron metabolism.

• Transthyretin transports thyroxine and retinol-binding protein and has no role in iron metabolism

Proteins involved in iron metabolism:

• Ferritin and hemosiderin: Iron storage

• Transferrin: Iron transport

• Ceruloplasmin: a copper-containing enzyme with ferroxidase activity

• Hepcidin: Chief regulator of systemic iron homeostasis

Solution to Question 8:

Selenocysteine, the 21st amino acid, is formed by co-translational modification. It is coded by the UGA codon, which is normally a stop codon. The protein synthetic apparatus can identify a selenocysteine-encoding UGA by the presence of the selenocysteine insertion sequence (SECIS) in the untranslated region of mRNA.

Selenocysteine is an analog of cysteine and is synthesized from serine.

Selenocysteine is present at the active site of several human enzymes that catalyze redox reactions such as thioredoxin reductase, glutathione peroxidase, and deiodinase. Since Glutathione peroxidase contains selenocysteine and hence it is an antioxidant.

Impairments in human selenoproteins have been implicated in tumorigenesis and atherosclerosis and are associated with selenium deficiency cardiomyopathy (Keshan disease).

Solution to Question 9:

Detectable levels of ketone bodies in urine (ketonuria) are seen in conditions characterized by increased ketogenesis such as starvation. The urine test done for ketone bodies is the Rothera's test in which formation of a purple ring indicates presence of ketone bodies. Gerhardt's test is also done to detect ketone bodies in urine.

Benedict' test done for reducing sugars.

Heat coagulation test done for proteins.

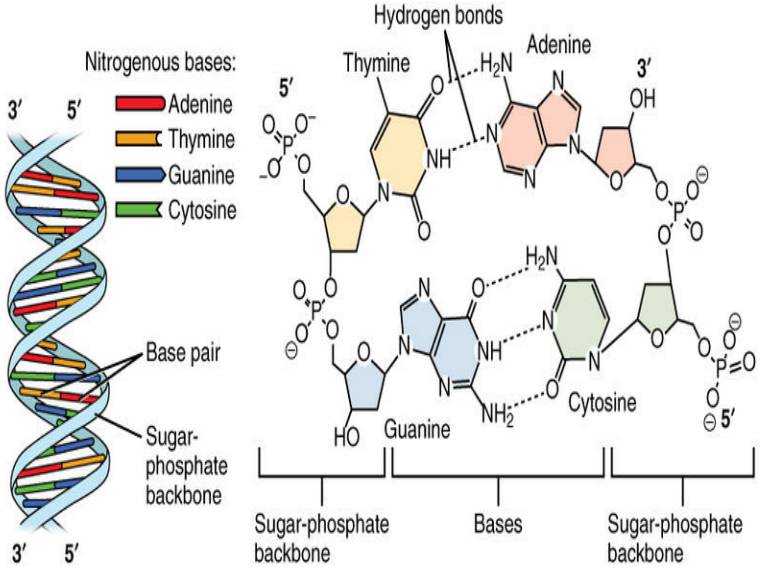
Solution to Question 10:

The marked bond represents a hydrogen bond between thymine and adenine.

The complementary nitrogenous bases of the 2 strands of the DNA double helix are linked by hydrogen bonds. Adenine and thymine are linked by two hydrogen bonds (A=T) whereas three hydrogen bonds are present between cytidine and guanine (C≡G). Van der Waals and hydrophobic interactions are present between the stacked adjacent base pairs.

A β-N-glycosidic bond is present between the nitrogenous base and deoxyribose sugar. C1 of deoxyribose/ribose sugar is joined covalently to N1 of pyrimidines and N9 of purines by β-N-glycosidic bond. An ester bond is present between the sugar and phosphate group of the same nucleotide. An acid anhydride bond is present between two phosphate groups.

A polymer of nucleotides is joined by 3'-5' phosphodiester bond. The bond is present between the sugar of one nucleotide and the phosphate group of another.

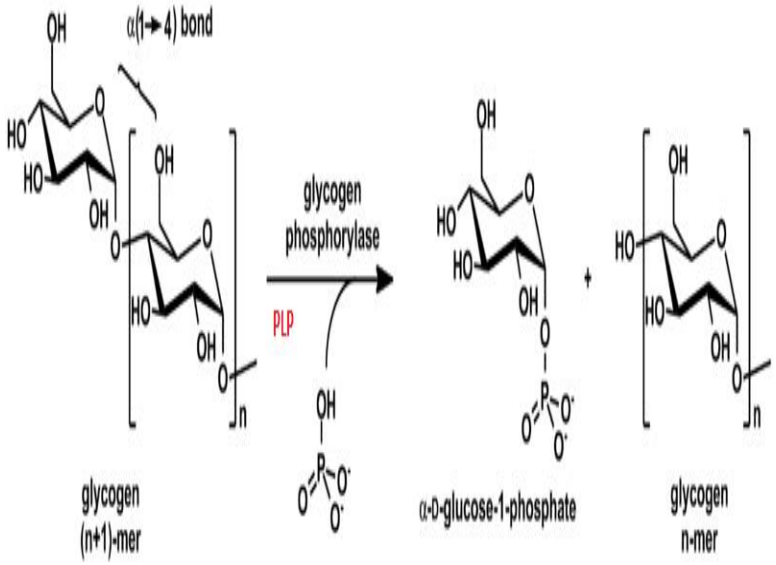


Solution to Question 11:

• Pyridoxal phosphate is a cofactor of glycogen phosphorylase, where the phosphate group is catalytically important.

• PLP also acts as the coenzyme for many enzymes involved in amino acid metabolism, especially transamination and decarboxylation.

• Glycogen phosphorylase is a debranching enzyme which cleaves alpha-1,4 bonds of the glycogen chain to produce glucose-1-phosphate in glycogenolysis.



Solution to Question 12:

The combined use of glucosamine sulfate and chondroitin sulfates in the treatment of degenerative joint disease has become an extremely popular supplementation protocol in arthritic conditions of the joints.

• Glucosamines are amino sugars which form the major component of glycosaminoglycans. (GAG's are tandem repeats of amino sugar and uronic acid)

• GAG's combine with proteins to form proteoglycans

• One such proteoglycan is aggrecan containing several GAGs (hyaluronic acid, chondroitin sulphate, and keratan sulphate) and both link and core proteins

• Aggrecan is the major proteoglycan in cartilage

• Hence, from this we can deduce that glucosamines being a major part of GAG's and proteoglycans such as aggrecan are protective against arthritis.

Solution to Question 13:

Restriction endonuclease enzymes act at specific palindromic sequences that create DNA fragments of different lengths. By analyzing the fragments, specific species of bacteria can be identified. Option B is the only palindromic sequence here, hence it is the answer.

RFLP is a restriction fragment length polymorphism (RFLP) analysis technique that involves cutting a particular region of DNA with known variability, with restriction enzymes, then separating the DNA fragments by agarose gel electrophoresis and determining the number of fragments and relative sizes.

Cleavage of a sample of DNA with a restriction enzyme produces a characteristic set of smaller DNA fragments. Deviations in the normal product pattern, produce RFLPs that occur if a mutation renders a restriction site unrecognizable and alternatively, generates a new recognition site.

Solution to Question 14:

Thiamine deficiency results in decreased energy production because thiamine pyrophosphate (TPP) is a coenzyme of pyruvate and α-ketoglutarate dehydrogenase, which are required for the production of ATP using NADH.

Thiamine pyrophosphate is an important coenzyme in three multienzyme complexes that catalyze oxidative decarboxylation reactions:

• Pyruvate dehydrogenase in carbohydrate metabolism.

• α-ketoglutarate dehydrogenase in the citric acid cycle.

• Branched-chain ketoacid dehydrogenase involved in the metabolism of leucine, isoleucine and valine.

NAD is a co-factor in pyruvate and α-ketoglutarate dehydrogenase. Hence in thiamine deficiency, there is decreased ATP production owing to reduced NADH entering into the electron transport chain.

Option A: Thiamine does not interfere in alcohol metabolism but alcohol interferes directly with the absorption of thiamine and with the synthesis of thiamine pyrophosphate.

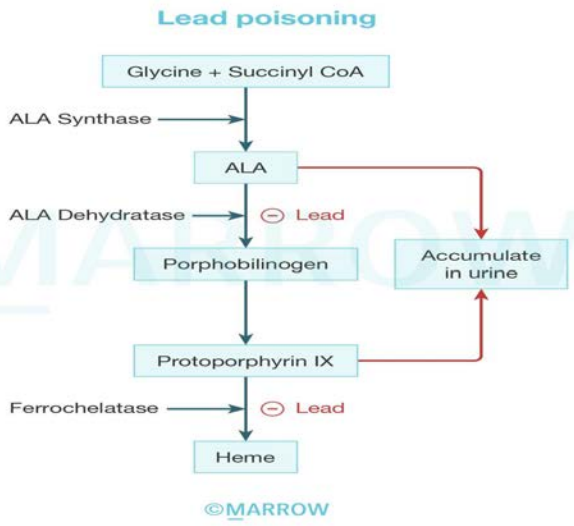
Option B: Thiamine is also the coenzyme for transketolase in the pentose phosphate pathway (HMP shunt) but there is no ATP synthesized in this pathway.

Solution to Question 15:

A child with acute abdominal pain, tingling sensation and weakness of limbs with history of eating paint likely has lead poisoning. It is characterized by impaired ALA dehydratase enzyme activity.

Lead is a potent inhibitor of both ALA dehydratase and ferrochelatase/ heme synthase (option C). However, it has the greatest inhibitory action on ALA dehydratase. Lead poisonining thus leads to the buildup of protoporphyrin and ALA. Lead also substitutes for calcium in many fundamental

cellular processes. It can cross red blood cell membranes as well as the blood-brain barrier and enter the neuroglial cells which support brain function. The fatal dose of lead is 20g of lead acetate and the fatal period is 1 to 2 days.



Other options:

Option A: ALA synthase 2 defect causes X-linked protoporphyria.

Option C: Heme synthase, or ferrochelatase, defect causes erythropoeitic protoporphyria.

Option D: Coproporphyrinogen oxidase defect causes hereditary corproporphyria.

Solution to Question 16:

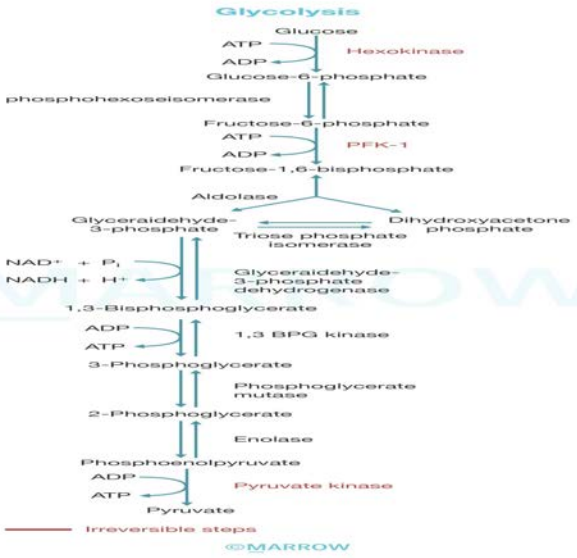
Breakdown of glycogen under anaerobic conditions yields 3 ATPs.

Breakdown of glycogen yields glucose-6-phosphate which can enter the glycolysis pathway. Since it bypasses the first step, one ATP is saved and anaerobic glycolysis yields 3 ATPs.

The first step in glycolysis involves the conversion of glucose to glucose-6-phosphate which requires one ATP. Glycogen breakdown leads to formation of glucose-6-phosphate which can enter glycolysis hence bypassing the first step and saving one ATP.

One ATP is used for conversion of fructose-6-phosphate to fructose 1,6 biphosphate hence net ATP formed from anaerobic glycolysis of glycogen is 3ATP

REACTION	ENZYME	METHOD OF ATP FORMATION	NET ATP PRODUCED
1,3-bisphosphoglycerate to 3 phosphoglycerate	Phosphoglycerate kinase	Substrate level phosphorylation	2 ATP
Phosphoenol pyruvate to Pyruvate	Pyruvate kinase	Substrate level phosphorylation	2 ATP
		TOTAL PRODUCED	4 ATP



Solution to Question 17:

Phenylbutyrate scavenges nitrogen by combining with amino acids to form a more water-soluble product, which can be easily excreted by the kidneys.

Phenylbutyrate combines with glutamate to form pheynylbutylglutamine.

Other substances that can be used as nitrogen scavengers are:

• Combination of benzoate (forms hippurate on combining with endogenous glycine)

• Phenylacetate (forms phenylacetylglutamine on combining with glutamate) available as ammonia.

• Arginine is also useful.

Solution to Question 18:

Epigenetics is defined as heritable changes in gene expression that are not caused by alteration in gene sequence.

It means “above genetics” and refers to the fact that gene regulatory mechanisms do not change the underlying regulated DNA sequence, but rather simply the expression patterns of the DNA.

Epigenetic mechanisms play a key role in establishment, maintenance, and reversibility of transcriptional states. A key feature is that the controlled transcriptional on/off states can be maintained through multiple rounds of cell division. This observation indicates there must be robust mechanisms to maintain and stably propagate these epigenetic states.

Histone Methylation Mostly Makes DNA Mute.

Histone Acetylation: Relaxes DNA coiling, allowing for transcription. Histone Acetylation makes DNA Active.

Solution to Question 19:

A low insulin/glucagon ratio indicates low insulin and high glucagon levels, which are observed in the fasting state. In the fasting state, all of the above processes (i.e., glycogen breakdown, ketogenesis, and gluconeogenesis) occur, but not glycogen storage.

Metabolic process	Fasting state/ low insulin-glucagon ratio	Fed state/ high insulin-glucagon ratio
Gluconeogenesis	Increased	Decreased
Glycogenolysis	Increased	Decreased
Ketogenesis	Increased	Decreased
Glycogen storage	Decreased	Increased

Biochemistry AIIMS 2018

Question 1:

An adolescent male patient presented with pain in the calf muscles on exercise. On biopsy, an excessive amount of glycogen was found to be present in the muscle. What is the most likely enzyme deficiency?

a) Muscle-debranching enzyme

b) Phosphofructokinase 1

c) Glucose 6 phosphatase

d) Muscle glycogen phosphorylase

Question 2:

Alkali disease of livestock is caused by an excess of which of the following minerals?

a) Selenium

b) Manganese

c) Molybdenum

d) Iron

Question 3:

Which of the following types of collagens is involved in wound healing?

a) Type II

b) Type III

c) Type IV

d) Type V

Question 4:

An infant is brought with a history of vomiting and poor feeding. A musty odor is noted in the baby. Guthrie test was done and it was found to be positive. All are true regarding this disease except

a) Phenylalanine hydroxylase enzyme defect

b) White patch of hair due to tryptophan deficiency

c) Phenylacetate positive in urine

d) Mental retardation is present

Question 5:

In a reaction, the substrate is available in a concentration that is 1000 times the Km value of the enzyme. After 9 minutes of reaction, 1% of substrate is converted to product (12 microgram/ml). If the concentration of the enzyme is changed to 1/3 and concentration of substrate is doubled, what is the time taken to convert the substrate into the same amount of product that i.e. 12 microgram/ml?

a) 9 minutes

b) 4.5 minutes

c) 27 minutes

d) 13.5 minutes

Question 6:

The best method to measure HbA1C is _____

a) Isoelectric focusing

b) Affinity chromatography

c) Ion exchange chromatography

d) Electrophoresis

Question 7:

Which of the following is the best screening investigation for metabolic disorders?

a) Western blot

b) Tandem mass spectrometry

c) PCR

d) Gel electrophoresis

Question 8:

Which of the following enzyme activity decreases in fasting?

a) Hormone-sensitive lipase

b) Glycogen phosphorylase

c) Pyruvate carboxylase

d) Phosphofructokinase 1

Question 9:

Fluoroacetate is a component of pesticides. Which of the following metabolic pathways is inhibited by this compound?

a) TCA cycle

b) Glycolytic pathway

c) Oxidative phosphorylation

d) ETC

Question 10:

Which of the following does not require 5' capping?

a) tRNA of Alanine

b) U6 snRNA

c) mRNA for Histone

d) siRNA

Question 11:

Vitamin K in its coenzyme form is regenerated by the enzyme ____

a) Glutathione reductase

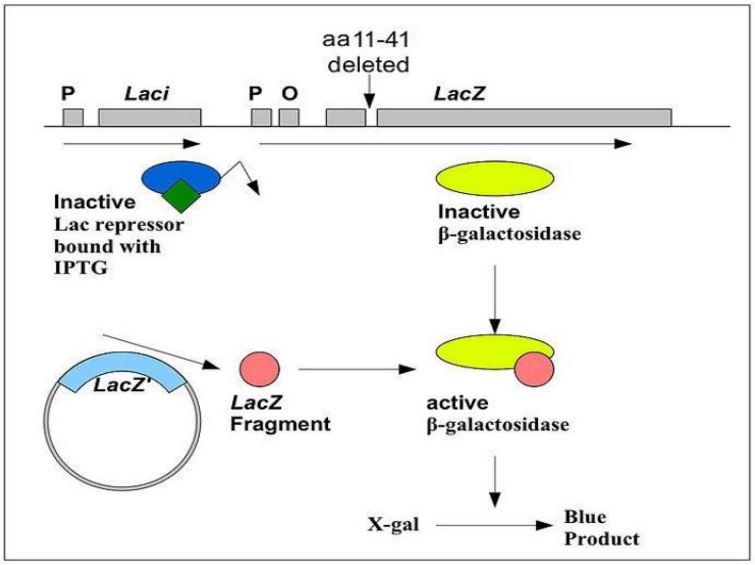
b) Quinone reductase

c) Vitamin K reductase

d) Epoxide reductase

Question 12:

Identify the phenomenon shown below



a) Translation

b) Transformation

c) Complementation

d) Conjugation

Question 13:

A middle-aged woman presents with fissured tongue and peripheral neuropathy. Investigations showed reduced glutathione reductase activity. Which vitamin deficiency is the likely cause of this?

a) Vitamin B1

b) Vitamin B2

c) Vitamin B6

d) Vitamin B12

Question 14:

Which of the following enhances iron absorption?

a) Vitamin A

b) Vitamin C

c) Thiamine

d) Riboflavin

Question 15:

Which of the following does not favor euchromatin formation due to changes occurring at cytosine residues at CpG islands in DNA?

a) Methylation

b) Phosphorylation

c) Alkylation

d) Sumoylation

Question 16:

Which of the following techniques is based on RNA?

a) RT PCR

b) Sanger's technique

c) Next generation sequencing

d) Western blot

Question 17:

Vitamin C cannot be produced in humans due to lack of

a) L- gulonolactone oxidase

b) Xylitol reductase

c) Pyruvate dehydrogenase

d) UDP glucose dehydrogenase

Question 18:

Klenow fragment lacks the activity of

a) 3'→5' Exonuclease

b) 5'→3' Exonuclease

c) 5'→3' DNA polymerase

d) 3'→5' DNA polymerase

Question 19:

Child presents with hypotonia and seizures. It was confirmed to be Zellweger syndrome. Which among the following accumulates in brain in this condition?

a) Glucose

b) Lactic acid

c) Long chain fatty acid

d) Triglycerides

Question 20:

A 12-year-old girl suffers from an inadequately treated type 1 diabetes mellitus. She is currently hyperglycemic. Which of the following is most likely to occur?

a) Glycogenesis in muscle

b) Increased protein synthesis

c) Increased conversion of fatty acids to acetyl-CoA

d) Decreased cholesterol synthesis

Question 21:

What would be the respiratory quotient if someone is on an exclusive carbohydrate diet?

a) 0.7

b) 0.8

c) 1

d) 1.2

Answer Key

Question No.	Correct Option

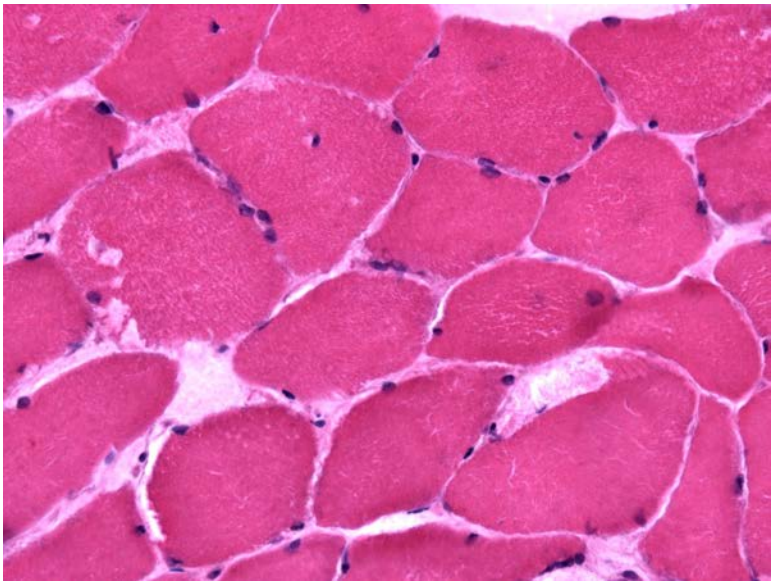
21	c

Detailed Explanations

Solution to Question 1:

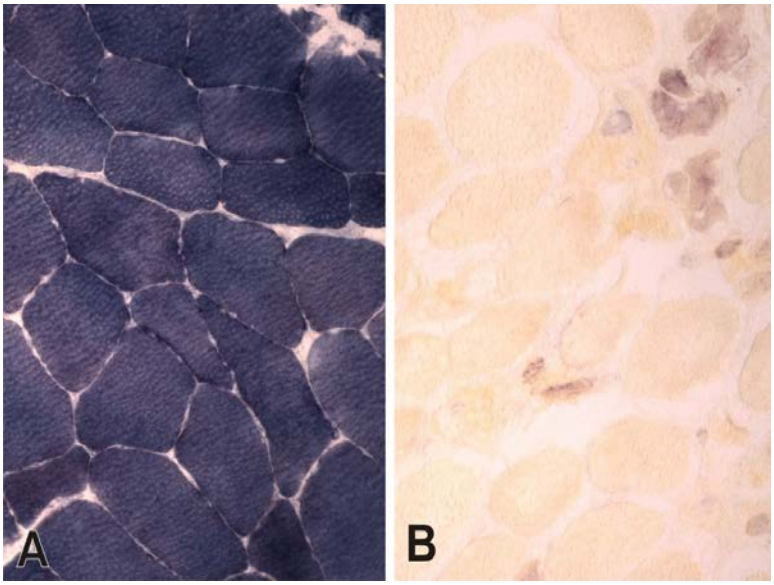
The given clinical features are seen in McArdle's disease. This patient has muscle glycogen phosphorylase deficiency.

The lack of muscle glycogen phosphorylase results in excess glycogen build-up in muscles. The image given below shows the vacuolar myopathy seen in McArdle's disease.



Clinical features include poor exercise tolerance, abnormally high muscle glycogen (2.5-4%), and a very low blood lactate after exercise

The images given below show myophosphorylase enzyme histochemistry showing (A) Normal muscle and (B) McArdle's disease.



Solution to Question 2:

Excess of selenium causes alkali disease in livestock.

Clinical types of selenium intoxication

• Acute selenosis

• Subacute selenosis (i.e., blind staggers type)

• Chronic selenosis (i.e., alkali disease type)

Alkali disease occurs when animals consume moderate levels of selenium for a period of weeks to months.

The common clinical signs of chronic selenosis in horses, cattle, and swine are loss of hair (horses and cattle lose long hair from the mane and tails), emaciation, hoof lesions, weight reduction, and lameness.

Solution to Question 3:

Type III collagen is involved in wound healing.

Collagen types I and III predominate in the skin and aponeurotic layers. In the early stages of wound healing, type III collagen is synthesized. It is replaced by type I collagen as wound healing progresses.

The tensile strength of the healing wound is directly proportional to the amount and type of collagen present. During healing, as disorganized collagen is degraded and reformed, covalent cross-links are formed that enhance tensile strength. The maximum strength of the healed wound depends upon the interconnection of collagen subunits. Approximately 80 percent of the original strength of the tissue is obtained by six weeks after surgery. Wounds slowly continue to get stronger but may never achieve 100 percent of their previous strength.

Solution to Question 4:

The given scenario of an infant with a history of vomiting and poor feeding with a musty odour is suggestive of phenylketonuria (PKU). Tryptophan deficiency is not a feature of this disorder. The deficiency of the enzyme phenylalanine hydroxylase causes PKU.

Characteristic clinical findings in Phenylketonuria:

• Mental retardation

• Failure to walk or talk

• Seizures

• Hyperactivity

• Tremor

• Microcephaly

• Failure to grow

• Deficiency of pigmentation (fair hair, light skin color, and blue eyes)

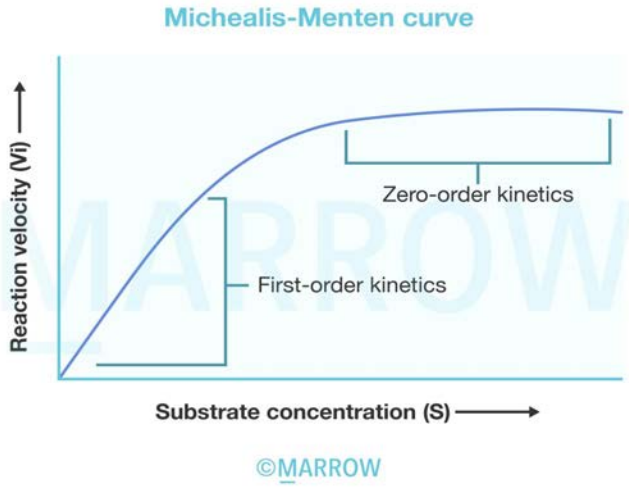
The Guthrie bacterial inhibition test is a screening test for phenylketonuria. This test uses a phenylalanine requiring strain of Bacillus subtilis. The ferric chloride test is also used as a screening test for PKU. Tandem mass spectrometry is the gold standard investigation.

Solution to Question 5:

The time taken for the formation of the same amount of product is 27 minutes.

In this reaction, the substrate concentration becomes 1000 times i.e much greater than the Km value. Thus, the rate of this reaction is equal to Vmax and is thus independent of the substrate concentration i.e. it follows zero-order kinetics. Thus, doubling the substrate concentration does not change the velocity of the reaction i.e. it remains as Vmax.

No matter the substrate concentration, the rate of the reaction is directly proportional to the concentration of the enzyme. In this situation the enzyme concentration becomes 1/3rd. Thus, the velocity of the reaction (Vmax) also becomes 1/3rd. This means that the time taken for the formation of the same amount of product will become tripled i.e 9 × 3 = 27 minutes.



Solution to Question 6:

The best method to measure HBA1C is ion-exchange chromatography.

In ion-exchange chromatography:

• Proteins interact with the stationary phase by charge-charge interactions.

• Proteins with a net positive charge at a given pH will tightly adhere to beads with negatively charged functional groups such as carboxylates or sulfates (cation exchangers).

• Proteins with a net negative charge adhere to beads with positively charged functional groups, typically tertiary or quaternary amines (anion exchangers).

• Non-adherent proteins flow through the matrix and are washed away.

• Proteins elute in inverse order of the strength of their interactions with the stationary phase.

Solution to Question 7:

Tandem mass spectrometry (MS) is the technique of choice for screening neonates for inherited metabolic diseases.

Tandem MS employs the equivalent of two mass spectrometers linked in series (MS-MS or MS2). It can be used to screen blood samples from newborns for the presence and concentrations of amino acids, fatty acids, and other metabolites.

Abnormalities in metabolite levels indicate inherited metabolic diseases, such as phenylketonuria, ethylmalonic encephalopathy, and glutaric acidemia type 1.

Solution to Question 8:

During fasting, there is low insulin, and hence, the activity of phosphofructokinase-1 gets inhibited.

Phosphofructokinase 1 is an enzyme of glycolysis. It is induced by insulin and a well-fed state.

Other options:

Option A: Hormone-sensitive lipase mobilizes stored fats in a fasting state.

Option B: Glycogen phosphorylase is active in fasting state so as to produce glucose from glycogen.

Option C: Pyruvate carboxylase is an enzyme of gluconeogenesis. During the fasting state, the liver is flooded with fatty acids mobilized from adipose tissue. The resulting elevated hepatic acetyl CoA activates pyruvate carboxylase. Other enzymes of gluconeogenesis that are elevated in fasting include Phosphoenolpyruvate carboxykinase, Fructose-1,6-bisphosphatase, and Glucose-6-phosphatase.

Solution to Question 9:

Fluoroacetate inhibits the TCA cycle enzyme aconitase.

Fluoroacetyl CoA condenses with oxaloacetate to form fluorocitrate which inhibits aconitase, causing citrate to accumulate. This way it inhibits TCA cycle enzyme non-competitively.

Sources of fluoroacetate exposure:

• Fluoroacetate in some plants

• Fluorinated compounds (anticancer agents, industrial chemicals, and pesticides) are metabolized to fluoroacetate.

Solution to Question 10:

tRNA of Alanine does not require 5’ capping.

Capping process protects the 5′ end of mRNA from the action of exonucleases and polyadenylation protects the 3′ end of the mRNA. All mRNA, snRNA, and siRNA undergo this

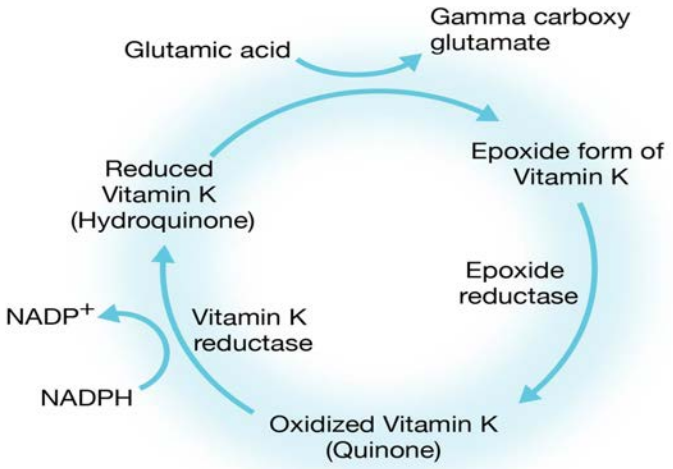
process, but tRNA are comparatively stable and do not require a capping at the 5’ end.

Note: rRNAs also do not require 5' capping.

Solution to Question 11:

The coenzyme form of Vitamin K is regenerated by the enzyme epoxide reductase.

Epoxide reductase reduces Vitamin K epoxide to its coenzyme form hydroquinone.



Note: In addition to vitamin K reductase, epoxide reductase can also catalyse the reduction of quinone to hydroquinone. Thus, it can regenerate hydroquinone by itself.

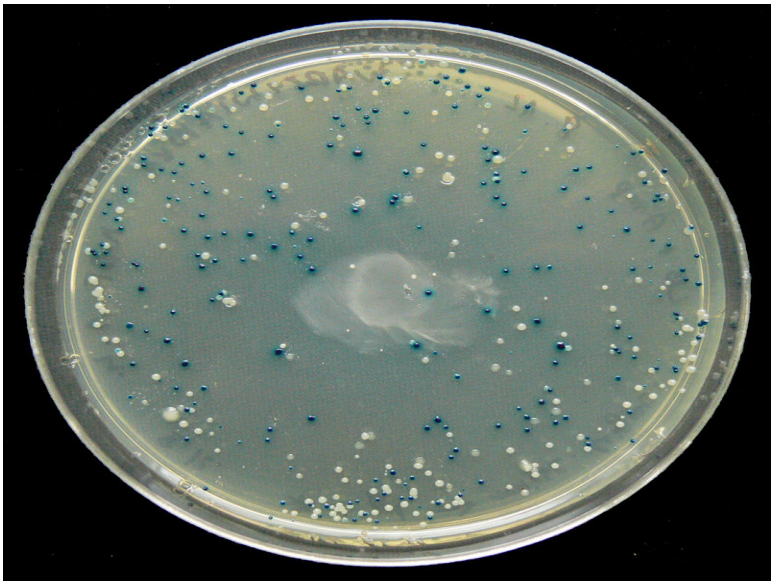
Solution to Question 12:

The image shows a schematic of the blue-white assay used in the screening of recombinant vectors for inserted DNA fragments. It uses the phenomenon of complementation (α-complementation of the β-galactosidase gene).

Blue–white assay:

The DNA of interest is ligated into a vector. The vector is then inserted into a competent host cell viable for transformation, which is then grown in the presence of X-gal (X-gal detects active β-galactosidase). Cells transformed with vectors containing recombinant DNA will produce white colonies; cells transformed with non-recombinant plasmids (i.e., only the vector) grow into blue colonies.

The image below shows the result of a blue–white assay.



Solution to Question 13:

This patient is most likely suffering from riboflavin/vitamin B2 deficiency.

Deficiency of riboflavin is characterized by cheilosis, desquamation, and inflammation of the tongue, seborrheic dermatitis, corneal vascularization, anemia, and personality changes.

Riboflavin nutritional status is assessed by measurement of the activation of erythrocyte glutathione reductase by FAD added in vitro.

Solution to Question 14:

Iron absorption is enhanced by vitamin C.

Vitamin C reduces the ferric iron to its ferrous form, thereby helping in the process of absorption of dietary iron from the intestine.

Vitamin C deficiency causes

• Decreased absorption of iron leading to microcytic-hypochromic anemia

• Decreased hydroxylation of proline and lysine, which results in defective collagen synthesis and bleeding manifestations.

Conversely, vitamin C toxicity (>2000 mg/ day) can lead to iron overloaded states.

Note: Alcohol and fructose also enhance iron absorption. However, the absorption of both inorganic and heme iron is impaired by calcium. So, a glass of milk with a meal significantly reduces iron availability.

Solution to Question 15:

Methylation does not favour euchromatin formation due to changes cytosine residues at CpG islands in DNA.

The transcriptional regulatory regions of active genes often contain a high frequency of CpG dinucleotides (referred to as CpG islands) and they are normally unmethylated. Therefore, methylation is an epigenetic modification that inactivates DNA, and hinders the formation of euchromatin (transcriptionally active chromatin). Epigenetic changes include alterations of chromatin structure by:

• Methylation of cytosine residues in CpG dinucleotides

• Modification of histones by acetylation or methylation

• Changes in higher-order chromosome structure

Sumoylation of histones (SUMO - Small Ubiquitin-related MOdifier) is associated with transcription repression. Other possible roles of posttranslationally modified histones:

• Acetylation of core histones is associated with chromosomal assembly during DNA replication.

• Phosphorylation of histone H1 is associated with the condensation of chromosomes during the replication cycle.

• ADP-ribosylation of histones is associated with DNA repair.

• Methylation of histones is correlated with activation and repression of gene transcription.

• Acetylation of histones H3 and H4 is associated with the activation or inactivation of gene transcription.

• Monoubiquitylation is associated with gene activation, repression, and heterochromatic gene silencing.

Solution to Question 16:

RT PCR is a RNA-based technique.

RT PCR is a method used to quantitate mRNA levels that relies upon the first step of cDNA copying of mRNAs catalyzed by reverse transcriptase prior to PCR amplification and quantitation.

Other techniques:

• Sanger's technique and Southern blot: DNA

• Western blot: protein

• Northern blot: RNA

• Next-generation DNA sequencing technologies include Illumina (Solexa) sequencing, Roche 454 sequencing, Ion torrent: Proton/PGM sequencing, SOLID sequencing.

Solution to Question 17:

Ascorbic acid (vitamin C) cannot be synthesized in human beings because of the absence of L-gulonolactone oxidase.

Uronic acid pathway catalyzes the conversion of glucose to glucuronic acid, ascorbic acid, and pentoses. Glucuronate is reduced to L-gulonate, the direct precursor of ascorbate in the animals capable of synthesizing this vitamin.

Solution to Question 18:

Klenow fragment lacks 5' → 3' exonuclease activity.

DNA polymerase I is an enzyme involved in DNA replication. It has polymerase activity along with both 3' → 5' and 5' → 3' exonuclease activity. When the 5' → 3' exonuclease domain is removed, the remaining fragment is called Klenow fragment. It retains the polymerization and proofreading activities of DNA polymerase I.

Solution to Question 19:

Elevated levels of very long chain polyenoic acids have been found in the brains of patients with Zellweger syndrome.

Zellweger syndrome:

• Autosomal recessive

• Cerebro-hepato-renal syndrome: Impaired neuronal migration and myelination, hepatomegaly, renal cysts

• Reduction or absence of functional peroxisomes in tissues.

• Accumulation of very long chain polyenoic acids in the brain.

• Severe neurological symptoms.

• Most patients die within the 1st year of life

Solution to Question 20:

With the background of inadequately treated type I diabetes mellitus, an insulin-deficient state in the body is expected which will lead to increased conversion of fatty acids to acetyl-CoA.

Type 1 diabetes mellitus is commonly found in the adolescent population. In response to certain precipitating factors, such patients may develop a severe insulin-deficient state. Since insulin is an inhibitor of hormone-sensitive lipase (HSL), an insulin-deficient state will cause HSL overactivity in adipocytes and the breakdown of lipid into fatty acids (lipolysis). Free fatty acids will undergo beta-oxidation and produce a large amount of acetyl CoA, which gets converted to ketone bodies (acetoacetate, acetone, beta-hydroxybutyrate, etc.)

Solution to Question 21:

The respiratory quotient, if someone is on an exclusive carbohydrate diet, is 1.

The respiratory quotient is the amount of CO_2 produced /O_2 consumed.

The respiratory quotient for various substances:

Substance	RQ
Carbohydrate	1.00
Protein	0.81
Fat	0.71
Alcohol	0.66

Biochemistry AIIMS 2019 (May & Nov)

Question 1:

Child presents with hypotonia and seizures. It was confirmed to be Zellweger syndrome. Which among the following accumulates in brain in this condition?

a) Glucose

b) Lactic acid

c) Long chain fatty acid

d) Triglycerides

Question 2:

Which of the following does not happen in 5' to 3' direction?

a) Transcription

b) DNA replication

c) DNA repair

d) RNA editing

Question 3:

Chimeric DNA is associated with:

a) Paternity test

b) Maternity test

c) Personal identification

d) Organ transplantation

Question 4:

A bodybuilder starts eating raw eggs for protein. He starts to develop fatigue on moderate exercise. The doctor prescribes a vitamin. Which enzyme is deficient in him?

a) Glucose 6 Phosphate

b) Pyruvate Carboxylase

c) PEPCK

d) Glycogen Phosphorylase

Question 5:

Which of the following shows functional assessment of B1 deficiency?

a) RBC Transketolase

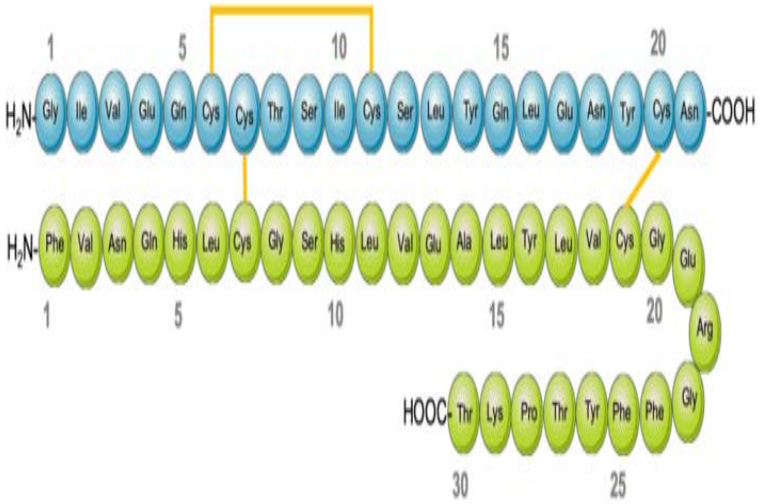
b) RBC Glutathione reductase

c) Serum Thiamine levels

d) RBC Glutathione Peroxidase

Question 6:

Which modification will lead to a change in the biological activity of the hormone given in the picture?



a) Hydrolysis of disulphide bonds

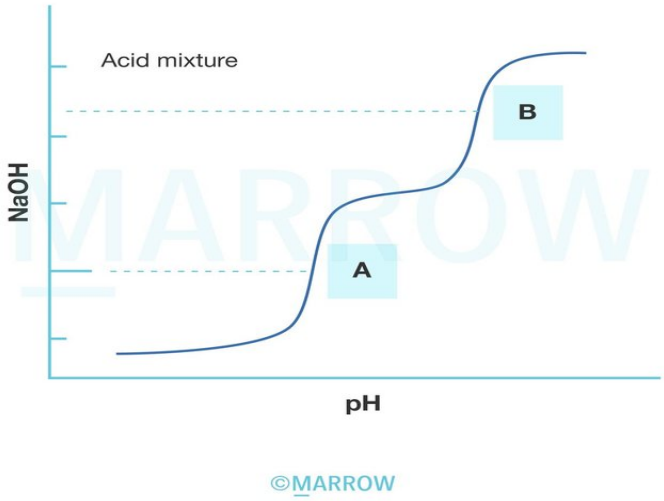
b) Change in 5-6 in A chain

c) Change in 29-30 in B chain

d) Change in 14-16 in A chain

Question 7:

The graph shown below is the titration curve of a biochemical compound. Which of the following statement is true?



a) The maximum buffering capacity of the compound is represented by points A and B

b) The points A and B represent the range of maximum ionization of the amine and carboxyl group

c) The compound has three ionisable side chains

d) The compound has one ionisable group

Question 8:

Which of the following TCA cycle intermediate is a part of heme metabolism?

a) Alpha ketoglutarate

b) Fumarate

c) Succinyl CoA

d) Malate

Question 9:

The catalytic efficiency of enzyme is best expressed by which of the following kinetic constants:

a) Kcat/Km

b) Km/Kcat

c) Km/Ka

d) Ka/Km

Question 10:

Type of mutation seen in sickle cell anemia:

a) Insertion

b) Deletion

c) Point mutation

d) Frameshift mutations

Question 11:

By which mechanism does gene repair occur when mediated by CRISPR-Cas9?

a) Base excision

b) Non-homologous end joining

c) Homologous end joining

d) Mismatch repair

Question 12:

Which of the following is deficient in a patient with features as shown below:

a) Phenylalanine

b) Tryptophan

c) Glutamine

d) Arginine

Question 13:

The attachment of Eukaryotic mRNA to the ribosome is mediated through _____

a) Poly A tail

b) tRNA

c) Guanyl Cap

d) Shine-Dalgarno Sequence

Question 14:

Which of the following would have no effect on the function of the protein product?

a) Glutamine replaced by asparagine

b) Glutamine replaced by alanine

c) Glutamine replaced by glutamate

d) Glutamine replaced by arginine

Question 15:

Which of the following is not true about of proteoglycans?

a) Carries negative charge

b) Chondroitin sulfate is a proteoglylcan

c) Made of amino acids and sugars

d) Holds less water

Question 16:

Which of the following has protective as well as lubricating property?

a) Collagen

b) Mucin

c) Albumin

d) Immunoglobulin

Question 17:

In urea cycle disorders, which of the following can be used to reduce the levels of ammonia?

a) Glutamate

b) Phenylbutyrate

c) Isoleucine

d) L-carnitine

Question 18:

Restriction endonuclease will act on which of the following:

a) AAGAAG

b) GAGAGG

c) AAGCTT

d) TACGAG

Answer Key

Question No.	Correct Option
1	c
2	d
3	d
4	b
5	a
6	c
7	a
8	c
9	a
10	c

11	b
12	b
13	c
14	a
15	d
16	b
17	b
18	c

Detailed Explanations

Solution to Question 1:

Elevated levels of very long chain polyenoic acids have been found in the brains of patients with Zellweger syndrome.

Zellweger syndrome:

• Autosomal recessive

• Cerebro-hepato-renal syndrome: Impaired neuronal migration and myelination, hepatomegaly, renal cysts

• Reduction or absence of functional peroxisomes in tissues.

• Accumulation of very long chain polyenoic acids in the brain.

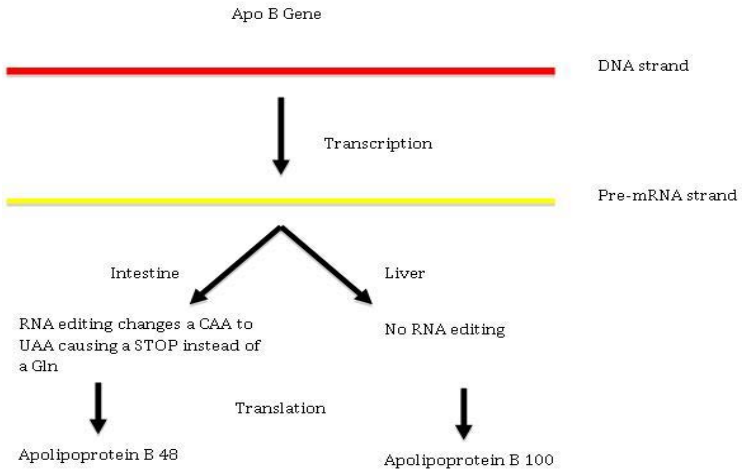
• Severe neurological symptoms.

• Most patients die within the 1st year of life

Solution to Question 2:

RNA editing occurs in 3’ to 5’ direction. It is the process by which the coding sequence is changed at the mRNA level before translation.

RNA editing occurs by insertion of additional Us at the 3’ end of the mRNA and proceeds in a 3’ to 5’ direction. The guide RNA (gRNA) acts as a template for the editing process. An example of RNA editing is apoB gene and mRNA shown in the image below:



Solution to Question 3:

Chimeric DNA is associated with organ transplantation, especially bone-marrow transplantation.

In organ transplantation, chimeric DNA refers to the mixture of donor and recipient genetic material that occurs when donor cells begin functioning within the recipient's body. It is used for long-term monitoring of bone marrow transplant recipients. Detecting changes in the levels of donor-derived cells can provide early warning signs of graft failure, rejection, or relapse of underlying disease.

Note: The practical applications of recombinant DNA technology include:

• Gene mapping using techniques such as fluorescence in situ hybridization (FISH).

• Producing proteins such as:

• Interferons, tPA (tissue plasminogen activator)

• Insulin, growth hormone

• Hepatitis B vaccine

• Molecular analysis of disease, to detect gene variations and mutations.

• Restriction Fragment Length polymorphism (RFLP) and single nucleotide polymorphism (SNP)

• Microsatellite DNA polymorphisms

• Gene therapy and bone marrow transplantation

Solution to Question 4:

The patient developed pyruvate carboxylase enzyme deficiency.

• Biotin serves as co-enzyme for the synthesis of several carboxylase enzymes such as:

• Acetyl-CoA carboxylase

• Pyruvate carboxylase

• Propionyl CoA carboxylase

• Methylcrotonyl-CoA carboxylase

• Individuals who eat an excess of uncooked egg-white, develops biotin deficiency and as a result deficiency of the carboxylase enzymes. This is because, a protein called, avidin present in the egg-white bind to biotin in the diet, and makes biotin unavailable for intestinal absorption.

Solution to Question 5:

Erythrocyte (RBC) transketolase test is the most widely used method for the functional assessment of thiamine deficiency.

Thiaminediphosphate is a co-enzyme for transketolase. Therefore, in thiamine (Vitamin B1) deficiency, the RBC transketolase activity is reduced. When thiamine diphosphate is added in-vitro to erythrocyte lysate, activation of apo-transketolase is suggestive of B1 deficiency.

Solution to Question 6:

The hormone shown in the above image is insulin. Among the given options, changes in 29-30 amino acids in the B chain cause the generation of short and long-acting insulins depending on the modification.

Structure:

The primary structure of insulin consists of 2 polypeptide chains: A-chain(21 Amino acids) and B-chain(30 amino acids).

It has two interchain disulfide bonds,

• Between 7th amino acid of A chain and 7th amino acid of B chain

• Between 20th amino acid of A chain and 19th amino acid of B chain

One intrachain disulfide bond is present between the 6th amino acid of A-chain and 11th amino acid in A-chain.

Modification:

Various short and long-acting insulin analogs have been developed by modifying these amino acid residues.

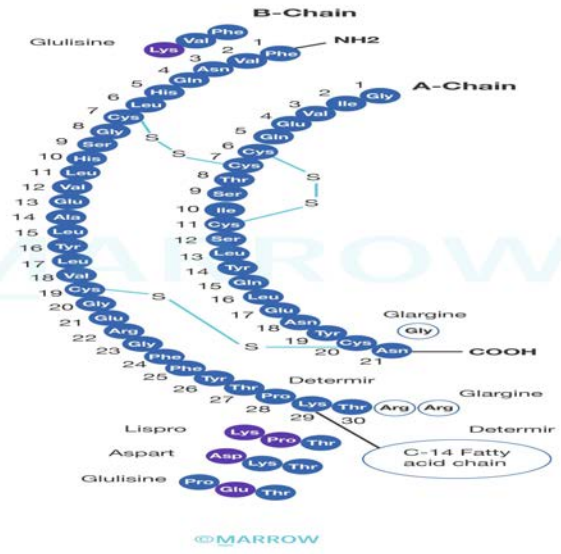
• Insulin lispro: Proline at position 28 and lysine at position 29 in the B-chain are interchanged.

• Insulin Aspart: Proline at position 28 in the B-chain is replaced by aspartic acid.

• Insulin glulisine: Asparagine at position 3 and lysine at position 29 in the B-chain are replaced by lysine and glutamic acid.

• Insulin glargine: Asparagine at position 21 in the A-chain is replaced by glycine and the B-chain contains two extra amino acids(two arginine residues) at positions 31 and 32.

• Insulin detemir: Threonine at position 30 of the B-chain is removed and a 14-carbon fatty acid chain is added to position 29 of the B-chain.



Solution to Question 7:

The maximum buffering capacity of the compound is represented by points A and B, which corresponds to the pK1 and pK2 of the compound.

Other options:

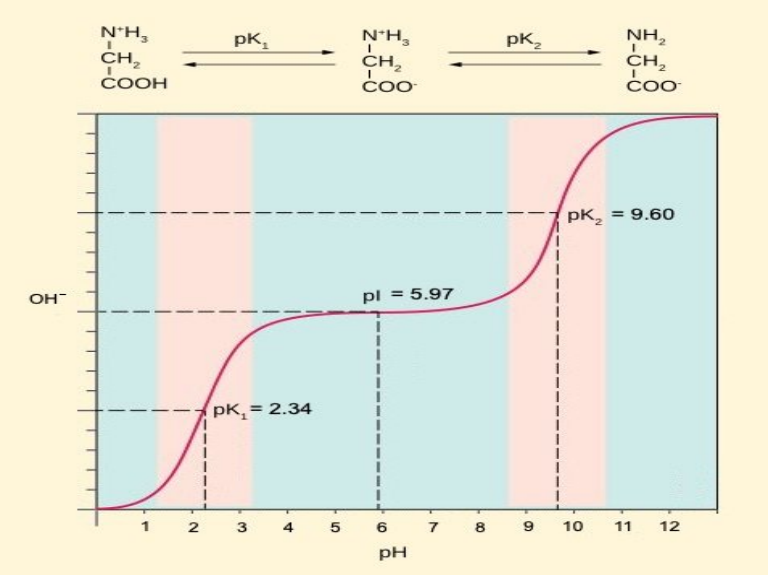
• The points A and B represent the pKa of carboxyl and amino groups respectively.

• The amino acid has no ionizable side chains as the graph shows only two pKas.

• The amino acid has two ionizable groups: an amino group and a carboxyl group.

The above graph resembles the titration curve of the amino acid glycine.

Titration curve of Glycine:



The titration is completed at a pH of 12, where the glycine predominantly exists in the form of H2N - CH2 - COO-.

pK1 and pK2 correspond to the point where the buffering capacity is maximum.

Characteristics of the titration curve:

• Buffering capacity is referred to as the ability of the aminoacid to resist the change in pH due to the addition of acid (H+) or base (OH- equivalents), by accepting or losing the protons respectively.

• An ionizable group refers to the group which can either lose or accept a proton and becomes negatively charged or positively charged ion respectively.

• During the titration, the buffering capacity of the compound reaches its maximum, at points where the pKa of the ionizable groups is reached.

• Each of these pKa are labeled as pK1, pK2, pK3, etc.

• The presence of two pKas indicates that the compound has two ionizable groups. Ex. Glycine.

• The presence of three or more pKas indicates the presence of side chains on the amino acid, with additional ionizable groups.

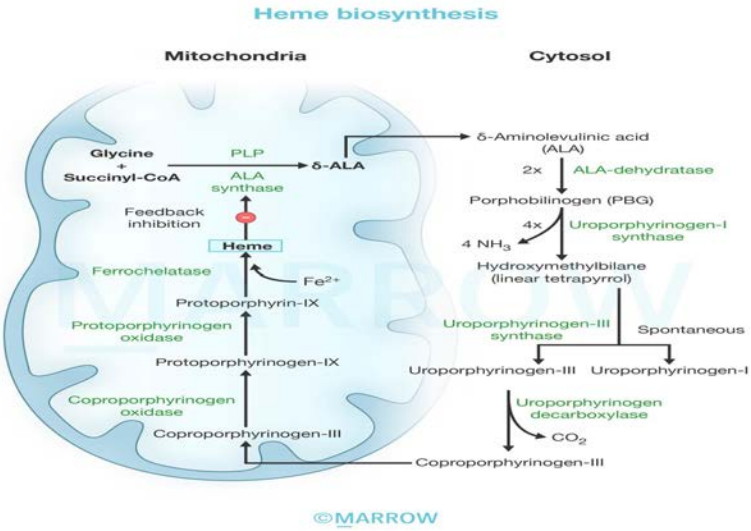
• Ex. histidine has three ionizable groups, an amino group, an imidazole group (on the side chain), and a carboxyl group. The pKas of these groups respectively correspond to the pK1, pK2, pK3 of the titration curve of histidine.

Solution to Question 8:

Succinyl Co-A, an essential part for heme biosynthesis, is an intermediate of the TCA cycle.

The synthesis of heme begins by condensation of succinyl Co-A and glycine to form α-amino-β-ketoadipate, which is then converted to δ-aminolevulinate. These steps are mediated by the enzyme ALA synthase in the mitochrondria.

Various steps involved in the synthesis of heme is illustrated in the image given below:



Solution to Question 9:

The catalytic efficiency of an enzyme is expressed as Kcat/Km.

Kcat is the rate constant, which is the limiting rate of an enzyme-catalyzed reaction at saturation. It is given by Vmax divided by number of active sites of the enzyme. Km is the Michaelis-Menten constant, which is defined as the substrate concentration at which the initial velocity(Vi) is half the maximum velocity (Vmax/2).

For some enzymes, when a substrate (S) binds to the active site of the enzyme (E), and forms an enzyme-substrate complex (ES), the product is instantaneously formed. For such enzymes, the reaction of E+S→ES becomes the rate-limiting step. Its rate is determined on the rate of diffusion of the molecules in a solution. Hence, these enzymes are called diffusion-limited or catalytically perfect.

Examples of the catalytically perfect enzymes, where the catalytic efficiency reaches the diffusion limit of 108-109 M−1s−1:

• Triosephosphate isomerase

• Carbonic anhydrase

• Acetylcholinesterase

• Adenosine deaminase

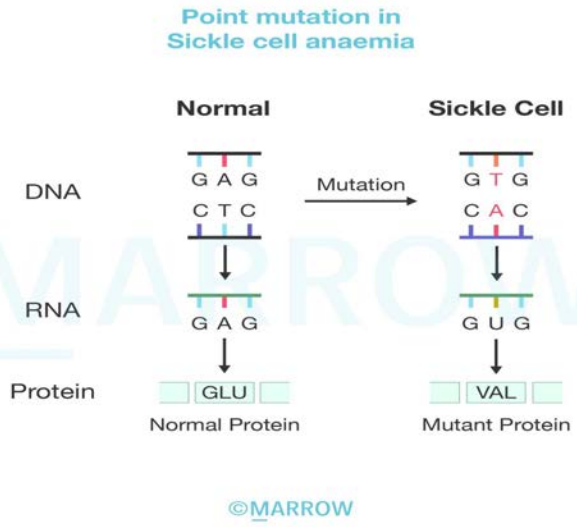
Solution to Question 10:

Point mutation is seen in sickle cell anemia.

• Sickle cell anemia is caused by the mutation of a single base in the β-globin gene, where adenine is replaced with thymine in the sixth codon of the DNA sequence.

• This leads to change from GAG in the normal gene to GTG in the sickle cell gene, leading to a change in mRNA sequence from GAG to GUG.

• As a result, the mutant gene now codes for valine instead of glutamic acid.

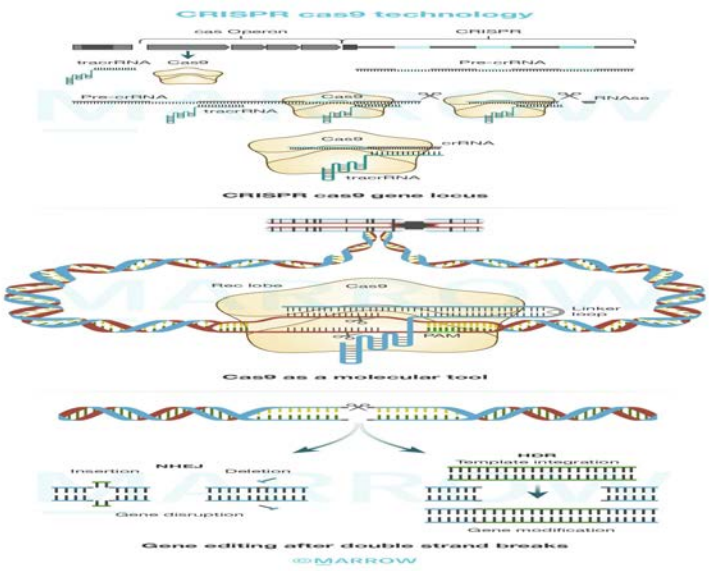


Solution to Question 11:

Non-homologous end joining (NHEJ) is the major mechanism used by CRISPR-Cas9 for gene repair.

The CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) are clustered palindromic sequences found in many bacteria. It is a form of acquired immunity to infection by bacteriophages which complements the system of restriction endonucleases and methylases. CRISPR uses RNA-based targeting to bring the Cas9 endonuclease to foreign (or any complementary) DNA. Within bacteria this CRISPR-RNA-Cas9 complex then degrades and inactivates the targeted DNA.

The CRISPR system has been adapted for use in eukaryotic cells for gene deletion, gene editing and even modulation of gene transcription.



Solution to Question 12:

The image provided is characteristic of Casal's necklace, seen in pellagra, and indicates a deficiency of Tryptophan.

Pellagra can occur due to:

• Vitamin B3 (niacin)

• Niacin is derived from tryptophan and needs B2 and B6 for its synthesis.

• Hartnup's disease (tryptophan malabsorption)

• Malignant carcinoid syndrome (↑ tryptophan metabolism)

• Isoniazid (↓ vitamin B6)

In Hartnup's disease, defective membrane transport of tryptophan across PCT and enterocytes leads to malabsorption of tryptophan. This causes a deficiency of tryptophan.

As a result, the production of niacin from tryptophan is reduced and this manifests as pellagra with dermatitis, diarrhea and dementia (3D's) and glossitis. A characteristic skin rash called the Casal’s necklace may also be seen.

Solution to Question 13:

The attachment of mRNA to the ribosome is mediated through the guanyl cap at the 5' end. Eukaryotic mRNAs have 7-methylguanosine caps at the 5' end and poly-A tails at the 3' end.

The 7-methylguanosine caps (Guanyl caps) are necessary for:

• Processing of primary transcripts to mRNA.

• Mediating the attachment of mRNA to the ribosome for translation.

• Protection of mRNA against nucleolytic attack by 5'exonucleases.

Other options:

Option A: AAUAAA is present at the 3’ end, which is the polyadenylation sequence (poly-A tail). They help stabilize the mRNA, facilitate its exit from the nucleus and aid in translation. After the mRNA enters the cytosol, the poly-A tail is gradually shortened.

Option B: tRNA molecules serve as adapters for the translation of the information in the sequence of nucleotides of the mRNA into specific amino acids.

Option D: Shine-Dalgarno sequence initiates translation in prokaryotes.

Note: The guanyl cap and poly-A tail aid in attaching the mRNA to the ribosome for translation, however, it is initiated and mediated first through the Guanyl cap. The poly(A) tail stimulates recruitment of the 40S ribosomal subunit to the mRNA, after which the ribosomal subunit binds to the guanyl cap at 5'end of mRNA.

Solution to Question 14:

When glutamine is replaced by asparagine, there is no change in the function of the protein product.

This is due to the concept of conservative or homologous replacement of amino acids. Asparagine and glutamine are both uncharged polar (hydrophilic) amino acids. Thus, when glutamine is replaced with asparagine there is no change in the polarity or the charge of the peptide/protein.

Solution to Question 15:

Proteoglycans can hold large amounts of water, and not less.

Proteoglycans are made of a central protein core with O-linked glycosaminoglycan side-chains. They hold large quantities of water and occupy space.

They provide the ground substance of connective tissue.

Chondroitin sulfate is a glycosaminoglycan that is bound to a protein to form chondroitin sulfate proteoglycan. It is present in the extracellular matrix. Hyaluronic acid and heparin are examples of glycosaminoglycans.

All of the other statements regarding proteoglycans are true.

Solution to Question 16:

Among the given options, mucin has both a protective as well as a lubricating properties.

Solution to Question 17:

Phenylbutyrate can be used to reduce ammonia levels in patients with urea cycle disorders.

Phenylbutyrate diverts urea into an alternate pathway and reduces the amount of ammonia. Hence, acting as an ammonia scavenger. Other drugs that can be used to achieve the same outcome (ammonia scavengers) include phenylacetate and benzoate.

Note: Arginine is used as first-line treatment as it provides ornithine; a positive regulator of the urea cycle. Arginine also activates NAG synthase which increases NAG; a positive regulator of the urea cycle

Solution to Question 18:

Restriction endonucleases can act on AAGCTT.

Restriction endonucleases act and cleave at the site of a palindromic sequence. A palindromic sequence is a sequence that reads the same backward and forward. An example is listed below.

5' --AAGCTT-- 3'

3' --TTCGAA-- 5'

Biochemistry AIIMS 2020 (May and Nov INI-CET)

Question 1:

Dicoumarol inhibits the action of vitamin K by?

a) Suicide inhibition

b) Competitive inhibition

c) Non competitive inhibition

d) Uncompetitive inhibition

Question 2:

A TPN bag consists of 100g glucose, 30g amino acids, and 40g lipids. What is the amount of calories delivered?

a) 840 KCal

b) 880 KCal

c) 640 KCal

d) 680 KCal

Question 3:

What is true about the Hayflick limit?

a) Human cells can divide a finite number of times only

b) Free radical oxidation level is unrestricted

c) Telomerase activity is unrestricted

d) RNA polymerase can function for. a finite number of times only

Question 4:

Ammonia in the brain is detoxified to form _____

a) Urea

b) Glutamine

c) Ammonium ions

d) Alanine

Question 5:

The sequence of vitamin D synthesis is?

a) Liver- Skin- Kidney

b) Skin- Liver- Kidney

c) Skin- Kidney- Liver

d) Liver- Kidney- Skin

Question 6:

Glucose is stored in the form of glycogen because _____

a) It is compact

b) It has multiple reducing ends

c) It can be stored at multiple organs

d) It can provide glucose for about 1 week when needed

Question 7:

DNA methylation is not related to?

a) Mismatch repair

b) Chromatin Remodelling

c) DNA replication

d) Gene silencing

Question 8:

The enzyme that is not used in cholesterol synthesis?

a) Thiolase

b) HMG CoA reductase

c) HMG CoA synthase

d) HMG CoA lyase

Question 9:

The enzyme that is common for both glycolysis and gluconeogenesis is?

a) Pyruvate kinase

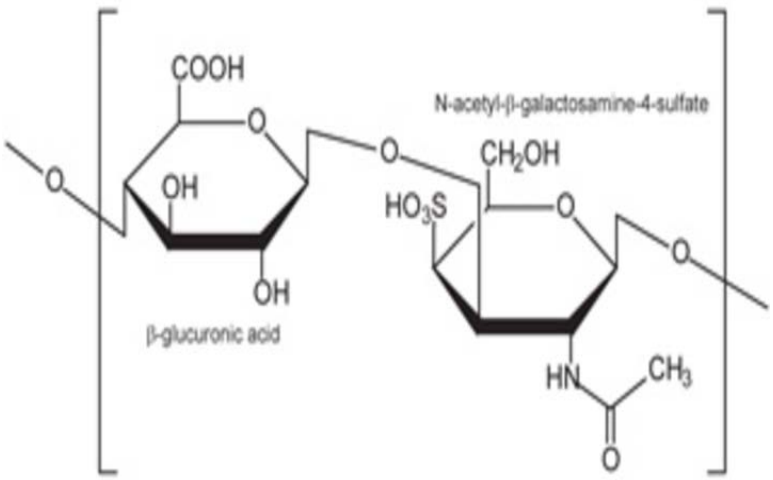
b) Phosphofructokinase

c) Phosphoenolpyruvate carboxykinase

d) Phosphoglycerate kinase

Question 10:

The given chemical structure is of:



a) Keratan sulfate

b) Chondroitin sulfate

c) Heparin

d) Dermatan sulfate

Question 11:

The correct order of steps in Polymerase Chain Reaction (PCR) is:

a) Hybridisation, Annealing, Elongation, Denaturation

b) Elongation, Denaturation, Hybridisation, Annealing

c) Denaturation, Annealing, Extension

d) Annealing, Extension, Denaturation

Question 12:

Which of the following is not a true statement regarding telomerase?

a) Has reverse transcriptase activity

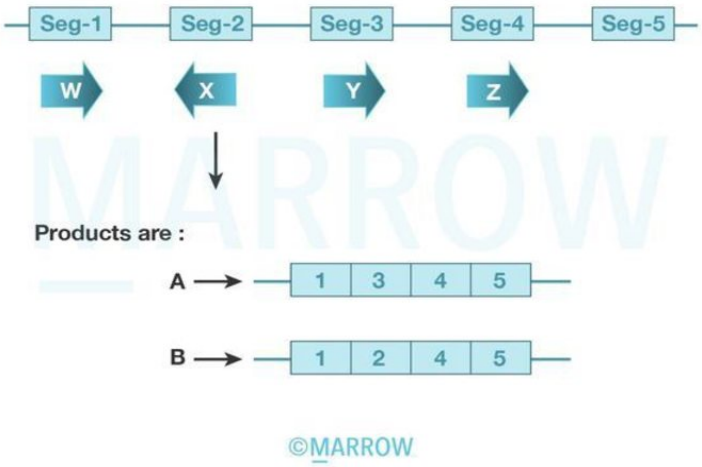
b) Present only in eukaryotes

c) Maintain the chromosome length

d) Involved in DNA repair

Question 13:

The illustration below shows alternative splicing of a gene which has intron segments 1, 2, 3, 4, and 5. It yields two products A and B, by the action of different promoters. You are provided with the promoters w, x, y, and z, each of which binds to a different segment as shown below and acts in the marked direction. Which of the following promoters will you use to get product A?



a) W,X,Y

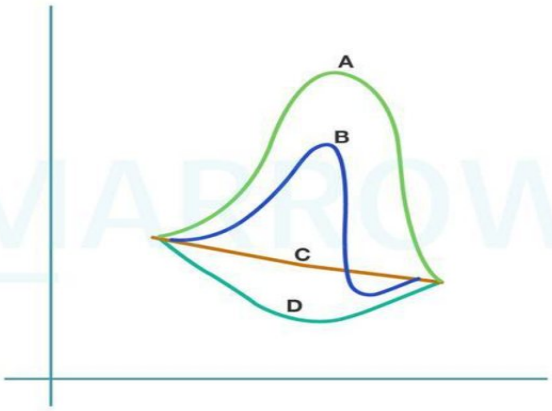
b) W,Z

c) W,X

d) W, Y

Question 14:

Gibbs free energy curve of an enzyme-catalyzed reaction is given by



©MARROW

a) B

b) A

c) C

d) D

Question 15:

The maximum thermic effect is seen with a meal which has

a) Protein

b) Fat

c) Carbohydrates

d) Mixed meal having all 3 in equal amount

Question 16:

DNA methylation is not involved in?

a) 1 and 2

b) 2 and 3

c) 1 and 4

d) 2 and 4

Question 17:

Which of the following enzymes has the highest catalytic efficiency?

a) Km of an enzyme = 10 micromole and Kcat = 20 per sec

b) Km of an enzyme = 2000 nanomole and Kcat = 50 per sec

c) Km of an enzyme = 2 micromole and Kcat = 200 per sec

d) Km of an enzyme = 4 micromole and Kcat = 200 per sec

Question 18:

Which of the following are vitamin-B12 dependent enzymes?

a) 1, 2 , 3 and 4

b) 1 and 4 only

c) 1 and 3 only

d) 1, 2, and 3

Question 19:

Which of the following enzymes are involved in gluconeogenesis? A. Pyruvate carboxylase B. Phosphoenol pyruvate kinase C. Hexokinase D. Pyruvate kinase E. Glucose 6 phosphatase

a) A,B,and E only

b) B and C only

c) A and E only

d) A, B and C only

Question 20:

Ketosis is common in type 1 DM due to:

a) 2,3 and 4

b) 1,2,3 and 4

c) 4 only

d) 1 and 2 only

Answer Key

Question No.	Correct Option
1	b
2	b
3	a
4	b
5	b
6	a
7	c
8	d
9	d
10	b
11	c
12	d
13	d
14	b
15	a
16	d
17	c
18	b
19	c
20	a

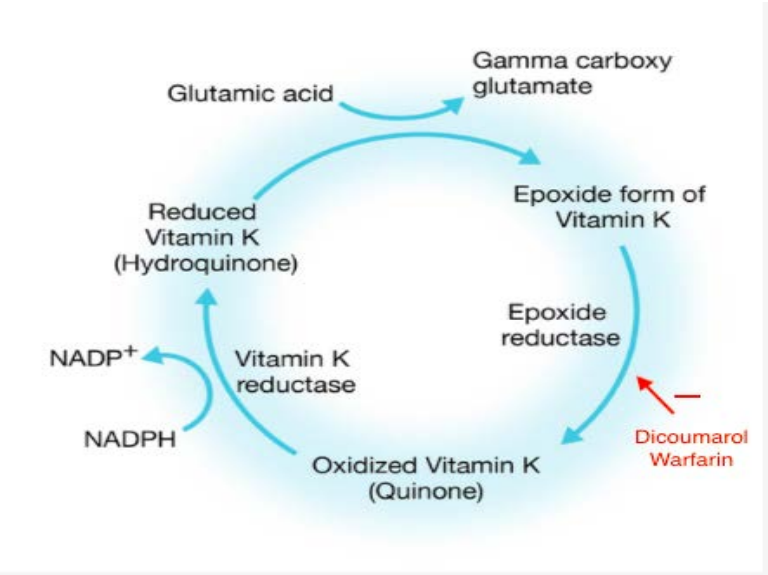
Detailed Explanations

Solution to Question 1:

Dicoumarol inhibits the action of vitamin K by competitive inhibition.

Dicoumarol and warfarin competitively inhibit the gamma-carboxylation system due to structural similarity with vitamin K. Therefore, they can act as anticoagulants used for therapeutic purposes.

Vitamin K epoxide is reduced to the quinone form by epoxide reductase, which is sensitive to inhibition by warfarin and dicoumarol.



Solution to Question 2:

The amount of calories delivered by the given TPN (Total Parenteral Nutrition) bag is 880 KCal.

The caloric value of different food components are:

• Carbohydrate (glucose) - 4KCal/g

• Proteins (amino acids) - 4.2KCal/g = ~4KCal/g

• Fat (lipids) - 9Kcal/g

Calculation of the number of calories:

• 100 gm of glucose = 100 x 4KCal=400 KCal

• 30 gm of amino acids = 30 x 4 KCal= 120 KCal

• 40 gm of lipids = 40 x 9 KCal= 360 KCal

Total amount of calories delivered= 400+120+360=880 Kcal

Note: The caloric value of alcohol is 7KCal/g.

Solution to Question 3:

The Hayflick limit says that human cells can divide for a finite number of times.

The Hayflick limit is the number of divisions a cell population can go through in culture before division stops and enters a state known as senescence. With the exception of stem cells, all the other human cells have only a limited capacity for cell division. This biological clock is of great help in the study of the normal ageing process.

The number of cell divisions of the cultured cell is roughly related to:

• The age of the cell donors

• The longevity of the species

For example, fibroblasts from the human embryos, when sustained in tissue culture, divide about 50 times before they die. Those taken from person after birth divide only 20 to 30 times.

Solution to Question 4:

Ammonia in the brain is detoxified to form glutamine.

Glutamine synthetase combines ammonia with glutamate to form glutamine. It requires the hydrolysis of ATP.

Deficiency of glutamine synthetase in neonates results in severe brain damage, multiorgan failure, and death.

Note: Glutamine is the transport form of ammonia from the brain and intestine to the liver; while alanine is the transport form from the muscle.

Solution to Question 5:

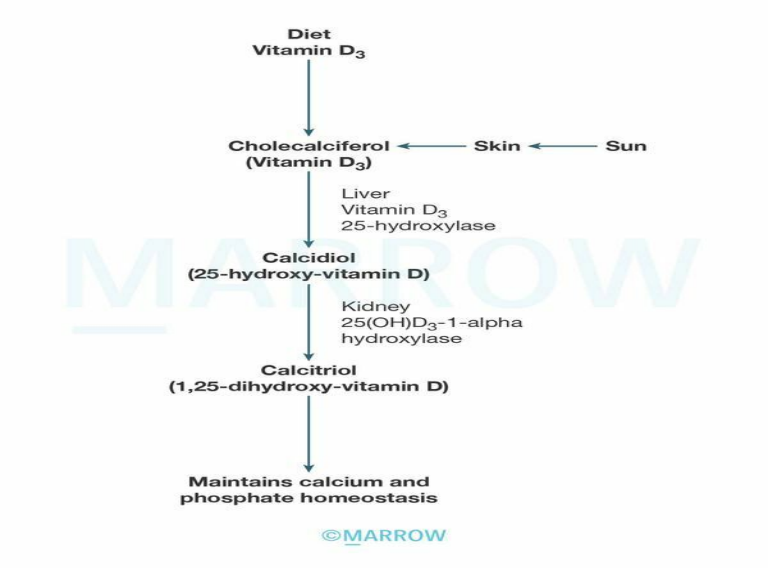
The sequence of vitamin D synthesis is skin-liver-kidney.

The sequence of vitamin D synthesis:

Step 1: In the skin: 7-Dehydrocholesterol (an intermediate in cholesterol synthesis that accumulates in the skin) undergoes a nonenzymic reaction on exposure to ultraviolet light, yielding cholecalciferol, which is absorbed into the bloodstream.

Step 2: In the liver: Cholecalciferol is hydroxylated to 25-hydroxycholecalciferol (calcidiol). This is released into the circulation bound to a vitamin D–binding globulin, which is the main storage form of the vitamin.

Step 3: In the kidney: 25-hydroxycholecalciferol is converted to either 1,25 dihydroxycholecalciferol (calcitriol), the biologically active form by the enzyme 1α-hydroxylase.



Solution to Question 6:

Among the given options, the most appropriate answer would be option A i.e Glucose is stored in the form of glycogen because it is compact.

Glycogen is the major storage carbohydrate in animals, corresponding to starch in plants. It is a branched polymer of α-d-glucose.

Other options:

The major sites of storage are liver and muscle, that is, it can't be stored at multiple sites.

It does not have multiple reducing ends. It instead has multiple non-reducing ends.

Liver glycogen functions as a reserve to maintain the blood glucose concentration in the fasting state. After about 18 hours of fasting, most of the liver glycogen is depleted and hence it can not provide glucose for up to 1 week.

Solution to Question 7:

DNA methylation is not related to DNA replication as DNA methylation is stable during replication and cell cycle arrest.

Chromatin remodeling by methylation/histone acetylation is an important aspect of transcription regulation.

Methylation of genes also plays an important part in gene silencing. Ex:- Promoter hypermethylation in tumor suppressor genes contributes to the development of cancers.

The process of mismatch repair relies upon a DNA-methylation excision signal, especially in E. coli.

Solution to Question 8:

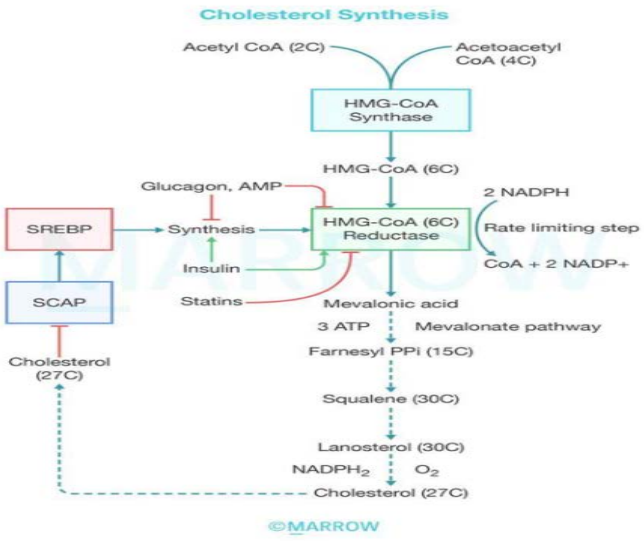
Among the given options, the enzyme HMG CoA lyase is not used in cholesterol synthesis. It is a mitochondrial enzyme involved in the breakdown of proteins and fats.

Cholesterol is a 27-carbon compound consisting of four rings and a side chain. It is synthesized from acetyl-CoA.

The major sites of synthesis of cholesterol are the liver, adrenal cortex, testes, ovaries, and intestine. All nucleated cells can synthesize cholesterol, including arterial walls. The enzymes involved in the synthesis of cholesterol are partly located in the endoplasmic reticulum and partly in the cytoplasm.

Initially, two molecules of acetyl-CoA condense to form acetoacetyl-CoA catalyzed by cytosolic thiolase. This acetoacetyl- CoA enters the cholesterol synthesis pathway along with a molecule of acetyl-CoA.

The image below shows the enzymes involved in cholesterol synthesis:



Solution to Question 9:

The enzyme phosphoglycerate kinase is common for both glycolysis and gluconeogenesis. Phosphoglycerate kinase catalyzes the conversion of 1,3-bisphosphoglycerate to 3-phosphoglycerate, which is a reversible step involved in both the processes.

Glycolysis and gluconeogenesis are processes that are reverse of each other. All the reversible steps of these two processes are catalyzed by the same enzymes, therefore are common to both.

The irreversible steps of glycolysis are catalyzed by the following enzymes:

• Hexokinase

• Phosphofructokinase

• Pyruvate kinase

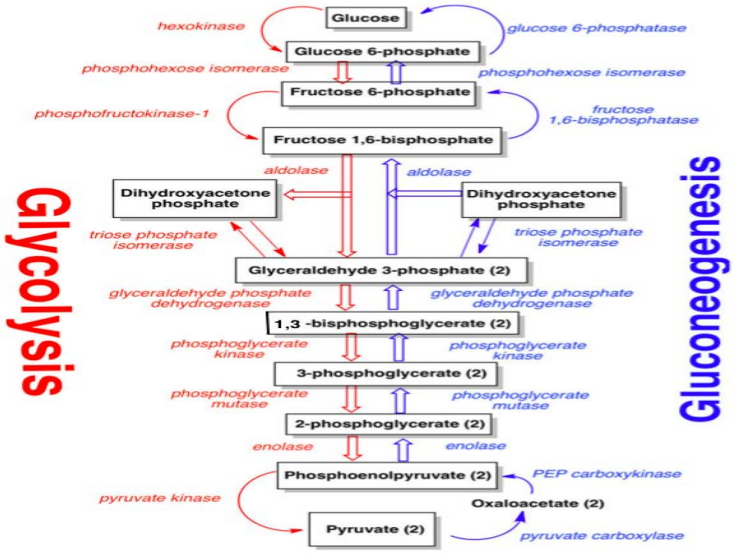
The irreversible steps of gluconeogenesis are catalyzed by the following enzymes:

• Pyruvate carboxylase

• Phosphoenolpyruvate carboxykinase

• Fructose-1,6-bisphosphatase

• Glucose-6-phosphatase



Solution to Question 10:

The given chemical structure is of chondroitin sulfate.

Chondroitin sulfate is composed of repeating units of N-acetyl galactosamine with sulfate and glucuronic acid. Some important features of chondroitin sulfate are as follows:

• The most abundant GAG in the body.

• Location: Cartilage, CNS, bone

• They are located at sites of calcification in endochondral bone and are a major component of cartilage.

• They are found in high amounts in the ECM of the central nervous system.

Solution to Question 11:

The correct sequence of events for PCR among the given options is denaturation, annealing, and extension.

The process of PCR is as follows:

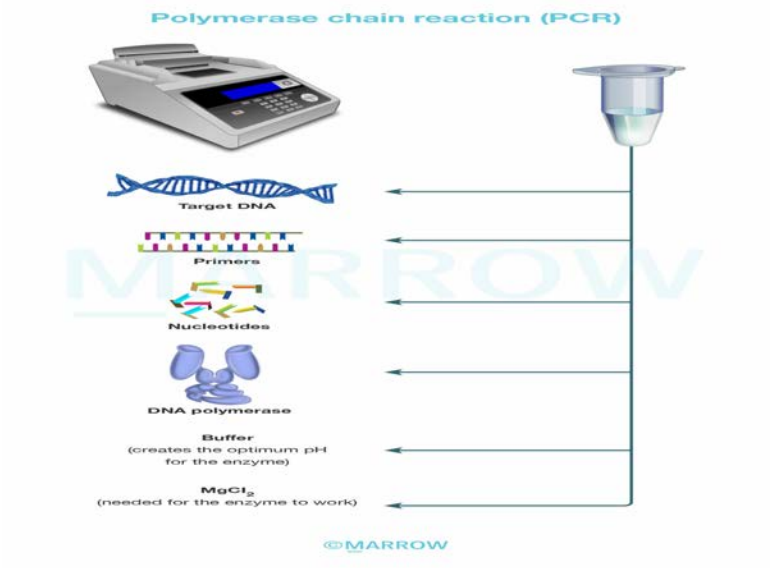
The DNA sample is first heat-denatured at >90°C (90-96 degrees Celsius for 3 minutes) to separate the two strands of the template DNA containing the target sequence; the primers (which attach to the 3' end of the flanking sequence) are added in excess, are allowed to anneal to the DNA (typically at 50-75°C) in order to generate the required template-primer hybridization complex. Under suitable conditions and presence of deoxynucleotides, elongation of the DNA stand occurs.

The number of copies produced in the presence of an unlimited supply of deoxynucleotides and enzymes is given by - 2 to the power n (where n is the number of PCR cycles)

• 20 cycles provide an amplification of 220 = 106 or 1 million copies

• 30 cycles provides an amplification of 230 =109 or 1 billion copies

Below is an image showing the various ingredients for carrying out PCR.



Solution to Question 12:

The false statement is that telomerase is involved in DNA repair.

Telomeres are the end of chromosomal DNA. Since prokaryotic DNA is circular, it does not have free ends and hence no telomeres. Thus, telomeres are present only in eukaryotes Telomeres have TG- rich repeats and usually do not code for any proteins. With every DNA replication during cell division, telomere shortening occurs. Once telomeres are almost negligible or non-existent in length, the DNA is unable to replicate and the cell dies. Hence, there is a limit to the number of times a cell can divide.

In stem cells and cancer cells, an enzyme telomerase having reverse transcriptase activity (RNA dependent DNA polymerase) adds telomeres to the chromosome ends, thereby preserving chromosomal length. It allows the stem cells and cancer cells to multiply a lot more number of times than a normal adult cell.

Solution to Question 13:

Among the given options, using primers W and Y will yield the desired product A.

Promoters or DNA regulatory elements usually precedes the desired exon to be transcribed. It helps redirect transcription of only the desired exons of a gene to yield a product. Alternative splicing utilizes different promoters to code slightly different products from the same gene.

In this question, the desired product A has segments 1,3,4,5 whilst the other product B has 1,2,4,5. The difference between both is the presence of seg 3 in product A and the presence of seg 2 in product B. As the product in question is A, only seg 3 is required while excluding seg 2 and ensuring seg 1,4 and 5 intact.

• Seg 1- Needs to be transcribed and so W is essential

• Seg 2- Does not need to be transcribed.

• Seg 3- Needs to be transcribed and so Y is essential

• Seg 4- Needs to be transcribed but Z is not essential as Y continues the transcription in the direction shown by the arrow.

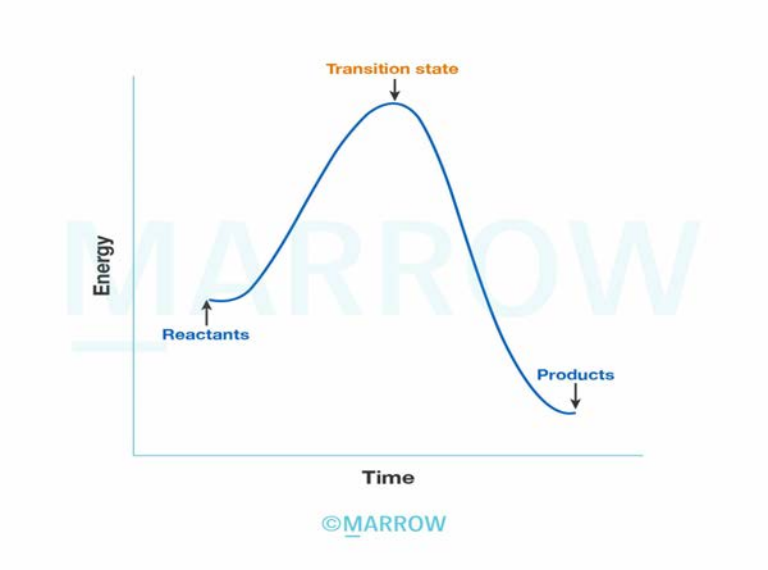
The answer is hence promoter W and Y.

Solution to Question 14:

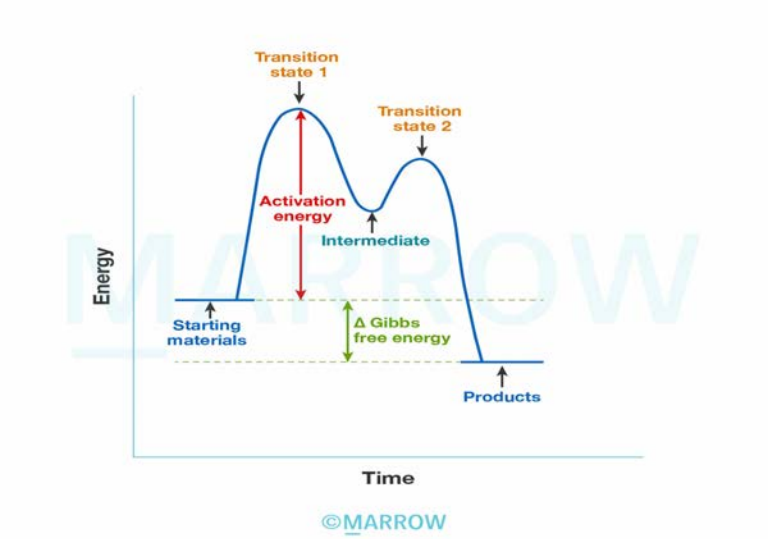
Among the given graphs, the Gibbs free energy change of an enzyme-catalyzed reaction is shown by graph A (Option B).

Graph B (Option A) cannot represent the Gibbs free energy of an enzyme-catalyzed reaction, as the energy state of an intermediate cannot be lower than the product. A lower energy state of the intermediate implies that the enzyme-intermediate complex is stable and such a complex will usually not further form a product.

During any chemical reaction, the product is formed by the breaking of substrate bonds and the conformational change of the substrate into a highly unstable transition state. This transition state is denoted by the peak of the graph. The Gibbs free energy curve of an enzyme-catalyzed reaction (with no intermediate state) is shown in the image given below:

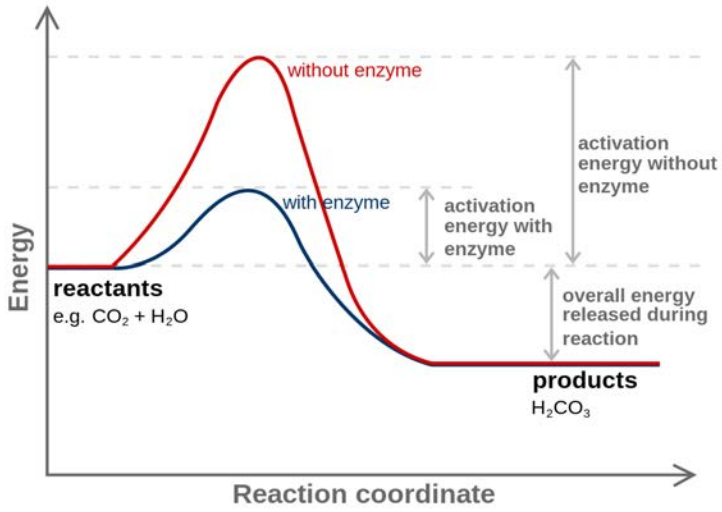


The below graph shows the normal intermediate formation with an energy state still higher than that of the product:



All the reactions have a transition state, but not all reactions have an intermediate state. Every intermediate state is again always followed by another transition state.

Activation energy is the energy difference between the free energy of the substrates and that of the transition state. Because of the high activation energy, the rates of uncatalyzed chemical reactions are often slow.



In an enzyme-catalyzed reaction, the activation energy is reduced by forming a relatively stable intermediate-enzyme complex. Enzymes provide attachment sites for the substrate and speed up the rate of reaction. They don't change the energy state of either the substrate or the product. The Gibbs free energy change remains the same.

Graph C: Free energy change cannot be a straight line. Every reaction passes through a high-energy intermediate transition state.

Graph D: The activation energy of any reaction is never lower than the free energy of the product.

Solution to Question 15:

Among the given options, maximum thermic effect is seen with proteins

Specific dynamic allowance (previously called as thermic effect of food): This refers to the increased heat production or increased metabolic rate following the intake of food (diet-induced thermogenesis).

The values of SDA are:

• 30% for proteins: This means that out of every 100 grams of proteins consumed, the energy available for doing useful work is 30% less than the calculated value.

• 15% for lipids, and

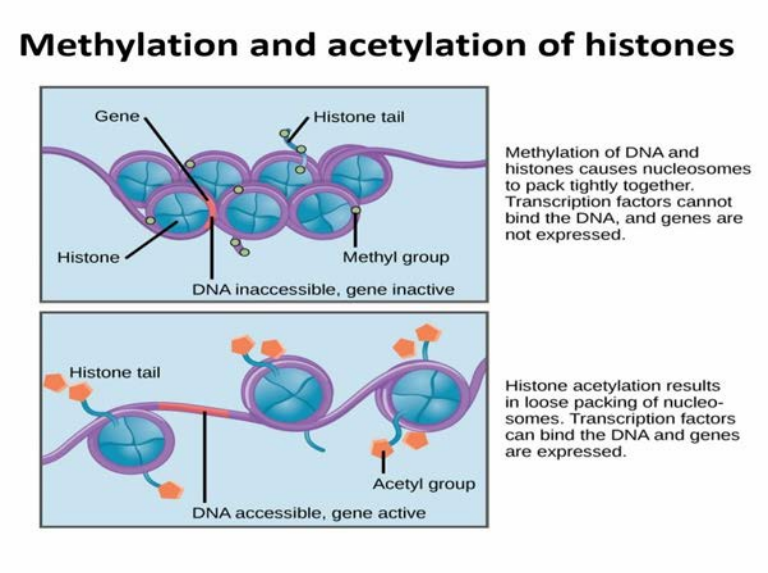
• 5% for carbohydrates.

Solution to Question 16:

DNA methylation is not involved in the base pair excision repair mechanism (statement 4) and RNA splicing (statement 2).

DNA methylation is an epigenetic modification used as a gene expression regulation mechanism. It causes gene silencing by inactivating DNA and hindering the formation of euchromatin (transcriptionally active chromatin). Thus, it also aids in chromatin remodelling.

It however is not involved in the base pair repair mechanism or RNA splicing.



Solution to Question 17:

The highest catalytic efficiency is seen when Km= 2 micromole and Kcat = 200 per sec.

Catalytic efficiency is calculated as Kcat/Km, where Km is inversely proportional to the binding affinity of the enzyme and Kcat is the catalytic constant (Vmax divided by the total number of active sites of the enzyme present). Higher values of Kcat and lower values of Km gives better catalytic efficiency. Catalytic efficiency can be used to compare the performance of 2 different enzymes in catalyzing a reaction.

Step 1: Km of each option after converting respective units to moles will be 10, 2, 2 and 4 (each multiplied by 10-6) moles.

Step 2: The catalytic efficiency is calculated as Kcat/Km. On substituting the values in various options after converting to moles, the values come out to be 2, 25, 100 and 50 (each multiplied by 106) M-1 s-1.

Some enzymes can be so efficient that they convert the substrate to product instantaneously. They are limited only by the rate at which substrate diffuses towards the enzyme in a solution. These are called diffusion-limited enzymes and their catalytic efficiency is as high as 108 M-1 s-1.

Solution to Question 18:

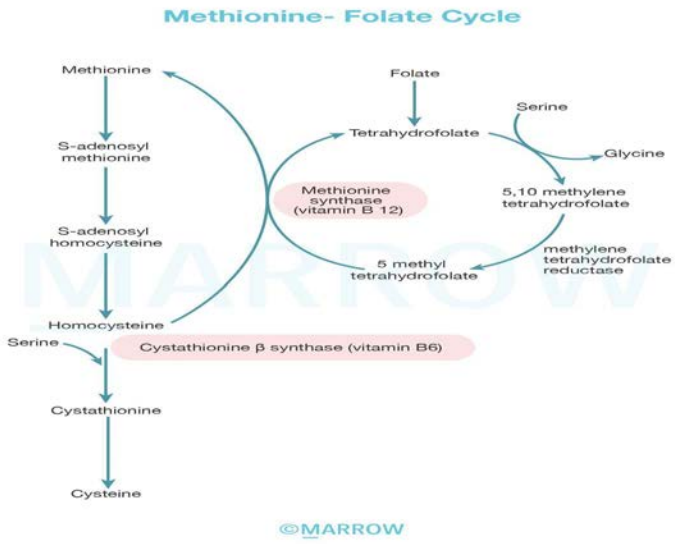
Among the given enzymes, methyl malonyl CoA isomerase and methionine synthase are vitamin B12 dependent enzymes.

There are two vitamin B12-dependent enzymes:

• Methionine synthase (homocysteine methyltransferase): Catalyzes the conversion of homocysteine to methionine

• Methylmalonyl CoA mutase: methylmalonyl CoA, formed as an intermediate in the catabolism of valine, isoleucine, and propionyl CoA is converted to succinyl CoA

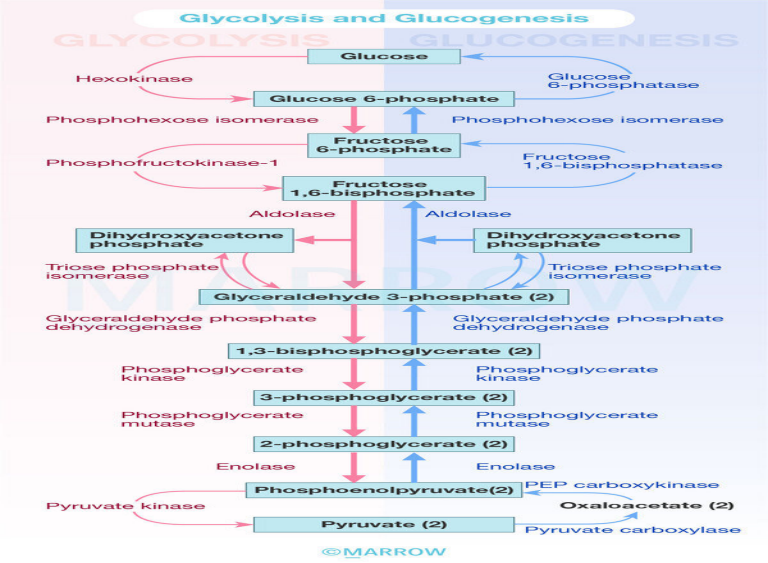
The below figure shows B12 serving as a cofactor of methionine synthase. Its deficiency may cause a folate trap.



Solution to Question 19:

Among the given options, A and E are correct. Pyruvate carboxylase and Glucose-6-phosphatase are enzymes used in gluconeogenesis.

Glycolysis and gluconeogenesis are 2 metabolic pathways in opposite directions (glucose being the substrate and product respectively). But a few reactions are not reversible in glycolysis. So a different pathway is used or a different enzyme is used by the body to make the reactions feasible.



Solution to Question 20:

2, 3 and 4 statements correctly explain the reason behind increased ketogenesis as seen in type1 DM.

Type 1 DM is characterized by a deficiency in insulin production. Since insulin is deficient, GLUT4 (insulin-dependent uptake) mediated glucose uptake is not possible in the heart or skeletal muscles. So adipose tissue mobilizes fat to be used as an energy source. These FFA (free fatty acids) are oxidized to acetoacetyl CoA which serves as a precursor for ketone body synthesis.

As the level of serum FFA is raised, proportionately more of the acetyl-CoA produced from their breakdown is converted to ketone bodies and less is oxidized via the citric acid cycle to CO_2. A fall in the concentration of oxaloacetate, particularly within the mitochondria, can impair the ability of the citric acid cycle to metabolize acetyl-CoA and divert fatty acid oxidation toward ketogenesis. Such a fall may occur because of an increase in the (NADH)/(NAD+) ratio caused when increased β-oxidation alters the equilibrium between oxaloacetate and malate so that the concentration of oxaloacetate is decreased.

Beta-hydroxy butyrate dehydrogenase is one of the enzymes used in ketone body synthesis. Increased rate of ketone body synthesis in insulin-deficient state implies an increased activity of beta-hydroxy butyrate dehydrogenase enzyme.

Biochemistry NEET 2018

Question 1:

Which of the following is responsible for the negative charge in fibrinopeptide A?

a) Glutamate and Valine

b) Histidine and Lysine

c) Aspartate and glutamate

d) Serine and Threonine

Question 2:

Serotonin is also known as?

a) 5 hydroxytryptamine

b) 5 hydroxytryptophan

c) 5 carboxytryptamine

d) 5 carboxytryptophan

Question 3:

Which of the following is true about DNA polymerase I?

a) It is involved in the creation of okazaki fragments.

b) It is found in prokaryotes.

c) It synthesises RNA primers.

d) It is the primary enzyme of DNA synthesis.

Question 4:

A patient presents with recurrent kidney stones. Microscopic examination finding of the urine specimen is shown below. Which of the following is not seen in the urine of this patient?

a) Ornithine

b) Lysine

c) Arginine

d) Histidine

Question 5:

In which condition is excessive urinary excretion of 5- hydroxy indole acetic acid seen?

a) Alkaptonuria

b) Albinism

c) Carcinoid syndrome

d) Phenylketonuria

Question 6:

Which of the following should be avoided by a patient of fish odour syndrome?

a) Biotin

b) Choline

c) Niacin

d) Pantothenic acid

Question 7:

Which of the following is true regarding an allosteric modifier?

a) Desaturates the enzyme

b) Causes the enzyme to work faster only.

c) Binds to the catalytic site

d) Participates in feedback regulation

Question 8:

Which of the following is the most common end-product of fatty acid synthesis pathway?

a) Arachidonic acid

b) Oleic acid

c) Palmitic acid

d) Acetyl CoA

Question 9:

Vanillyl mandelic acid is excreted in urine in which of the following conditions?

a) Pheochromocytoma

b) Alkaptonuria

c) Carcinoid syndrome

d) Diabetic ketoacidosis

Question 10:

Which of the following statements is true about vitamin K?

a) Deficiency of vitamin K leads to hypercoagulability.

b) It is a water soluble vitamin.

c) Prolonged use of antibiotics leads to vitamin K deficiency.

d) Menaquinone is the dietary source of vitamin K found in green vegetables.

Question 11:

What do chaperones assist in?

a) Ubiquitinization of proteins

b) Protein modification

c) Protein folding

d) Protein cleavage

Question 12:

Defective fumarylacetoacetate hydrolase enzyme is associated with _____.

a) Type 1 Tyrosinemia

b) Type 2 Tyrosinemia

c) Type 3 Tyrosinemia

d) Type 4 Tyrosinemia

Question 13:

A newborn baby refuses breast milk since the 2nd day of birth but accepts glucose water. He develops vomiting and severe jaundice by the 5th day. Benedict's test was positive for urine and blood glucose was low. The most likely cause is due to the deficiency of

a) Aldose reductase

b) Galactokinase

c) Galactose-1-phosphate uridyl transferase

d) UDP galactose-4-epimerase

Question 14:

A 45-year-old woman with hypertriglyceridemia is considered for niacin therapy. She is a known diabetic managed adequately with sugars well under control. Why should niacin be used cautiously in this patient?

a) It can cause hyperglycemia.

b) It can cause scleroderma which makes injecting insulin difficult.

c) It can increase the metabolism of oral hypoglyemic drugs.

d) It can cause hypoglycemia.

Question 15:

Which of the following can alter the gene expression by methylation and acetylation but not change the gene sequence?

a) Mutation

b) Epigenetics

c) Translocation

d) Inversion

Question 16:

The flipped LDH ratio implies _____.

a) LDH 1 > LDH 2

b) LDH2 > LDH1

c) LDH 2 > LDH 3

d) LDH 3 > LDH 2

Answer Key

Question No.	Correct Option
1	c
2	a
3	b
4	d
5	c
6	b
7	d
8	c
9	a
10	c
11	c
12	a
13	c
14	a

15	b
16	a

Detailed Explanations

Solution to Question 1:

Aspartate and glutamate are responsible for the negative charge in fibrinopeptide A and B of fibrinogen.

The negative charges contribute to the solubility of fibrinogen in plasma and importantly also serve to prevent aggregation by causing electrostatic repulsion between fibrinogen molecules.

Solution to Question 2:

Serotonin is also known as 5 hydroxy-tryptamine, and it is a monoamine neurotransmitter. Serotonin is produced by hydroxylation of tryptophan and subsequent decarboxylation. It is a potent vasoconstrictor and stimulator of smooth muscle contraction.

Clinical correlation:

In carcinoid syndrome, excessive levels of serotonin is produced which causes flushing, diarrhea, wheezing, damage to the tricuspid valve, etc. The levels of 5-OH indole acetic acid (serotonin metabolite) is elevated in the urine.

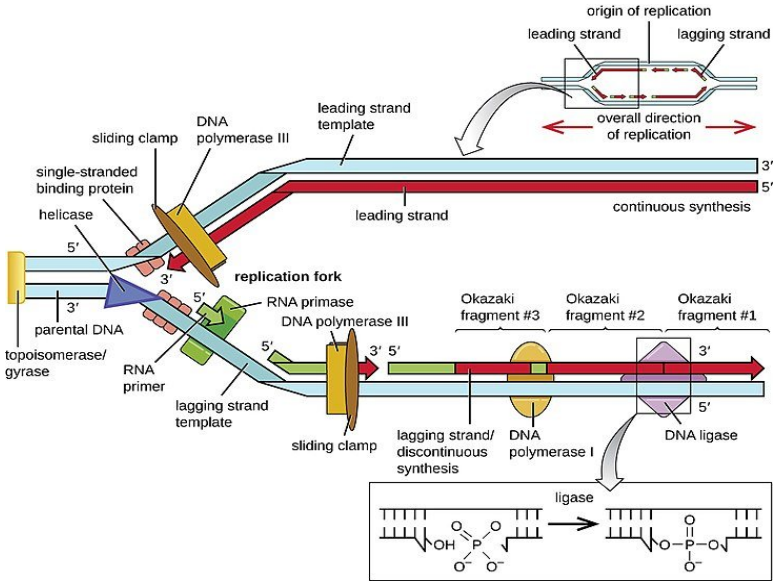
Solution to Question 3:

The true statement is that DNA polymerase I (pol I) is found in prokaryotes.

The prokaryotic polymerases are DNA polymerases I, II, and III. DNA polymerase I recognize a “nick” or break in the phosphate backbone, and then removes each RNA primer and fills the gaps with DNA. It does this through its 5'→3' exonuclease activity. It has DNA repair activity through 3'→5' exonuclease activity. DNA polymerase II carries out DNA proofreading and repair. DNA polymerase III is the primary enzyme for the synthesis of the leading strand of DNA.

Option A: DNA polymerase δ (eukaryotic polymerase) synthesizes Okazaki fragments which are short, newly synthesized DNA fragments that are formed on the lagging template strand during DNA replication. They are complementary to the lagging template strand.

Option C: Primase synthesizes RNA primers to start the replication.



Solution to Question 4:

The image shows hexagonal, translucent and white crystals suggestive of cystinuria. Histidine is not seen in the urine of this patient.

Cystinuria is an autosomal-recessive disease due to a defect in renal PCT & intestinal amino acid transporter that is essential for reabsorptive transport of Cystine and the dibasic amino acids Ornithine, Lysine, and Arginine (COLA).

Diagnosis of cystinuria is by the cyanide–nitroprusside test. Initial treatment is with adequate hydration, alkalization of the urine with citrate supplementation or acetazolamide, and dietary modification to reduce salt and protein intake. If this fails then patients are usually started on chelation therapy with penicillamine.

Solution to Question 5:

Excessive urinary excretion of 5-hydroxy indole acetic acid (5-HIAA) is seen in carcinoid syndrome.

Carcinoid syndrome is marked by symptoms of bronchospasm, cutaneous flushing, abdominal cramps, and diarrhea. It occurs due to excessive production of serotonin, a specialized product of tryptophan metabolism by tumors commonly in the small intestine, liver and lungs. It is then metabolized and excreted in urine as 5-HIAA.

Solution to Question 6:

A fishy odor is seen in trimethylaminuria. Consumption of food products with choline should be avoided in fish odor syndrome.

Fish odor syndrome (trimethylaminuria) is an autosomal recessive disease where TMA(trimethylamine) is not converted to the non-odorous TMAO (TMA-N-oxide) in the liver. This is due to the deficiency of flavin-containing mono oxygenase 3 (FMO3). TMA then builds up in the body and is released in sweat, urine, and breath, giving off a strong odor of rotting fish from the body.

Choline, lecithin, and TMAO are precursors of trimethylamine which are found in food products. These food products are eggs, liver, peanuts, meat, poultry, fish, dairy foods, pasta, and rice.

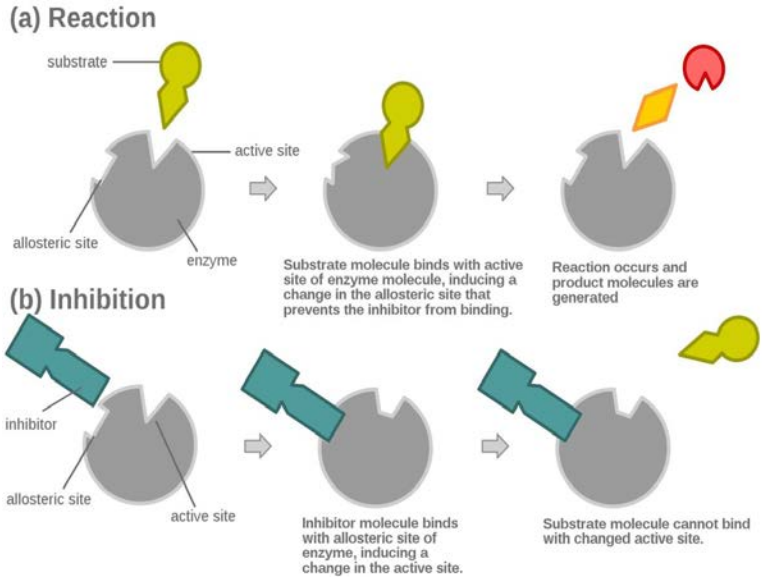
Solution to Question 7:

An allosteric modifier of an enzyme usually participates in feedback regulation.

Allosteric regulations are a natural example of control loops, such as feedback from downstream products or feedforward from upstream substrates. Allosteric regulation is also particularly important in the cell's ability to adjust enzyme activity.

An allosteric modifier or effector binds to the allosteric site to induce a conformational change in the catalytic or active site. Those modifiers or effectors that enhance the protein's activity are referred to as allosteric activators, whereas those that decrease the protein's activity are called allosteric inhibitors.

Some examples of allosteric modifiers		
Enzyme	Allosteric inhibitor	Allosteric activator
1. ALA synthase	Heme	-
2. Aspartate transcarbamoylase	CTP	ATP
3. HMG CoA reductase	Cholesterol	-
4.Phosphofructokinase	Citrate, ATP	AMP, F2,6P
5. Acetyl CoA carboxylase	Acyl CoA	Citrate
6. Citrate synthase	ATP	-
7. Carbamoyl phosphate synthase-I	-	NAG
8. Carbamoyl phosphate synthase-II	ATP	-



Solution to Question 8:

The most common end product of fatty acid synthesis is palmitic acid.

Palmitic acid is a 16 carbon saturated long chain fatty acid (LCFA). The substrate for its synthesis is acetyl CoA. Acetyl CoA is also the end product of fatty acid beta-oxidation.

Solution to Question 9:

• Vanillyl Mandelic Acid is the end product of catabolism of catecholamines and is excreted in urine in Pheochromocytoma.

• VMA is the urinary product of both epinephrine and norepinephrine.

• In pheochromocytoma and neuroblastoma, there is an excessive synthesis of catecholamines which causes enhanced synthesis of VMA and its excretion in the urine.

• It is a good screening test for pheochromocytoma and is also used to diagnose and follow up neuroblastoma and ganglioneuroma.

Solution to Question 10:

Prolonged use of antibiotics leads to vitamin K deficiency. This is due to the loss of normal bowel flora that synthesizes menaquinones (vitamin K2).

Vitamin K is a fat-soluble vitamin. The following are the vitamers of vitamin K:

• Phylloquinone (Vitamin K1) is the normal dietary source of Vitamin K that is found in green vegetables.

• Menaquinones (Vitamin K2) are synthesized by intestinal bacteria.

• Menadione (Vitamin K3) is a synthetic compound that is metabolized to phylloquinone.

Solution to Question 11:

Chaperones assist in protein folding.

Chaperones are heat shock proteins. They bind to the short sequences of hydrophobic amino acids of an extended polypeptide. Thus, they shield the new polypeptide being synthesized from aggregating. This provides the polypeptide an opportunity to form an appropriate secondary structure.

When a protein is thermodynamically trapped in a misfolded dead-end form, chaperones can rescue the protein by unfolding their hydrophobic ends. Thus, they provide the protein a second chance to fold productively.

Solution to Question 12:

Defective fumarylacetoacetate hydrolase enzyme is associated with type I tyrosinemia (tyrosinosis). It is the most common type of tyrosinemia.

There are three types of tyrosinemias:

• Type 1 (Hepatorenal tyrosinemia): Fumaryl acetoacetate hydrolase deficiency

• Type 2 (Oculocutaneous tyrosinemia/Richner-Hanhart syndrome): Tyrosine transaminase deficiency

• Type 3 (Neonatal tyrosinemia)

Solution to Question 13:

The above clinical features on ingestion of breastmilk at birth suggest classical galactosemia, a disorder of galactose metabolism. Galactose-1-phosphate uridyl transferase deficiency leads to classical galactosemia.

It is an autosomal recessive disorder. Clinical features include:

• Accumulation of galactose-1-phosphate in the liver causes liver damage & leads to hepatomegaly, vomiting, convulsions.

• Accumulation of galactose-1-phosphate depletes the liver of inorganic phosphate leading to diminished ATP synthesis which affects gluconeogenesis resulting in hypoglycemia.

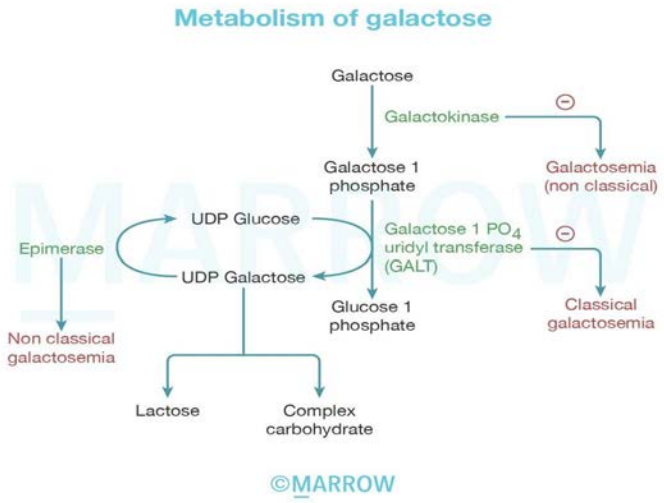
• Accumulation of galactose-1-phosphate in the nerves causes intellectual disability.

• Accumulation of galactitol in the lens causes an oil-drop cataract.

Urinary reducing sugar (Benedict's test) and the Mucic acid test are positive.

Treatment is a galactose-free diet.

The flowchart given below depicts galactose metabolism.



Solution to Question 14:

Niacin should be used cautiously in diabetics as it can cause hyperglycemia.

Niacin induces insulin resistance and also decreases glucose-stimulated insulin secretion, which may result in severe hyperglycemia. When niacin is prescribed for patients with known or suspected diabetes, blood glucose levels should be monitored at least once a week.

Solution to Question 15:

Epigenetics is defined as heritable changes in gene expression that are not caused by alteration in gene sequence.

It means “above genetics” and refers to the fact that gene regulatory mechanisms do not change the underlying regulated DNA sequence, but rather simply the expression patterns of the DNA.

Epigenetic mechanisms play a key role in establishment, maintenance, and reversibility of transcriptional states. A key feature is that the controlled transcriptional on/off states can be maintained through multiple rounds of cell division. This observation indicates there must be robust mechanisms to maintain and stably propagate these epigenetic states.

Histone Methylation Mostly Makes DNA Mute.

Histone Acetylation: Relaxes DNA coiling, allowing for transcription. Histone Acetylation makes DNA Active.

Solution to Question 16:

The flipped lactate dehydrogenase (LDH) ratio is LDH 1 > LDH 2.

Under normal conditions, LDH 2 is predominantly present in the blood and LDH 1 is predominantly present in the heart. When cardiac tissue is damaged LDH 1 is released into the bloodstream.

LDH 1 > LDH 2 (flipped pattern) in the blood is suggestive of myocardial infarction.

LDH is a tetrameric enzyme with 4 subunits. It has four subunits with two isoforms: H isoform (heart) and M isoform (muscle)

LDH Type	Composition	Location
LDH-1	HHHH	Heart and RBC
LDH-2	HHHM	Heart and RBC
LDH-3	HHMM	Lungs, brain, lymphatic tissues, and platelets
LDH-4	HMMM	Liver and skeletal muscle
LDH-5	MMMM	Liver and skeletal muscle

Biochemistry NEET 2019

Question 1:

Which of the following diseases have autosomal recessive inheritance?

a) Albinism

b) G6PD deficiency

c) Marfan's syndrome

d) Lesch-Nyhan syndrome

Question 2:

Deficiency of which of the following causes increased glutamine in blood?

a) Arginosuccinate lyase

b) Alpha-galactosidase-A

c) Ornithine transcarbamoylase

d) Arginase

Question 3:

Which of the following amino acid is necessary for the conversion of nor-epinephrine to epinephrine

a) Tyrosine

b) Tryptophan

c) Phenyl alanine

d) Methionine

Question 4:

An infant presents with hypotonia and seizures. It was confirmed to be cerebrohepatorenal syndrome. Which of the following is accumulated in the brain in cerebrohepatorenal syndrome?

a) Glucose

b) Long chain fatty acid

c) Lactic acid

d) Triglycerides

Question 5:

Excess ammonia reduces which of the following substrates of the Krebs cycle?

a) Malate

b) Oxaloacetate

c) Fumarate

d) Alpha ketoglutarate

Question 6:

Which of the following is autosomal dominant?

a) Cystic fibrosis

b) Duchene muscular dystrophy

c) Sickle cell anemia

d) Achondroplasia

Question 7:

In Menke's disease, which of the following enzymes would be affected?

a) Lysyl hydroxylase

b) Lysyl oxidase

c) Prolyl oxidase

d) Prolyl hydroxylase

Question 8:

Common precursor amino acid for urea, creatine and nitric oxide is____.

a) Glycine

b) Arginine

c) Aspartate

d) Alanine

Question 9:

True regarding mitochondrial genome:

a) Maternal inheritance

b) Low rate of mutation

c) Single stranded DNA

d) Paternal inheritance

Question 10:

In a patient with lipoprotein lipase deficiency, which of the following is increased following a fatty meal?

a) Chylomicron

b) LDL

c) HDL

d) Apo A

Question 11:

In a patient with Wilson's disease which of the following is decreased in urine?

a) Tyrosine

b) Phosphorous

c) Serine

d) 3-methylhistidine

Question 12:

NADPH is used in _____.

a) Fatty acid synthesis

b) Ketone synthesis

c) Gluconeogenesis

d) Glycolysis

Answer Key

Question No.	Correct Option
1	a
2	c
3	d
4	b
5	d
6	d
7	b
8	b
9	a
10	a
11	d
12	a

Detailed Explanations

Solution to Question 1:

Albinism is inherited in an autosomal recessive pattern.

Solution to Question 2:

Deficiency ornithine transcarbamoylase causes increased glutamine in blood

Ornithine transcarbamoylase catalyzes the condensation of carbamoyl phosphate with ornithine to form citrulline in the urea cycle. Its deficiency leads to the accumulation of carbamoyl phosphate. The carbamoyl phosphate is then shunted to pyrimidine biosynthesis, resulting in high ammonia and orotic acid levels in the blood. This condition is thus called hyperammonemia type 2.

As a compensatory mechanism, ammonia is then combined with glutamate to form glutamine (by the enzyme glutamine synthetase). The levels of glutamine are elevated in the blood, cerebrospinal

fluid, and urine, probably as a result of this dysregulated glutamine synthesis.

Other options:

Option A: Deficiency of argininosuccinate lyase leads to argininosuccinic aciduria

Option C: Deficiency of alpha-galactosidase-A leads to Fabry's disease and an accumulation of globotriaosylceramide.

Option D: Deficiency of arginase leads to hyperargininemia

Solution to Question 3:

Methionine is necessary for the conversion of nor-epinephrine to epinephrine.

Solution to Question 4:

Cerebrohepatorenal syndrome or Zellweger's syndrome is characterized by the accumulation of very-long-chain fatty acid, abnormalities of synthesis of bile acids and a marked reduction of plasmalogens.

It occurs in individuals with a rare inherited absence of peroxisomes. It is due to mutations in genes encoding certain proteins called peroxins (involved in various steps of peroxisome biogenesis) in all tissues. They accumulate C26-C38 polyenoic acids in brain tissues and also exhibit a generalized loss of peroxisomal functions. It causes severe neurological symptoms and most patients die in the first year of life.

Solution to Question 5:

Excess ammonia results in depletion of levels of alpha-ketoglutarate.

This happens because excess ammonia reacts with alpha-ketoglutarate to form glutamate, mainly in the CNS.

Solution to Question 6:

Achondroplasia is an autosomal dominant disorder.

It is caused by a mutation of the fibroblast growth factor receptor-3 (FGFR-3) gene.

The primary defect is abnormal chondrocyte proliferation at the growth plate that causes development of short and thick bones.

Clinical features:

• Short limbs

• Normal trunk

• Large head

• Saddle nose

• Exaggerated lumbar lordosis

• Severe spinal deformity may lead to cord compression

Solution to Question 7:

Menke's disease is due to defective lysyl oxidase.

It is an X■linked recessive disorder caused by a mutation in ATP7A, which encodes for a copper-transporting ATPase■α polypeptide.

Solution to Question 8:

Arginine is the common precursor for urea, creatine and nitric oxide.

Solution to Question 9:

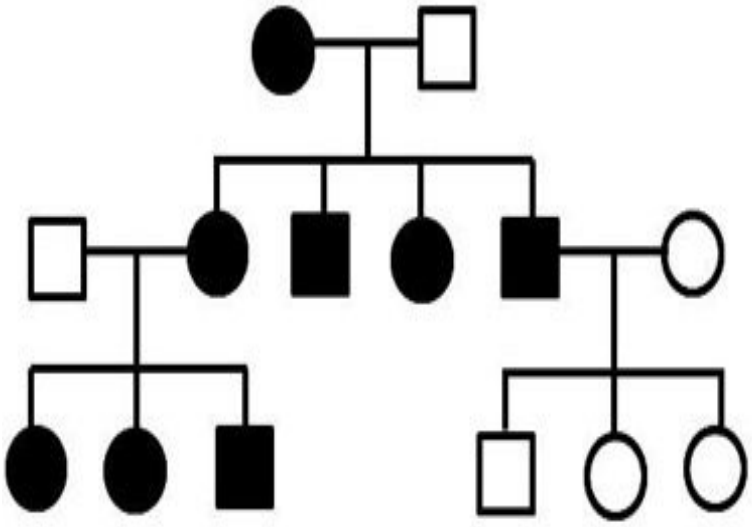
Mitochondrial genome is maternally inherited.

Mitochondrial inheritance:

• Inherited exclusively from the affected mother (ovum) as an individual's mitochondrial genome is entirely derived from the mother because sperms contain few mitochondria, which are typically shed upon fertilization.

• Both male and female children born to an affected mother will inherit the disease.

Pedigree shows mitochondrial inheritance.



Solution to Question 10:

After a fatty meal, chylomicrons are elevated in lipoprotein lipase deficiency.

Chylomicrons transport dietary lipids from the intestine to the peripheral tissues. They are synthesized in the intestine by assembling apo B-48 with lipids (mainly triacylglycerols). This is called a nascent chylomicron, which upon receiving apo C-II and apo E from HDL is remodelled into mature chylomicron.

Apo C-II activates lipoprotein lipase present on the endothelium. Lipoprotein lipase hydrolyzes the triacylglycerols into fatty acids and glycerol which are either used for storage or energy. Therefore, patients who are deficient in lipoprotein lipase or apo C-II (type I hyperlipoproteinemia) show increased levels of chylomicrons in the plasma after a fatty meal.

Solution to Question 11:

Urinary levels of 3-methylhistidine are decreased in patients with Wilson disease.

Amino acids in urine exist either in conjugated form (most) or in free form. In Wilson's disease the amount of conjugated amino acids far exceeds the amount of free amino acids. Methyl Histidine largely exists in free form and does not increase in amount on hydrolysis of acids in urine. Hence low amounts is seen in Wilson's disease.

Wilson disease is an autosomal-recessive disorder caused by mutation of the ATP7B gene located on chromosome 13. The ATP7B gene, encodes a transmembrane copper-transporting ATPase, expressed on the hepatocyte canalicular membrane.

Deficiency in the ATP7B protein causes a decrease in copper excretion into the bile, impairs its incorporation into ceruloplasmin, and inhibits ceruloplasmin secretion into the blood, leading to the accumulation of toxic levels of copper in the liver, brain, and eye.

Solution to Question 12:

NADPH is the source of reducing equivalent for fatty acid synthesis.

This NADPH is derived from 3 sources:

- HMP shunt pathway (main source)
- Extramitochondrial isocitrate dehydrogenase (minor source)
- Malic enzyme

Biochemistry NEET 2020

Question 1:

What is the function of the proteasome?

a) Protein folding

b) Post-translational modification

c) Protein degradation

d) Protein sorting

Question 2:

Replacing alanine by which amino acid, will increase UV absorbance of protein at 280nm wavelength?

a) Leucine

b) Proline

c) Arginine

d) Tryptophan

Question 3:

Vitamin B12 is found maximum in:

a) Animal products

b) Green leafy vegetables

c) Roots and tubers

d) Vegetarian diet

Question 4:

The process of apolipoprotein B48 synthesis involves which of the following?

a) RNA alternate splicing

b) RNA editing

c) DNA editing

d) RNA interference

Question 5:

A patient presents with a clinical scenario of obstructive jaundice. Which of the following results can be seen on Van den bergh's reaction?

a) Direct positive

b) Indirect positive

c) Both positive

d) Coproporphyrin

Question 6:

If the percentage of thymine residues in DNA is 28%. What is the percentage of cytosine?

a) 28%

b) 44%

c) 36%

d) 22%

Question 7:

Enzyme activated by a decrease in insulin: glucagon ratio is:

a) Glucokinase

b) Hexokinase

c) Phosphofructokinase

d) Glucose 6-phosphatase

Question 8:

A patient presented with symptoms of peripheral neuropathy and macrocytic anemia. She was given folate 5mg and the blood picture improved. However, the neurologic manifestations were aggravated. What is the most likely cause?

a) Malabsorption of folate

b) Treatment with folate unmasking pyridoxine deficiency

c) Deficiency of folate reductase in CNS

d) Folate therapy using the B12 stores

Question 9:

Which of the following is true regarding non-competitive inhibition?

a) Constant Km and increased Vmax

b) Constant Km and decreased Vmax

c) Decreased Km and decreased Vmax

d) Decreased Km and increased Vmax

Question 10:

A patient came to the hospital with complaint of abdominal pain. Routine investigations were unremarkable. On observation, the urine turned black on standing. Which of the following enzymes is likely to be defective in this patient?

a) Homogentisate oxidase

b) Xanthine oxidase

c) Phenylalanine hydroxylase

d) Dihydro oratate dehydrogenase

Question 11:

A 34-year-old male was on maize as a staple diet for a prolonged period. He presented with diarrhoea and lesion over his neck as shown in the image below. The condition occurs due to deficiency of:

a) Niacin

b) Zinc

c) Thiamine

d) Iron

Question 12:

Which vitamin, when infused in supraphysiological doses, causes macular edema and macular cysts?

a) Vitamin A

b) Vitamin D

c) Vitamin E

d) Vitamin B3

Question 13:

Which of the following is true about the structural organization of proteins?

a) Tertiary structure is three dimensional

b) Primary, secondary and tertiary structures are destroyed by denaturation

c) Secondary structure is stabilised by disulphide bonds

d) Secondary and tertiary structures depend upon amino acid sequence

Question 14:

Nitric oxide is synthesized from:

a) L - arginine

b) L - citrulline

c) Glycine

d) Lysine

Answer Key

Question No.	Correct Option

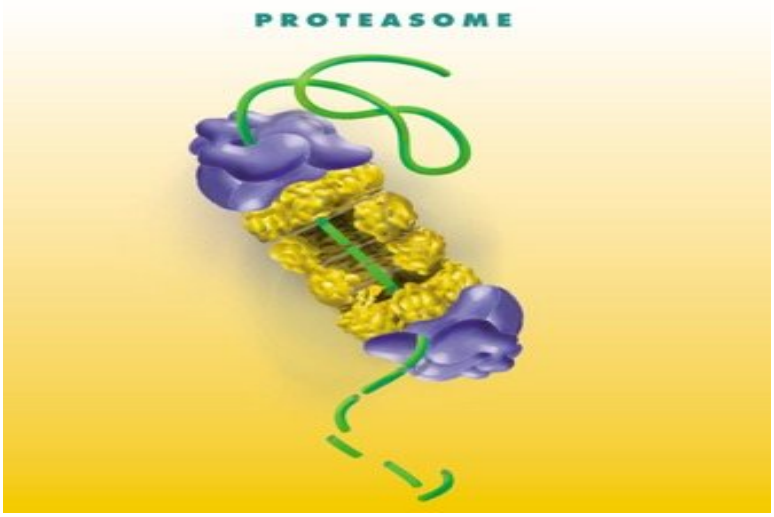
Detailed Explanations

Solution to Question 1:

The proteasome takes part in protein degradation.

The proteasome is a cylindrical structure in the cytosol that degrades polyubiquitinated proteins. It has a central core with proteolytic enzymes. Proteins that are tagged by ubiquitin to be degraded enter the core through regulatory rings on either side of the cylinder.



Clinical relevance: It plays an important role in antigen presentation to T lymphocytes as it degrades viruses and other molecules to small peptides.

Solution to Question 2:

Replacing alanine with tryptophan will increase UV absorbance of protein at 280nm wavelength

The amino acids which absorb 250-290nm (maximum at 280nm) UV light are Tryptophan (Maximum Absorption), Tyrosine, Phenylalanine.

Solution to Question 3:

Vitamin B12 is found maximum in animal products.

Vitamin B12 or cobalamin is synthesized only by microorganisms. Thus, the only source of cobalamin for humans is animal products. It is not found in plant sources. Therefore, individuals who are strict vegetarians are usually at the risk of developing vitamin B12 deficiency.

Solution to Question 4:

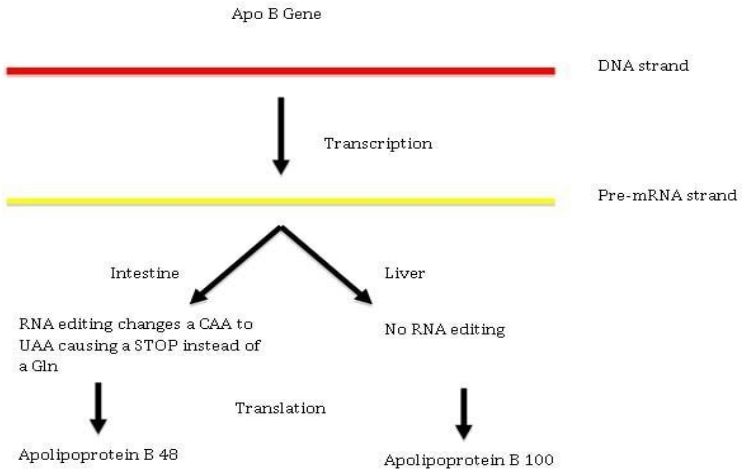
The process of apolipoprotein B48 synthesis involves RNA editing.

RNA editing is the process by which the coding sequence of the mRNA is changed before translation. As a result, the mRNA template differs from the DNA from which it was transcribed. This leads to the formation of a different protein. This occurs by insertion of additional uracils at the 3' end of the mRNA and proceeds in 3' to 5' direction.

RNA editing in apoB synthesis:

• In the liver, the apoB gene is transcribed to mRNA which is then translated to apoB 100.

• In the intestine, the same apoB gene is transcribed to the same mRNA. But now, the mRNA undergoes editing by an enzyme cytidine deaminase which converts the CAA codon in the mRNA to UAA at a single specific site. This edited mRNA translates to apoB 48.



Solution to Question 5:

In a patient with obstructive jaundice , van der bergh reaction gives direct positive result due to conjugated hyperbilirubinemia .

Van den Bergh reaction is used to determine the serum bilirubin level.

Van den Bergh reaction is a colorimetric method to measure serum bilirubin. It is based on the formation of red azodipyrroles when diazotised sulfanilic acid reacts with bilirubin.

Interpretation:

• In the absence of methanol, the water-soluble conjugated bilirubin reacts rapidly with the reagent and is called direct bilirubin.

• In the presence of methanol, both conjugated and unconjugated bilirubin react, providing the total bilirubin.

• Unconjugated (Indirect) bilirubin = Total-direct bilirubin

Solution to Question 6:

The percentage of cytosine in the DNA is 22%.

As per the Chargaff's rule, in the DNA molecules, the concentration of deoxyadenosine (A) equals that of thymidine (T), and the concentration of deoxyguanosine (G) equals that of deoxycytidine (C). Therefore, A=T and G=C.

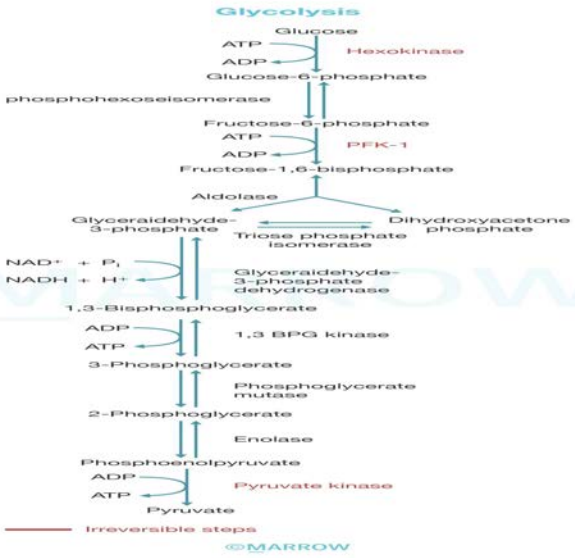
In the question, the concentration of thymine is given as 28%, therefore the concentration of adenine is also 28%, both of which add up to 56%. The remaining 44% (100-56) of the DNA consists of G-C base pairs. Of which the guanine constitutes 22% and the cytosine constitutes another 22%.

Solution to Question 7:

Enzyme activated by a decrease in insulin: glucagon ratio is glucose 6-phosphatase.

A decrease in insulin: glucagon ratio is seen in fasting state, in which there is the activation of gluconeogenesis and inhibition of glycolysis.

Among the given options, only glucose 6-phosphatase is an enzyme of gluconeogenesis and therefore is activated. The enzymes mentioned as other options are irreversible enzymes of glycolysis and are inhibited in the fasting state.

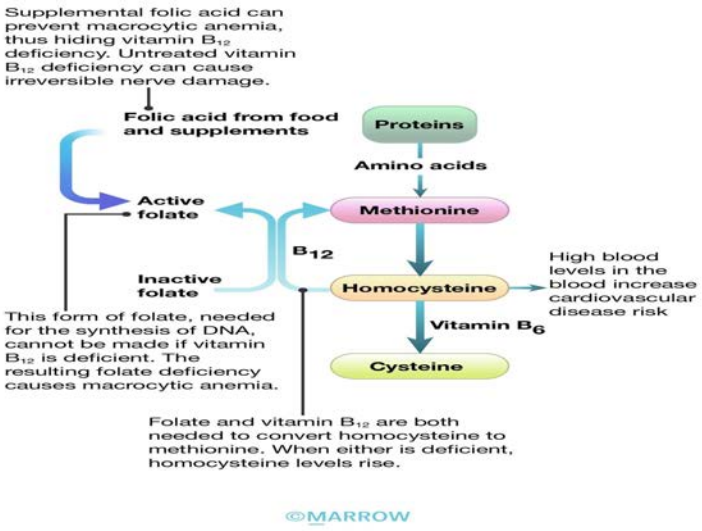


Solution to Question 8:

The most likely cause is folate therapy which used up the B12 stores, aggravating the symptoms.

Administration of folic acid for patients with macrocytic anemia can partially reverse the hematologic abnormalities associated with vitamin B12 deficiency. However, the neurologic manifestations of vitamin B12 deficiency are not treated by folic acid.

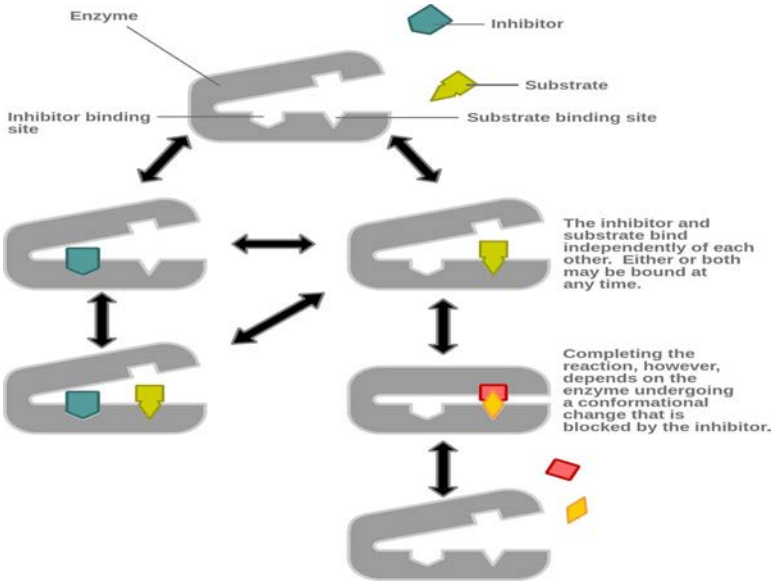
Administration of folic acid to an individual with vitamin B12 deficiency can potentially mask untreated vitamin B12 deficiency or even worsen the neurologic complications. Hence, testing for and/or treatment of vitamin B12 deficiency is required in all patients being treated with folic acid.



Solution to Question 9:

Noncompetitive inhibition has constant Km and decreased Vmax.

Noncompetitive inhibition occurs when the inhibitor binds at a site different from the substrate-binding site. The structure of the inhibitor does not resemble that of the substrate and the inhibitor does not affect the binding of the substrate.



Solution to Question 10:

Urine turning black on exposure to air is suggestive of alkaptonuria which occurs due to the defect in homogentisate oxidase enzyme.

Alkaptonuria is a disorder of tyrosine metabolism, that develops due to the defect in homogentisate oxidase, which oxidizes homogentisate to maleylacetoacetate. The defect in this enzyme leads to the accumulation of homogentisate, which is then excreted in the urine. The excreted homogentisate gets oxidized when exposed to the air and causes the urine to turn black.

In some cases, the excessive homogentisate may get oxidized to benzoquinone acetate, which binds to the connective tissue. This leads to arthritis and pigmentation of the connective tissue, a condition called ochronosis.

Other options:

Option B: Xanthine oxidase deficiency results in hypouricemia, xanthinuria, and xanthine lithiasis.

Option C: Defects in phenylalanine hydroxylase can lead to phenylketonuria characterised by hyperreflexia, seizures, hypopigmentation, low IQ, hyperactivity, and tremors.

Option D: Defects in dihydroorotate dehydrogenase are rarely seen in clinical practice. Miller syndrome is associated with this defect.

Solution to Question 11:

The above history and clinical features suggest niacin/vitamin B3 deficiency.

Excessive consumption of maize-based diets can cause pellagra. Corn/Maize has low levels of niacin and tryptophan. Jowar has high leucine content which inhibits QPRTase, an enzyme in the synthesis of Niacin.

Niacin deficiency leads to a disease called pellagra which is characterized by

- Diarrhea
- Dermatitis
- Dementia

The lesion in the neck is characteristic Casal's necklace pattern, seen in pellagra. The Casal collar or Casal necklace is a clinical sign in which there is an erythematous pigmented skin rash in the distribution of a broad collar (dermatomes C3 and C4).

Solution to Question 12:

Macular cysts and edema may develop in patients due to the infusion of supraphysiological doses of vitamin B3 (niacin toxicity).

The toxic effects of niacin include:

• Flushing associated with skin dryness, itching, paresthesia, and headache is seen. These effects may be seen with even a low dose of 30mg/day. Pre-medication with aspirin alleviates these symptoms as these symptoms are mediated by prostaglandins.

• Macular edema and macular cysts

• Nausea, vomiting, and abdominal pain.

• Hepatic toxicity presents as jaundice with elevated AST and ALT levels.

• Fulminant hepatitis requiring liver transplantation.

• Glucose intolerance

• Hyperuricemia

Solution to Question 13:

The tertiary structure is three dimensional is the right answer among the given options.

Proteins are structurally organised into four levels, as follows:

• Primary: The linear sequence of amino acids in the polypeptide chain

• Secondary: Folded and geometrically ordered units of short segments of polypeptides. Eg: alpha helix, beta-pleated sheets, loops, and bends

• Tertiary: Secondary structures arranged into larger functional units called domains

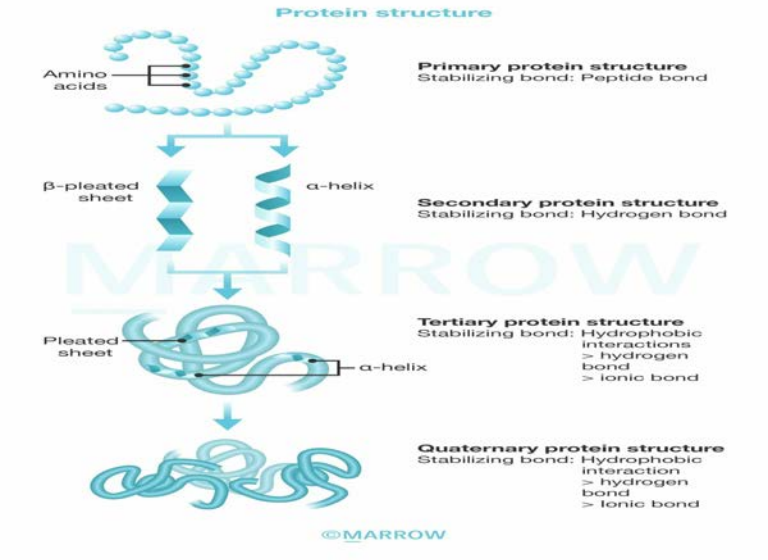
• Quaternary: Different types of polypeptides arranged in a spatial manner

Other options:

Option B: Protein denaturation results in the unfolding and disorganization of the secondary and tertiary structures without the hydrolysis of peptide bonds, which form the primary structure.

Option C: Hydrogen bond and Van der Waal interactions are involved in the stabilization of secondary structure(helix). Disulfide bonds stabilize the tertiary structure of proteins.

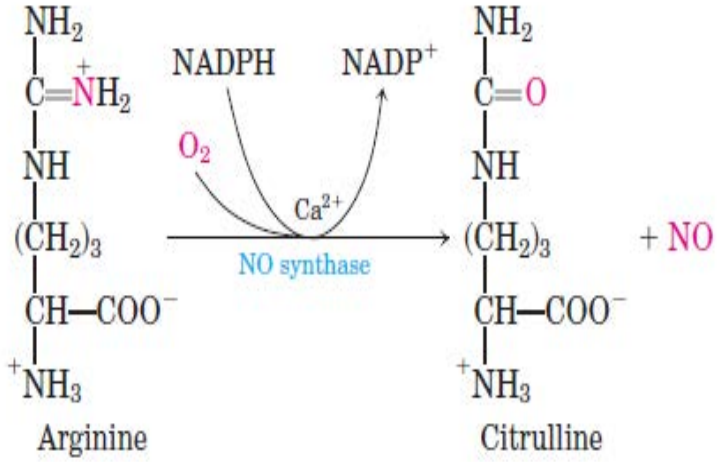
Option D: Primary structure depends upon the amino acid sequence, not secondary or tertiary.



Solution to Question 14:

Nitric oxide is synthesized from arginine by a calcium-dependent reaction catalyzed by NO synthase.

The co-enzymes of NO synthase include FMN, FAD, Heme, and Tetrahydrobiopterin (BH4).



NADPH
NADP+
O2
Ca2+
NO synthase
+ NO
Arginine
Citrulline

Biochemistry INI-CET 2021

Question 1:

What is the effect of RNAi on gene expression?

a) Knock out

b) Knock down

c) Knock up

d) Knock in

Question 2:

Methyl-tetrahydro-folic acid gets accumulated in deficiency of which of the following?

a) B2

b) B12

c) B1

d) B6

Question 3:

Cytochrome oxidase is inhibited in all of the following poisonings except:

a) Hydrogen sulphide

b) Carbon monoxide

c) Methane

d) Cyanide

Question 4:

Which of the following molecular analysis methods is used to detect RNA ?

a) Sanger's method

b) G banding

c) Western blot

d) RT-PCR

Question 5:

Insulin inhibits which of the following lipase enzymes?

a) Lipoprotein lipase

b) Pancreatic lipase

c) Gastric lipase

d) Hormone sensitive lipase

Question 6:

Glycated hemoglobin (HbA1c) is best measured using?

a) Ion exchange chromatography

b) Affinity chromatography

c) Isoelectric focussing

d) Electrophoresis

Question 7:

What is the main substrate and metabolic fuel used by RBCs during fasting?

a) Ketone bodies

b) Glucose

c) Free fatty acids

d) Amino acids

Question 8:

miRNA binds to which part of the mRNA to inhibit translation?

a) Gene body

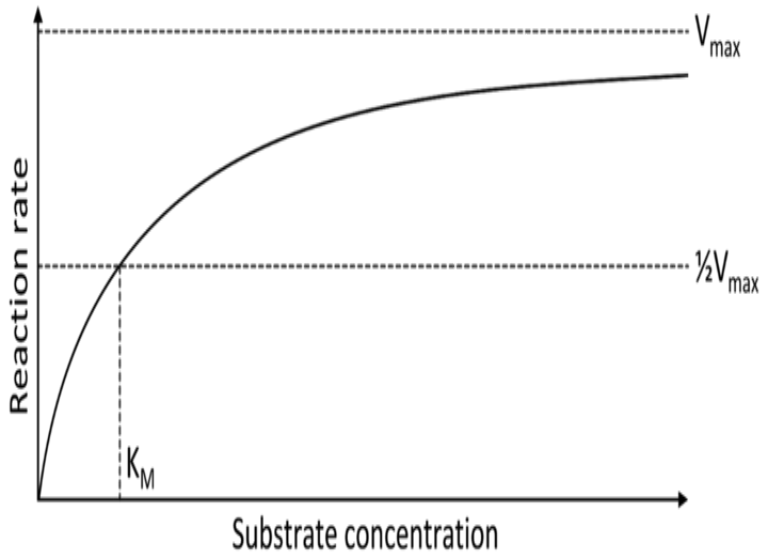
b) Gene promoter

c) 3' UTR

d) 5' UTR

Question 9:

The enzyme kinetics depicted in the Graph is suggestive of-



a) Allosteric Activation

b) Cooperative Binding

c) Michaelis Menten kinetics

d) Sigmoid Curve

Question 10:

Which of the following methods cannot be used to precipitate proteins?

a) Add alcohol and acetone

b) Using heavy metal ions

c) Moving pH away from isoelectric pH

d) Adding trichloroacetic acid

Question 11:

Which of the following diagnostic markers is/are incorrectly paired?

a) 1 only

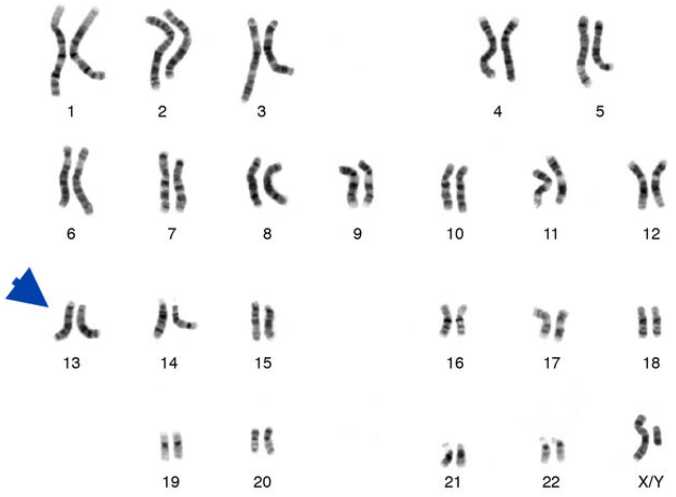
b) 1 and 2

c) 1, 2 and 4

d) 2, 3 and 4

Question 12:

Identify the type of marked chromosome in the given karyotype.



a) Acrocentric

b) Metacentric

c) Submetacentric

d) Telocentric

Question 13:

Which of the following consumes the highest energy during assimilation?

a) Proteins

b) Carbohydrates

c) Mono-unsaturated fatty acids

d) Poly-unsaturated fatty acids

Question 14:

Which of the following is the best method to detect HbA1c?

a) Ion-exchange chromatography

b) Electrophoresis

c) Immunoassay

d) Affinity chromatography

Question 15:

Which of the following options is false in a patient with advanced liver disease?

a) Hyperammonemia

b) Decreased ATP synthesis

c) Oxidative decarboxylation of alpha-keto glutarate

d) Increased synthesis of glutamine and glutamate from alpha-ketoglutarate

Question 16:

Which of the following is associated with a defect in collagen maturity?

a) Scurvy

b) Rickets

c) Beri-beri

d) Night blindness

Question 17:

Which of the following is not a substrate for glucose formation?

a) Acetyl coenzyme A

b) Glycerol

c) Alanine

d) Lactate

Question 18:

Which of the following is the best test for quantitative analysis of an RNA sample?

a) Real time PCR

b) Reverse transcriptase PCR

c) PCR - Restriction Fragment Length Polymorphism

d) RTPCR followed by Real time PCR

Question 19:

Wobble hypothesis explains which of the following concepts of the genetic code?

a) Universal

b) Unambiguous

c) Degeneracy

d) Non-punctuated

Question 20:

Which of the following statements are true regarding mitochondrial DNA?

a) 1 and 3

b) 1 and 2

c) 2 and 4

d) 2 and 3

Question 21:

What is the repair mechanism associated with CRISPR-Cas9?

a) Non-homologous end joining

b) Base excision repair

c) Nucleotide excision repair

d) Mismatch repair

Question 22:

A patient with thiamine deficiency develops lactic acidosis. Which of the following enzymes is affected?

a) Pyruvate carboxylase

b) Pyruvate dehydrogenase

c) Phosphoenolpyruvate carboxykinase

d) Transketolase

Question 23:

Which of the following is not amphipathic?

a) Sphingolipids

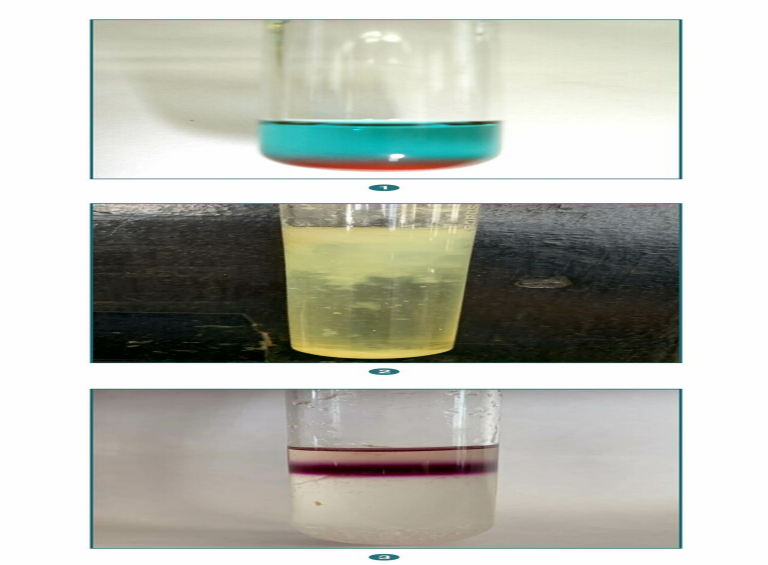
b) Phosphoglycerol

c) Triglycerides

d) Glycolipids

Question 24:

Which of the following tests will be positive in the urine of a patient who has undergone prolonged starvation?



a) 1 and 3

b) Only 3

c) 1, 2 and 3

d) 1 and 2

Question 25:

The action of inhibition of acetylcholinesterase enzyme by organophosphorus compounds is through which of the following mechanisms?

a) Non-competitive inhibition

b) Reversible competitive inhibition

c) Irreversible competitive inhibition

d) Suicidal inhibition

Detailed Explanations

Solution to Question 1:

RNA interference(RNAi) is a biological process in which miRNA/siRNA molecules inhibit gene expression ("knockdown") by neutralizing the targeted mRNAs.

• miRNA regulates the expression of the target gene by post-transcriptional silencing.

• Small interfering RNAs (siRNAs) are short RNA sequences that can be introduced experimentally into cells and then serve as substrates for the Dicer enzyme and interact with the RNA-induced silencing complex (RISC) in a manner similar to that observed for endogenous miRNAs.

• Synthetic siRNAs targeted against specific mRNA species are useful in the study of gene function and this technique is referred to as knockdown technology.

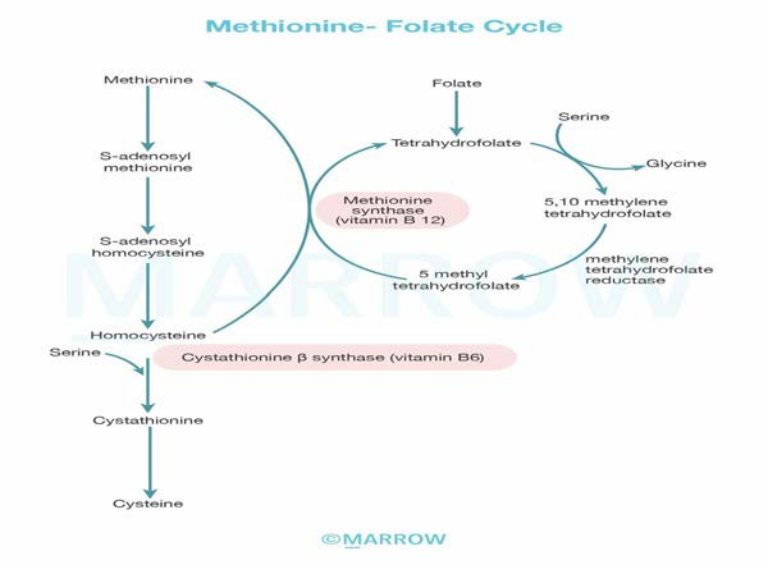
• siRNAs are also being developed as possible therapeutic agents to silence pathogenic genes like oncogenes involved in neoplastic transformation.

Knock out: Mice generated through genetic manipulation of embryonic stem (ES) cells such that a specific genetic locus is targeted and rendered non-functional ("knocked-out"), either by insertion of an irrelevant DNA sequence or by deletion of the endogenous DNA sequence.

Knock-in: Mice generated through genetic manipulation of embryonic stem (ES) cells such that a specific genetic locus is altered either by one-for-one substitution of DNA sequence or by addition of sequence not found in the endogenous genetic locus.

Solution to Question 2:

Accumulation of methyl tetrahydro folic acid is seen in vitamin B12 deficiency. Vitamin B12 acts as a cofactor of methionine synthase, an enzyme involved in the regeneration of tetrahydrofolate from methyl-tetrahydrofolate. Hence, in vitamin B12 deficiency methyl-tetrahydrofolate accumulates leading to functional folate deficiency known as the folate trap.



The conversion of 5,10-methylene-THF into 5-methyl-THF (methyltetrahydrofolate) is an irreversible process. The major source of tetrahydrofolate for tissues is 5-methyl-THF. The only way to make further use of 5-methyl-THF and to maintain the folate cycle is by the vitamin B12-dependent remethylation of homocysteine to methionine by the methionine synthase enzyme.

Decreased activity of methionine synthase in vitamin B12 deficiency results in the accumulation of methyltetrahydrofolate, which cannot be used, resulting in a folate trap. The folate cycle acts as the link between the functions of folate and vitamin B12, and deficiency of vitamin B12 can cause a functional deficiency of folate.

Note: Since vitamin B12 is also linked to the regeneration of methionine from homocysteine, its deficiency can result in hyperhomocysteinemia as well. This in turn increases the risk of atherosclerosis, hypertension, and thrombosis.

Solution to Question 3:

Cytochrome oxidase is a hemoprotein, which is the terminal component of the respiratory chain carriers (complex IV) in mitochondria. The action of cytochrome oxidase is inhibited in carbon monoxide, cyanide, and hydrogen sulfide poisoning, resulting in prevention of cellular respiration.

Hemoproteins are metalloproteins that have a typical heme prosthetic group. They are present in myoglobin, hemoglobin, and other cytochromes. Cytochrome oxidase contains two molecules of heme, each having one Fe atom that oscillates between Fe^{3+} and Fe^{2+} during oxidation and reduction. It also contains two atoms of copper, each associated with a heme unit.

Complexes of ETC :

Complex I: NADH-CoQ oxidoreductase

Contains - FeS, FMN, Coenzyme Q

Inhibitors – Rotenone

Complex II: Succinate-CoQ reductase

Contains - FeS, Coenzyme Q

Inhibitor - Carboxin

Complex III: CoQH2-cytochrome c oxidoreductase

Contains - cytochrome c, b, C1, and FeS

Inhibitor - Antimycin A

Complex IV: cytochrome oxidase

Contains - Cytochrome a, a3, and Copper

Inhibitor - Cyanide, Azide, Carbon monoxide

Complex V (informally): ATP Synthase

Inhibitor - Oligomycin

Note: MELAS (mitochondrial encephalopathy, lactic acidosis, and stroke) is an inherited condition due to NADH-Q oxidoreductase (Complex I) or cytochrome oxidase (Complex IV) deficiency.

Solution to Question 4:

RT PCR(Reverse Transcriptase PCR) is a molecular analysis method used for the detection of RNA. It can be used to quantitate mRNA levels by generating complementary DNA (cDNA) copies of the mRNA using the reverse transcriptase enzyme.

The northern blot technique can also be used to detect RNAs. Here, the mixture of mRNA molecules is separated by electrophoresis and then transferred to a nitrocellulose membrane and hybridized with radiolabeled probes.

Sanger's technique:

• This was the first technique used to determine the sequence of proteins.

• Sanger's reagent is 1- Flouro 2,4 Dinitro benzene.

• The first protein to be sequenced by this method was insulin.

• Only dipeptides and tripeptides can be sequenced by this method.

G banding (Giemsa banding):

It is the most common technique used in cytogenetics to produce a visible karyotype by staining condensed chromosomes. It is useful for identifying genetic diseases through the photographic representation of the entire chromosome complement. The metaphase chromosomes are treated with trypsin (to partially digest the chromosome) and stained with Giemsa stain.

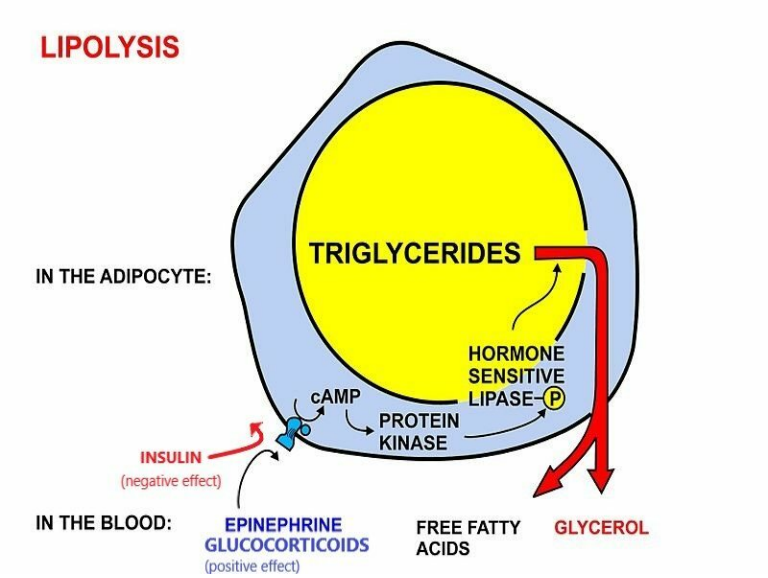
Heterochromatic regions, which tend to be rich with adenine and thymine (AT-rich) DNA and relatively gene-poor, stain darker and appear as dark bands in G-banding. In contrast, less condensed chromatin, which tends to be rich with guanine and cytosine (GC-rich) and more transcriptionally active incorporates less Giemsa stain, and these regions appear as light bands in G-banding. The image below shows a G-banding karyogram of a normal human male.

Western blot, also called immunoblots, is a technique used to study protein molecules. The proteins undergo electrophoresis and then are transferred to a membrane. These proteins are then tagged with the specific antibodies and visualized.

Solution to Question 5:

Insulin has an inhibitory effect on lipolytic hormones like hormone sensitive lipase (HSL). In adipose tissues, the stored triglycerides are broken down (lipolysis) by hormone sensitive lipase (HSL) into free fatty acids (FFAs). Insulin inhibits HSL and thus reduces the release of FFAs and also glycerol.

In diabetic patients, low insulin level corresponds to an increase in HSL activity, promoting the breakdown of lipids and release of FFAs from adipose tissue. Hormone-sensitive lipase activity is accelerated by hormones like epinephrine, norepinephrine, glucagon, ACTH, TSH, GH, ADH, and Melanocyte stimulating hormones (MSH).



Insulin induces the activity of lipoprotein lipase (LPL) which is present on the walls of capillaries. LPL promotes hydrolysis of TGs and degradation of VLDL and chylomicrons. In diabetes, low insulin leads to decreased LPL activity resulting in increased VLDL and TGs levels.

Effects of insulin on various tissues:

Well-fed state (Insulin)	During fasting (Glucagon)
Lipogenesis increased	Lipogenesis inhibited
Lipolysis inhibited	Lipolysis increased
Insulin inhibits HS-lipase	Glucagon activates HS-lipase
Lipoprotein lipase active	Lipoprotein lipase inactive

Tissue	Increases	Decreases
Adipose tissue	Increased glucose entryIncreased fatty acid synthesisIncreased glycerol phosphate synthesisIncreased triglycerides depositionActivation of lipoprotein lipaseIncreased K+ uptake	Inhibition of hormone-sensitive lipase
Muscle	Increased glucose entryIncreased glycogen synthesisIncreased amino acid uptakeIncreased protein synthesis in ribosomeIncrease ketone uptakeIncrease K+ uptake	Decrease protein catabolism Decrease release of glucogenic amino acids
Liver	Increased protein synthesisIncreased lipid synthesisIncreased glycogen synthesis & glycolysis	Decrease ketogenesisDecreased glucose output due to decreased gluconeogenesis

Tissue	Increases	Decreases
General	Increased cell growth	

Solution to Question 6:

Glycated hemoglobin (HbA1c) is best measured using ion-exchange chromatography.

HbA1c is formed by non-enzymatic glycation of hemoglobin A present in RBCs. Normally this occurs to a small extent but is increased in diabetic patients with poor glycemic control. Since the half-life of RBCs is typically 60 days, HbA1c can be used to monitor mean blood glucose concentration over the past 6 to 8 weeks.

In ion-exchange chromatography:

• Proteins interact with the stationary phase by charge-charge interactions.

• Proteins with a net positive charge at a given pH will tightly adhere to beads with negatively charged functional groups such as carboxylates or sulfates (cation exchangers).

• Proteins with a net negative charge adhere to beads with positively charged functional groups, typically tertiary or quaternary amines (anion exchangers).

• Non-adherent proteins flow through the matrix and are washed away.

• Proteins elute in inverse order of the strength of their interactions with the stationary phase.

Solution to Question 7:

Glucose is the main substrate and metabolic fuel used by RBCs during fasting. RBCs lack mitochondria and are dependent fully on glycolysis (anaerobic) and pentose phosphate pathway during fasting state.

Glucose is always required by brain and RBCs. Brain can meet only about 20 percent of energy requirements by using ketone bodies and the remaining is supplied by glucose. Metabolic changes occuring during fasting state and starvation therefore serve to preserve glucose and glycogen reserves for brain and RBCs.

Solution to Question 8:

Micro-RNA (miRNA) is an endogenous non-coding RNA that typically binds to the 3'-untranslated regions (UTRs) of target messenger-RNAs (mRNAs). The primary function of miRNA is to modulate the translation of target mRNAs into their corresponding proteins. After the target RNA is transcribed from its gene (post-transcriptional), the miRNA may either induce mRNA cleavage or repress its translation. This is referred to as post-transcriptional gene silencing or RNA interference.

RNA interference(RNAi) is a biological process in which miRNA or siRNA molecules inhibit gene expression by neutralizing targeted mRNAs.The microRNA (miRNA) belongs to a group of non-coding genes. The miRNA genes are transcribed but not translated into proteins. They play a role in the regulation of the expression of the target gene by post-transcriptional silencing.

Mechanism:

• The miRNA gene present in the nucleus is transcribed to primary miRNA, which is further converted to pre-miRNA by an enzyme DROSHA intranuclearly and exported to the cytoplasm by an export protein called Exportin 5.

• The pre-miRNA undergoes trimming, by an enzyme called DICER, into mature single-stranded miRNA.

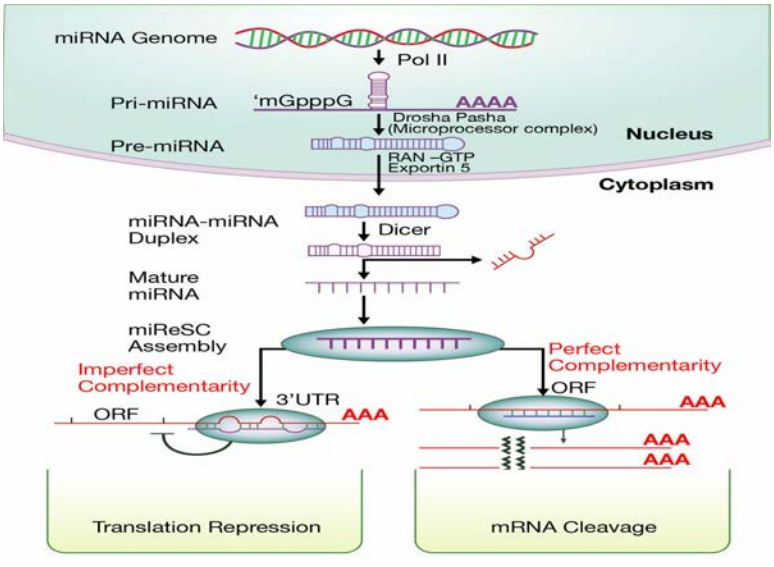
• The mature miRNA is associated with a multiprotein aggregate called RNA-induced silencing complex (RISC).

• The target mRNAs contain seed sequences in their 3′ untranslated region (UTR) that determines the specificity of miRNA binding and gene silencing.

Depending on the base pairing between the miRNA strand and its target mRNA, the RISC causes gene silencing either by mRNA cleavage (degradation or deadenylation) or by repressing its translation.

siRNA is similar in function to miRNA and is used in RNA interference.

miRNA expression has been found to be dysregulated in many cancers. Such misregulation is thought to have a causal role in the pathogenesis of such cancers. Some types of miRNAs are oncogenic (referred to as oncomiRs) and are overexpressed in cancerous tissue. On the other hand, tumor-suppressive miRNAs that counteract oncogenic characteristics are found to be underexpressed in cancers.



Solution to Question 9:

The graph shows a hyperbola which is suggestive of Michaelis - Menten Kinetics of the enzyme.

For enzymes showing michaelis menten kinetics, there is an increase in Rate of reaction, V, with increase in substrate concentration till a point Vmax is reached beyond which rate of reaction shows saturation.

Cooperative Binding would result in a sigmoid curve and is suggestive of Non Michaelis Menten Kinetics.

Solution to Question 10:

Precipitation of proteins is maximum at isoelectric pH and decreases as pH moves away from it. Hence, moving pH away from isoelectric pH cannot be used for precipitating proteins.

The isoelectric point or isoelectric pH (pI) is the pH at which the molecule carries no net charge.

Significance of Iso-electric pH (pI):

• The number of anions and cations present on the protein molecule will be equal and the net charge is zero.

• The proteins will not migrate in an electrical field

• Buffering capacity is minimum (note: maximum buffering action of an amino acid is seen when pH=pKa, and not at isoelectric pH)

• Viscosity will be minimum

• Precipitability will be maximum and solubility is minimum

Various precipitation reactions of proteins are:

• Salting out: higher the molecular weight of protein, the lesser the salt required. Globulins would require only half-saturated salt whereas albumin would need full saturation.

• Isoelectric precipitation: proteins are least soluble at their isoelectric pH and get precipitated immediately.

• Precipitation by organic solvents like alcohol and acetone.

• Precipitation by heavy metal ions: positively charged metal ions precipitate the negatively charged proteins in an alkaline medium. Salts of heavy metals can precipitate normal proteins of the GI tract in poisoning.

• Precipitation by alkaloidal reagents like tungstic acid, trichloroacetic acid, and picric acid.

• Heat coagulation is an irreversible precipitation process.

Solution to Question 11:

Beta glucocerebrosidase deficiency is seen in Gaucher's disease. It is an inborn error of metabolism due to the deficiency of the enzyme β-glucocerebrosidase (β-glucosidase) that leads to the accumulation of glucocerebroside in the lysosomes of cells.

• It is the most common lysosomal storage disorder. It is inherited in an autosomal recessive manner.

• The clinical features result from the accumulation of lipid-laden macrophages in the spleen, liver, bone marrow, bone, and other tissues.

• There are 3 clinical subtypes, delineated by the difference of neurologic manifestations: type 1, or the adult, non-neuronopathic form; type 2, the infantile or acute neuronopathic form; and type 3, the juvenile or subacute neuronopathic form

• Typical clinical features include delayed puberty, painless hepatomegaly and splenomegaly, liver cirrhosis, hypersplenism and pancytopenia, bleeding tendencies, bone pain due to avascular necrosis, osteoporosis, and pathological fractures.

• Neurological symptoms such as developmental delay, hypertonia, strabismus, and supranuclear gaze palsy (seen in type 3).

• Bone marrow examination usually reveals the presence of Gaucher cells having a characteristic wrinkled-paper appearance.

• Enzyme replacement therapy for Gaucher's disease includes imiglucerase, velaglucerase alfa, taliglucerase alfa, and eliglustat.

Von Gierke disease occurs due to deficiency of glucose-6-phosphatase enzyme in the liver, kidney, and intestinal mucosa. Patients present commonly by 3-4 months of age with hypoglycemia (leading to seizures), lactic acidosis, and hepatomegaly. Affected children often have a doll-like face with fat cheeks, relatively thin extremities, short stature, and a protuberant abdomen due to massive hepatomegaly. The kidneys are also enlarged, whereas spleen and heart are not involved. Laboratory findings include hypoglycemia, lactic acidosis, hyperuricemia, and hyperlipidemia.

Elevated serum lipase and serum amylase levels are associated with acute pancreatitis. Serum amylase levels do not correlate with the severity of pancreatitis and lack specificity whereas serum lipase is a more specific marker.

Low serum ceruloplasmin level is suggestive of hepatolenticular degeneration seen in Wilson's disease. However, it should not be used for definitive diagnosis as levels are normal in 10% of the affected patients and reduced in 20% of carriers. The diagnosis of Wilson's disease is based on the following:

• Increased 24-hour urinary excretion of copper (screening test)

• Decrease in serum ceruloplasmin

• Kayser–Fleischer rings under slit lamp

• Genetic testing for mutations in ATP7B gene

• Liver biopsy with quantitative copper assay (>200 μg/g dry weight of liver) is the gold standard investigation.

A higher level of LDH1 than LDH 2 in the blood is suggestive of myocardial infarction. Under normal conditions, LDH 2 is predominantly present in the blood and LDH 1 is predominantly present in the heart. When cardiac tissue is damaged LDH 1 is released into the bloodstream resulting in a high LDH1:LDH2 ratio known as the flipped LDH ratio (LDH1 > LDH2). LDH is a tetrameric enzyme with 4 subunits. It has four subunits with two isoforms: H isoform (Heart) and M isoform (Muscle)

• LDH-1: Heart

• LDH-2: Blood

• LDH-3: Brain, kidney, lungs, spleen, pancreas

• LDH-4: Liver and skeletal muscle

• LDH-5: Liver and skeletal muscle

Solution to Question 12:

The marked chromosome is chromosome 13 and the type is acrocentric.

Each chromatid has a long arm q and a short arm p. The two arms are separated by a centromere. In this image, the centromere is not midway between the two ends of the chromatids. It is seen towards one end with a marked difference in length between the p and q arms, hence it is an acrocentric chromosome.

Chromosomes are classified based on the position of the centromere as follows:

•

Metacentric: Centromere is centrally placed and the two arms are equal in length

•

Submetacentric: Centromere is slightly away from the center and the two arms are only slightly different in length

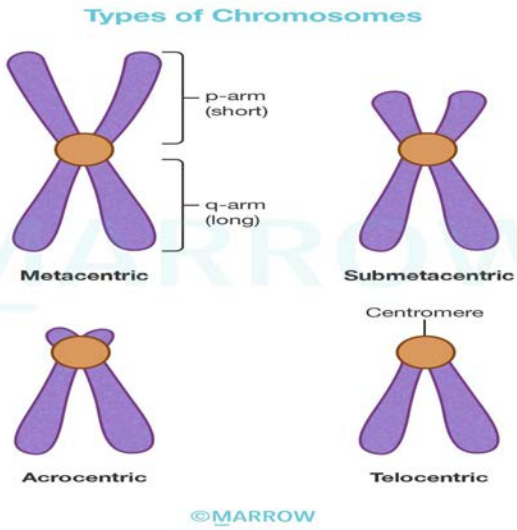
•

Acrocentric: Centromere is nearer to one end and the difference in length of arms is marked

•

Telocentric: Centromere lies at one end.

Group	Pairs of chromosomes	Features
A	1–3	Long, metacentric
B	4, 5	Long, submetacentric
C	6–12, X-chromosome	Medium, Submetacentric
D	13–15	Medium, acrocentric Satellite bodies +
E	16–18	Short, metacentric (16) or submetacentric (17 and 18)
F	19, 20	Short, metacentric
G	21, 22 + Y-chromosome	Short, acrocentricSatellite bodies +



Solution to Question 13:

Proteins consume the highest energy during assimilation.

The energy wasted in the assimilation of food is represented as diet-induced thermogenesis or specific dynamic action(SDA). Diet-induced thermogenesis (DIT) can be defined as the increase in energy expenditure above the basal metabolic rate and is expressed as a percentage.

The values for diet-induced thermogenesis are relatively higher protein and alcohol consumption and lower at a high-fat consumption, the hierarchy for it, being in the sequence of alcohol> protein> fat> carbohydrate. The value of DIT for protein is 30%, the lipid is 15% and carbohydrate is 5%. Hence, taking into account the loss of energy as DIT, additional 10% calories should be provided in a mixed diet.

Solution to Question 14:

Ion exchange chromatography is the best method to detect HbA1c.

Ion-exchange chromatography allows the separation of ionizable molecules according to differences in charge. It involves the use of a column which contains a matrix consisting of resin-bound charged groups.

If the charged group is anionic or negatively charged, it is called a cation exchanger and is used in cation exchange chromatography where proteins with a net positive charge migrate through the matrix more slowly than those with a net negative charge due to retardation of the migration of the former which is attracted to the negative charges bound to the resin. Cation exchange chromatography is used for negatively charged HbA1c estimation and is used as a diagnostic tool for diabetes mellitus.

Glycated hemoglobin, reported as HbA1c, has been used to monitor glycemic control in patients with diabetes for many years. HbA1c results from the attachment of glucose to the N-terminal

valine of the hemoglobin β-chain.

The concentration of HbA1c depends on both the concentration of glucose in the blood and the lifespan of the erythrocyte. Since the half-life of an RBC is 60 days, the level of glycated haemoglobin reflects the mean blood glucose concentration over the preceding 6 to 8 weeks. Normal glucose tolerance is characterized by an HbA1c < 5.7%; any value of HbA1c equal to or exceeding 6.5 % is diagnostic of the patient being diabetic. Also, ion exchange chromatography has the advantage of separating hemoglobin variants into peaks with the least interference by other hemoglobin variants; its disadvantage is that it is temperature dependant.

Other options:

Option B: Electrophoresis is an electrochemical process where macromolecules or colloidal particles depending on the electric charge migrate in a solution under the influence of an electric current. It can also be used for HbA1c estimation, its advantage being able to identify different variants of haemoglobin and disadvantage being interference of the process by fetal hemoglobin(HbF).

Option C: Immunoassays are used to quantify molecules based on the specificity and selectivity of antibody reagents generated. It can provide quantitative estimates of HbA1c but HbF produces falsely low results and hemoglobin variants such as HbS and HbC may cause a false increase in HbA1c measurements.

Option D: Affinity chromatography is a type of liquid chromatography. It involves the passing of a matrix through a solution that consists of the molecules of interest. These molecules would have a specific affinity for ligands present in the matrix and bind with them and end up getting separated from the solution. It can be used to measure HbA1c without being affected by temperature. High levels of HbF seen in thalassemia may interfere with its result.

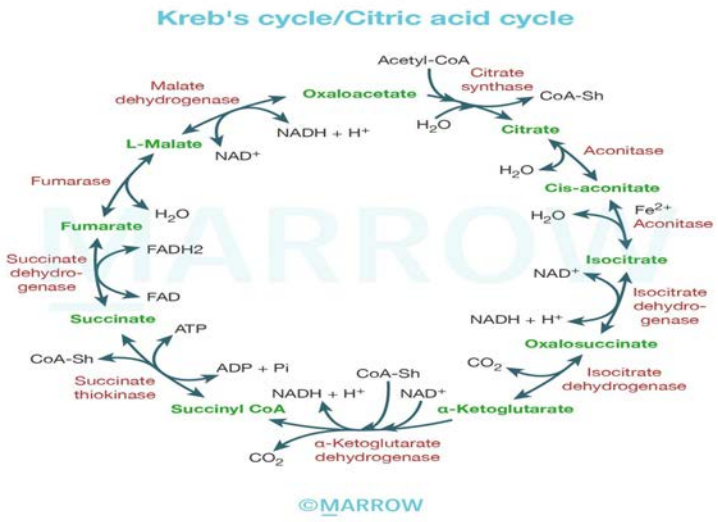
Solution to Question 15:

Oxidative decarboxylation of alpha-ketoglutarate is not seen in a patient with advanced liver disease. Option C is false.

Normally, ammonia, a toxic by-product of protein catabolism, is excreted as urea upon being metabolised in the urea cycle, which takes place in the liver. In advanced liver disease, impaired ammonia metabolism leads to hyperammonemia. Ammonia withdraws α-ketoglutarate to form glutamate and glutamine. This leads to lowered concentrations of all citric acid cycle intermediates, and hence reduced generation of ATP.

The Krebs cycle involves a sequence of reactions occurring in mitochondria that oxidize the acetyl moiety of acetyl-CoA to CO_2 and reduces the coenzymes that are reoxidized through the electron transport chain. It is the final common pathway for the oxidation of carbohydrates, lipids, and protein also has a central role in gluconeogenesis, lipogenesis, and interconversion of amino acids. Although processes occur in many tissues, the liver is the only tissue in which all occur to a significant extent.

The reactions that occur in Kreb's cycle are shown in the image below.



One of the steps of the Krebs cycle involves α-ketoglutarate undergoing oxidative decarboxylation in a reaction catalyzed by α-ketoglutarate dehydrogenase, resulting in the formation of succinyl-CoA. High concentrations of ammonia inhibit α-ketoglutarate dehydrogenase, thereby preventing its oxidative decarboxylation.

Solution to Question 16:

Scurvy is associated with a defect in collagen maturity.

Scurvy results from ascorbic acid or vitamin C deficiency. Vitamin C is an essential cofactor for the enzyme prolyl hydroxylase, required for the hydroxylation of prolyl residues in collagen. This enables each collagen fibril to form a uniform and flexible triple helix configuration in the body's connective tissues.

Its deficiency results in a defective prolyl hydroxylase activity, thereby resulting in the impaired formation of mature connective tissue; the clinical manifestations of this deficiency include petechiae, ecchymosis, coiled hairs, inflamed and bleeding gums, joint effusion, tooth loss, bone fracture, poor wound healing, and fatigue which can be attributed to impaired collagen synthesis all of which are typical of scurvy.

Risk factors include chronic alcoholism, diseases such as celiac disease and Crohn's disease, associated with malabsorption and poor nutrition.

It is treated with vitamin C supplementation.

Other options:

Option B- Rickets is caused due to deficiency of vitamin D in children which is characterized by the continued formation of the collagen matrix of bone but its incomplete mineralization or demineralization. Children have soft, pliable bones.

Option C- Beriberi is caused due to deficiency of thiamine. It can either be dry beriberi characterized by peripheral neuropathy or wet beriberi characterized by edema due to dilated cardiomyopathy.

Option D- Night blindness is caused by a deficiency of vitamin A. Deficiency can also lead to pancreatic insufficiency, repeated gastrointestinal, pulmonary, and urinary infections, and xeropthalmia.

Solution to Question 17:

Acetyl coenzyme A (CoA) is not a substrate for glucose formation.

Acetyl CoA and compounds that give rise to acetyl CoA alone like acetoacetate, lysine, and leucine cannot give rise to a net synthesis of glucose. This is because of the irreversible nature of the pyruvate dehydrogenase complex, which converts pyruvate to acetyl CoA. These compounds give rise to ketone bodies instead.

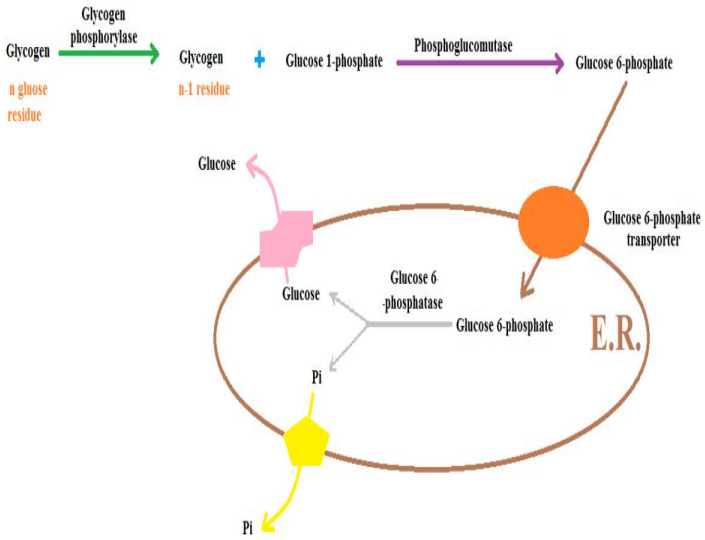
The synthesis of glucose in the body, in the absence of dietary carbohydrates, occurs in two ways:

• From liver glycogen, by a process known as glycogenolysis in the absence of dietary carbohydrate, for up to 24 hours.

• De novo, from non-carbohydrate sources, by a process known as gluconeogenesis, when glycogen stores have depleted. This occurs primarily in the liver and to a lesser extent in the kidneys while fasting overnight or primarily in the kidneys during prolonged fasting of 48 hours or longer.

The substrate for glycogenolysis is glycogen and during this process, glycogen is first converted into glucose-1-phosphate by the enzyme glycogen phosphorylase. This is a rate-limiting step in the process. Glucose-1-phosphate is then converted to glucose-6-phosphate by the enzyme phosphoglucomutase and eventually, glucose is obtained from glucose-6-phosphate by the enzyme phosphatase. There is no involvement of acetyl CoA.

The steps with enzymes involved in glycogenolysis are shown in the image below.



In gluconeogenesis, the substrates can be:

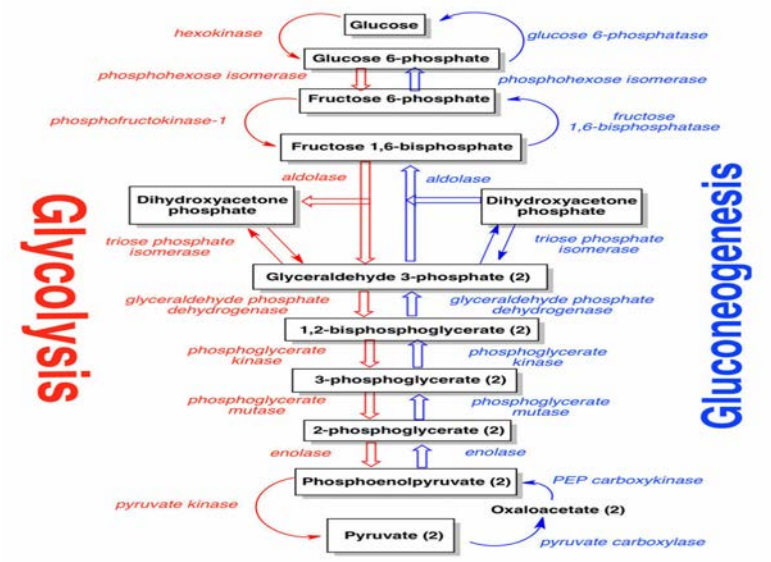
• Oxaloacetate (from its conjugate acid, oxaloacetic acid) is a direct precursor of phosphoenolpyruvate

• Pyruvate, an α-keto acid that can be converted to glucose. Alanine is a glucogenic amino acid that is transaminated to form pyruvate by the enzyme alanine amino-transferase in the liver; the pyruvate formed, can be used for the synthesis of glucose.

• Lactate, obtained from anaerobic glycolysis, released from skeletal muscles and RBCs into the blood, to be taken up by the liver in the Cori cycle to be oxidised to pyruvate, to eventually synthesize glucose

• Glycerol from adipose tissue is converted to dihydroxyacetone phosphate in the liver, which itself is an intermediate of glycolysis and gluconeogenesis.

The steps and enzymes involved in gluconeogenesis are shown in blue in the flowchart below.



Solution to Question 18:

RTPCR followed by real-time PCR is the best test for quantitative analysis of an RNA sample.

RTPCR (reverse transcriptase PCR) involves the generation of complementary DNA (cDNA) copies of the mRNA using the reverse transcriptase enzyme followed by amplification of the cDNA copies by PCR technique.

Quantification of DNA involves the assessment of the amount/concentration of DNA that is present in a sample when carrying out a technique like PCR. Real-time PCR or quantitative PCR/qPCR involves the quantification of DNA after each cycle of amplification, or, in "real-time" than at the end of the procedure; therefore real-time PCR helps in quantitative analysis of DNA.

When reverse transcriptase PCR and qPCR are combined, they can be used to determine the relative concentrations of a particular mRNA molecule in a cell.

Other options:

Option A: Real-time PCR alone can only be used for the quantification of DNA only.

Option B: RTPCR can convert the RNA into cDNA by reverse transcriptase enzyme and then amplify the cDNA copies by means of PCR but cannot quantify the DNA/RNA.

Option C: PCR-Restriction fragment length polymorphism (PCR-RFLP) is also called cleaved amplified polymorphic sequence (CAPS) assay. Polymorphisms are inherited differences found among individuals in more than 1% of the normal population. PCR-RFLP is a technique in which organisms may be differentiated by variations in their DNA sequence by restriction endonucleases. Typically, gel electrophoresis is used to visualize RFLPs. Thus, DNA but not RNA molecules can be quantified in this process.

Solution to Question 19:

The wobble hypothesis explains the degeneracy of the genetic code.

The wobble hypothesis states that codon-anticodon pairing follows the traditional Watson–Crick rules (G pairs with C and A pairs with U) for the first two bases of the codon but can be less stringent for the third/last base. It has been observed that a tRNA can recognize more than one codon for a specific amino acid, especially in the last nucleotide of the codon triplet. This is referred to as degeneracy and its mechanism can be explained by the wobble hypothesis.

The first base of the anticodon moves to permit nontraditional pairing with the last base of the codon. This movement is called wobble and is possible because the first base of the anticodon is not as spatially defined as the other two bases. Due to the wobbling, 61 tRNA species are not required to read the 61 codons.

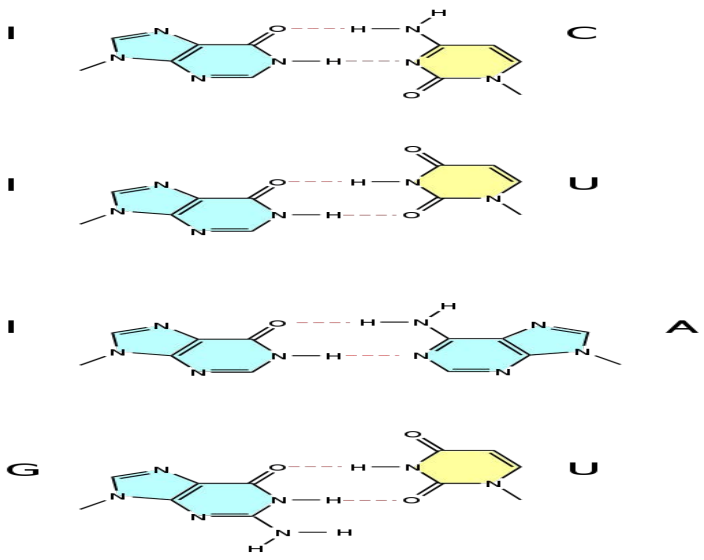
For example, three codons for glycine—GGU, GGC, and GGA—can form a base pair from one anticodon, 3′ CCI 5′ ie, I, inosine, can base pair with U, C, and A, as shown in the diagram below.

Other options:

Option A: The genetic code is universal because it is the same for all living organisms.

Option B: The genetic code is unambiguous because each codon is specific for only one amino acid. Example: GGA only codes for Glycine.

Option D: The genetic code is non-punctuated. This means that once the reading commences at a specific start codon, it is continuous and is read continuously as triplets until a stop codon is reached without stopping.



Solution to Question 20:

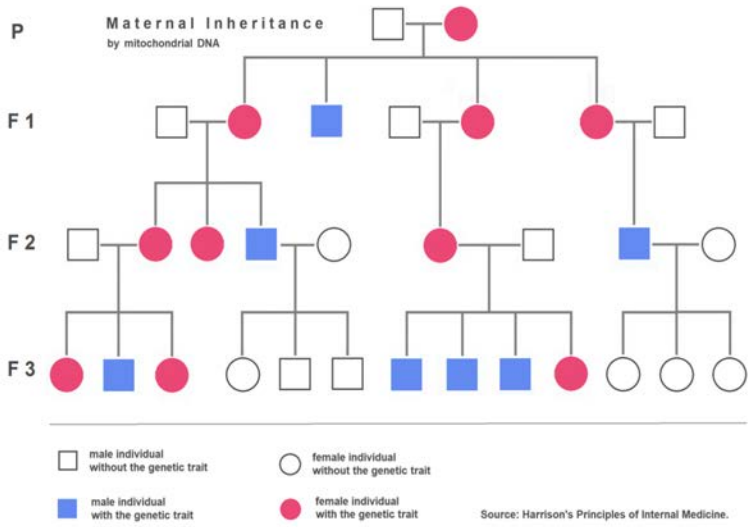
Statements 1 and 2 are true regarding mitochondrial DNA; it has a higher rate of mutations as compared to the nuclear genome and is a circular double-stranded DNA with about 16,000 base pairs.

Mitochondrial DNA is circular, double-stranded DNA composed of heavy and light chains and comprises about 1% of total cellular DNA. It contains about 16,569 base pairs and encodes about 13 protein subunits of the electron transport chain, of a total of about 67 protein subunits.

Its genetic code/ nucleotide sequence largely differs from that of the standard cellular code. For example, the standard stop codon UGA is read as tryptophan (Trp); in addition, few untranslated sequences exist and a very high mutation rate, about 5-10 times compared to that of nuclear DNA of the cell is observed.

As all mitochondria are contributed by the ovum during zygote formation, human mitochondrial DNA is transmitted by maternal non-mendelian inheritance. This is clinically significant because in diseases resulting from mutations of mitochondrial DNA, except in a few cases, an affected mother would pass the disease to all of her children but only her daughters would transmit the trait.

The below image shows the mitochondrial inheritance



Solution to Question 21:

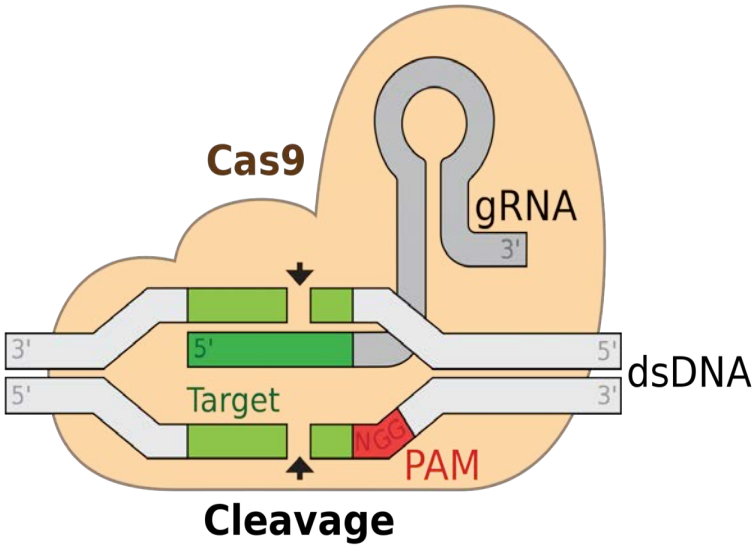
The repair mechanism associated with CRISPR-Cas9 is non-homologous end-joining.

Non-homologous end-joining (NHEJ) is a mechanism by which a group of proteins mediates the recognition, processing, and direct ligation of the ends of two DNA fragments where a double-strand break in DNA has occurred. This is in contrast to homologous recombination (HR), another mechanism to repair a double-strand break, where DNA repair needs an undamaged homologous DNA template to replace an adjacent damaged one.

Clustered regularly interspaced short palindromic repeats-associated gene 9 or CRISPR-Cas9 is a DNA editing/gene regulatory system. It involves two essential components, Cas9, an endonuclease that causes a double-stranded DNA break, allowing modifications to the genomic DNA to be made; and a synthetic single guide RNA or sgRNA responsible for guiding Cas9 to its target.

Once the sgRNA has directed the Cas9 to the section of the genomic DNA to be edited, the 3' end of the sgRNA comes to lie across a specific sequence of DNA adjacent to the editing side called the protospacer adjacent motif or PAM. The Cas9 now causes a double-stranded break in the DNA at the PAM site which is then repaired by a non-homologous end-joining.

The following image shows CRISPR-Cas9 system



Solution to Question 22:

Pyruvate dehydrogenase is the enzyme affected in a patient with thiamine deficiency who develops lactic acidosis.

Pyruvate is transported from the cytosol into the mitochondria, where undergoes oxidative decarboxylation to form acetyl CoA in the presence of the multi-enzyme pyruvate dehydrogenase complex (PDHC) in the mitochondrial matrix.

The PDHC primarily consists of three enzymes: Pyruvate decarboxylase (also called Pyruvate dehydrogenase), dihydrolipoyl transacetylase, and dihydrolipoyl dehydrogenase. It also requires the following co-enzymes:

• Thiamine pyrophosphate, essential for pyruvate decarboxylase and is tightly bound to it

• Lipoic acid and coenzyme A, essential for dihydrolipoyl transacetylase

• FAD and NAD+, essential for dihydrolipoyl dehydrogenase.

In a patient with thiamine deficiency, due to the inactive thiamine pyrophosphate, the pyruvate dehydrogenase complex is unable to act on pyruvate, which begins to accumulate on the body and is then shunted towards lactic acid formation by the enzyme lactate dehydrogenase.

This results in lactic acid accumulation and subsequent lactic acidosis in the patient.

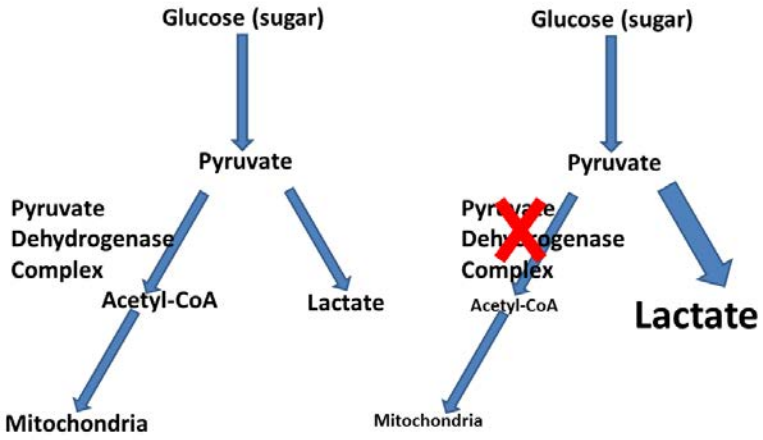
Wernicke–Korsakoff, an encephalopathy-psychosis syndrome due to thiamine deficiency, may be seen in chronic alcoholics. It occurs due to insufficient production of ATP by the brain cells via the citric acid cycle as the PDHC is inactive.

Other options:

Option A: Pyruvate carboxylase facilitates the conversion of pyruvate to oxaloacetate by carboxylation.

Option C: Phosphoenolpyruvate carboxykinase is involved in the decarboxylation and phosphorylation of oxaloacetate to form phosphoenolpyruvate seen in gluconeogenesis.

Option D: Transketolase with coenzyme thiamine pyrophosphate is an enzyme involved in the non-oxidative phase of the pentose phosphate pathway.



Solution to Question 23:

Triglycerides are not amphipathic.

Amphipathic substances are those which have both a hydrophilic or polar region and a hydrophobic or nonpolar region.

Phosphoglycerols or glycerol-based phospholipids have a hydrophilic head which is a phosphate group with alcohol attached to it and a hydrophobic tail containing fatty acids or fatty acid-based hydrocarbons. Therefore, they are amphipathic.

Sphingolipids, like all membrane-based lipids, are amphipathic molecules having hydrophobic and hydrophilic properties.

Glycolipids are amphipathic molecules consisting of a hydrophilic oligosaccharide chain attached to a hydrophobic lipid that anchors the glycolipid in cell membranes.

But lipids like triacylglycerol and cholesteryl esters are termed neutral lipids and thus are not amphipathic.

Cholesterol is amphipathic.

Solution to Question 24:

Only test 3, which is Rothera's test for ketone bodies in the urine will be positive in the urine of a patient with prolonged starving.

Urine tests

Test 1 - Benedict's test for reducing sugars

Test 2 - Heat and acetic acid test for presence of albumin

Test 3 - Rothera's test for ketone bodies

In case of prolonged starvation,

• After a meal till about 2 hours later, maintenance of blood glucose is primarily from the diet. During this time, hepatic glycogen stores are getting replenished.

• As dietary blood glucose levels start to decline, glucagon secretion increases and insulin secretion decreases, resulting in rapid mobilisation of hepatic glycogen stores.

• If there is fasting for a longer period of time, hepatic glycogen stores cannot maintain blood glucose levels. 12 hours after the last meal, gluconeogenesis becomes the primary source of blood glucose, since most of the hepatic glycogen would have depleted. If an individual continues fasting, gluconeogenesis continues to be the main source.

• However, over the first few days of fasting, ketogenesis happens. This is when the concentration of acetyl CoA from fatty acid oxidation exceeds the oxidative capacity of the TCA cycle. Also, ketogenesis releases CoA, ensuring its availability for continued fatty acid oxidation.
Water-soluble ketone bodies are used as fuel by most tissues, including the brain during fasting. It also reduces the need for gluconeogenesis from amino acid carbon skeletons, thus preserving essential protein in the body.

Therefore, during prolonged fasting, the levels of ketone bodies in the body rise and subsequently begin to be eliminated in urine. Hence, in starvation ketosis, Rothera's test will be positive, but Benedict's test will be negative.

Both Benedict's and Rothera's tests will be positive in diabetic ketoacidosis. (Option 1)

• Benedict's test (Test 1) for reducing sugars is a semiquantitative method for the estimation of sugar in the urine.

• Rothera's test (Test 3) is performed by saturating urine with solid ammonium sulfate. On adding sodium nitroprusside and liquor ammonia along the sides of the test tube, a purple ring is formed at the junction of the two liquids if there is acetone or acetoacetic acid in urine.
Beta-hydroxybutyrate does not give a purple ring.

• Heat and acetic acid test (Test 2) for proteinuria is based on the fact that when heated to an isoelectric point, proteins get coagulated.

Color	Concentration
Green	0.5 g%
Yellow	1 g%
Orange	1.5 g%
Red	2 g%

Solution to Question 25:

The action of inhibition on acetylcholinesterase enzyme by organophosphorus compounds is through irreversible competitive inhibition.

Competitive inhibition is a type of inhibition that occurs when the inhibitor binds reversibly to the same site that the substrate would normally occupy. It, therefore, competes with the substrate for binding to the enzyme active site. The effect of competitive inhibition can be overcome by increasing the concentration of the substrate. Km is increased, but Vmax is unaltered in this type of inhibition.

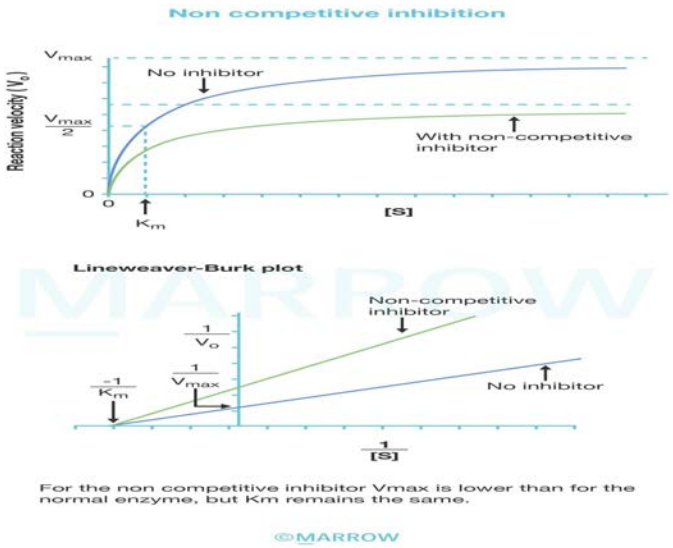
Competitive inhibition is of two types:

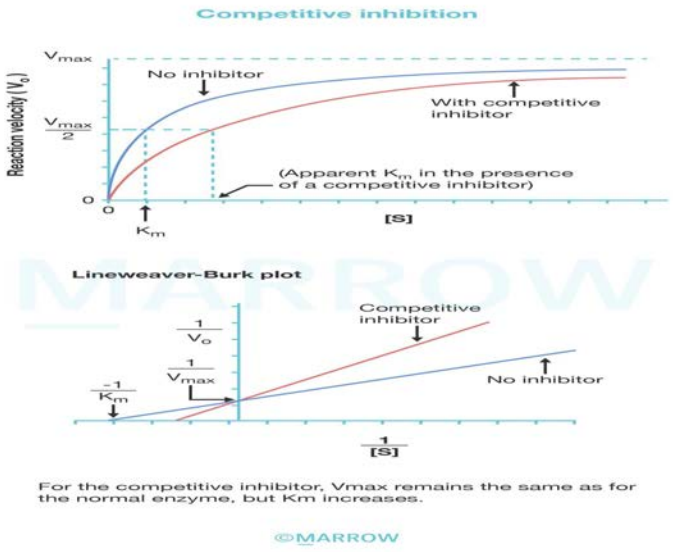
• Irreversible (non-equilibrium type) competitive inhibition: The inhibitor forms strong covalent bonds or has such a high affinity for the enzyme that the normal substrate is not able to displace the inhibitor. For example, organophosphorus poisoning inhibits acetylcholinesterase(AChE). Once an organophosphate binds to AChE, endogenous hydrolysis of the phosphorylated enzyme by esterases further leads to irreversible binding and permanent enzyme inactivation which is termed aging.

• Reversible (equilibrium type) competitive inhibition: Substrate concentration is sufficiently increased, it can displace the inhibitor. Statin drug inhibits HMG CoA reductase.

Noncompetitive inhibitors bind to enzymes at remote sites from the active site. Therefore, noncompetitive inhibition cannot be overcome by increasing the concentration of the substrate. Thus, noncompetitive inhibitors decrease the Vmax of the reaction. They do not interfere with the binding of the substrate to the enzyme. Thus, the enzyme shows the same Km in the presence or absence of noncompetitive inhibitors. For eg, acetazolamide inhibits carbonic anhydrase, digoxin inhibits Na+ K+ ATPase

Graph showing the changes in Vmax and Km noncompetitive and competitive inhibition.





Suicidal inhibition is a special type of irreversible inhibition. It is also known as mechanism-based inactivation. The inhibitor is a specialised substrate analog that can be transformed by the enzyme it is inhibiting. After binding to the active site of the enzyme, a highly reactive group is generated. This covalently binds to and inhibits the enzyme. An example is allopurinol, which is oxidised by xanthine oxidase to alloxanthine. Alloxanthine in turn is a strong inhibitor of xanthine oxidase.

Biochemistry NEET 2021

Question 1:

An alcoholic patient presented with itchy lesions as shown in the image, He also has a red-colored beefy tongue. Which of the following histories would you like to additionally ask/ elicit in this patient?

a) Ask for diarrhea and history of memory loss

b) Ask for diarrhea, thiamine deficiency features, and detailed dietary history

c) History of allergy

d) Ask for diarrhea and conjunctivitis

Question 2:

A patient presented with symptoms of delayed adaptation to vision in dark places, gritty sensation in the eyes, dry eyes, and softening of the cornea. What is the likely deficiency in this case?

a) Retinoic acid

b) Riboflavin

c) Niacin

d) Pantothenic acid

Question 3:

You are conducting an experiment on mitochondrial respiration. You add malate/pyruvate and respiration is normal. You add succinate and respiration is normal. When you add another substance in the presence of pyruvate/succinate and malate, respiration is blocked. Which of the following substances is most likely added?

a) Rotenone

b) Antimycin A

c) Oligomycin

d) 2,4-dinitrophenol

Question 4:

A patient presented with tendon xanthomas. His lipid profile showed serum cholesterol levels to be 283 mg/dL and serum LDL to be 202 mg/dL. He was started on lovastatin. What is the likely diagnosis?

a) Familial hypercholesterolemia

b) Tangier's disease

c) Lipoprotein lipase deficiency

d) Familial hyperchylomicronemia

Question 5:

Which of the following glycosaminoglycans (GAGs) are responsible for corneal transparency?

a) Keratan sulfate

b) Chondroitin sulfate

c) Heparan sulfate

d) Hyaluronic acid

Question 6:

A person who had dinner at 8 pm the previous night, tested his blood glucose levels at 7 am the next morning. What is the source of blood glucose in this case?

a) Hepatic glycogenolysis

b) Hepatic gluconeogenesis

c) Muscle glycogenolysis

d) Dietary glucose

Question 7:

A patient who has been diagnosed with multiple gastrointestinal polyps and carcinoma, with a positive family history/history of hereditary non-polyposis colon carcinoma has a defect in which of the following?

a) Mismatch repair

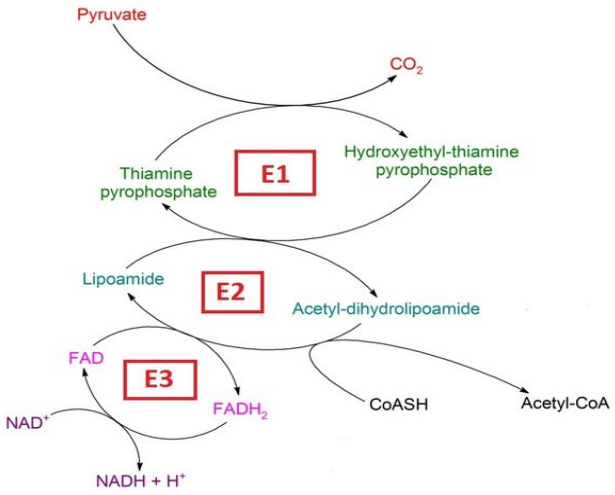
b) Nucleotide excision repair

c) Base excision repair

d) Point mutation

Question 8:

The enzymes that convert pyruvate to acetyl CoA are given in the diagram. What are the enzymes marked as E1 and E2 respectively?



a) Pyruvate dehydrogenase and dihydrolipoyl transacetylase

b) Pyruvate carboxylase and dihydrolipoyl transacetylase

c) Pyruvate dehydrogenase and dihydrolipoyl dehydrogenase

d) Pyruvate carboxylase and dihydrolipoyl dehydrogenase

Question 9:

A young girl presented to the OPD for examination. She is tall and thin with slender fingers, and dislocated lenses. Workup revealed cystathionine beta-synthase deficiency. Which amino acid supplement is required in this case?

a) Cysteine

b) Methionine

c) Serine

d) Tyrosine

Question 10:

A patient presented with joint pain and on evaluation, urine turns black on standing. What is the likely enzyme deficiency?

a) Homogentisic acid 1, 2 - dioxygenase

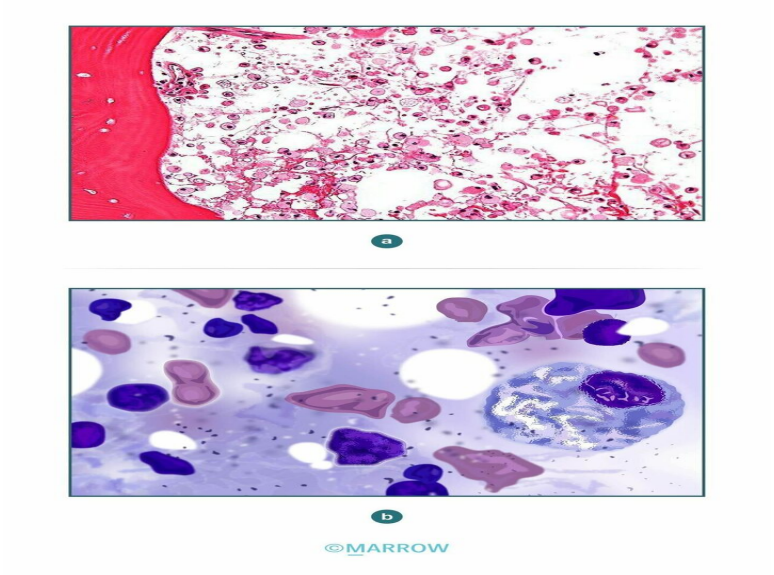
b) Tyrosine transaminase

c) Fumarylacetoacetate hydrolase

d) 4-hydroxy-phenyl pyruvate dioxygenase

Question 11:

A 5-year-old boy presented with easy fatigability, irritability and inability to concentrate. Labs revealed the following findings a and b (light and oil immersion respectively) on the bone marrow aspiration. Which of the following is the most likely enzyme deficient in this condition?



a) Hexosaminidase

b) Glucocerebrosidase

c) Sphingomyelinase

d) N-acetylglucosaminidase

Question 12:

A farmer presented with loose stools and rashes over the sun-exposed areas. Careful diet history reveals a diet rich in maize. Which of the following deficiencies would you suspect?

a) Niacin

b) Pyridoxine

c) Thiamine

d) Biotin

Answer Key

Question No.	Correct Option
1	a
2	a
3	c
4	a

5	a
6	a
7	a
8	a
9	a
10	a
11	b
12	a

Detailed Explanations

Solution to Question 1:

An alcoholic patient with a red-colored beefy tongue, itching and the characteristic Casal's necklace, shown in the image, is suggestive of pellagra. It is caused by niacin/vitamin B3 deficiency. Hence, one should ask for a history of diarrhea and memory loss in this case.

Pellagra presents with 4 Ds: Diarrhea, Dermatitis, Dementia, and if untreated, Death. Early symptoms of pellagra are loss of appetite, generalized weakness and irritability, abdominal pain, and vomiting. Photosensitive dermatitis is seen over sun-exposed areas. Diarrhea occurs due to proctitis or malabsorption. Bright red glossitis (beefy tongue) and Casal's necklace (a pigmented, scaly skin rash that forms a ring around the neck) follow. Depressive psychosis and dementia also commonly occur.

Corn/ maize/ jowar based diets are the main causes of niacin deficiency. Corn/maize lacks niacin and tryptophan. The excess leucine in jowar and maize disrupts the conversion of tryptophan to niacin. Niacin deficiency is also seen in alcoholism. Hence, additional histories of diarrhea and memory loss will aid in supporting the diagnosis of pellagra (along with dietary history).

Treatment includes oral supplementation with 100–200 mg of nicotinamide or nicotinic acid three times daily for 5 days.

Option B: Thiamine deficiency (vitamin B1) features include CVS manifestations like heart failure and edema (wet beriberi), peripheral neuritis (dry beriberi), and Wernicke encephalopathy (in alcoholics).

Option C: Dermatitis seen in pellagra is due to dietary deficiency of niacin and so allergy history is not relevant.

Option D: Conjunctivitis is not a feature of niacin deficiency.

Solution to Question 2:

The clinical picture of delayed adaptation to vision in dark places, gritty sensation in the eyes, dry eyes, and softening of the cornea is suggestive of vitamin A deficiency in the patient. Hence

retinoic acid (the active form of vitamin A) is likely to be deficient.

Vitamin A is a fat-soluble vitamin that can occur as carotenoids (most common - beta carotene from plant sources) or retinoids (from animal sources).

3 forms of retinoids are:

• Retinal is required mainly for normal vision (present in the visual pigment rhodopsin).

• Retinol is important for the normal functioning of the reproductive system.

• Retinoic acid has a role in the regulation of gene expression and tissue differentiation.

Ocular manifestations of vitamin A deficiency include loss of sensitivity to green light (earliest to appear), nyctalopia (night blindness), xerophthalmia.

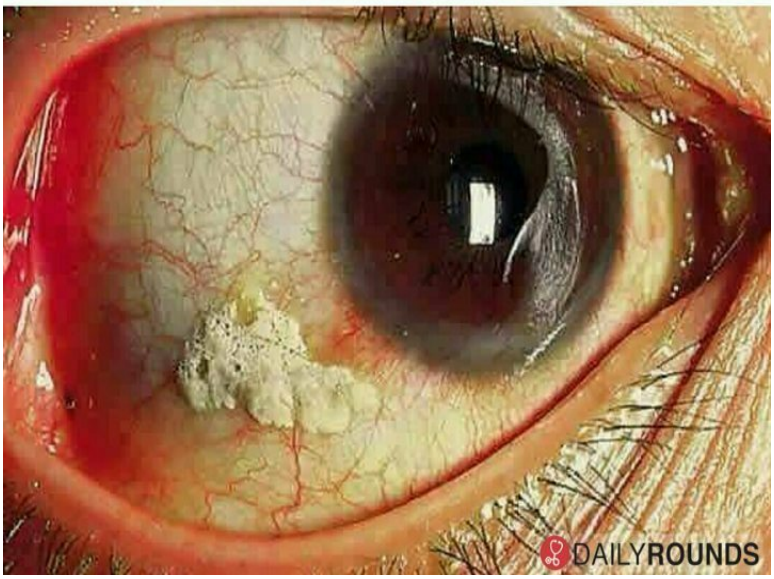
Xerophthalmia includes conjunctival xerosis (dryness) with Bitot's spots (white patches of keratinized epithelium appearing on the sclera), corneal ulcers, and keratomalacia (softening of the cornea) that leads to corneal scarring and ultimately, blindness.

Other manifestations: General impairment of immunity, keratinization of skin (phrynoderma/toad skin).

Treatment: The WHO recommended schedule for all patients above the age of 1 year (except women of reproductive age): 200,000 IU of vitamin A orally or 100,000 IU by intramuscular injection should be given immediately on diagnosis (day 0) and repeated the following day (day 1) and 14 days later.

Dietary sources of vitamin A are liver, fish, eggs, dark green, and deeply colored fruits and vegetables.

Bitot's spots

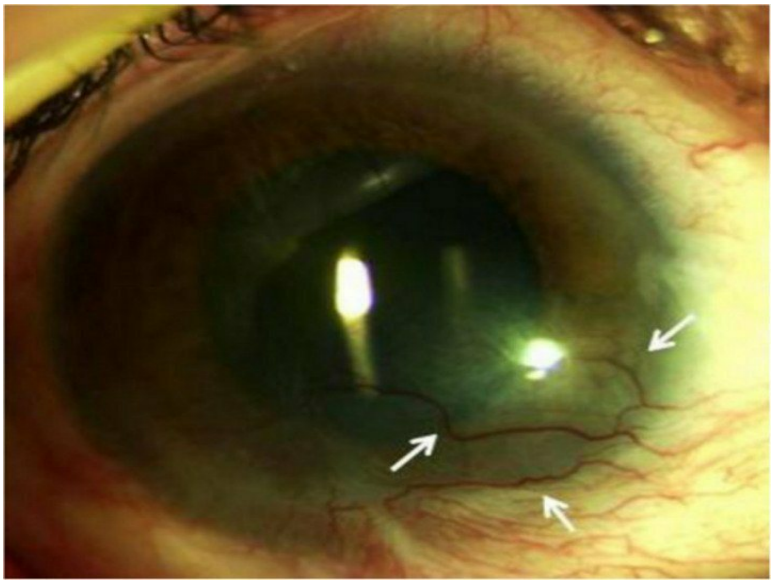


The below image shows phrynoderma with multiple keratotic papules

Other options:

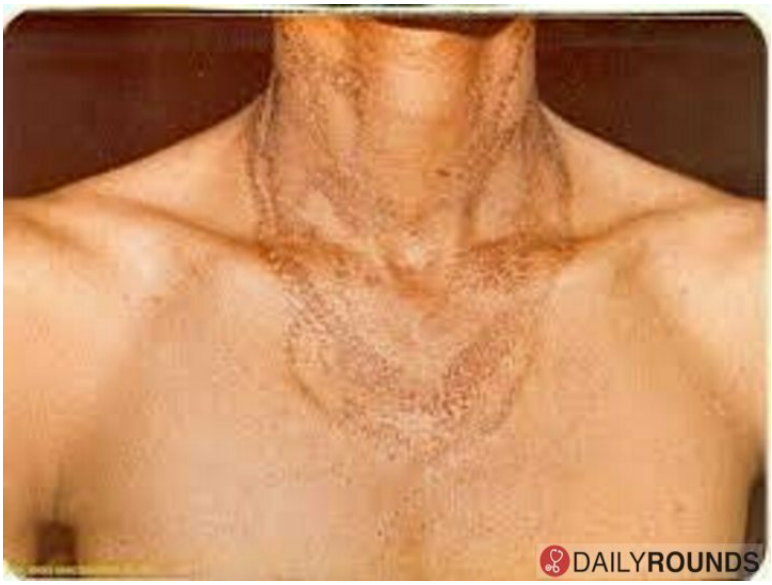
Option B: Ocular manifestations of riboflavin deficiency (vitamin B2) are photophobia, burning sensation, and vascularization of the cornea. Other features include cheilosis, magenta-colored tongue, glossitis, and seborrheic dermatitis.

Corneal vascularization. Seen in riboflavin (Vitamin B2) deficiency.



Option C: Niacin deficiency (vitamin B3) leads to pellagra. Dermatitis, diarrhea, and dementia are its common features.

Casal's necklace finding in niacin deficiency



Option D: Features of pantothenic acid deficiency (vitamin B5) are burning foot syndrome ("nutritional melalgia"), dermatitis, enteritis, alopecia, ataxia.

Solution to Question 3:

In the experiment conducted on mitochondrial respiration, respiration will be blocked by the addition of oligomycin, an antibiotic, when added in the presence of pyruvate/ succinate and malate. Oligomycin inhibits oxidative phosphorylation in the mitochondria and hence blocks respiration.

Electron transport chain (ETC)/respiratory chain is the final pathway by which all the electrons derived from the oxidation of carbohydrates, fatty acids, and amino acids are directed towards the final reaction with oxygen, to form water and adenosine triphosphate (ATP).

The chemiosmotic theory states that the flow of electrons through the respiratory chain generates a proton motive force. This force drives the formation of ATP by the process of oxidative phosphorylation.

In the given experiment, malate and pyruvate are electron donors (NADH) at complex I of the ETC, and succinate is the electron donor ($FADH_2$) at complex II. Normal respiration is observed on the addition of substances at both complexes I and II i.e., both oxygen consumption and ATP synthesis from ADP (adenosine diphosphate) take place.

Oligomycin is a competitive inhibitor of the Fo (oligomycin-sensitive) complex of ATP synthase (complex V) and blocks oxidation and phosphorylation by stopping the flow of protons through the ATP synthase enzyme complex. Hence the addition of oligomycin will inhibit complex V and stop respiration.

Other options:

Options A and B: Rotenone (option A) if added, will inhibit complex I. Electron transfer before complex I will be blocked but not after. Hence, normal respiration will occur. Similarly, antimycin A (option B) inhibits complex III, and electron transfer prior to complex III will be blocked and

not after. Hence, respiration will not be completely hindered.

Option C: 2,4-dinitrophenol (DNP) is an uncoupler that dissociates oxidation in the respiratory chain from phosphorylation. Hence, respiration continues without ATP synthesis.

Complexes of ETC	Inhibitors
Complex I: NADH-CoQ oxido reductase	Piericidin, amobarbital, roten one
Complex II: Succinate-CoQ r eductase	TTFA (thenoyltrifluoroaceton e), carboxin, malonate
Complex III: CoQH2-cytochr ome c oxidoreductase	BAL(British anti-lewisite), an timycin A
Complex IV: cytochrome oxid ase	Hydrogen sulfide, carbon mo noxide, cyanide
Complex V (informally): ATP Synthase	Atractyloside, oligomycin

Solution to Question 4:

The clinical presentation with tendon xanthomas and elevated serum LDL (low-density lipoprotein) and elevated serum cholesterol points to a diagnosis of familial hypercholesterolemia (FH).

Familial hypercholesterolemia (type IIa hyperlipoproteinemia) is an inherited disorder due to defects in LDL receptors. This defect causes a decrease in the uptake of LDL and cholesterol. As a result, the blood levels of both LDL and cholesterol are elevated. Such patients are at increased risk to develop atherosclerosis and coronary artery disease.

Features of FH:

• Painful polyarthritis and tendinitis are common.

• Physical findings seen are corneal arcus and tendon xanthomas over Achilles tendon and the dorsum of hands. Xanthomas are tumorous masses produced by foamy cell clusters (lipid-laden macrophages) found in the connective tissue of the skin and in tendons.

Diagnosis is done clinically based on hypercholesterolemia with

• LDL > 190 mg/dl,

• Family history of hypercholesterolemia and/or

• Premature coronary artery disease.

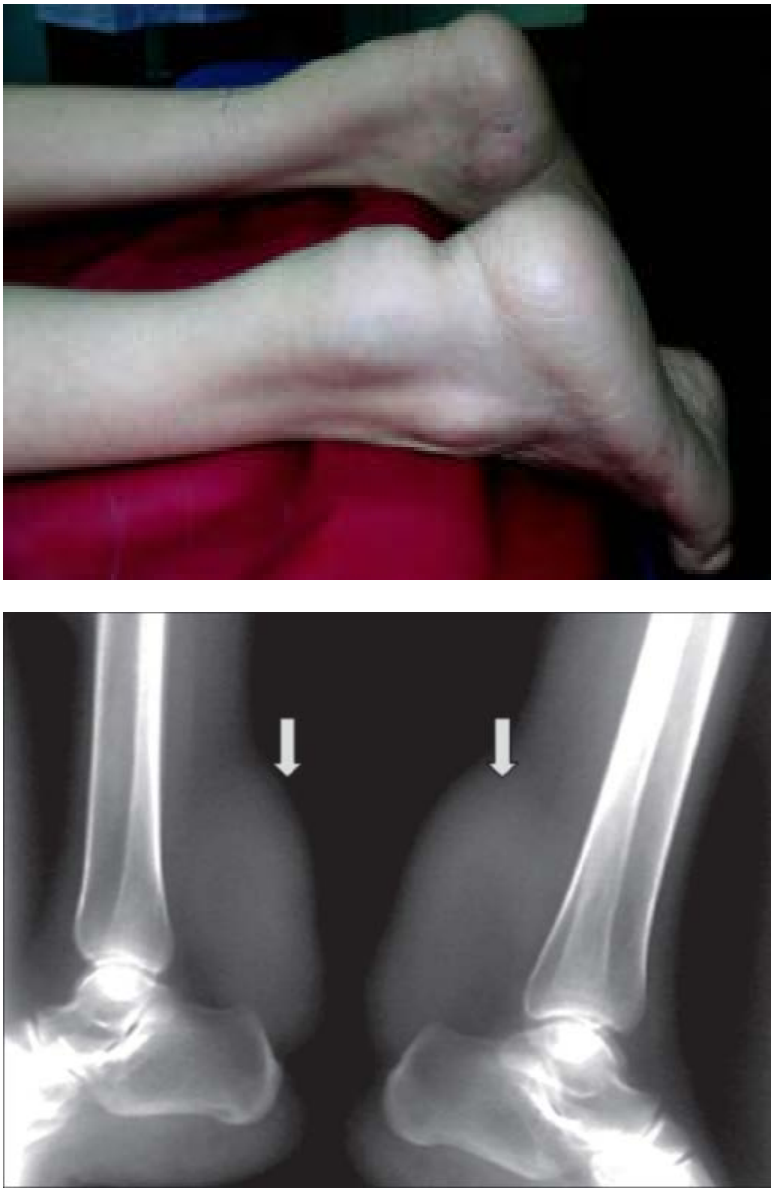
Treatment includes lifestyle changes, restriction of a fatty diet, and pharmacotherapy with statins in heterozygous FH patients.

Recent drugs for specific treatment of homozygous FH are:

• Lomitapide, a microsomal triglyceride transfer protein (MTP) inhibitor, and

• Mipomersen, an antisense oligonucleotide against apoB.

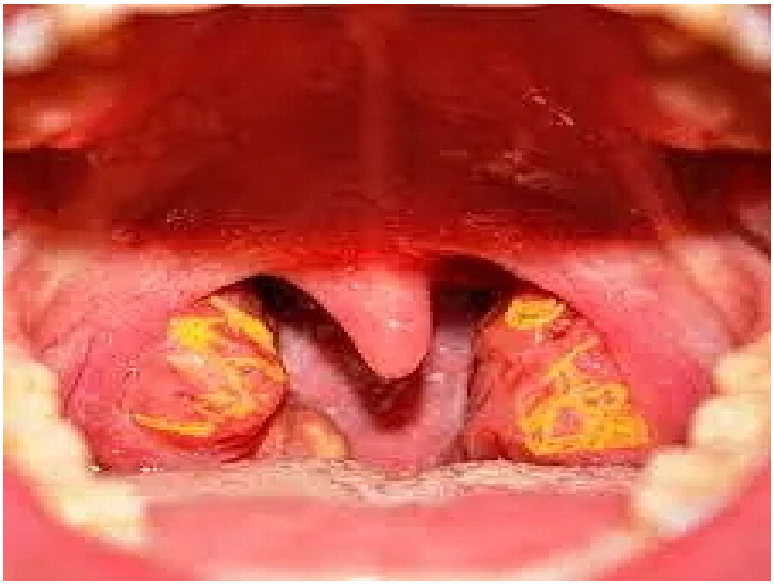
The image below shows Achilles tendon xanthoma and a plain lateral radiograph of both ankles showing bilateral symmetrical swellings (arrows) superior to the calcaneum respectively.



Other options

Option B: Tangier's disease is a hypolipoproteinemia caused by a mutation of the ABCA1 gene. Enlarged orange tonsils are pathognomonic. Low HDL levels are seen. There is an increased risk for atherosclerosis.

The image below shows enlarged yellow-orange colored tonsils in Tangier's disease.



Option C: Lipoprotein lipase (LPL) deficiency causes type I hyperlipoproteinemia due to defects in LPL or apo C-II. Eruptive xanthomas are seen. Chylomicrons and VLDL are elevated. LDL and HDL are low. There is no risk for coronary disease.

Option D: Familial hyperchylomicronemia syndrome is caused due to either LPL deficiency, ApoC-II deficiency, ApoA-V deficiency, or GPIHBP1 mutation. Clinically, patients present with recurrent episodes of severe abdominal pain due to acute pancreatitis. The retinal blood vessels may be opalescent and are called lipemia retinalis. Increased levels of triglycerides (mostly >1000 mg/dL) is seen. The risk of premature coronary heart disease is low.

Solution to Question 5:

The glycosaminoglycan (GAG) responsible for corneal transparency is keratan sulfate.

Glycosaminoglycans or mucopolysaccharides are complex carbohydrates made up of amino sugars and uronic acids. They may be attached to a protein molecule to form a proteoglycan.

Keratan sulfate is a mucopolysaccharide that does not contain uronic acid. It is constituted by repeating disaccharide units of N-acetyl glucosamine and galactose.

Keratan sulfate is present between the collagen fibrils in the cornea and plays a major role in corneal transparency.

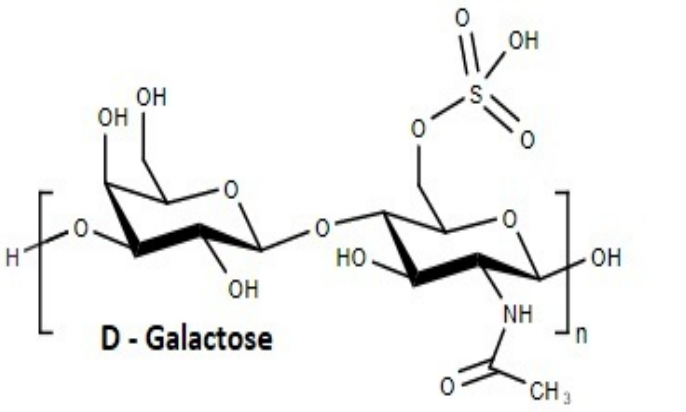
2 types of keratan sulfate are seen:

• Keratan sulfate I is present in the cornea.

• Keratan sulfate II is mainly present in the cartilage.

Keratin sulfate I and II differ in their linkage to the core proteins. Keratan sulfate I links to a core protein L-asparagine via N-acetylglucosamine and Keratan sulfate II to L-Serine (or L-Threonine) via N-acetylgalactosamine.

The chemical structure of Keratan sulfate is shown in the image below.



Other options:

Option B: In chondroitin sulfates (chondroitin 4-Sulfate & chondroitin 6-Sulfate), the repeating disaccharide units are glucuronic acid and N-acetylgalactosamine. They maintain the structure of the extracellular matrix (ECM) and are located in endochondral bone and cartilage. They are also found in the ECM of the central nervous system. They act as signaling molecules in the prevention of the repair of nerve endings after injury.

Option C: Heparan sulfate is found on many extracellular cell surfaces and contains glucosamine with fewer N-sulfates than heparin. The predominant uronic acid is d-glucuronic acid. In the plasma membrane of cells, they act as receptors and mediate cell growth and cell-cell communication. It is also found in the basement membrane of the kidney along with type IV collagen and laminin, where it determines the charge selectiveness of glomerular filtration.

Option D: Hyaluronic acid is present in synovial fluid. It is also found in skin, bone, cartilage, vitreous humor, and embryonic tissues. It contains repeating units of N Acetyl Glucosamine and glucuronic acid. It plays a role in morphogenesis and wound repair. The high concentrations of hyaluronic acid along with chondroitin sulfates in cartilage contribute to its compressibility.

Solution to Question 6:

The source of blood glucose in a person fasting overnight for 11 hours (8 pm to 7 am) is hepatic glycogenolysis.

First stage of fasting: The fasting state begins two to four hours after the absorptive/well-fed state. In early fasting i.e; 4-18 hours after the well-fed state, the blood glucose level is maintained by hepatic glycogenolysis. The glycogen stores are sufficient for around 18 hours after a meal following which they start to deplete. So the source of blood glucose in a person fasting for 11 hours will be liver glycogenolysis.

Second stage of fasting: Gluconeogenesis begins 4–6 hours after the last meal but becomes fully active only after stores of liver glycogen are depleted (after 18 hours). They can serve as a source

of glucose for up to 2 days.

Substrates for gluconeogenesis are:

• Glucogenic amino acids (mainly alanine) from the muscle and

• Glycerol from adipose tissue

During fasting, the glucogenic amino acids are transported to the liver, transaminated into pyruvate, and converted to glucose.

Third stage of fasting:

• Lipolysis occurs in the adipose tissue due to the activity of hormone-sensitive lipase, stimulated by increased glucagon:insulin ratio.

• Free fatty acids are the source of energy in this stage and not glucose. Triacylglycerols will be hydrolyzed to fatty acids and glycerol.

• Beta oxidation of fatty acids takes place which provides acetyl CoA.

• In prolonged starvation (>3 days), acetyl CoA is converted to ketone bodies in the liver which will act as the main fuel source for skeletal and heart muscle and can meet up to 20% of the brain's energy needs.

Final stage of fasting: After several weeks of starvation, ketone body synthesis will not take place due to depleted triacylglycerol stores. Proteins remain the only source of fuel. Protein degradation increases, and death results from a loss of heart, liver, or kidney function.

Role of insulin and glucagon:

When blood glucose falls during fasting, there is increased secretion of glucagon and decreased release of insulin. Hence glucagon:insulin ratio is increased.

Effects of increased glucagon:insulin ratio on enzymes of glycogenolysis and gluconeogenesis:

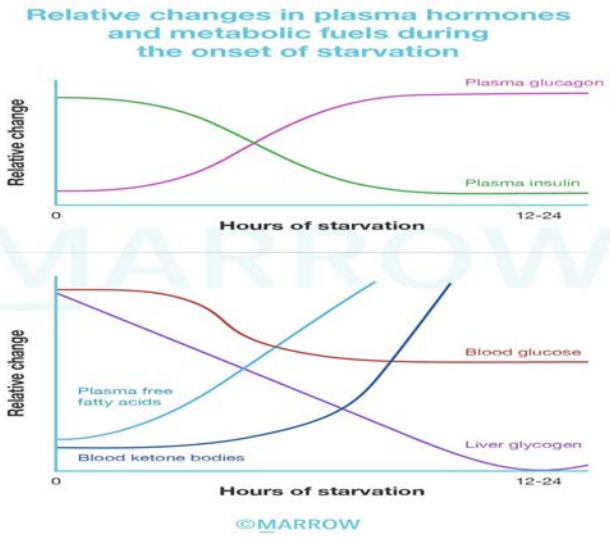
• It activates glycogen phosphorylase, the key enzyme of glycogenolysis, and deactivates glycogen synthase. This causes a rapid mobilization of liver glycogen stores to be utilized as fuel.

• It favors the synthesis of glucose-6-phosphatase which converts glucose-6-phosphate to glucose. The resulting glucose is used by red blood cells (lack mitochondria) and the brain as they are largely dependant on glucose in the fasting state.

• Phosphoenol pyruvate carboxykinase and fructose-1, 6-bisphosphatase are induced, leading to increased gluconeogenesis.

Metabolic process	Fasting state	Fed state
Glucagon: insulin	Increased	Decreased
Gluconeogenesis	Increased	Decreased
Glycogenolysis	Increased	Decreased
Ketogenesis	Increased	Decreased

Metabolic process	Fasting state	Fed state
Glycogen storage	Decreased	Increased

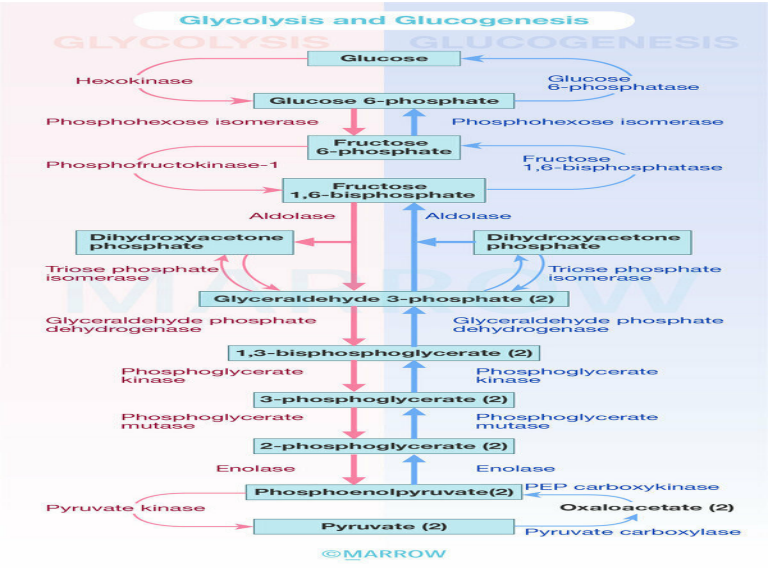


Other options:

Option C: Muscle glycogen cannot contribute directly to plasma glucose, since muscle lacks glucose-6-phosphatase. So glycogen cannot be converted to glucose to be used as fuel during starvation.

Option D: In the well-fed state/ absorptive state of two to four hours after a meal, dietary glucose is the main source of fuel.

The below image shows steps of glycolysis and gluconeogenesis.



Solution to Question 7:

Mismatch repair will be defective in a patient with multiple gastrointestinal polyps and carcinoma, with a positive family history/history of hereditary non-polyposis colon carcinoma (HNPCC)

Mismatch repair is a DNA repair mechanism that corrects single-nucleotide mismatches, insertions, and deletions introduced by the DNA polymerase during DNA replication.

HNPCC or Lynch syndrome is an autosomal dominant genetic condition. It occurs due to defects in DNA mismatch repair genes like MLH1 and MSH2. The genomes of these patients show microsatellite instability. HNPCC is associated with a high risk of colon cancer. It may also be associated with a risk of developing carcinomas of the endometrium, stomach, small bowel, ovary, pancreas, and transitional cell carcinoma of the ureter and renal pelvis.

The diagnostic criteria for HNPCC are referred to as the Amsterdam criteria or the 3-2-1-0 rule. It includes:

• Three or more relatives with HNPCC-associated cancer (colorectal cancer, endometrial cancer, cancer of the small bowel, ureter, or renal pelvis), one of whom is a first-degree relative of the other two.

• At least two successive generations affected

• At least one case diagnosed before age 50 years

• Familial adenomatous polyposis excluded

• Tumors verified by pathologic examination.

Other options:

Option B: Patients with xeroderma pigmentosum have a defect in the nucleotide excision repair pathway.

Option C: Defect in base excision repair pathway is seen in patients with MUTYH-associated polyposis.

Option D: Sickle cell disease and beta-thalassemia are examples of diseases seen in patients with point mutations.

Solution to Question 8:

E1 is pyruvate dehydrogenase and E2 is dihydrolipoyl transacetylase in the image showing oxidative decarboxylation of pyruvate. This is catalyzed by the pyruvate dehydrogenase (PDH) complex where E1, E2, and E3 are the three enzyme components of the complex.

The pyruvate dehydrogenase (PDH) complex is a multienzyme complex that is associated with the inner mitochondrial membrane. It catalyzes the oxidative decarboxylation of pyruvate to acetyl-CoA which enters the citric acid/Kreb's cycle.

Steps of pyruvate decarboxylation:

• Pyruvate is transported into the mitochondria by a proton symporter.

• Pyruvate is decarboxylated by pyruvate dehydrogenase (E1). TPP is required for this step. The decarboxylated pyruvate remains bound to the enzyme, as hydroxyethyl thiamine pyrophosphate.

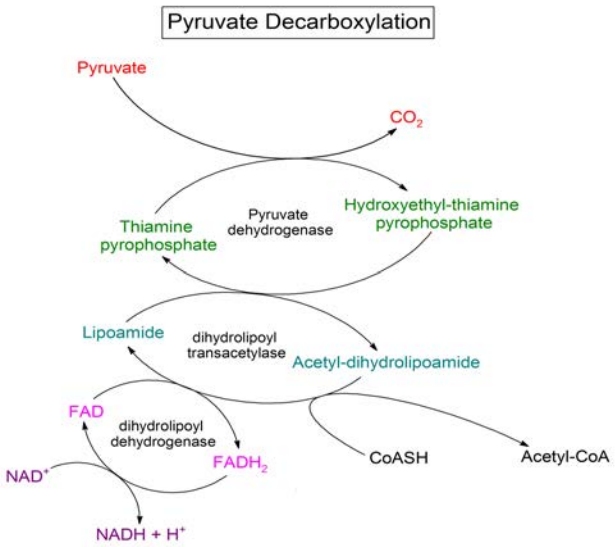
• The hydroxyethyl group is oxidized to form an acetyl group. It is then transferred from TPP to lipoamide to form acetyl lipoamide. This step is catalyzed by dihydrolipoyl transacetylase (E2).

• Acetyl lipoamide reacts with coenzyme A to form acetyl-CoA and reduced lipoamide.

• The reduced lipoamide is reoxidized by FAD-dependent dihydrolipoyl dehydrogenase (E3).

The overall reaction is : Pyruvate + NAD+ + CoA → Acetyl-CoA + NADH + H+ + CO2

Enzyme components of PDH complex	Co-factors
Pyruvate dehydrogenase (E1)	Thiamine pyrophosphate (TPP)
Dihydrolipoyl transacetylase (E2)	Lipoic acidCoenzyme A
Dihydrolipoyl dehydrogenase (E3)	Flavin adenine dinucleotide (FAD)Nicotinamide adenine dinucleotide (NAD+)



Clinical significance:

• Dietary deficiency of thiamine inhibits PDH. Chronic alcoholics may develop potentially fatal pyruvic and lactic acidosis. Lactic acidosis is a common presentation in patients with inherited pyruvate dehydrogenase deficiency too.

• In arsenic and mercury poisoning, the heavy metal ions react with -SH groups of lipoic acid and inhibit pyruvate dehydrogenase.

Other multienzyme complexes include alpha-ketoglutarate dehydrogenase and branched-chain ketoacid dehydrogenase. All the five coenzymes of PDH are common to these two complexes too.

Solution to Question 9:

The clinical picture of a tall and thin young girl with slender fingers, dislocated lenses, and cystathionine beta-synthase deficiency is suggestive of classic homocystinuria. The amino acid supplement required in this scenario is cysteine.

Classic homocystinuria is a metabolic disorder of methionine metabolism, due to cystathionine beta-synthase deficiency. It is an autosomal recessive condition.

Cystathionine beta-synthase is a pyridoxal phosphate-dependent enzyme that condenses homocysteine with serine to form cystathionine. The absence of this enzyme will cause cysteine deficiency, hence cysteine needs to be supplemented in the diet.

Clinical features:

• Affected children are initially asymptomatic.

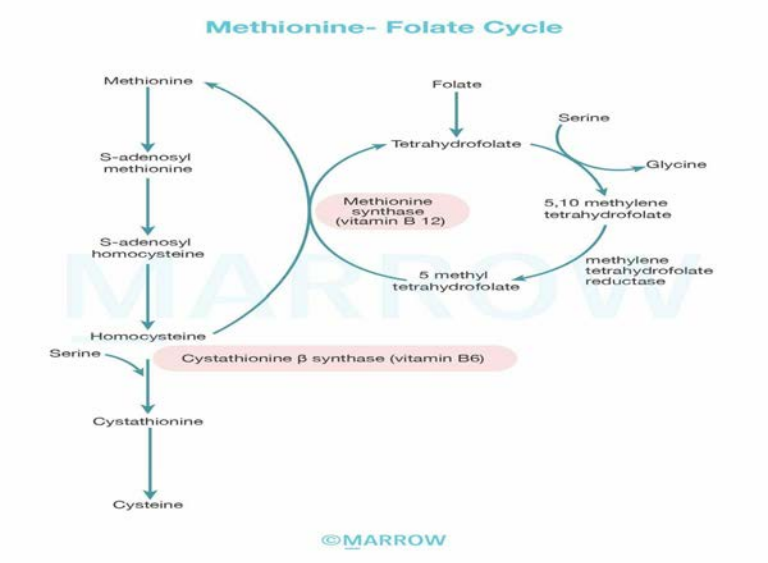
• Ectopia lentis (subluxation of the lens) is seen first, after 3 years of age.

• Intellectual disability and psychiatric and behavioral disorders.

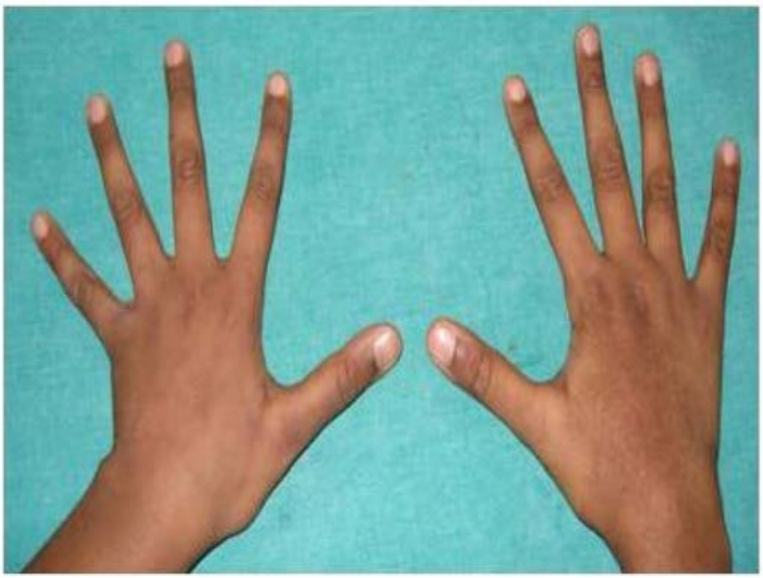
• Thromboembolic episodes.

• Skeletal abnormalities resembling those of Marfan syndrome: They are tall and thin with elongated limbs and arachnodactyly (slender fingers).

Elevations of both methionine and homocysteine in body fluids are the diagnostic laboratory findings. The diagnosis is established by molecular analysis of cystathionine β-synthase (CBS) or by assay of the enzyme in cultured fibroblasts, phytohemagglutinin-stimulated lymphocytes, or liver biopsy specimens. Treatment includes restriction of methionine intake and supplementation with cysteine, betaine, vitamins B6, B12, and folate.



The image below shows arachnodactyly.



Methionine supplementation is required in non-classical homocystinuria. It is due to impaired re-methylation of homocysteine to methionine. This can be caused by defective methionine synthase or reduced availability of two essential cofactors, 5-methyltetrahydrofolate, and methylcobalamin.

Elevated homocysteine levels with low levels of methionine will be seen. Treatment includes methionine supplementation and administration of methyl folate, hydroxocobalamin, and betaine.

Solution to Question 10:

The urine turning black in color, on exposure to air, along with joint pain is suggestive of alkaptonuria. It occurs due to the defect in the homogentisic acid 1, 2 - dioxygenase enzyme.

Alkaptonuria is an autosomal recessive disorder of tyrosine metabolism, that develops due to the defect in homogentisate oxidase/homogentisic acid 1, 2 - dioxygenase, which oxidizes homogentisate to maleylacetoacetate. The defect in this enzyme leads to the accumulation of homogentisate, which is then excreted in the urine.

Alkaptonuria is characterized by homogentisic aciduria, ochronosis, and arthropathy (joint pain).

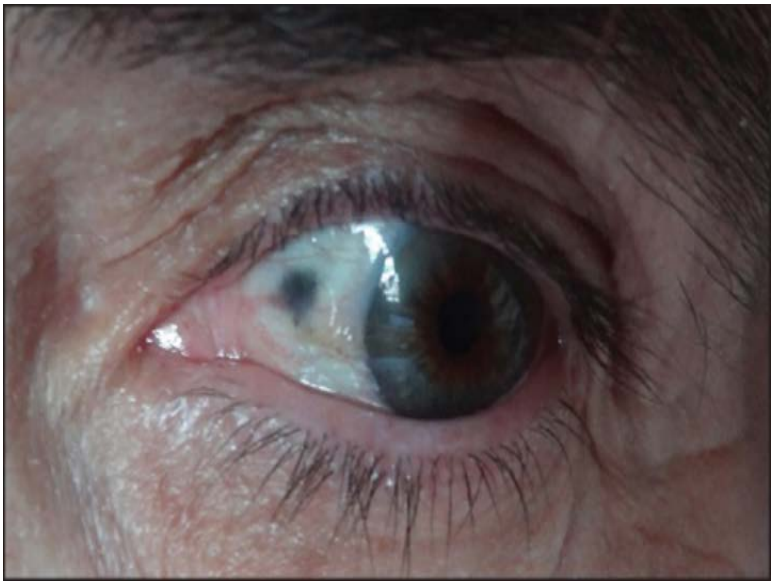
Homogentisic aciduria is the black discoloration of urine on prolonged exposure to air caused due to oxidation of the excreted homogentisate.

Ochronosis is the accumulation of oxidized homogentisic acid pigment (alkaptone bodies) in connective tissues leading to bluish-black discoloration of tissues mostly involving ear cartilage, ocular tissue, the skin of the eyelids, forehead, cheeks, and hands, nail beds, and intervertebral discs. The compound that accumulates in the tissues in ochronosis is benzoquinone acetate.

Painful arthritis (arthropathy) may be seen from the fourth or fifth decade.

Diagnosis: Blackish discoloration of urine on standing is diagnostic of alkaptonuria (shown below). The ferric chloride test will be positive.

The image further below shows Ochronosis.



Treatment: No specific treatment is required. Symptomatic treatment with analgesics, spinal surgery, and arthroplasty along with ascorbic acid and protein restriction can be considered. Nitisinone (p-hydroxyphenylpyruvic acid (pHPPA) oxidase inhibitor) reduces urinary excretion of homogentisic acid.

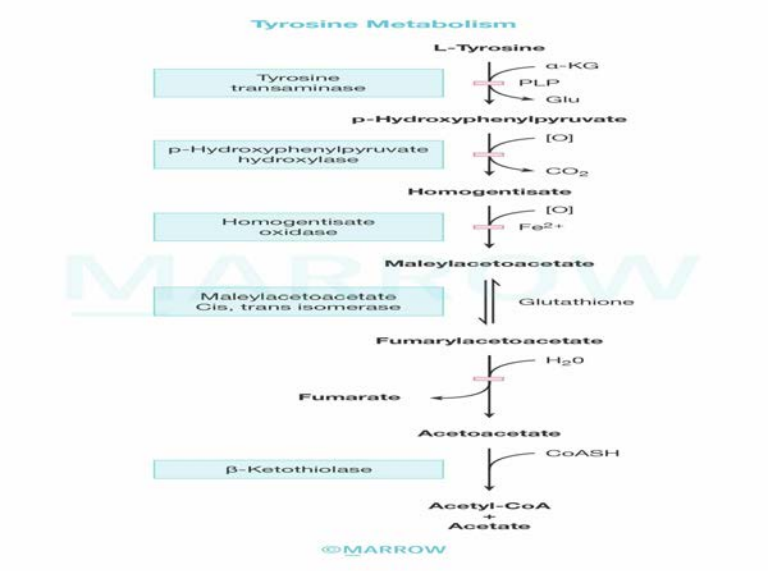
Other options:

Option B: Tyrosine transaminase deficiency causes type II tyrosinemia (Richner-Hanhart syndrome). Patients present with painful corneal erosions with photophobia, learning disability, and palmoplantar keratosis.

Option C: Fumarylacetoacetate hydrolase deficiency causes type I tyrosinemia (Tyrosinosis). Patients generally present with failure to thrive, neuropathy, boiled-cabbage urine, and liver failure secondary to cirrhosis.

Option D: 4-hydroxy-phenyl pyruvate dioxygenase deficiency causes type III tyrosinemia (neonatal tyrosinemia). Patients might rarely have a mental disability. The liver function is generally normal.

The steps of tyrosine metabolism are shown below.



Solution to Question 11:

The given clinical scenario of a child with easy fatiguability, irritability, and inability to concentrate with the images showing a crumpled tissue paper appearance(Gaucher's cell) is suggestive of Gaucher's disease. The deficient enzyme is glucocerebrosidase (also known as beta-glucosidase). I

Gaucher's disease is an inborn error of metabolism caused due to a deficiency of beta glucocerebrosidase. It is the most common lysosomal storage disorder and the mode of inheritance is autosomal recessive. There is an accumulation of lipid-laden macrophages in the spleen, liver, and other tissues.

There are three clinical subtypes - type I (chronic non-neuronopathic), type II (acute neuronopathic), and type III (intermediate). Clinical features include anemia, thrombocytopenia, hepatosplenomegaly, and neurological features depending on the subtype.

Gaucher's cells - These are formed as a result of the accumulation of massive amounts of glucocerebrosides within the phagocytes. The cells have a fibrillary cytoplasm and give a crumpled tissue paper appearance.

Option A: Deficiency of beta-hexosaminidase A is seen in Tay-Sachs disease. The deficiency of beta-hexosaminidase A and B causes Sandhoff's disease. Clinical features are seizures, macrocephaly, and hyperacusis.

Option C: Deficiency of sphingomyelinase leads to Niemann-Pick disease. It is characterized by the presence of foam cells in the bone marrow. There may be pulmonary infiltrates leading to lung failure.

Option D: Deficiency of N-acetylglucosaminidase leads to Sanfillipo's disease. It is a type of mucopolysaccharidosis (MPS - III). There is an accumulation of heparan sulfate leading to severe cognitive degeneration.

Solution to Question 12:

History of a maize-rich diet along with loose stools and rashes over the sun-exposed areas is suggestive of niacin/vitamin B3 deficiency.

Niacin deficiency causes pellagra, found mostly among people eating corn/maize-based diets, which is low in niacin and tryptophan. Excess leucine in jowar and maize disrupts the conversion of tryptophan to niacin.

Niacin can be synthesized in the body from tryptophan. Two compounds- nicotinic acid, and nicotinamide have the biological activity of niacin. The nicotinamide ring of the coenzymes NAD (nicotinamide adenine dinucleotide) and NADP (nicotinamide adenine dinucleotide phosphate) participate in oxidation/reduction reactions.

The initial symptoms of pellagra include loss of appetite, generalized weakness, irritability, abdominal pain, and vomiting. This is followed by bright red glossitis and a characteristic pigmented, scaly skin rash in sun-exposed areas. This rash is known as Casal’s necklace when it forms a ring around the neck.

The 4Ds of pellagra:

• Diarrhea

• Dermatitis

• Dementia, leading to

• Death

It is diagnosed by measuring urinary levels of 2-methyl nicotinamide and 2-pyridone.

It is treated by oral supplementation of 100–200 mg of nicotinamide or nicotinic acid three times daily for 5 days.

Casal’s necklace finding in niacin deficiency

Other options:

Option B: Dietary pyridoxine deficiency (vitamin B6) is rare but has been observed in alcoholics, newborn infants formulas low in vitamin B6, and women taking oral contraceptives. Isoniazid, an anti-TB drug, leads to pyridoxine deficiency resulting in peripheral neuropathy. Hence pyridoxine supplementation is included in ATT regimens.

Option C: Thiamine deficiency (vitamin B1) can manifest as wet beriberi (CVS features like heart failure and edema) or Shoshin beriberi, an acute and fulminant form of wet beriberi, dry beriberi (peripheral neuritis), or as Wernicke encephalopathy with Korsakoff psychosis (in alcoholics). Dietary deficiency of thiamine inhibits pyruvate dehydrogenase. Chronic alcoholics may develop potentially fatal pyruvic and lactic acidosis.

Option D: Dietary biotin deficiency is unknown but rarely, dermatitis, glossitis, loss of appetite, and nausea may occur after consumption of large amounts of uncooked egg white, which contains the protein avidin. It binds biotin and makes it unavailable for absorption.

Note: A similar image-based question on vitamin B3 deficiency was previously asked in NEET PG 2020. Vitamin deficiencies are a high-yield topic and are repeatedly tested every year.

Biochemistry INI-CET 2022

Question 1:

Which is the correct sequence of steps in the isolation of desirable protein using recombinant DNA technology?

a) 2, 1, 3, 5, 4

b) 1, 2, 4, 3, 5

c) 1, 5, 2, 4, 3

d) 2, 4, 5, 3, 1

Question 2:

Which of the following techniques is used to detect DNA-protein interaction?

a) DNA footprinting

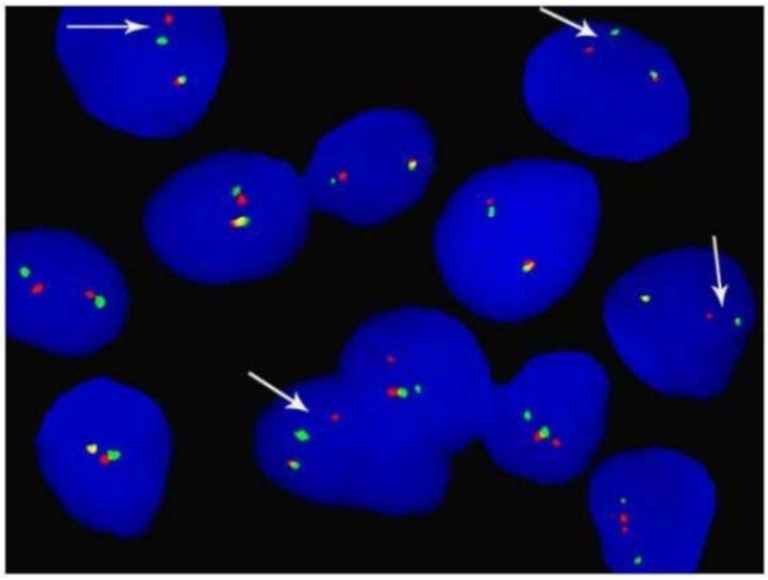
b) DNA fingerprinting

c) ELISA

d) Northern blotting

Question 3:

A patient was diagnosed with Ewing sarcoma with EWSR1 gene mutation. The technique shown in the image was performed to confirm the diagnosis. Identify the technique shown in the image.



a) Fluorescent in situ hybridisation

b) Karyotyping

c) Immunohistochemistry

d) Sanger's technique

Question 4:

In a patient with maple syrup urine disease, all of the following amino acids should be restricted in diet except?

a) Methionine

b) Valine

c) Leucine

d) Isoleucine

Question 5:

Which of the following statements about the human genome project is false?

a) Total 20,500 genes were identified

b) The project spanned over 13 years

c) It required international collaboration

d) Next generation sequencing was used

Question 6:

Banding technique used for dicentric chromosomes is:

a) G banding

b) C banding

c) NOR

d) R banding

Question 7:

Affinity maturation of antibodies is because of?

a) Somatic hypermutation

b) Differential mRNA processing

c) CD40

d) Gene rearrangements

Question 8:

Best method for detection of mutations with low allele frequency is

a) Droplet digital PCR

b) FISH

c) Nested PCR

d) Sanger Sequencing

Question 9:

In Sanger sequencing, ddNTP is used because:

a) It is used to increase DNA polymerase activity

b) It can be made fluorescent

c) They exhibit higher affinity for DNA polymerases

d) It doesn't allow further elongation of DNA

Question 10:

Misincorporation of uracil into DNA is seen in deficiency of:

a) Vitamin B12

b) Folate

c) Vitamin B6

d) Vitamin E

Question 11:

Deamination of methylated cytosine forms which of the following?

a) Uracil

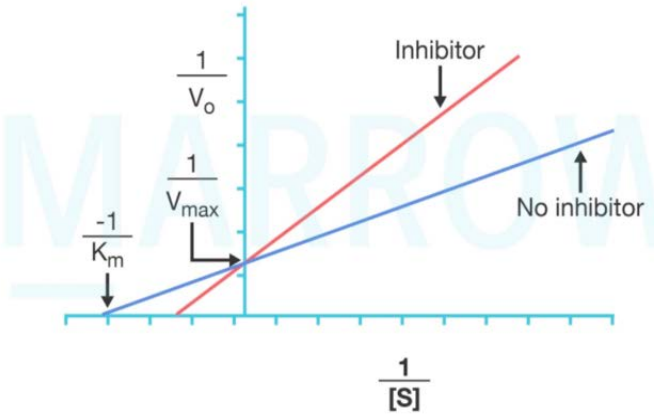
b) Cytosine

c) Guanine

d) Thymine

Question 12:

Which of the following types of inhibition is depicted in the given Lineweaver-Burk plot?



©MARROW

a) Competitive inhibition

b) Non-competitive inhibition

c) Uncompetitive inhibition

d) Suicidal inhibition

Question 13:

Glycogen phosphorylase is activated by:

a) Calcium

b) Glucose-6-phosphate

c) Insulin

d) Protein phosphatase

Question 14:

Mutation of the gene of cystic fibrosis occurs with:

a) Tryptophan at 708 position, chloride channel

b) Phenylalanine at 708 position, calcium channel

c) Phenylalanine at 508 position, chloride channel

d) Tryptophan at 508 position, calcium channel

Question 15:

A baby is brought to the OPD with complaints of lethargy and poor feeding. On examination, it is noted that the urine had a smell of burnt sugar. A defect in which of the following enzymes causes this disease?

a) Branched-chain ketoacid dehydrogenase

b) Branched-chain amino acid dehydrogenase

c) Branched-chain ketoacid oxidase

d) Branched-chain amino acid oxidase

Question 16:

All are true about the hexose monophosphate shunt, except:

a) Source of ribose-5-phosphate

b) Source of Acetyl CoA

c) Source of NADPH

d) Utilises ribose

Question 17:

Which of the following enzymes use selenocysteine?

a) 1, 3, 4

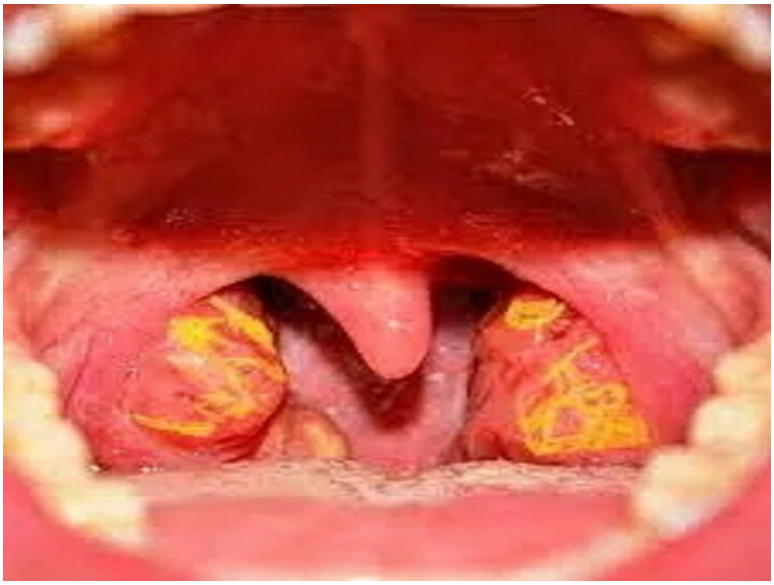
b) 1, 2, 3

c) 2, 3, 4

d) 1, 2, 4

Question 18:

A patient presented with reduced levels of high-density lipoprotein, and ABCA1 mutation. On examination, tonsils appeared as shown in the image. What is the diagnosis?



a) Tangier's disease

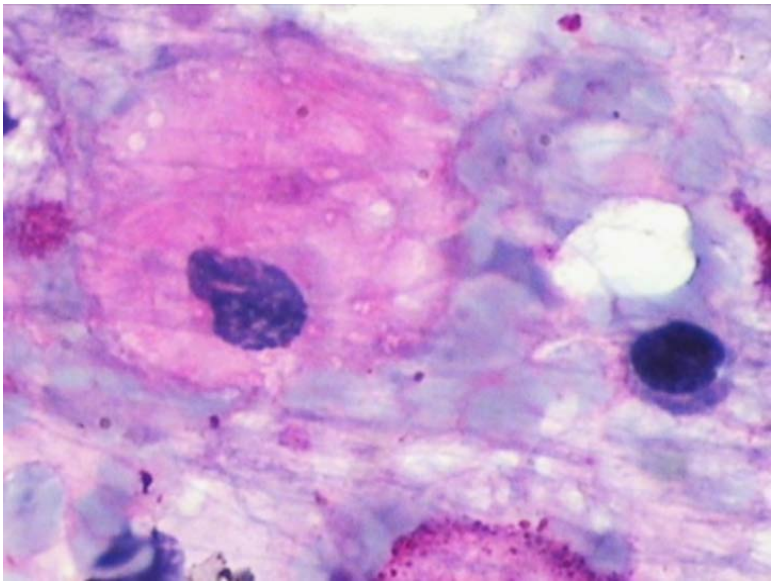
b) Abetalipoprotenemia

c) Hyperlipoproteinemia

d) Wolman's disease

Question 19:

A baby is being evaluated for delayed developmental milestones. On examination, the child has hepatosplenomegaly. A microscopic image of the bone marrow evaluation is shown below. What is the diagnosis?



a) Gaucher disease

b) Niemann-Pick disease

c) Hunter disease

d) Hurler disease

Question 20:

Refsum disease is due to:

a) Absence of alpha oxidation in peroxisomes

b) Absence of beta oxidation in peroxisomes

c) Absence of alpha oxidation in lysosomes

d) Absence of beta oxidation in lysosomes

Question 21:

Choose the right sequence of steps in the conversion of cholesterol to testosterone.

a) b, d, a, c

b) a, c, d, b

c) b, a, c, d

d) d, a, b. c

Question 22:

Which of the following describes the relationship between the melting temperature (Tm) of DNA and the concentration of G-C and A-T?

a) No relation of GC with Tm

b) Tm increases with more A-T

c) Tm decreases with more G-C

d) Tm increases with more G-C

Question 23:

An elderly patient on a vegetarian diet presenting with easy fatigability and pallor was investigated. Peripheral smear showed findings of macrocytic anemia. What is the probable cause of anemia in this patient? Other lab findings are as follows:

a) Folate deficiency

b) Alcohol-induced macrocytosis

c) Vitamin B12 deficiency

d) Thiamine deficiency

Question 24:

Zellweger syndrome is due to a defect in the biogenesis of:

a) Peroxisomes

b) Lysosomes

c) Mitochondria

d) Nucleus

Question 25:

True statement about the action of enhancers of gene expression?

a) Work only when in close conjugation with promoter region

b) Work only when in upstream of promoter region

c) They are very specific to the gene

d) Recruit chromatin and modify regulatory mechanisms

Question 26:

Increased H+ ions in the intermembrane space of mitochondria are due to?

a) Decreased oxidative phosphorylation

b) Increased ATP production

c) Reduced chemiosmosis

d) Water retention in inner mitochondrial space

Question 27:

Fructosamine is obtained by glycation of:

a) Frustose

b) Albumin

c) Urea

d) Glycosaminoglycans

Answer Key

Question No.	Correct Option
1	a
2	a
3	a
4	a

Detailed Explanations

Solution to Question 1:

The correct sequence of isolation of desirable protein in recombinant DNA technology is 2, 1, 3, 5, 4.

I) Incorporation of genes into bacteria: The gene needed to produce the desired proteins is to be incorporated into the bacteria. This is done using cloning vectors like bacterial plasmids, phages, or cosmids. The DNA of interest is ligated into the vector DNA and is called recombinant DNA. This vector is then inserted into a competent host cell (eg: E.coli bacteria) where it is replicated.

II) Expression of protein and lysis of bacterial cell: After incorporation of recombinant DNA, bacteria express the inserted gene and produce the desired protein on a large scale along with other indigenous bacterial proteins. To release these proteins bacterial cell is lysed.

III) SDS-PAGE (sodium dodecyl sulfate-polyacrylamide gel electrophoresis): It is the most widely used method for determining the purity of a protein. After the proteins are released, to separate the desirable protein, we subject it to SDS-PAGE. It separates proteins based on molecular weight.

IV) Hybridization and blotting: It is done to confirm that the isolated protein is the desired protein. It is done using western blotting techniques on nitrocellulose paper.

V) Protein elution - extraction of the produced protein.

The practical applications of recombinant DNA technology include:

• Gene mapping using techniques such as fluorescence in situ hybridization (FISH).

• Producing proteins such as:

• Interferons, tPA (tissue plasminogen activator)

• Insulin, growth hormone

• Hepatitis B vaccine

• Molecular analysis of disease, to detect gene variations and mutations.

• Restriction Fragment Length polymorphism (RFLP) and single nucleotide polymorphism (SNP)

• Microsatellite DNA polymorphisms

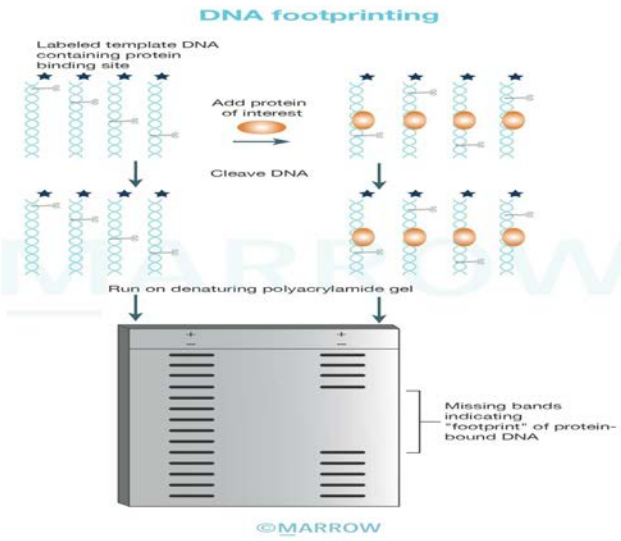
• Gene therapy and bone marrow transplantation

Solution to Question 2:

The technique used to detect DNA-protein interaction is DNA footprinting.

The parts of DNA that are protein-bound (Eg: RNA polymerase bound to the promoter region of DNA) are resistant to digestion by nuclease enzymes. Since the nucleases are unable to cleave the protein-bound regions of DNA, when the cleaved DNA fragments are run on polyacrylamide gel electrophoresis, there are missing bands indicating, protected sites of protein-bound DNA. These missing areas represent the footprint of the protected DNA-protein complexes. Hence DNA footprinting technique helps to identify the specific binding site of protein on a DNA sequence.

The image below illustrates the DNA footprinting technique.



Other options:

Option B: DNA fingerprinting uses RFLPs (restriction fragment length polymorphism) or repeat sequence DNA to identify a person's unique pattern of DNA. Polymorphisms are inherited differences found among individuals. with this technique, individuals can be differentiated by variations in their DNA sequence, using restriction endonucleases followed by gel electrophoresis, to visualize RFLPs. DNA fingerprinting is used for forensic analysis of crime scenes, and for paternity testing.

Option C: ELISA uses antibodies linked to certain enzymes to detect certain antigens present in the sample.

Option D: Northern blotting technique can be used to detect RNA. Here, the mixture of mRNA molecules is separated by electrophoresis and then transferred to a nitrocellulose membrane and hybridized with radiolabeled probes.

Solution to Question 3:

The technique shown in the image is FISH demonstrating a positive EWSR1 gene rearrangement, characteristic of Ewing sarcoma. The fused region denoted by Yellow corresponds to a normal intact gene, while a split signal pattern showing separate red and green signals is indicative of EWSR1 gene rearrangement.

Fluorescent In Situ Hybridisation (FISH) is a simple technique for the detection of specific genetic information on morphologically intact tissue using fluorescent probes. FISH can be performed on prenatal samples, peripheral blood cells, touch preparations from cancer biopsies, and even fixed archival tissue sections. It is used to detect

• numeric abnormalities of chromosomes (aneuploidy)

• subtle microdeletions and rearrangements.

• complex translocations that are not demonstrable by routine karyotyping

• gene amplification (e.g., HER2 in breast cancer or NMYC amplification in neuroblastomas)

Other options:

Option B: Karyotyping is the process by which chromosomes are isolated, stained, and examined to find chromosomal anomalies. It is used in prenatal diagnosis, investigation of repeat pregnancy loss, investigation of children and adults suspected of having a chromosomal disorder, and subtyping of lymphomas and leukemias for the purpose of exact diagnosis, giving a prognosis, and treatment.

Option C: IHC (Immunohistochemistry) is a staining method for histopathological specimens. It helps in the diagnosis and classification of tumors based on their distinct protein expression patterns. Eg: The expression of estrogen receptor (ER), progesterone receptor (PR), and HER2/neu in breast cancer cells is mainly assessed by immunohistochemistry.

Option D: Sanger's technique: This was the first technique used to determine the sequence of proteins. The first protein to be sequenced by this method was insulin. Sanger's reagent is 1-Flouro 2,4 Dinitro benzene. Only dipeptides and tripeptides can be sequenced by this method.

Solution to Question 4:

In maple syrup urine disease (MSUD), only branched-chain amino acids are restricted, hence, methionine does not need any restriction in diet.

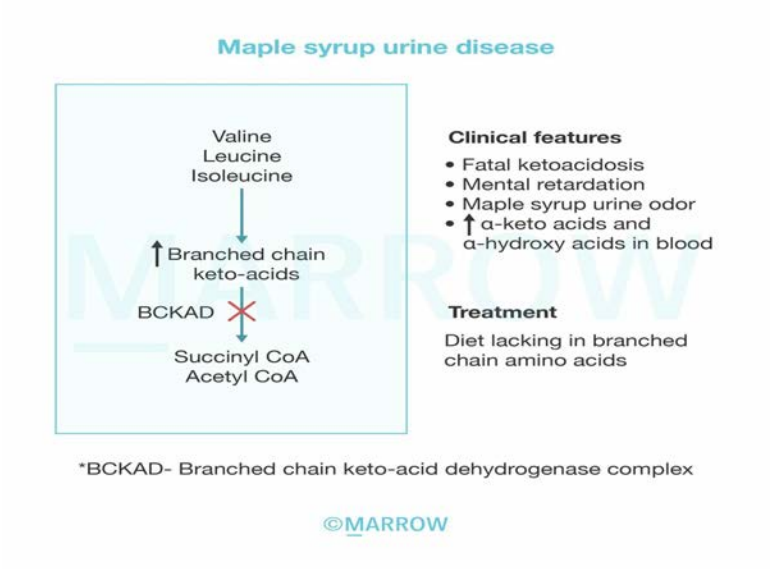
Branched-chain amino acids are:

• Leucine (L)

• Isoleucine (I)

• Valine (V)

MSUD is an autosomal recessive disorder in which there is a partial or complete deficiency of branched-chain ketoacid dehydrogenase complex (BCKD). This impairs the metabolism of branched-chain amino acids. These amino acids, particularly leucine and their metabolite accumulate in the blood, causing toxic effects on the brain. Features include feeding problems, vomiting, ketosis, and a characteristic burnt sugar odor /maple syrup-like odor found in urine, sweat, and cerumen.



Laboratory investigations will show increased levels of branched-chain amino acids in the plasma and urine. Leucine levels are usually higher than isoleucine, and valine.

Treatment involves restricted intake of branched-chain amino acids using commercially available formulas and judicious supplementation of isoleucine and valine. Very high levels of leucine are removed by hemodialysis.

Solution to Question 5:

The human genome project did not use next-generation sequencing.

The Human Genome Project (HGP) was an international, collaborative research program, which involved agencies such as UNESCO, HUGO, the National Institute of Health/Department of Energy (USA), the Medical Research Council (UK), Genethon (France), and the European Union. The primary goal of the Human Genome Project was to determine the sequence of all nucleotide base pairs, that make up human DNA and to create a single linear map of all genes from the human genome. The project was active from 1990 to 2003, taking around 13 years to complete. A total of 20500 genes were identified and mapped. Scientists used various methods of first-generation sequencing technologies including sanger's technique, SGS technique, etc. The HGP has produced a curated and accurate reference sequence for the majority of human

chromosomes. The reference sequence has provided the foundation for the use of second-generation sequencing technologies such as array techniques.

Next-generation sequencing (NGS) is a new technology used for sequencing DNA and RNA and mutation detection. NGS can sequence the genome faster and in a shorter period of time than first-generation sequencing technologies. NGS allows for the detection of a spectrum of mutations, including single nucleotide substitutions, small insertions and deletions, large genomic duplications and deletions, and rare variations. Next-generation DNA sequencing technologies include

• Illumina sequencing

• Roche 454 sequencing

• Ion torrent: Proton/PGM sequencing

• SOLID sequencing.

Solution to Question 6:

The banding technique used for dicentric chromosomes is C banding.

Heterochromatin includes non-coding regions of DNA, such as centromeric regions. The staining of these constitutive heterochromatins, is done by C-banding using silver salt staining. A dicentric chromosome having two centromeres can hence be identified by C banding.

Various techniques are used in karyotyping to study chromosomes. Staining with various compounds produces various results and helps us to understand the chromosomes better.

Common techniques used are:

• Q banding - Fluorescence staining with quinacrine mustard.

• G banding - Giemsa staining after partial denaturation of chromatin. It is the most common technique used in cytogenetics to produce a visible karyotype by staining condensed chromosomes.

• R banding - Reverse Giemsa staining. In this, the light and dark areas are reversed.

• C banding - staining of heterochromatin with silver salts.

• T banding - staining the telomeres of chromosomes.

Solution to Question 7:

Affinity maturation of antibodies is because of somatic hypermutation.

Affinity maturation is the process by which antibodies gain
increased affinity, avidity, and anti-pathogen activity. It is a result of somatic hypermutation of immunoglobulin genes in B cells, coupled with selection for antigen binding.

Somatic hypermutation is a cellular response by which the immune system adapts to the new foreign elements that confront it. They do so by adding nucleotides in V gene regions of heavy and

light chains, resulting in a better fit of antigen with the antibodies. This hence increases the affinity of antibodies to antigens. Due to this, the subset of plasma cells with these improved hypervariable regions are more strongly

selected by the antigen and therefore constitute a larger part of the population of antibody-producing cells. This process is called affinity maturation.

This process occurs in the germinal centers and proceeds for weeks after acute infection or vaccination, or for many cycles during chronic infection. The resulting antibodies can be highly mutated from their germline-encoded counterparts, with an increase in several orders of magnitude in affinity for antigen compared to the corresponding naïve B cell receptors (BCRs).

Solution to Question 8:

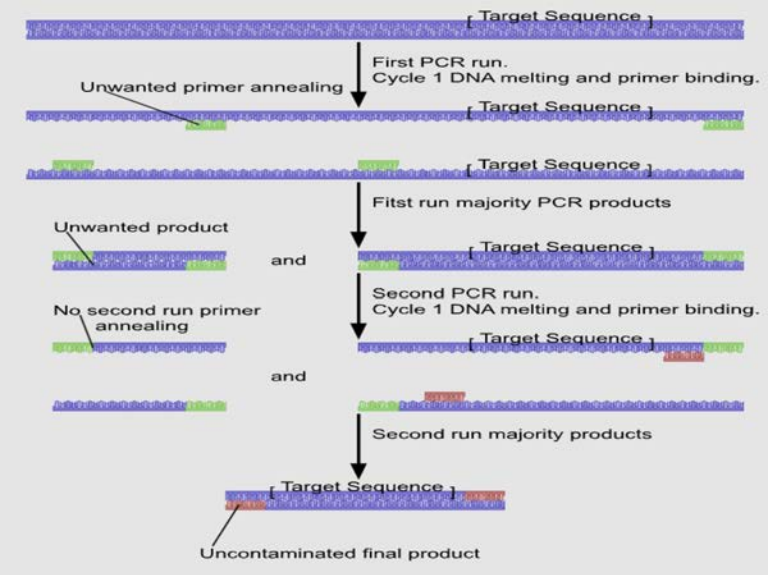
Best method for detection of mutation with low allele frequency is Droplet digital PCR (ddPCR)

It is an advanced and more precise type of quantitative PCR which gives more consistent and reproducible results. It can accurately quantify the target nucleic acid sequence within a sample. It is useful for determining somatic mutation with low allele frequency. Mutant alleles of frequency as low as 0.25% can also be detected using this technique.

Polymerase chain reaction (PCR) is a rapid automated method for the amplification of specific DNA sequences (or genes). Reverse transcriptase PCR- The enzyme reverse transcriptase (RT) is used to synthesize a complimentary copy of DNA (cDNA) from RNA and this cDNA is then used as a template for PCR.

Other special PCR types:

Nested PCR- It involves the sequential use of two primer sets. The first primer set is used for amplification and the target sequence for the second primer is present only on the amplicon with the target sequence. Nested PCR is intended to reduce non-specific binding due to the amplification of unexpected primer binding sites.



Multiplex PCR- Multiple primers are used to amplify several DNA sequences simultaneously. As this process targets multiple genes at once, a single test run gives additional information that would otherwise require several times the reagents and technician time to perform.

The Sanger sequencing technique is used for DNA sequencing. It is based on controlled termination of synthesis of DNA by using chain terminating agents like dideoxynucleotides.

Fluorescent In Situ Hybridisation (FISH) is a simple technique for the detection of specific genetic information on morphologically intact tissue using fluorescent probes. FISH can be performed on prenatal samples, peripheral blood cells, touch preparations from cancer biopsies, and even fixed archival tissue sections.

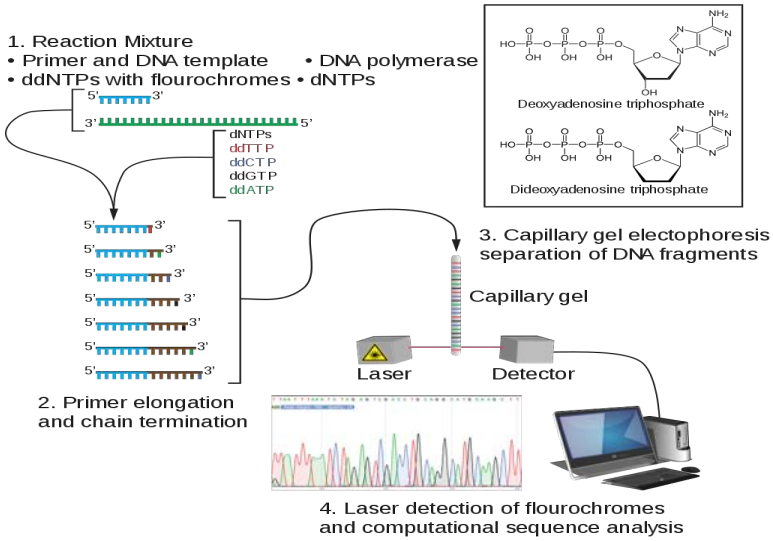
Solution to Question 9:

In Sanger sequencing, dideoxynucleotides triphosphates (ddNTP) are used because it doesn't allow further elongation of DNA.

The Sanger method is used for DNA sequencing. This method uses the mechanism of synthesis of DNA by DNA polymerases. In the process of synthesis of DNA, the 3'-hydroxyl group of primer reacts with an incoming dNTP to form a new phosphodiester bond. This reaction is catalyzed by DNA polymerase.

In the Sanger sequencing method, ddNTP is used because it halts the DNA synthesis. ddNTPs can bind to the template strand but lack the 3'-hydroxyl group which is required to add the next nucleotide. The products of this reaction are a mixture of DNA strands of varying lengths. This mixture is then separated using polyacrylamide gel electrophoresis and autoradiography. This produces a pattern of bands from which the DNA sequence can be read.

The image given below shows the steps involved in Sanger's method.



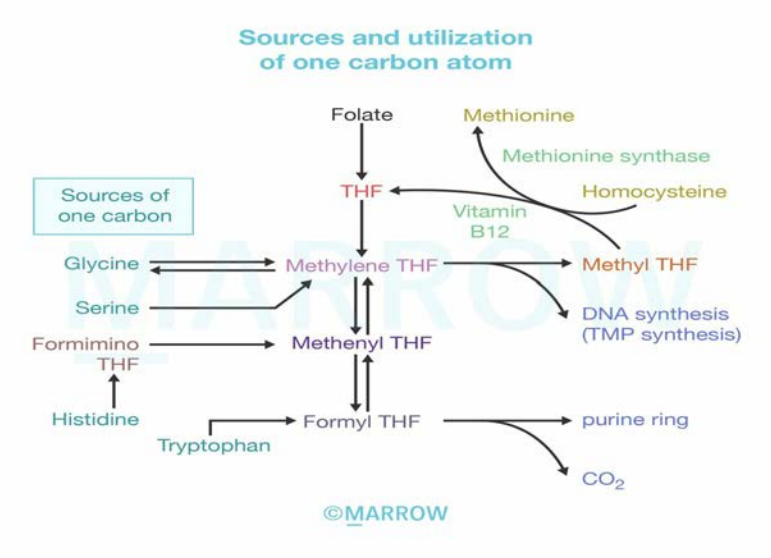
Sanger's technique was the first technique used to determine the sequence of proteins. The first protein to be sequenced by this method was insulin. Sanger's reagent is 1- fluoro 2,4 dinitro benzene.

Solution to Question 10:

Misincorporation of uracil into DNA is seen in the deficiency of folate.

Folate deficiency leads to decreased thymidylate synthesis from deoxyuridylate due to deficient methylation of deoxyuridine monophosphate (dUMP) to thymidine monophosphate (TMP). The methylation of dUMP to TMP is catalyzed by thymidylate synthase and requires tetrahydrofolate (THFA) as a methyl group donor. This decreased TMP synthesis can result in an imbalance of deoxyribonucleotides and hence leading to excessive uracil misincorporation into DNA during replication and repair.

Folic acid (vitamin B9) is a water-soluble vitamin, and its active form is tetrahydrofolate (THFA). It acts as a carrier of one-carbon groups. Tetrahydrofolate receives one-carbon fragments from donors such as serine, glycine, and histidine and transfers them to intermediates in the synthesis of amino acids, purines, and pyrimidines.



Folate deficiency results in:

- Megaloblastic anemia
- Homocystenemia
- Neural tube defects (spina bifida, Anencephaly) in the fetus.

Solution to Question 11:

Deamination of methylated cytosine forms thymine.

Deamination is the removal of an amino group(NH2) from a chemical compound. Enzymes that catalyze this reaction are called deaminases. Deamination of 5-methylcytosine forms thymine.

Other significant deaminations are given below:

• Deamination of adenosine forms inosine. This is a metabolic step involved in uric acid formation by purine catabolism. It is mediated by the enzyme adenosine deaminase (ADA). ADA deficiency leads to sparse or defective T cells and B cells and patients suffer from Severe combined immunodeficiency (SCID).

• Deamination of cytosine leads to uracil formation - The production of apolipoprotein B-48 (apoB-48) in the intestine is the result of RNA editing in the intestine. This involves post-transcriptional deamination of cytosine to uracil by enzyme cytidine deaminase. This converts sense codon (CAA) in the mRNA to nonsense codon (UAA)at a single specific site. This edited mRNA translates to apoB-48.

• Deamination of guanine forms xanthine. This is a metabolic step involved in uric acid formation by purine catabolism.

Solution to Question 12:

The given graph shows competitive inhibition, in which the value of Vmax remains constant and the Km value increases.

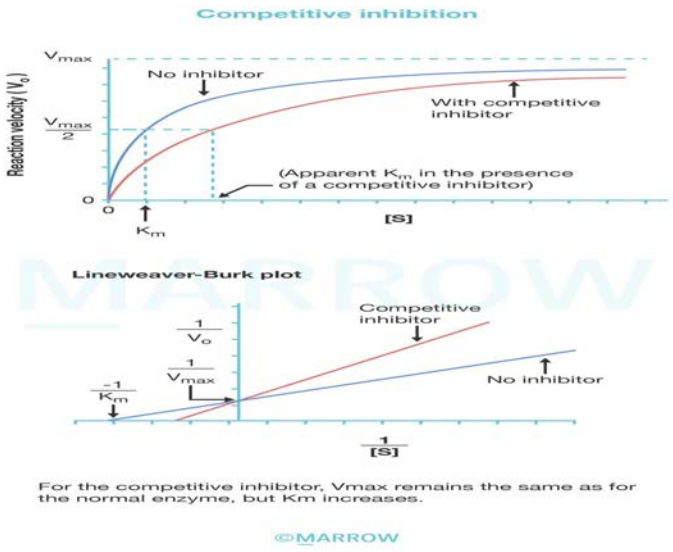
• Km is the substrate concentration at which velocity is half maximum.

• Vmax is the maximum velocity of a reaction.

Competitive inhibition is when the inhibitor binds reversibly to the substrate-binding site and competes with the substrate for the active enzyme-binding site. This effect of competitive inhibition can be overcome by increasing the substrate concentration by which maximum velocity can still be achieved. Therefore, Vmax is unaltered in this type of inhibition. However, the concentration of the substrate required to achieve half of the maximum velocity is increased. Therefore, Km is increased in this condition.

The graph shows the changes in Vmax and Km in competitive inhibition.

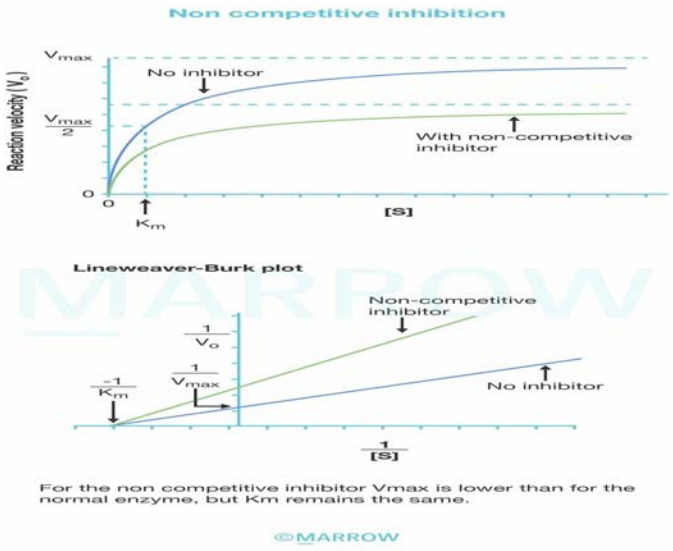
Inhibition	Km	Vmax
Competitive	Increases	Same
Non Competitive	Same	Decreases
Uncompetitive	Decreases	Decreases



Other options:

Option B: Non-competitive inhibition is by binding inhibitors to enzymes in locations remote from the active site. Increasing the concentration of the substrate does not overcome non-competitive inhibition. Thus, noncompetitive inhibitors decrease the Vmax of the reaction. They do not interfere with the binding of the substrate to the enzyme. Thus, the enzyme shows the same Km in the presence or absence of noncompetitive inhibitors.

The graph shows the changes in Vmax and Km in non-competitive inhibition.



Option C: In uncompetitive inhibition, inhibitors bind with the enzyme-substrate intermediate complex, and inhibit it. This leads to decrease in both Vmax and Km. An example is the inhibition of placental alkaline phosphate (ALP) by phenylalanine.

Option D: Suicidal inhibition is a special type of irreversible inhibition. The inhibitor here makes use of the enzyme's own reaction mechanism to inactivate it and is hence known as mechanism-based inactivation. An example is allopurinol, which is oxidized by xanthine oxidase

to alloxanthine. Alloxanthine in turn is a more potent inhibitor of xanthine oxidase.

Solution to Question 13:

Glycogen phosphorylase is activated by calcium in the muscle.

Glycogen phosphorylase is the rate-limiting enzyme of glycogenolysis and is decreased in the fed state.

In the muscle, the increased cytosolic calcium ion concentration initiates both contraction and glycogenolysis. Muscle phosphorylase kinase has four different subunits, α, β, γ, and δ. The α and β subunits are phosphorylated by cAMP-dependent protein kinase. The δ subunit is identical to the calcium-binding protein calmodulin and binds four calcium ions. Calcium coordinates the activation of Glycogen Phosphorylase with the contraction of the muscle.

Glycogen phosphorylase catalyzes the cleavage of $\alpha 1 \rightarrow 4$ linkages of glycogen to single units of glucose 1-phosphate. It uses pyridoxal phosphate as the coenzyme. Different isoenzymes of glycogen phosphorylase are seen in the liver, muscles, and brain.

Other options:

Option B: During glycogenolysis, glucose 6-phosphate allosterically inhibits glycogen phosphorylase.

Option C: Insulin entirely suppresses glycogenolysis in the skeletal muscle and liver.

Option D: In glycogenolysis protein phosphatase is inactivated by inhibitor proteins in response to cAMP, to maintain the glycogen phosphorylase in an active state.

Solution to Question 14:

The mutant gene of cystic fibrosis (CF gene) produces a mutant CFTR protein with the deletion of a phenylalanine residue at 508 (F508del), characterised by impaired chloride secretion.

Cystic fibrosis is a condition with an autosomal recessive mode of inheritance. It results due to a defective mutation in the gene encoding for cystic fibrosis transmembrane conductance regulator (CF gene). It plays an important role in mucociliary transport along the respiratory mucosa. It also helps to regulate the amount of exocrine gland secretion.

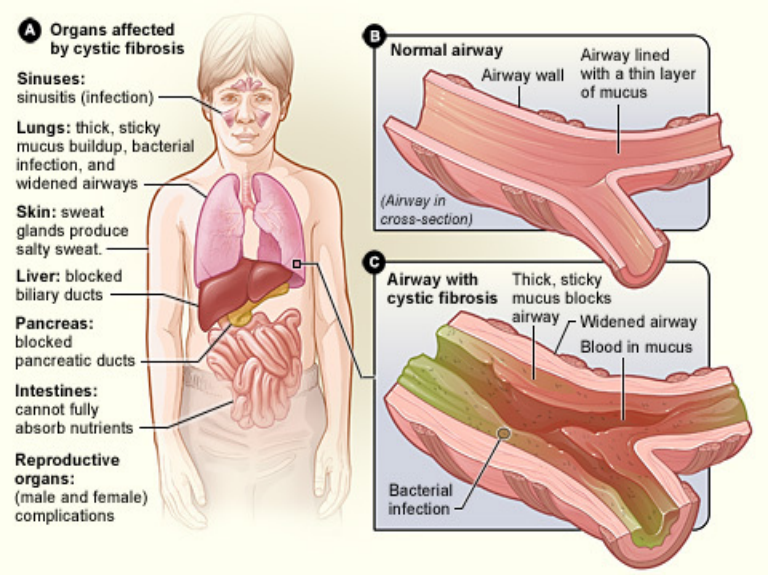
The defect in the ion channel results in the production of hyper-viscous, adherent secretions which can obstruct the airways. Organisms such as Pseudomonas aeruginosa and Staphylococcus aureus can grow in the sputum. The exocrine pancreas can undergo fibrotic scarring, cyst formation, and acinar tissue loss. The viscid secretions can lead to pancreatic duct obstruction. The flow of digestive enzymes to the duodenum is hence impaired.

Symptoms include sinusitis, steatorrhea, and abdominal pain. Distal intestinal obstruction is a complication due to difficulty in excreting intestinal contents. In neonates, it can present as meconium ileus.

Detection of high levels of trypsinogen is used in newborn screening. Chloride level >60mEq/L in the sweat of affected patients is diagnostic. Hyponatremic hypochloremic alkalosis is seen.

Postural drainage, short-term antibiotics, and inhaled bronchodilators can be used for medical management. The definitive treatment is lung transplantation.

The image below shows the features of the disease.



Solution to Question 15:

The diagnosis, in this case, is that of maple syrup urine disease (MSUD). This disease occurs due to a defect of the enzyme branched-chain keto acid dehydrogenase.

MSUD is an autosomal recessive disorder that occurs due to a deficiency of branched-chain ketoacid dehydrogenase complex. This impairs the metabolism of branched-chain amino acids valine, leucine, isoleucine, and alloisoleucine. These amino acids, particularly leucine and its metabolite accumulate in the blood, causing toxic effects on the brain.

The affected child develops poor feeding and vomiting a few days after birth. There is a period of hypertonicity with a period of flaccidity in between. These appear as repetitive boxing and bicycling movements. The babies may also have hypoglycemia, but this is not corrected by the administration of glucose. The urine, sweat, and cerumen of the baby have a sweetish maple syrup-like odor.

Laboratory investigations will show increased levels of branched-chain amino acids in the plasma and urine. Leucine levels are usually higher than isoleucine, valine, and alloisoleucine. Since the patient excretes ketone bodies in the urine, the urine will be positive for the dinitrophenylhydrazine test.

Treatment involves controlled intake of branched-chain amino acids using commercially available formulas and judicious supplementation of isoleucine and valine. Very high levels of leucine are removed by hemodialysis.

Solution to Question 16:

The hexose monophosphate (HMP) shunt produces ribose and does not utilize it.

The pentose phosphate pathway, also known as the HMP shunt pathway, is an alternative route for the metabolism of glucose. It contributes in two major ways:

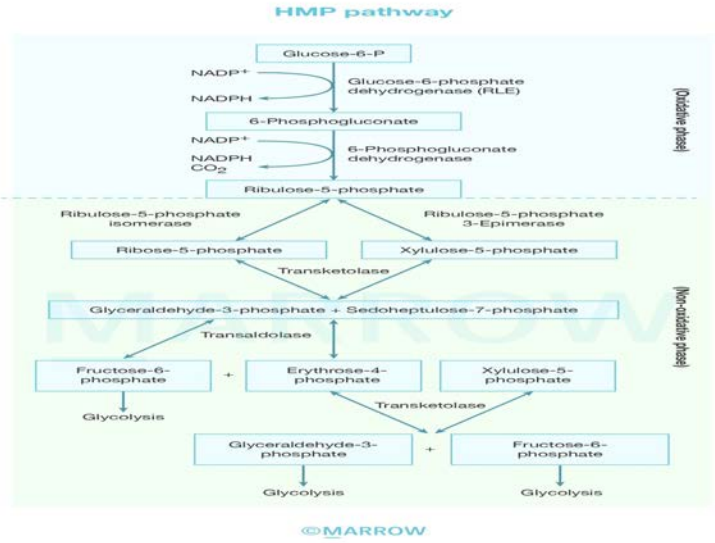
• Formation of NADPH for the synthesis of fatty acids and steroids and maintenance of reduced glutathione for antioxidant activity.

• Formation of ribose for the synthesis of nucleic acid and nucleotides

The enzymes for this pathway are found in the cytosol. There are two phases:

• Irreversible oxidative phase: Glucose-6-phosphate is dehydrogenated and decarboxylated to form ribulose-5-phosphate which in turn gets converted to ribose-5-phosphate.

• Reversible non-oxidative phase: Ribulose-5-phosphate is converted back to glucose-6-phosphate.



Solution to Question 17:

The enzymes that use selenocysteine are glutathione peroxidase, deiodinase, and thioredoxin reductase.

Selenocysteine is the 21st amino acid coded by the UGA codon, which is normally a stop codon. It is formed by co-translational modification. The protein synthetic apparatus can identify a selenocysteine-encoding UGA by the presence of the selenocysteine insertion sequence (SECIS) in the untranslated region of mRNA.

Enzymes such as thioredoxin reductase, glutathione peroxidase, and deiodinase use selenocysteine to catalyze redox reactions. Defects in human selenoproteins are associated with tumorigenesis and atherosclerosis. It can cause cardiomyopathy due to selenium deficiency, which is known as Keshan disease.

Glutathione synthase is the second enzyme in the synthesis of glutathione. Glutathione plays an important role in oxidative stress, redox signalling, and regulates cell proliferation and apoptosis.

Solution to Question 18:

The diagnosis in this case with reduced levels of high-density lipoprotein (HDL), ABCA1 mutation, and orange tonsils on examination is Tangier's disease. It is caused by a defect in ABCA1 receptors.

ABCA1 plays a role in the efflux of cholesterol from peripheral cells of HDL. LCAT (lecithin cholesterol acyltransferase) converts cholesterol to cholesterol esters, which accumulate in the core of HDL. Thus, defective ABCA1 will lead to low levels of HDL in the blood.

Other options:

Option B: Abetalipoproteinemia is a hypolipoproteinemia caused by a defect in the MTP gene. Here, loading apolipoprotein B with lipids is defective. Hence, few very low density-lipoproteins (VLDLs) or chylomicrons are formed, leading to the accumulation of triacylglycerols in the liver and intestine.

Option C: Hyperlipoproteinemia is a disorder that causes the body to metabolize lipids incorrectly. This results in hyperlipidemia and can lead to the development of multiple small xanthomas in the skin.

Option D: Acid lipase deficiency can lead to Wolman's disease which is a lysosomal storage disease. The pathognomic feature of this condition is adrenal calcification. So patients generally present with adrenal insufficiency and are neonates.

Solution to Question 19:

The microscopic image of the bone marrow biopsy shows Gaucher cells and the diagnosis is Gaucher disease.

Gaucher disease is a lysosomal storage disease with autosomal recessive inheritance. The condition results due to the deficiency of acid β-glucosidase. This results in the accumulation of glucosylceramide (a glycolipid substrate) in the reticuloendothelial cells. There is progressive infiltration of the liver, spleen, and bone marrow.

There are three clinical types:

• Type 1: Adult (non-neuronopathic form)

• Type 2: Infantile (acute neuronopathic form)

• Type 3: Juvenile (subacute neuronopathic form)

Type 1 is the most common. It presents with a myriad of symptoms, such as bruising secondary to thrombocytopenia, fatigue due to anemia, hepatosplenomegaly, and bone pain. Lytic lesions and osteosclerosis of the femur, ribs, and pelvis may also be seen. A few patients may have pulmonary involvement. Growth retardation may be observed in cases presenting in the first decade.

Type 2 is rare, and presents with hypertonia, strabismus, and organomegaly. Neurodegeneration is the characteristic feature. Stridor and failure to thrive can also be the presenting features.

Ultimately, death can occur due to respiratory arrest.

Type 3 presents with intermediate symptoms, as seen in the other two types. By the age of 10-15 years, the child succumbs to death.

Gaucher cells are reticuloendothelial cells with glucosylceramide, and have a wrinkled-paper appearance due to intracytoplasmic substrate inclusions. These cells stain strongly with periodic acid-Schiff (PAS) stain. This is characteristic of Gaucher's disease.

Other options:

Option B - Acid sphingomyelinase deficiency results in Niemann-Pick disease types A and B. Both are autosomal recessive conditions. Type A has a neurodegenerative course, while type B is non-neuronopathic. The former presents with hepatosplenomegaly, lymphadenopathy, and psychomotor retardation. Type B is associated with hepatosplenomegaly and mild pulmonary involvement.

Option-C - Hunter disease is an X-linked inherited disorder due to a deficiency of the enzyme iduronate sulfatase. It leads to the accumulation of dermatan and heparan sulfate. Clinical features involve coarse facies, cardiovascular involvement, and distinctive skin lesions.

Option-D - Hurler/Scheie disease is a mucopolysaccharidosis that has childhood and adult onset. It presents with cognitive degeneration.

Solution to Question 20:

Refsum disease is due to the absence of alpha oxidation in peroxisomes.

Refsum's disease is a rare autosomal recessive disorder. The defective enzyme is phytanoyl CoA hydroxylase, which causes alpha oxidation of fatty acids and leads to elevated levels of phytanic acid in the blood.

Clinical features are dysmorphic facies and severe neurological symptoms such as polyneuropathy, retinitis pigmentosa, nerve deafness, ichthyosis, and cerebellar ataxia.

Restricted dietary intake of phytanic acid reduces the symptoms. Management includes avoiding sources of phytanic acid such as dairy products, meat, nuts, and green leafy vegetables.

Solution to Question 21:

The correct sequence of steps in the conversion of cholesterol to testosterone is:

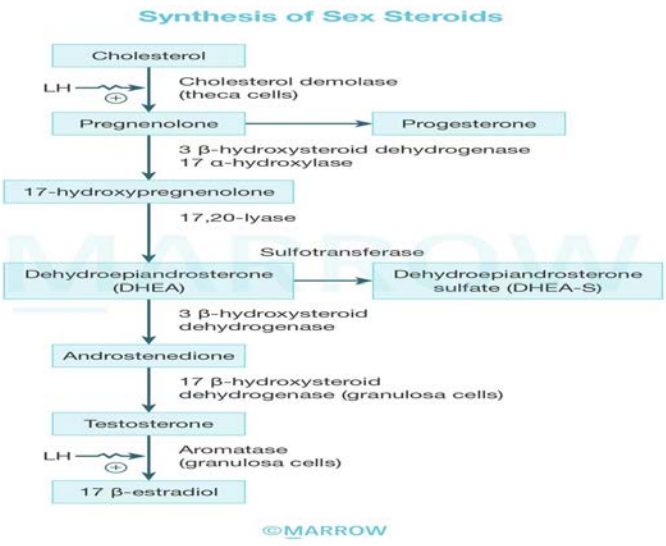
b. 20, 22 desmolase

d. 3 beta-hydroxy steroid dehydrogenase

a. 17 alpha-hydroxylase

c. 17, 20 lyase

The step of synthesis of sex steroids is illustrated in the diagram below.



Solution to Question 22:

The correct statement about the melting temperature of DNA (Tm) is that it increases with more G-C concentration.

On heating the DNA, the temperature at which one-half of the helical structure loses its structure defines the melting temperature Tm. The two strands of the double helix structure of the DNA get separated when the hydrogen bonds between the base pairs are disrupted. Thus, the Tm is influenced by the concentrationbase composition of the DNA.

Since G-C pairing has 3 hydrogen bonds and A-T pairing has 2 hydrogen bonds, DNA rich in G-C base pairs requires higher temperatures to denature in comparison to DNA rich in A-T base pairs.

Solution to Question 23:

The probable cause of anemia in this patient of folate deficiency.

The given clinical scenario of macrocytic anemia in a vegetarian with elevated homocysteine levels is due to megaloblastic anemia, which can be caused by the deficiency of vitamin B12 or folic acid. Vitamin B12 deficiency is associated with raised serum methylmalonic acid (MMA) levels, which are normal in this patient; hence, folic acid deficiency is the cause of megaloblastic anemia in this patient.

Folic acid deficiency is associated with the following clinical and laboratory findings:

• Raised MCV (normal range: 80–100 fL) - macrocytosis

• Normal MCHC (normal range: 33–36 g/dL)

• Increased MCH

• Elevated RDW

• Decreased reticulocyte count - due to destruction of abnormal erythroid precursors

• Elevated homocysteine level

• Normal MMA level

where MCV, mean corpuscular volume; MCHC, mean corpuscular hemoglobin concentration; mean corpuscular hemoglobin, MCH; RDW, red cell distribution width

In vitamin B12 deficiency, neurological abnormalities, elevated homocysteine, and elevated MMA levels are seen.

Solution to Question 24:

Zellweger syndrome is due to a defect in the biogenesis of peroxisomes.

Zellweger syndrome is also known as cerebrohepatorenal syndrome. It is caused by mutations in the PEX family of genes. This results in defective beta-oxidation of very long-chain fatty acids.

The child presents with

• Dysmorphic facial features.

• Weakness, hypotonia.

• Neonatal seizures

• Eye abnormalities.

Biochemical findings will show :

• Accumulation of very-long-chain fatty acids, phytanic acid

• Abnormalities in the synthesis of bile acids

• Marked reduction of plasmalogens

There is no appropriate treatment for Zellweger syndrome. It is very severe and infants rarely survive beyond a few months.

Solution to Question 25:

The correct statement about the action of enhancers is that they recruit chromatin and modify regulatory mechanisms.

A promoter is a sequence on DNA where RNA polymerase binds and acts as the start signal for transcription. They are present upstream or downstream but close to the gene that is undergoing transcription.

Enhancers or repressors are proteins that regulate the expression of a gene
by recruiting chromatin(DNA bound with histones) and modifying regulatory
mechanisms and making it more or less accessible to transcription by RNA polymerase. They may be located upstream or downstream and can be present at any distance from the promoter region. These are not specific to any single gene and interact with many other proteins.

Solution to Question 26:

Increased H+ ions in the intermembrane space of mitochondria are due to decreased oxidative phosphorylation.

ATP is synthesized in mitochondria by a process called oxidative phosphorylation. The oxidation of substrates like carbohydrates, amino acids, or fats produces reducing equivalents (NADH, FADH2). These equivalents enter the electron transport chain and transfer a proton (H+) to the inter-membrane space. The inner mitochondrial membrane is not permeable to protons leading to the accumulation of H+ in the intermembrane space. The flow of these protons through the Fo releases the energy that phosphorylates ADP to form ATP.

Drugs that inhibit oxidative phosphorylation like oligomycin inhibit the flow of protons through Fo causing an increase in H+ ions in the intermembrane space.

Solution to Question 27:

Fructosamine is obtained by the glycation of albumin.

Fructosamine is a measure of non-enzymatic glycation of circulating proteins including albumin, globulins, and lipoproteins. It is now used as a reasonable alternative to HbA1c measurement when it is not reliable. Since albumin is the most abundant of the serum proteins, fructosamine is predominantly a measure of glycated albumin.

Fructosamine is used as a short-term marker of glucose control. It reflects the average glycemia over the preceding 2 to 3 weeks. HbA1c reflects glucose control over a period of the preceding 8 to 12 weeks.

Biochemistry NEET 2022

Question 1:

A patient from a Mediterranean country visits Africa, where he develops malaria. He is treated with primaquine and later develops hemolytic anemia. Deficiency of an enzyme involved in which of the following pathways could be the cause?

a) Glycolysis

b) Gluconeogenesis

c) Hexose monophosphate (HMP) pathway

d) Luebering–Rapoport pathway

Question 2:

Which of the following disorders follows autosomal recessive inheritance pattern?

a) Huntington's disease

b) Treacher Collins syndrome

c) Cystic fibrosis

d) Achondroplasia

Question 3:

Which of the following helps in the transport of fatty acids across the inner mitochondrial membrane?

a) Acyl carrier protein

b) Carnitine

c) Lecithin-cholesterol acyltransferase

d) Carnitine and albumin

Question 4:

A single mutation in a nucleotide base pair resulting in a termination codon is known as?

a) Missense mutation

b) Nonsense mutation

c) Stop mutation

d) Silent mutation

Question 5:

DNA packing is done by which of the following ?

a) Histone

b) Glycoprotein

c) Nucleic acid

d) Adenine

Question 6:

An adolescent male patient presents to you with exercise intolerance. He gives a history of developing cramps on exertion. Which of the following enzyme deficiencies could be the cause?

a) Myophosphorylase

b) Hexokinase

c) Glucose-6-phosphatase

d) Hepatic glycogen phosphorylase

Question 7:

Which of the following enzyme activities can be estimated in red blood cells to diagnose vitamin B2 deficiency?

a) Transketolase

b) Glutathione reductase

c) Kynureninase

d) Pyruvate dehydrogenase

Question 8:

The following is due to the deficiency of?

a) Vitamin C

b) Vitamin A

c) Vitamin B

d) Vitamin E

Question 9:

A child presents to you with anemia, thrombocytopenia, and bony pain. On examination, hepatosplenomegaly was noticed. If light microscopy of bone marrow aspirate reveals "crumpled tissue paper" appearance, what is the enzyme defect?

a) Glucocerebrosidase

b) Sphingomyelinase

c) Hexosaminidase

d) Glucose 6-phosphatase

Question 10:

The electron transport chain is a series of redox reactions that result in ATP synthesis. Which of the following is a cytochrome complex IV inhibitor?

a) Cyanide

b) Carbon dioxide

c) Oligomycin

d) Ouabain

Answer Key

Question No.	Correct Option
1	c
2	c
3	b
4	b
5	a
6	a
7	b
8	b
9	a
10	a

Detailed Explanations

Solution to Question 1:

The deficiency of glucose-6-phosphate dehydrogenase (G6PD) enzyme, which is involved in the hexose monophosphate (HMP) pathway, could be the cause behind this presentation.

G6PD is an enzyme that plays a critical role in redox reactions that occur in all aerobic cells. It is the only source of NADPH in erythrocytes, which helps in the formation of reduced glutathione. This reduced form protects erythrocytes against oxidative stress.

G6PD deficiency is an X-linked inheritance disorder. Most patients with this condition are asymptomatic. But when exposed to oxidative agents, they are prone to develop acute hemolytic anemia. The various oxidative triggers include:

• Fava beans

• Infections

• Drugs such as primaquine, dapsone, and nitrofurantoin

A hemolytic attack can present with weakness and abdominal/ lumbar pain. Later, the patient can develop jaundice, hemoglobinemia, and hemoglobinuria. Investigations will show elevated levels of lactate dehydrogenase (LDH) and low levels of plasma haptoglobin. Anisocytosis and spherocytes can be seen on peripheral smear. Acute renal failure is a complication seen in adults.

Other options:

Option A - Glycolysis, the main pathway of glucose, can occur either aerobically or anaerobically. A deficiency of the enzyme pyruvate kinase can present as hemolytic anemia. Fatigue can be the presentation when there is phosphofructokinase. Both these are enzymes of glycolysis.

Option B - Gluconeogenesis is the process by which non-carbohydrate precursors are used to synthesize glucose. Pyruvate carboxylase, phosphoenolpyruvate carboxykinase, and glucose-6-phosphatase are the enzymes in the pathway. Glucose-6-phosphatase deficiency leads to von Gierke disease, which is a glycogen storage disorder. Defective gluconeogenesis results in hypoglycemia.

Option D - Luebering–Rapoport pathway is a shunt mechanism that generates and dephosphorylates 2,3-bisphosphoglycerate (2,3-BPG). 2,3-BPG mutase is the enzyme involved. A deficiency of this enzyme can cause erythrocytosis.

Solution to Question 2:

Cystic fibrosis is a condition with an autosomal recessive mode of inheritance.

It results due to a defective mutation in the gene encoding for cystic fibrosis transmembrane conductance regulator (CFTR gene). It functions as an epithelial anion channel. It plays an important role in mucociliary transport along the respiratory mucosa. It also helps regulate the amount of exocrine gland secretion.

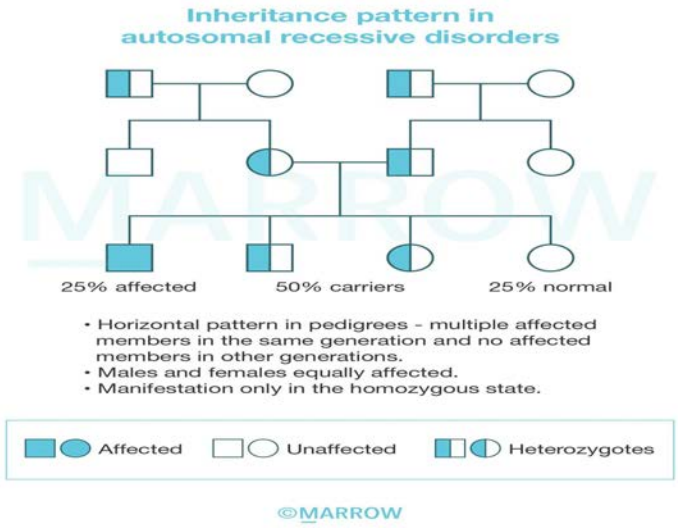
The defect in the ion channel results in the production of hyper viscous, adherent secretions which can obstruct the airways. Organisms such as Pseudomonas aeruginosa and Staphylococcus aureus can grow in the sputum. The exocrine pancreas can undergo fibrotic scarring, cyst formation, and acinar tissue loss. The viscid secretions can lead to pancreatic duct obstruction. The flow of digestive enzymes to the duodenum is hence impaired.

Symptoms include sinusitis, steatorrhea, and abdominal pain. Distal intestinal obstruction is a complication due to difficulty in excreting intestinal contents. In neonates, it can present as meconium ileus.

Detection of high levels of trypsinogen is used in newborn screening. Chloride level >60mEq/L in the sweat of affected patients is diagnostic. Hyponatremic hypochloremic alkalosis and hypokalemia may also be seen.

Postural drainage, short-term antibiotics, and inhaled bronchodilators can be used for medical management. The definitive treatment is lung transplantation.

In autosomal recessive inheritance, multiple affected members are seen in the same generation. Other generations are not affected. The following pedigree chart depicts an autosomal recessive pattern of inheritance.



Other options:

Option A - Huntington's disease is a trinucleotide (CAG) repeat disorder with an autosomal dominant mode of inheritance. It is characterized by involuntary movements known as chorea.

Option B - Treacher Collins syndrome is an autosomal dominant disorder that presents as mandibular and malar hypoplasia.

Option D - Achondroplasia has an autosomal dominant inheritance pattern and presents with short limbs, saddle nose, and spinal deformity.

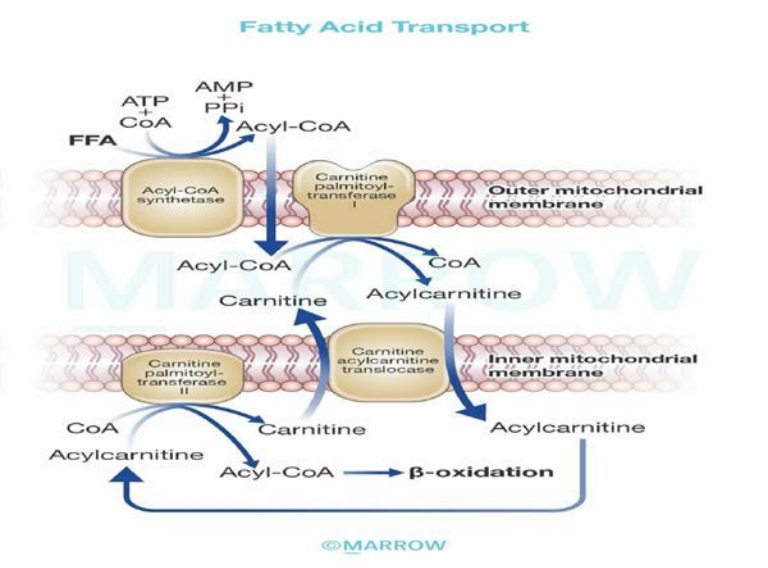
Solution to Question 3:

Carnitine is responsible for the transport of fatty acids or long-chain acyl-CoA across the inner mitochondrial membrane.

Fatty acids are oxidized in the mitochondria to produce acetyl-CoA to produce energy. They must first be converted to acyl-CoA (active fatty acid) before they can be catabolized.

Carnitine palmitoyltransferase - I (CPT- I) transports acyl-CoA across the inner mitochondrial membrane only in the presence of carnitine. The acyl group of acyl-CoA is transferred to carnitine. The acylcarnitine so formed can penetrate the inner mitochondrial membrane via the carnitine-acylcarnitine translocase. This transporter transfers the acyl group back to CoA, restoring acyl-CoA and liberating carnitine, which is moved back to the intermembrane space. Carnitine palmitoyltransferase -II catalyzes this reaction. The deficiency of this enzyme is a common cause of recurrent myoglobinuria.

Carnitine deficiency can lead to hypoglycemia and restrictive or dilated cardiomyopathy. It can also cause hepatic steatosis.



Other options:

Option A - Acyl carrier protein is a component of the fatty acid synthase complex involved in the biosynthesis of fatty acids. It has vitamin pantothenic acid (vitamin B5).

Option C - Lecithin-cholesterol acyltransferase (LCAT) is present in the plasma and plays an important role in the esterification of cholesterol. Deficiency leads to low levels of lysolecithin and cholesteryl esters.

Option D - The long-chain fatty acids are bound to albumin in the plasma. But albumin does not transport fatty acids across the inner mitochondrial membrane. Albumin is a negative acute-phase reactant synthesized by the liver. It is a carrier for acidic drugs.

Solution to Question 4:

A single mutation in a nucleotide base pair resulting in a termination codon is known as a nonsense mutation.

A codon is a sequence of three bases present on the mRNA (messenger RNA), and it codes for amino acids. Out of the 64 codons possible, only 61 code for the 20 amino acids. Three codons, UAA, UAG, and UGA do not code for any of the 20 amino acids. These are known as nonsense/punctator/termination/stop codons and function as translation termination signals. The UGA codon is traditionally considered a stop codon, but it codes for selenocysteine (21st amino acid).

The tRNA (transfer RNA) contains the anticodon which recognizes specific codons present on the mRNA. The sequence of the anticodon is complementary to the codon. The pairing between the codon and anticodon can wobble at the third base. For example, GGU, GGC, and GGA all pair with the anticodon CCI. The wobble phenomenon along with degeneracy reduces the effect of mutations.

A mutation involving a single nucleotide base is known as a point mutation. A nonsense mutation is a type of point mutation where a codon previously coding for an amino acid is changed to a stop

codon. This results in premature termination of translation and the formation of a truncated protein. mRNA containing premature stops are removed by the nonsense-mediated degradation pathway.

Other options:

Option A: A missense mutation is a type of point mutation where the new codon, formed by the changed base, codes for a different amino acid.

Option C: Stop mutation is a term that can be used interchangeably with nonsense mutation. Here, nonsense mutation is the best answer.

Option D: Silent mutations are point mutations where the new codon formed still codes for the same amino acid as the codon before the mutation.

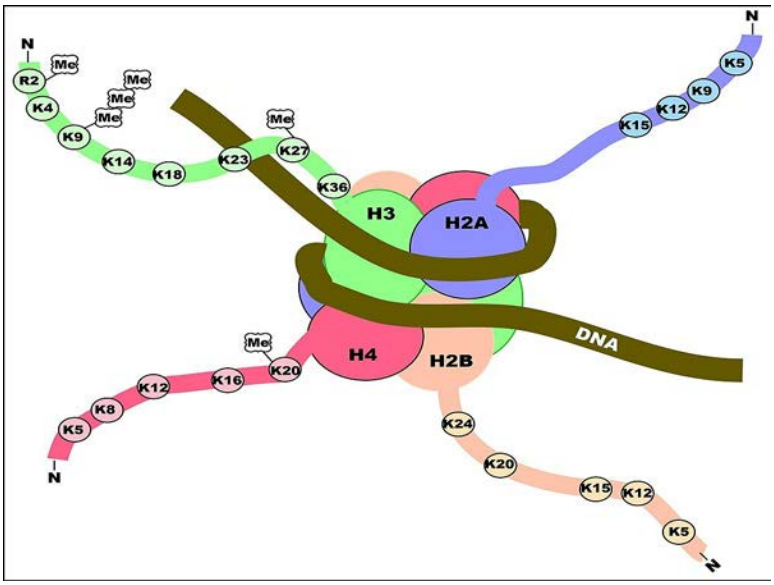
Solution to Question 5:

The proteins involved in DNA packing are histones.

Chromatin contains double-stranded DNA molecules and small basic proteins known as histones. In addition, nonhistone proteins are present that are involved in DNA replication and repair, and RNA synthesis. Histones play a role in condensing the DNA.

Nucleosomes are the organizational unit of chromatin and contain an octamer of histones around which 150 base pairs of DNA are packed. There are various types of histone proteins. H2A, H2B, H3, and H4 groups are components of nucleosomes and are known as core histones. They undergo post-translational modifications such as acetylation and methylation. This plays a critical part in chromatin structure and function.

The DNA in the nucleosome is arranged in a left-handed helical configuration over the histone octamer.



Other options:

Option B - Glycoproteins are proteins with oligosaccharide chains (glycans) bound to amino acids. Certain plasma proteins, peptide hormones, and cell membrane proteins are examples. Structural changes in the glycoproteins present in cancer cells may play a role in metastasis.

Option C - Nucleic acids can be either DNA or RNA. DNA is thought to be arranged in a double-stranded helix model. RNA on the other hand exists as a single strand. There are different types of RNA such as mRNA (messenger RNA), tRNA (transfer RNA), and rRNA (ribosomal RNA).

Option D - Adenine is a purine base that when linked to ribose forms adenosine, a nucleoside. When a nucleoside is esterified with a phosphate group a nucleotide is formed. Guanine is the other purine base. Cytosine is the pyrimidine base common to DNA and RNA. Thymine is present only in DNA and Uracil in RNA.

Solution to Question 6:

The clinical scenario points to a diagnosis of McArdle disease, which results due to a deficiency of the enzyme myophosphorylase (muscle glycogen phosphorylase).

McArdle disease, also known as type V glycogen storage disorder, is an autosomal recessive condition. It typically presents during late childhood or in the second decade of life. The muscle glycogen phosphorylase enzyme deficiency interferes with ATP generation by glycogenolysis in the muscles. This causes muscle glycogen accumulation.

Symptoms are exercise intolerance associated with muscle cramps. A second wind phenomenon, where the symptoms subside after a short period of rest, can also be seen. Myoglobinuria secondary to rhabdomyolysis leads to the passage of burgundy-colored urine in some patients.

Rarely, it can present during infancy as hypotonia, muscle weakness, and respiratory complications. It is generally fatal.

Muscle biopsy to measure glycogen content is the standard diagnosis. Avoiding strenuous exercise prevents symptoms. Glucose administration before exercise can improve tolerance. Vitamin B6 is also recommended.

Other options:

Option B - Hexokinase is a glycolytic enzyme. Its deficiency leads to hemolytic anemia. Splenomegaly may be another presenting feature.

Option C - Glucose-6-phosphatase is an enzyme involved in gluconeogenesis. Its deficiency leads to von Gierke disease also known as type I glycogen storage disease.

Option D - Hepatic glycogen phosphorylase deficiency results in type VI glycogen storage disease, also known as Hers disease.

Solution to Question 7:

Glutathione reductase activity in red blood cells can be estimated to diagnose vitamin B2 deficiency.

Vitamin B2, also known as riboflavin, is a water-soluble vitamin. Its active forms are FMN (flavin mononucleotide) and FAD (flavin adenine dinucleotide). Glutathione reductase is a FAD-containing enzyme (flavoenzyme). Hence, riboflavin deficiency can be detected by measuring erythrocyte glutathione reductase activity. Red blood cell and urinary concentrations of riboflavin can also be estimated to detect a deficiency.

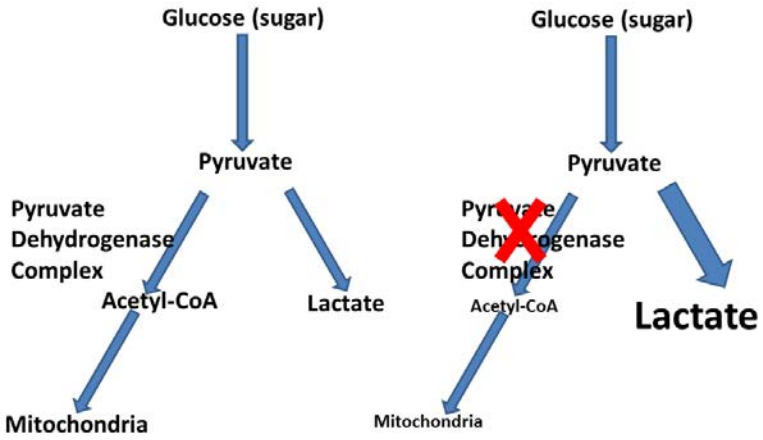
Deficiency of riboflavin can present as anemia, corneal vascularization, mucocutaneous lesions, and personality changes. Milk and other dairy products are important dietary sources.

Other options:

Option A - Transketolase contains thiamine diphosphate as a coenzyme. Estimation of erythrocyte apotransketolase (enzyme protein) after in vitro addition of thiamine diphosphate, can be used to assess thiamine nutritional status. Thiamine deficiency can result in peripheral neuritis, beriberi, and Wernicke encephalopathy with Korsakoff psychosis.

Option C - Kynureninase is an enzyme that requires pyridoxal phosphate as a coenzyme. It converts 3-hydroxykynurenine, a tryptophan metabolite, to 3-hydroxyanthranilate. In vitamin B6 deficiency, this is impaired and results in the formation and subsequent urinary excretion of xanthurenate. This can be used for diagnosis.

Option D - Pyruvate is decarboxylated by pyruvate dehydrogenase for which thiamine diphosphate acts as the cofactor. Therefore thiamine deficiency results in the accumulation of pyruvate. This leads to pyruvic and lactic acidosis, commonly seen in alcoholics.



Solution to Question 8:

The given image depicts Bitot's spots characteristically seen in deficiency of vitamin A. Bitot's spots are seen as white patches of keratinized epithelium on the sclera. It is more commonly bilateral and on the temporal side.

Vitamin A deficiency arises mostly due to the inadequate amounts of vitamin A in diet. It can present as night blindness, conjunctival xerosis, Bitot's spots, and keratomalacia. In later stages, it

can lead to xerophthalmia. It also increases the risk of developing measles, diarrhea, and dysentery. Skin manifestations include xerosis, scaling, and dermomalacia. Phrynoderma may also be seen as keratotic follicular papules affecting the thighs and upper arms. It is shown in the image below.

In patients above the age of 1 year, vitamin A deficiency is treated with 200,000 IU of vitamin A orally or 100,000 IU by intramuscular route. It should be repeated the next day and two weeks later.

Vitamin A is a fat-soluble vitamin that plays an essential role in vision, reproduction, and maintenance of epithelial integrity. The various forms of vitamin A include retinol (storage form), retinal, retinoic acid, and beta-carotene. It is stored in the liver perisinusoidal stellate (Ito) cells as retinyl ester (retinyl palmitate).

Other options:

Option A - Vitamin C is a water-soluble vitamin that aids in iron absorption and collagen maturation. It cannot be synthesized in humans because of the absence of L-gulonolactone oxidase. Vitamin C deficiency results in scurvy.

Option C - Vitamin B deficiency has clinical manifestations pertaining to each type.

Option D - Vitamin E deficiency can present as posterior column and spinocerebellar symptoms. Peripheral neuropathy, ophthalmoplegia, and pigmented retinopathy are other features seen.

Solution to Question 9:

The clinical scenario points to a diagnosis of Gaucher's disease, where there is a defect in the enzyme glucocerebrosidase.

Gaucher's disease is a lysosomal storage disease with autosomal recessive inheritance. The condition results due to the deficiency of beta-glucocerebrosidase. This results in the accumulation of glucosylceramide (glycolipid substrate) in the reticuloendothelial cells. There is progressive infiltration of the liver, spleen, and bone marrow.

There are three clinical types:

• Type 1: Adult (non-neuronopathic) form

• Type 2: Infantile (acute neuronopathic) form

• Type 3: Juvenile (subacute neuronopathic) form

Type 1 is the most common. It presents with a myriad of symptoms, such as bruising secondary to thrombocytopenia, fatigue due to anemia, hepatosplenomegaly, and bone pain. Pathologic fractures and lytic lesions of the femur, ribs, and pelvis may also be seen. A few patients may have pulmonary involvement. Growth retardation may be observed in cases presenting in the first decade.

Type 2 is rare, and presents with hypertonia, strabismus, and organomegaly. Neurodegeneration is the characteristic feature. Stridor and failure to thrive can also be the presenting features. Ultimately, death can occur due to respiratory arrest.

Type 3 presents with intermediate symptoms, as seen in the other two types. By the age of 10–15 years, the child succumbs to death.

The Gaucher cells, which are the reticuloendothelial cells with glucosylceramide, have a wrinkled-paper appearance due to intracytoplasmic substrate inclusions. These cells stain strongly with periodic acid-Schiff (PAS) stain. This is characteristic of Gaucher's disease.

Other options:

Option B - Acid sphingomyelinase deficiency results in Niemann-Pick disease types A and B. Both are autosomal recessive conditions. Type A has a neurodegenerative course, while type B is non-neuronopathic. The former presents with hepatosplenomegaly, lymphadenopathy, and psychomotor retardation. Death occurs by the age of 3 years. Type B is associated with hepatosplenomegaly and mild pulmonary involvement.

Option C - Hexosaminidase deficiency causes Sandhoff disease. It has an autosomal recessive pattern of inheritance. Clinical features include ataxia, dysarthria, and mental retardation.

Option D - Glucose-6-phosphatase deficiency leads to von Gierke disease, which is a glycogen storage disorder. It is an autosomal recessive condition. The affected children have characteristic doll-like facies. Hyperuricemia, lactic acidosis, and triglyceridemia can be seen. Hepatomegaly and renal enlargement is also associated.

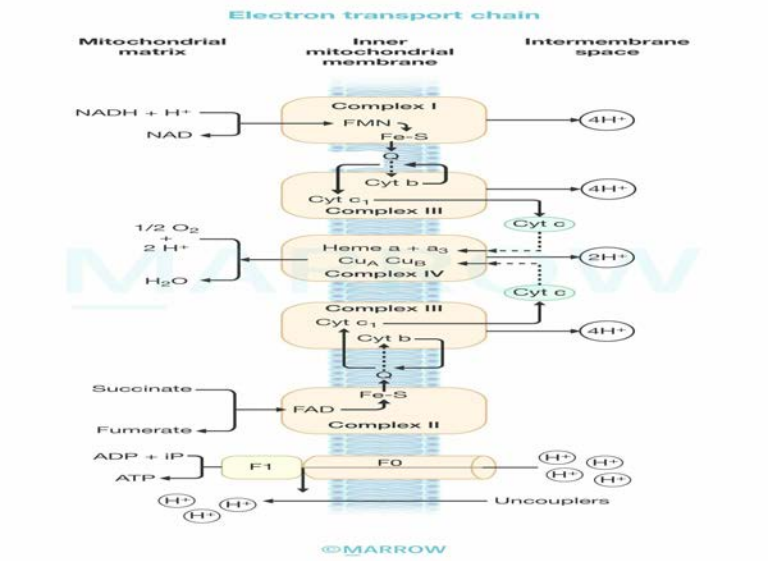
Solution to Question 10:

Cyanide is an inhibitor of cytochrome complex IV or cytochrome a+a3 (cytochrome c oxidase). It is a component of the electron transport chain.

The electron transport chain (ETC) is a specialized set of electron carriers that can accept electrons. Energy-rich molecules like glucose are oxidized to produce water and carbon dioxide. The intermediate substrates in these reactions can pass on electrons to certain coenzymes such as nicotinamide adenine dinucleotide (NAD+) and flavin adenine dinucleotide ($FADH_2$). The reduced forms can then donate electrons to the ETC by which they lose most of their free energy which is used to move H^+ through the inner mitochondrial membrane. The H^+ gradient thus produced results in the production of ATP. ATP synthesis together with electron transport is

known as oxidative phosphorylation.

The reactions in oxidative phosphorylation and the arrangement of complexes that form the ETC are shown below.



These complexes can accept or donate electrons to coenzyme Q (CoQ) and cytochrome c, which are mobile electron carriers. Certain site-specific inhibitors can inhibit ATP synthesis.

Other options:

Option B - Carbon dioxide along with water is produced by the oxidation of energy-rich molecules in oxidative phosphorylation.

Option C - Oligomycin, an antibiotic, blocks the flow of protons through ATP synthase. This inhibits oxidative phosphorylation.

Option D - Ouabain is a cardiac drug that inhibits the Na+ - K+ ATPase of cell membranes by acting on the extracellular surface.

Complexes of ETC	Inhibitors
Complex I	Piericidin A, amobarbital, rot enone
Complex II	TTFA (thenoyltrifluoroaceton e), carboxin, malonate
Complex III	BAL(British anti-lewisite), an timycin A
Complex IV	Hydrogen sulfide, carbon mo noxide,cyanide

Biochemistry NEET 2023

Question 1:

Which of the following zymogens requires gamma-glutamyl carboxylase?

a) Factors II, VIII, IX, X

b) Factors II, VII, IX, and X

c) Factors II, VII, IX, XI

d) Factors II, VIII, X, XI

Question 2:

A patient presented with diarrhea, dermatitis, and dementia. Which of the following vitamin deficiencies would you suspect in this patient?

a) Vitamin B3 deficiency

b) Vitamin B1 deficiency

c) Vitamin B6 deficiency

d) Vitamin B12 deficiency

Question 3:

A young boy presents to the OPD with hypoglycemia and muscle cramps, on exertion or while playing. Then he becomes normal after resting for a while. These episodes are recurrent after a period of activity. He has decreased serum lactate and glucose levels. Which of the following diseases is he most likely to be suffering from?

a) McArdle disease

b) Hers disease

c) Cori's disease

d) Andersen disease

Question 4:

A family consumes only polished rice. Which of the following combination of vitamin deficiency and enzymatic defect will be present in this family?

a) Riboflavin-glutathione reductase

b) Thiamine-transketolase

c) Thiamine-transaminase

d) Riboflavin-transketolase

Question 5:

A chronic alcoholic patient presented to the casualty with confusion, ataxia, and painful eye movements. What could be the vitamin deficiency seen in this patient?

a) Vitamin B deficiency

b) Vitamin A deficiency

c) Vitamin D deficiency

d) Vitamin C deficiency

Question 6:

A 4-year-old child presents with easy fatiguability. The mother also complains that the child has increased hunger between meals, which is relieved after food. Liver examination revealed no glycogen. The enzyme most likely deficient is _____.

a) Glycogen phosphorylase

b) Glycogen synthase

c) Debranching enzyme

d) Glucose 6 phosphatase

Question 7:

A child was brought with pedal edema and cheilosis. Cardiomegaly was present. What is the vitamin deficiency associated with this clinical presentation?

a) Riboflavin

b) Thiamine

c) Pyridoxine

d) Niacin

Question 8:

A chronic alcoholic patient is diagnosed with gouty arthritis. What biochemical changes will be seen in this patient?

a) Decreased NADH/NAD+ ratio

b) Increased urea and urate levels

c) Increased urate and lactate levels

d) Increased level of alkaline phosphatase

Question 9:

A child presents with erythematous scaly patches in the perioral region, mucosal ulcers, and impaired epithelial wound healing. The most likely mineral deficiency associated with this condition is _____.

a) Iron deficiency

b) Zinc deficiency

c) Calcium deficiency

d) Copper deficiency

Question 10:

A patient presenting with bleeding gums and easy bruisability was diagnosed with scurvy. This is due to _____.

a) Low calcium

b) Defective collagen formation

c) Inhibition of clotting factors

d) Increased keratinization of epithelium

Question 11:

Which of the following is seen in low insulin:glucagon ratio?

a) Activation of lipoprotein lipase

b) Activation of glycogen synthase

c) Activation of phosphofructokinase 1

d) Activation of hormone-sensitive lipase

Question 12:

An infant is brought by his parents with complaints that his urine turns black on standing. Which of the following metabolic disorders is likely?

a) Phenylketonuria

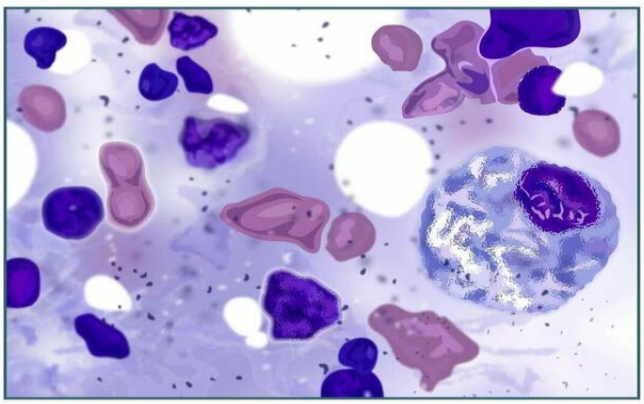
b) Alkaptonuria

c) Homocystinuria

d) Maple syrup urine disease

Question 13:

A child presents with bone pain and hepatosplenomegaly. A trephine biopsy and aspirate show the following finding. Which of the following is the most likely enzyme deficient in this condition?



a) Hexosaminidase

b) Glucocerebrosidase

c) Sphingomyelinase

d) Alpha 1,4-glucosidase

Question 14:

A child presents with thinning of hair and scaling of the scalp. On taking further history, it is found that she consumes raw eggs in her diet regularly. The given manifestations are due to the deficiency of which of the following vitamins?

a) Niacin

b) Pyridoxine

c) Biotin

d) Thiamine

Question 15:

A child presents with mental retardation, bone pain, and inability to walk. On funduscopy examination, a cherry red spot is seen. There is no organomegaly. What is the most likely diagnosis?

a) Tay-Sachs disease

b) Niemann-Pick disease

c) Hurler syndrome

d) Gaucher disease

Answer Key

Question No.	Correct Option
1	b
2	a
3	a
4	b
5	a
6	b
7	b
8	c
9	b
10	b
11	d

12	b
13	b
14	c
15	a

Detailed Explanations

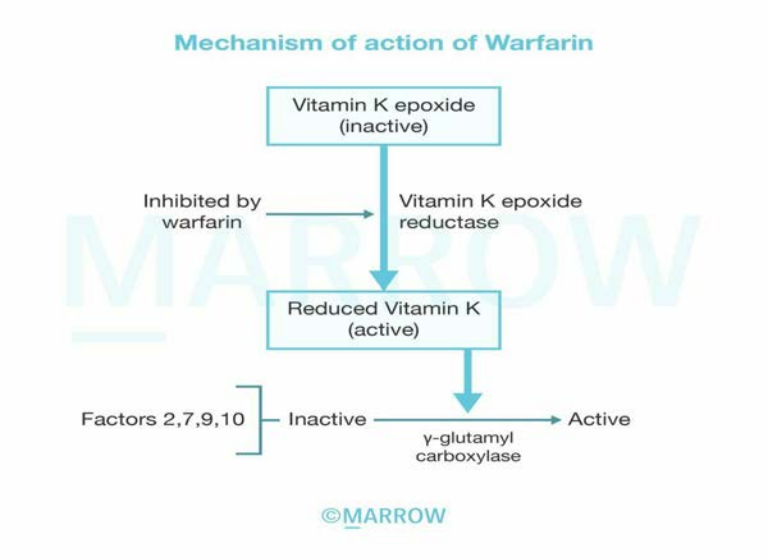
Solution to Question 1:

Clotting factors II, VII, IX, and X are zymogens of serine proteases that contain glutamic acid residues. These residues undergo vitamin-K-dependent carboxylation via gamma-glutamyl carboxylase to form gamma-carboxyglutamic acid residues. These residues chelate calcium ions, allowing the binding of clotting factors to the platelet surface.

Zymogens are the proprotein form of enzymes (proenzymes) that require proteolytic activation to carry out their function.

The reduced form of vitamin K acts as a cofactor in the post-synthetic modification of these zymogens and their activation. This reduced form of vitamin K is recycled back from its oxidized form by the enzyme vitamin K epoxide reductase, which is inhibited by warfarin.

The absence of vitamin K or the presence of warfarin inhibits carboxylation of the glutamate residues, leading to the release of abnormal precursors of clotting factors in the blood.



Solution to Question 2:

The given clinical scenario of a patient with diarrhea, dermatitis, and dementia is suggestive of niacin/vitamin B3 deficiency.

Niacin deficiency causes pellagra, found mostly among people eating corn/maize-based diets, which are low in niacin and tryptophan. Excess leucine in jowar and maize disrupts the conversion of tryptophan to niacin.

Niacin can be synthesized in the body from tryptophan. Two compounds, nicotinic acid and nicotinamide, have the biological activity of niacin. The nicotinamide ring of the coenzymes nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP) participate in oxidation/reduction reactions.

The initial symptoms of pellagra include loss of appetite, generalized weakness, irritability, abdominal pain, and vomiting. This is followed by bright red glossitis and a characteristic pigmented, scaly skin rash in sun-exposed areas. This rash is known as Casal's necklace when it forms a ring around the neck.

The 4Ds of pellagra:

• Diarrhea

• Dermatitis

• Dementia, leading to

• Death

It is diagnosed by measuring urinary levels of 2-methyl nicotinamide and 2-pyridone.

It is treated by oral supplementation of 100–200 mg of nicotinamide or nicotinic acid three times daily for 5 days.

Casal's necklace finding in niacin deficiency:

Other options:

Option B: Vitamin B1/Thiamine deficiency can manifest as wet beriberi (CVS features like heart failure and edema) or Shoshin beriberi, an acute and fulminant form of wet beriberi, dry beriberi (peripheral neuritis), or as Wernicke encephalopathy with Korsakoff psychosis (in alcoholics). Dietary deficiency of thiamine inhibits pyruvate dehydrogenase. Chronic alcoholics may develop potentially fatal pyruvic and lactic acidosis.

Option C: Vitamin B6/Pyridoxine deficiency is rare but has been observed in alcoholics, newborns, formulas low in vitamin B6, and women taking oral contraceptives. Isoniazid, an anti-TB drug, leads to pyridoxine deficiency resulting in peripheral neuropathy. Hence pyridoxine supplementation is included in ATT regimens.

Option D: Vitamin B12/Cobalamin deficiency causes megaloblastic anemia, dementia, spinal cord degeneration, homocysteinemia, etc.

Solution to Question 3:

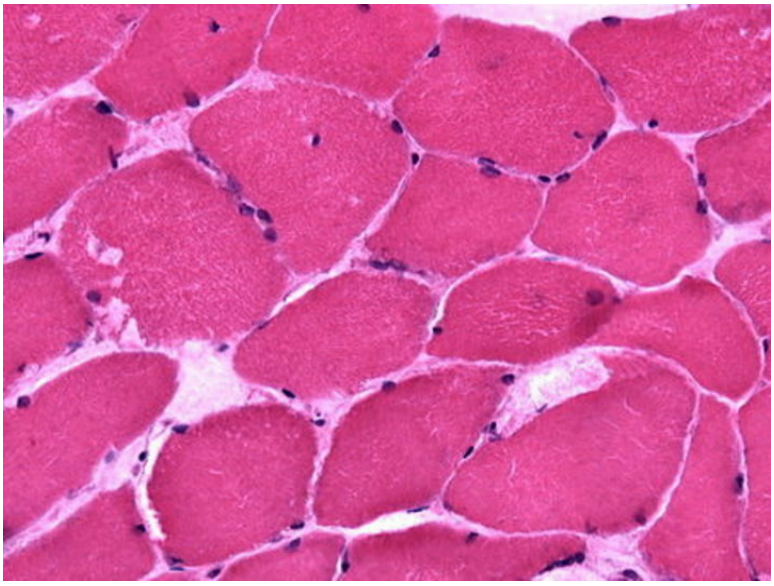
A clinical scenario of a patient with muscle cramps, pain, weakness with exertion, myoglobinuria, and the muscle biopsy specimen showing vacuolar myopathy are suggestive of McArdle's disease, which is due to the deficiency of muscle glycogen phosphorylase.

McArdle disease, also known as type V glycogen storage disorder, is an autosomal recessive condition. It typically presents during late childhood or in the second decade of life. The muscle glycogen phosphorylase enzyme deficiency interferes with ATP generation by glycogenolysis in the muscles. This causes muscle glycogen accumulation.

Symptoms are exercise intolerance associated with muscle cramps. Due to high-intensity exercise, sudden persistent muscle contraction occurs. This leads to severe muscle damage resulting in a massive release of muscle proteins and myoglobin in the blood. Myoglobinuria secondary to rhabdomyolysis leads to the passage of burgundy-colored urine in some patients.

A unique feature associated with McArdle is the improvement in symptoms after rest for a few minutes. This is termed as the second wind phenomenon. This occurs due to the increased blood flow to the muscles and increased utilization of free fatty acids (FFAs) for energy production after resting for a few minutes. This compensates for the impaired ATP generation from glycogenolysis. Patients with McArdle disease can benefit from engaging in regular aerobic exercises, such as walking or cycling, which can help increase their exercise tolerance and cardiovascular fitness. However, they should avoid high-intensity exercises or activities that can trigger muscle cramps and rhabdomyolysis. Glucose administration before exercise can improve tolerance. Vitamin B6 is also recommended.

Standard diagnosis includes muscle biopsy, which shows periodic acid Schiff (PAS)-positive vacuoles (Shown in the image below) of high glycogen content due to lack of myophosphorylase and genetic testing (PYGM gene sequencing).



Other options:

Option B: Hers disease (type VI glycogen storage disorder) - It is caused by the deficiency of liver glycogen phosphorylase. Patients with Hers disease exhibit growth retardation, hepatomegaly, and mild hypoglycemia. They do not typically present with muscle cramps and myoglobinuria.

Option C: Cori's disease (type III glycogen storage disorder) - It is caused by a deficiency of glycogen debranching enzyme. Patients with Cori's disease present with hepatomegaly, growth retardation, and hypoglycemia. Muscle weakness may be present but not muscle cramps or myoglobinuria.

Option D: Andersen disease (type IV glycogen storage disorder) - It is caused by the deficiency of glycogen branching enzyme. This disease presents with hepatomegaly, cirrhosis, and liver failure. It does not cause muscle cramps or myoglobinuria.

Solution to Question 4:

The consumption of polished rice leads to thiamine deficiency which leads to defective transketolase activity.

Polished rice is rice that has had its husk, bran, and germ removed, leaving only the endosperm. This processing method results in a loss of nutrients, including thiamine.

Thiamine pyrophosphate (Vit B1) is the cofactor of transketolase. This reaction requires two cofactors:

• Mg^{2+}

• Thiamine diphosphate (vitamin B1)

Transketolase and transaldolase are involved in the non-oxidative phase of the HMP pathway.

Thiamine deficiency can lead to beriberi, a condition characterized by peripheral neuropathy, weakness, and cardiovascular symptoms. In severe cases, it can also lead to Wernicke-Korsakoff syndrome, which is characterized by confusion, ataxia, and vision disturbances. Thiamine

deficiency can be prevented by consuming a balanced diet that includes unprocessed grains, legumes, and other sources of thiamine. Diagnosis of thiamine deficiency can be established by erythrocyte transketolase activity assessment.

Solution to Question 5:

The above clinical history is suggestive of Wernicke encephalopathy, which is caused by vitamin B1 (Thiamine) deficiency.

Vitamin B1/thiamine deficiency leads to following conditions:

• Wernicke encephalopathy:

• An acute, neuropsychiatric syndrome characterized by nystagmus and ophthalmoplegia, mental status changes (confusion), and unsteadiness of stance and gait.

• Wernicke's encephalopathy is a medical emergency, and thiamine should be initiated immediately, either intravenously or intramuscularly.

• The current standard of treatment for patients with symptoms of Wernicke's encephalopathy is to give thiamine 100 mg intravenously before administering glucose-containing IV fluids.

• Korsakoff psychosis:

• Korsakoff syndrome is characterized by a pronounced anterograde and retrograde amnesia along with potential impairment in visuospatial, abstract, and other types of learning.

• Symptoms are similar to that of Wernicke encephalopathy, but also include memory loss and confabulation.

• Permanent in at least a partial form in about 50% of the people affected.

• Beriberi: It can present with:

• Dry beriberi: sensorimotor peripheral neuropathy, muscle weakness

• Wet beriberi: tachycardia, cardiomegaly, high-output cardiac failure

Solution to Question 6:

The most likely enzyme deficiency in a child with fatigue, excessive hunger between meals, and absent liver glycogen is glycogen synthase deficiency.

Glycogen is a storage carbohydrate synthesized from glucose (glycogenesis) and is stored in the liver, muscles, and brain. Glycogen synthase is a regulating enzyme for glycogenesis.

Glycogen synthase exists in both phosphorylated (inactive) and dephosphorylated (active) forms. Phosphorylation is stimulated by epinephrine, norepinephrine, and glucagon via cAMP. Dephosphorylation is stimulated by insulin via phosphodiesterase.

A deficiency of glycogen synthase leads to glycogen storage disorder and presents in infancy with early morning drowsiness and fatigue, fasting hypoglycemia, pallor, emesis, and hypoglycemic convulsions. It leads to a marked decrease in liver glycogen stores. Hepatomegaly is absent.

Laboratory investigations reveal prolonged hyperglycemia, glycosuria, ketosis, lactic acidosis, low alanine levels, and normal insulin levels after glucose administration. A liver biopsy is diagnostic.

Treatment involves protein-rich frequent meals, and nighttime supplementation with cornstarch to prevent hypoglycemia and hyperketonemia.

Other options:

Option A: Glycogen phosphorylase deficiency, also known as McArdle's disease or glycogen storage disease type V, primarily affects skeletal muscle glycogen metabolism. Affected individuals experience muscle weakness, cramps, and exercise intolerance, but it doesn't typically cause the symptoms mentioned in the question.

Option C: Debranching enzyme deficiency, also known as Cori's disease or glycogen storage disease type III, presents with hepatomegaly, hypoglycemia, and growth retardation. The liver would still contain glycogen, albeit with an abnormal structure.

Option D: Glucose-6-phosphatase deficiency, known as von Gierke's disease or glycogen storage disease type I, is characterized by severe fasting hypoglycemia, lactic acidosis, hyperuricemia, and hepatomegaly. In this case, glycogen is present in the liver but cannot be broken down efficiently into glucose.

Solution to Question 7:

The given clinical presentation with pedal edema and cardiomegaly is suggestive of wet beriberi due to thiamine (vitamin B1) deficiency.

Early symptoms of thiamine deficiency include peripheral neuropathy, irritability, loss of deep tendon reflexes and proprioception. As the disease progresses, increased intracranial pressure, meningismus and coma develop.

Wet beriberi results due to cardiac and renal dysfunction which leads to fluid accumulation. It is associated with tachycardia, cardiomegaly, cardiac failure, and edema. It is commonly seen in the refugee camps where people consume polished rice-based monotonous diets.

Dry beriberi is associated with neurological deficits such as peripheral neuropathy, optic atrophy, ataxia, and irritability. Complications include lactic acidosis and Wernicke encephalopathy in adults.

Diagnosis of thiamine deficiency can be established by erythrocyte transketolase activity assessment.

Other options:

Option A: Riboflavin deficiency can present with cheilosis, but it does not typically cause pedal edema and cardiomegaly.

Option C: Pyridoxine (vitamin B6) deficiency can cause neurological symptoms, anemia, and dermatitis but is not associated with pedal edema, cardiomegaly, and cheilosis.

Option D: Niacin (vitamin B3) deficiency leads to pellagra, characterized by the triad of dermatitis, diarrhea, and dementia. It is not associated with pedal edema, cardiomegaly, and cheilosis.

Solution to Question 8:

This patient with chronic alcoholism and gouty arthritis will most likely have elevated levels of lactate and urate.

The oxidation of ethanol to acetate by alcohol dehydrogenase is accompanied by the reduction of nicotinamide adenine dinucleotide (NAD+) to NADH. This results in a high concentration of NADH, leading to an increased NADH/NAD+ ratio (Option A).

Due to this, the following metabolic reactions that require NAD+ are inhibited:

• Glycolysis

• Citric acid cycle (ketogenesis favored)

• Pyruvate dehydrogenase

• Fatty acid oxidation

Decreased fatty acid oxidation leads to increased esterification and production of triacylglycerol, which causes fatty liver.

Also, there is an increase in two reactions:

• Pyruvate to lactate

• Oxaloacetate to malate

Increased lactate leads to hyper-lactic-acidemia, which leads to increased renal reabsorption of urate and decreased excretion of uric acid. This results in aggravation of gout. Alcoholics are deficient in thiamine which inhibits pyruvate dehydrogenase and leads to lactic acidosis.

A decrease in pyruvate and oxaloacetate levels, which are substrates for gluconeogenesis, leads to a decrease in blood glucose levels, causing symptoms of agitation, impaired judgment, and combativeness.

Other options:

Increased urea and urate levels are not specifically associated with alcoholism and gouty arthritis. While urate levels may be increased due to gout, urea levels are not directly related to the condition (Option B).

Increased levels of alkaline phosphatase can be seen in alcohol-induced hepatitis due to intrahepatic cholestasis but is not directly related to gouty arthritis in a chronic alcoholic patient. Therefore, this option is less relevant compared to increased urate and lactate levels (Option D).

Solution to Question 9:

The clinical features of periorificial dermatitis and stomatitis in a young child are suggestive of acrodermatitis enteropathica, seen in zinc deficiency.

Acrodermatitis enteropathica is a genetic disorder that results in the inability to absorb dietary zinc.

The clinical features develop after weaning and the infant presents with:

• Failure to thrive

• Skin manifestations such as symmetrical vesiculobullous dermatitis in the perioral, perianal, and acral regions

• Anorexia, diarrhea

• Recurrent infections due to T-cell immunodeficiency

• Alopecia with a reddish tint

• Impaired wound healing

• Male hypogonadism, growth retardation

• Neurological manifestations like tremors, nystagmus, photophobia, hypogeusia, irritability, and night blindness

Oral zinc supplementation is the treatment of choice.

Other options:

Option A- Iron deficiency is the most common micronutrient deficiency globally. It presents with iron-deficiency anemia and neurocognitive impairment. It presents clinically with pallor, fatigue, atrophic glossitis, and pica.

Option C- Calcium deficiency leads to rickets as a result of early weaning. It presents with typical symptoms of rickets, including failure to thrive; protruding abdomen; muscle weakness; fractures; craniotabes; delayed dentition; caries; enlargement of wrists and ankles; and hypocalcemic symptoms of tetany, stridor, and seizures.

Option D- Copper deficiency leads to anemia, growth retardation, defective keratinization and pigmentation of hair, hypothermia, degenerative changes in aortic elastin, osteopenia, and mental retardation.

Solution to Question 10:

Bleeding gums and easy bruisability seen in scurvy are due to defective collagen formation.

Scurvy results from the deficiency of vitamin C, which is required for the hydroxylation of prolyl and lysyl residues of collagen reactions. Hence, deficiency of vitamin C results in a defective prolyl hydroxylase activity, leading to defective collagen formation and resulting in generalized bleeding tendencies.

Hemorrhagic manifestations of scurvy include petechiae, purpura, ecchymoses at pressure points, epistaxis, gum bleeding, and characteristic perifollicular hemorrhages. Other manifestations are poor wound and fracture healing, hyperkeratosis of hair follicles, arthralgia, and muscle weakness. It also results in defective osteoid formation. Costo-chondral separation leads to the formation of tender nodules that are sharply angulated and are also known as the scorbutic rosary.

The cutaneous manifestations of scurvy include

• Phrynoderma over posterolateral arms which can then generalize over the back and thighs and legs.

• Corkscrew hairs - fractured and coiled hairs due to impaired keratin cross■links by disulfide bonds

• Perifollicular hemorrhage and purpura

• Lower limb edema

• Splinter hemorrhages

It is treated with vitamin C supplementation.

Other options:

Option A: Low calcium levels do not cause scurvy; they may contribute to other clinical conditions like osteoporosis or muscle cramps.

Option C: Inhibition of clotting factors is not responsible for scurvy. Vitamin K deficiency, however, can lead to the inhibition of clotting factors and cause bleeding tendencies.

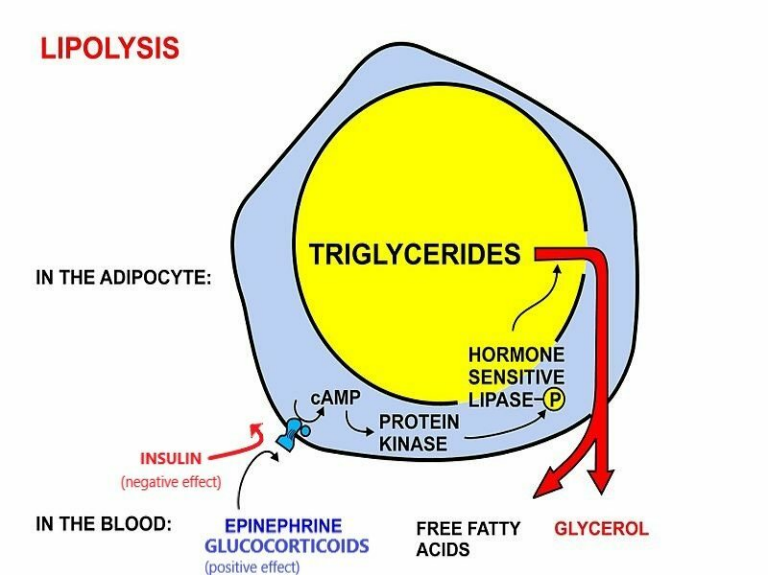
Option D: Increased keratinization of epithelium is not the cause of scurvy. Vitamin A deficiency, on the other hand, can result in hyperkeratoses and epithelial changes, such as xerosis and Bitot's spots.

Solution to Question 11:

Low insulin:glucagon ratio occurs in the fasting state. Since insulin has an inhibitory effect on hormone-sensitive lipase (lipolytic hormone), low insulin:glucagon ratio results in the activation of hormone-sensitive lipase.

In adipose tissues, decreased insulin results in the inhibition of lipogenesis and activation of intracellular hormone-sensitive lipase. The stored triglycerides are broken down (lipolysis) by hormone-sensitive lipase (HSL) into free fatty acids (FFAs) and glycerol. In the fasting state, glucose is spared for the brain and glycerol is used as a substrate for gluconeogenesis.

In diabetic patients, low insulin level corresponds to an increase in HSL activity, promoting the breakdown of lipids and the release of FFAs from adipose tissue. HSL activity is accelerated by hormones like epinephrine, norepinephrine, glucagon, ACTH, TSH, GH, ADH, and melanocyte-stimulating hormones (MSH).



Other options:

Option A: Activation of lipoprotein lipase (LPL) is promoted by insulin, not low insulin: glucagon ratio. LPL is involved in the breakdown of triglycerides and is active in the well-fed state. In low insulin: glucagon ratio, lipoprotein lipase activity is reduced, leading to decreased hydrolysis of triglycerides.

Option B: Activation of glycogen synthase is promoted by insulin. In low insulin: glucagon ratio, glycogen synthase activity is reduced, leading to decreased glycogenesis. Instead, glycogenolysis and gluconeogenesis are promoted to maintain blood glucose levels.

Option C: Activation of phosphofructokinase 1 (PFK1) is promoted by insulin. PFK1 is a rate-regulating enzyme in glycolysis. In low insulin: glucagon ratio, glycolysis is downregulated, and gluconeogenesis is upregulated to maintain blood glucose levels.

Well-fed state (Insulin)	During fasting (Glucagon)
Lipogenesis increased	Lipogenesis inhibited
Lipolysis inhibited	Lipolysis increased
Insulin inhibits HS-lipase	Glucagon activates HS-lipase
Lipoprotein lipase active	Lipoprotein lipase inactive

Solution to Question 12:

Blackening of urine on standing is characteristic of alkaptonuria.

Alkaptonuria is an autosomal recessive disorder of tyrosine metabolism, that develops due to the defect in homogentisate oxidase/homogentisic acid 1, 2 - dioxygenase, which oxidizes homogentisate to maleylacetoacetate. The defect in this enzyme leads to the accumulation of homogentisate, which is then excreted in the urine.

Alkaptonuria is characterized by homogentisic aciduria, ochronosis, and arthropathy (joint pain).

Homogentisic aciduria is the black discoloration of urine on prolonged exposure to air caused due to oxidation of the excreted homogentisate.

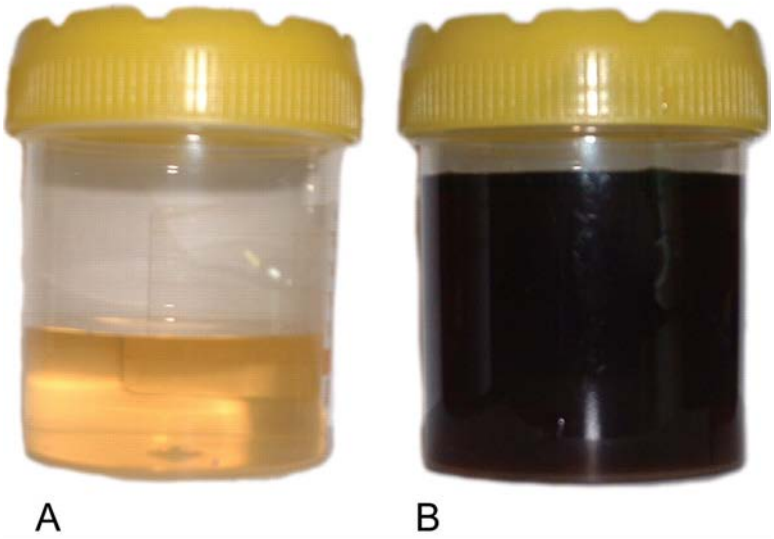
Ochronosis, which is bluish-black pigmentation in connective tissue, generally occurs after the third decade of life, and it occurs due to the accumulation of homogentisic acid and its oxidation products like benzoquinone acetic acid in connective tissue.

Arthritis generally begins in the third decade. Arthritis often begins in the spine and resembles ankylosing spondylitis in its large-joint distribution. Radiographs of the spine showing flattened and calcified intervertebral discs are pathognomonic. Other findings include degeneration of the intervertebral discs, followed by disc calcification and eventually fusion of the vertebral bodies. Osteophyte formation and calcification of the intervertebral ligaments also occur.

Diagnosis: Blackish discoloration of urine on standing is diagnostic of alkaptonuria (shown below). The ferric chloride test will be positive. The blackening of urine occurs due to the excretion of homogentisic acid in the urine.

Image A - Normal urine

Image B - Alkaptonuria



Other options:

Option A: Phenylketonuria (PKU) is a metabolic disorder resulting from a deficiency of the enzyme phenylalanine hydroxylase. It does not lead to black urine. Patients with PKU have a musty or mousy odor due to phenylacetic acid accumulation.

Option C: Homocystinuria is an inborn error of methionine metabolism caused by a deficiency of the enzyme cystathionine β-synthase. It is characterized by tall stature, long limbs, dislocation of

the lens of the eye, and predisposition to thromboembolism, but it does not lead to black urine.

Option D: Maple syrup urine disease (MSUD) is an inherited metabolic disorder caused by a deficiency of branched-chain α-ketoacid dehydrogenase. It does not cause black urine. Patients with MSUD have urine with a characteristic sweet odor, resembling maple syrup.

Solution to Question 13:

The given clinical scenario of a child with bone pain, hepatosplenomegaly, and biopsy showing Gaucher's cell with a characteristic crumpled tissue paper appearance is suggestive of Gaucher's disease. The deficient enzyme is glucocerebrosidase (also known as beta-glucosidase).

Gaucher's disease is an inborn error of metabolism caused due to a deficiency of beta-glucocerebrosidase. It is the most common lysosomal storage disorder and the mode of inheritance is autosomal recessive. There is an accumulation of lipid-laden macrophages in the spleen, liver, and other tissues.

There are three clinical subtypes - type I (chronic non-neuronopathic), type II (acute neuronopathic), and type III (intermediate). Clinical features include anemia, thrombocytopenia, hepatosplenomegaly, and neurological features depending on the subtype.

Gaucher's cells - These are formed as a result of the accumulation of massive amounts of glucocerebrosides within the phagocytes. The cells have a fibrillary cytoplasm and give a crumpled tissue paper appearance.

Option A: Deficiency of hexosaminidase A is seen in Tay-Sachs disease. The deficiency of beta-hexosaminidase A and B causes Sandhoff's disease. Clinical features are seizures, macrocephaly, and hyperacusis.

Option C: Deficiency of sphingomyelinase leads to Niemann-Pick disease. It is characterized by the presence of foam cells in the bone marrow. There may be pulmonary infiltrates leading to lung failure.

Option D: Pompe's disease (type 2 glycogen storage disease) occurs due to alpha 1,4-glucosidase (acid maltase) deficiency. It is the only glycogen storage disease that is a lysosomal storage disease and causes lysosomal glycogen accumulation in cardiac, skeletal, and smooth muscle cells. The clinical symptoms of Pompe disease are hypotonia (floppy infant), skeletal muscle weakness, hepatomegaly, hypertrophic cardiomyopathy, and macroglossia.

Solution to Question 14:

The given clinical scenario of scaling and alopecia and the history of raw egg consumption are suggestive of biotin deficiency.

Raw egg white contains a glycoprotein known as avidin, which tightly binds to biotin and renders it unabsorbable from the intestine. Hence, there can be a biotin deficiency state.

Biotin deficiency may cause:

• Dermatitis, scaling, seborrheic, and erythematous rash

• Mental status changes (depression, hallucinations)

• Hyperesthesia

• Alopecia

• Atrophic glossitis

In infants, biotin deficiency presents as hypotonia, lethargy, and apathy. In addition, infants may develop alopecia and a characteristic rash that includes the ears.

Solution to Question 15:

The given clinical scenario, along with the fundoscopy image showing a macular cherry-red spot, indicates that the most likely diagnosis is Tay-Sachs disease.

Tay-Sachs disease is a lysosomal storage disease caused by the deficiency of β-hexosaminidase. It can present during infancy with macrocephaly, increased startle reaction, gradual loss of motor skills, and a macular cherry-red spot. Affected children usually die by the age of 10–15 years.

It is of two types—juvenile-onset and adult-onset. The symptoms of the juvenile-onset form include ataxia and dementia. Dysarthria, lower motor neuron signs, and psychiatric disorders are common in the adult-onset type.

Other options:

Options B - Niemann-Pick disease is an autosomal recessive inborn error of lipid metabolism. It results due to the deficiency of the sphingomyelinase enzyme. This results in the accumulation of sphingomyelin in the brain, lungs, liver, and spleen. The clinical features include a combination of hepatosplenomegaly, developmental delay, failure to thrive, severe psychomotor regression, interstitial lung disease, and a cherry-red spot in the macula.

Option C - Hurler syndrome (mucopolysaccharidosis I) is an autosomal recessive condition that affects multiple organs. Presentation is usually at 6–24 months with corneal clouding, coarse facial features, joint stiffness, and skeletal dysplasia. Glaucoma, retinal degeneration, and nasal discharge are the other features. The condition is generally fatal.

Option D - Gaucher disease is a glycolipid storage disorder that can present with hepatosplenomegaly, mental retardation, and erosion of long bones. It is caused by the deficiency of β-glucosidase. The Gaucher cell has a wrinkled-paper appearance due to intracytoplasmic inclusions, which is a characteristic feature.

Biochemistry INI-CET 2023

Question 1:

Xanthurenic aciduria is seen in which of the following vitamin deficiency?

a) Vitamin B2

b) Vitamin B1

c) Vitamin B12

d) Vitamin B6

Question 2:

A 12-year-old boy with type 1 diabetes mellitus presents with unconsciousness. His urine is subjected to a test and the results are shown below. What is the test done?

a) Seliwanoff's test- Fructose

b) Benedict's test- Reducing sugars

c) Fouchet's test- Bilirubin

d) Rothera's test- Ketone bodies

Question 3:

The template DNA strand is 5'CATTCAATATCGATC3'. The resulting mRNA sequence after transcription is?

a) 3'GAUCGAUAUUGAAUA5'

b) 5'GATCGATATTGAATUT3'

c) 5'GAUCGAUAUUGAAUG3'

d) 3'GATCGATATTGAATU5'

Question 4:

Arrange the following steps of Karyotyping in the correct order :

a) 1, 2, 3, 4, 5

b) 1, 3, 2, 4, 5

c) 1, 2 , 3, 5, 4

d) 2, 1, 3, 4, 5

Question 5:

A patient came with complaints of muscle weakness to the OPD. The doctor found that he has cardiomyopathy and diagnosed him to be a case of Barth Syndrome, where the patient has mitochondrial dysfunction. What is the defect in this patient?

a) Cephalin

b) Cardiolipin

c) Lecithin

d) Lysolecithin

Question 6:

In Pompe's disease, the enzyme deficient is?

a) Lactic acid dehydrogenase

b) Phosphofructokinase

c) Muscle glycogen phosphorylase

d) Lysosomal alpha glucosidase

Question 7:

The thermic effect is highest in _____.

a) Carbohydrates

b) Proteins

c) Lipids

d) Independent of components

Question 8:

Which of the following statements are false about collagen?

a) Most common fibrous protein

b) Prolysyl and lysyl hydroxylase are involved in post translational modification

c) Phenylalanine is the most abundant AA in its structure

d) Triple helix structure is important for its function

Question 9:

Ketone bodies are not utilized by the liver because it lacks:

a) Thiokinase

b) Thiophorase

c) Thiolase

d) Thiotransferase

Question 10:

Which of the following methods can detect the alterations in DNA sequence?

a) 1 and 3

b) 1, 2, and 3

c) 2, 3, and 4

d) 1, 2, and 4

Question 11:

Which anticoagulant present in the light blue vacutainer is used for plasma glucose estimation?

a) Sodium fluoride

b) Heparin

c) Sodium Citrate

d) Potassium oxalate

Question 12:

Which of the following is not involved in the repair of DNA following double-stranded breaks?

a) ATM

b) BRCA1

c) MSH2

d) Ku70

Question 13:

2-3 BPG binds to?

a) Heme part of myoglobin

b) Globin part of Hemoglobin

c) Globin part of myoglobin

d) Heme part of Hemoglobin

Question 14:

Which of the following is complementary to the active site of the enzyme?

a) Product

b) Substrate

c) Allosteric activator

d) Transition site

Question 15:

Cytochrome P450 monooxygenase utilises which of the following cofactors during the phase 1 reaction of detoxification of xenobiotics?

a) FMN

b) NADPH

c) FAD

d) NAD

Question 16:

Which biochemical cycle/process is used by monoclonal antibodies in hybridoma technology?

a) TCA cycle

b) Glycolytic pathway

c) Pentose phosphate pathway

d) Purine salvage pathway

Question 17:

Glycogen phosphorylase requires which of the following for its activation?

a) Insulin

b) Glucose 6 phosphate

c) Ca2+

d) cAMP independent protein kinase

Answer Key

Question No.	Correct Option
1	d
2	d
3	c
4	a
5	b
6	d

7	b
8	c
9	b
10	a
11	c
12	c
13	b
14	b
15	b
16	d
17	c

Detailed Explanations

Solution to Question 1:

Xanthurenic aciduria is seen in deficiency of vitamin B6 (pyridoxal phosphate), a coenzyme required by kynureninase enzyme to convert 3-OH kynurenine to 3-OH anthranilic acid during tryptophan metabolism.

Other options-

Option A: Riboflavin or Vitamin B2 deficiency manifests as angular stomatitis, magenta tongue, seborrhea, corneal vascularization. It is seen in alcoholism, and individuals with a poor diet and decreased intake of dairy products.

Option B: A patient with thiamine or vitamin B1 deficiency presents either dry Beriberi with predominantly neurological symptoms like neuropathy, muscle weakness, and wasting or wet Beriberi with predominant cardiac symptoms like cardiomegaly, tachycardia, high output congestive cardiac failure.

Option C: Vitamin B12 or cobalamin deficiency presents as anemia, fatigue, and pallor symptoms. Other presenting complaints may include peripheral neuropathy, glossitis, diarrhea, headaches, neuropsychiatric disturbances like dementia, and subacute combined degeneration of the spinal cord (SACD) leading to ataxia. A peripheral smear shows macrocytic anemia and hypersegmented neutrophils.

Solution to Question 2:

The given clinical scenario points towards a diagnosis of diabetic ketoacidosis. Rothera's test as shown in the image is a specific test used for the determination of ketone bodies in the urine.

Type I diabetes mellitus is a low insulin state. There is an increased conversion of fatty acids to acetyl-CoA which in turn leads to increased ketone body production. The presence of

ketosis can be established by the detection of ketone bodies in urine by Rothera's test.

The test involves the saturation of 5 mL of urine with solid ammonium sulfate. This is followed by the addition of a few drops of freshly prepared sodium nitroprusside followed by 2 mL of liquor ammonia along the sides of the test tube. The development of a purple ring indicates the presence of ketone bodies in urine. Strip tests based on the same principle are also available.

Other options-

Option A: Seliwanoff's test will distinguish glucose and fructose. The reagent is resorcinol in HCl. 3 ml of the reagent and 0.5 ml of urine are heated for 30 seconds up to a boiling point. A red color indicates the presence of fructose.

Option B: Benedict's test is a test commonly used in the follow-up of diabetics for the detection of glucose in urine (glucosuria). It uses Benedict's reagent containing sodium carbonate, copper sulfate, and sodium citrate. Reducing sugars (containing a free aldehyde/ keto group) will reduce Benedict's reagent. Examples include glucose, fructose, and lactose. The test is a semi-quantitative test. The blue color indicates no reducing sugar.

Option C: Fouchet's test is used for detecting the presence of bile pigments in urine. Here, urine is heated with barium sulfate, which adsorbs bilirubin. Ferric chloride is added, which oxidizes the adsorbed bilirubin to biliverdin which produces a green color. Principle for all tests to detect bile pigments: Oxidizing agents readily oxidize bilirubin to biliverdin to form a green color.

Solution to Question 3:

5'GAUCGAUAUUGAAUG3' will be the sequence of mRNA produced from this fragment of template DNA.

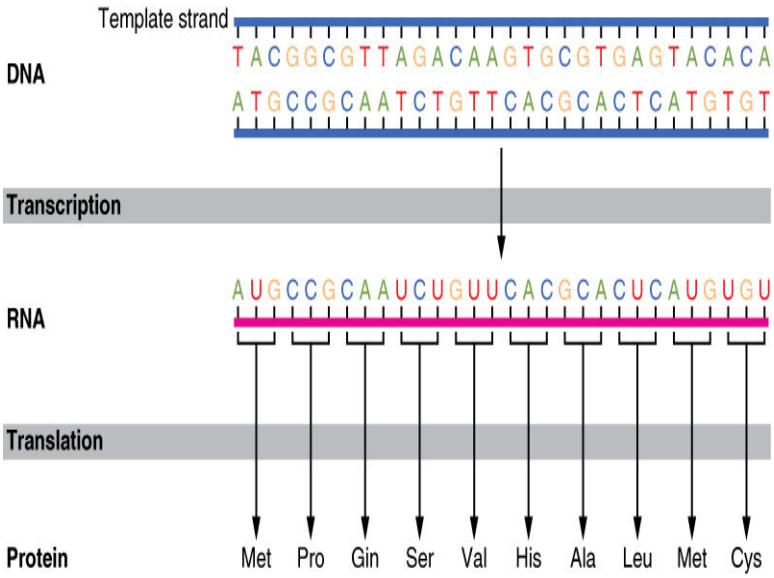
The non-template strand or coding strand or sense/plus strand in the DNA will have the same sequence of the RNA that is produced, except that the non-template or coding strand has T is in place of U.

As all sequences are written in the 5′ to 3′ direction, unless otherwise specified, an RNA sequence of GAUCGAUAUUGAAUG would correspond to a DNA sequence, on the non-template strand, of CATTCAATATCGATC. Both the non-template strand and RNA produced will be a complementary sequence to the template strand.

Note:

Template strand - known as minus or antisense or non-coding strand.

Coding strand- known as plus or sense or non-template strand.



Solution to Question 4:

The correct order of steps of Karyotyping is as follows:

• Collect cells by peripheral vein using a heparin syringe.

• Culture in phytohaemoagglutinin.

• Incubation at 37 degrees C for 3 days.

• Harvest with colchicine.

• Routine staining with Giemsa

Karyotyping is the process by which chromosomes are isolated, stained, and examined to find chromosomal anomalies. It is used in prenatal diagnosis, investigation of repeat pregnancy loss, investigation of children and adults suspected of having a chromosomal disorder, and subtyping of lymphomas and leukemias for the purpose of exact diagnosis, giving a prognosis, and treatment.

Various techniques are used in karyotyping to study chromosomes. Staining with various compounds produces various results and helps us to understand the chromosomes better.

Common techniques used are:

• Q banding - fluorescence staining with quinacrine mustard

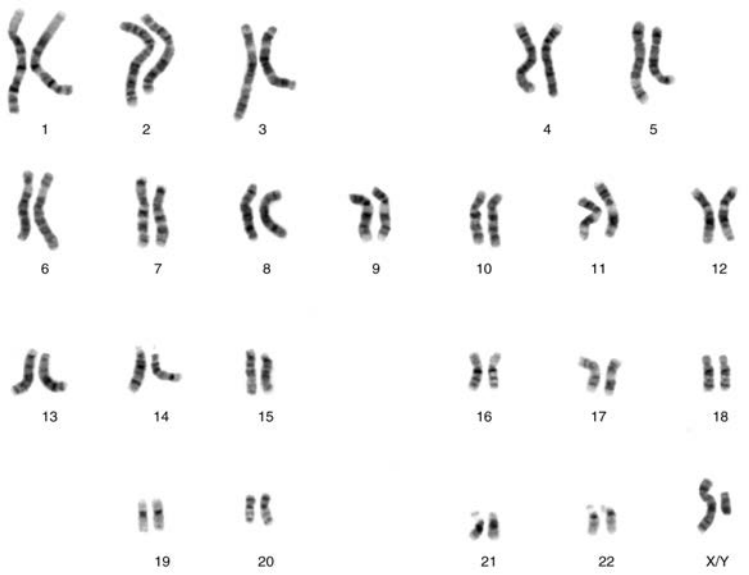
• G banding - Giemsa staining after partial denaturation of chromatin

• R banding - reverse Giemsa staining. In this, the light and dark areas are reversed

• C banding - staining of heterochromatin with silver salts

• T banding - staining the telomeres of chromosomes

The karyotyping of a normal human male is given below.



Solution to Question 5:

Decreased cardiolipin or alteration in its metabolism results in mitochondrial dysfunction seen in Barth syndrome (cardio skeletal myopathy) which is characterized by an enlarged and weakened heart (dilated cardiomyopathy), weakness in muscles used for movement (skeletal myopathy), recurrent infections due to small numbers of white blood cells (neutropenia), and short stature.

Diphosphatidyl glycerol, also called cardiolipin, is the phospholipid found only in the mitochondria. Cardiolipin, which is a phospholipid with antigenic properties, is responsible for the false-positive VDRL test.

It is an important component of the inner mitochondrial membrane, where it is essential for the following:

• Optimal function of numerous mitochondrial enzymes that are involved in mitochondrial energy metabolism.

• Maintenance of the structure of the mitochondrial membrane.

Other options-

Option A: Phosphatidylethanolamine, also called cephalin, is found in the cell membranes of nervous tissue, particularly in the brain.

Option C: Defect in the synthesis of dipalmitoyl lecithin leads to Respiratory distress syndrome (RDS), also known as hyaline membrane disease.

option D: Lysolecithin is obtained by removing one fatty acid from lecithin. Oxidized lysolecithin is associated with atherosclerosis.

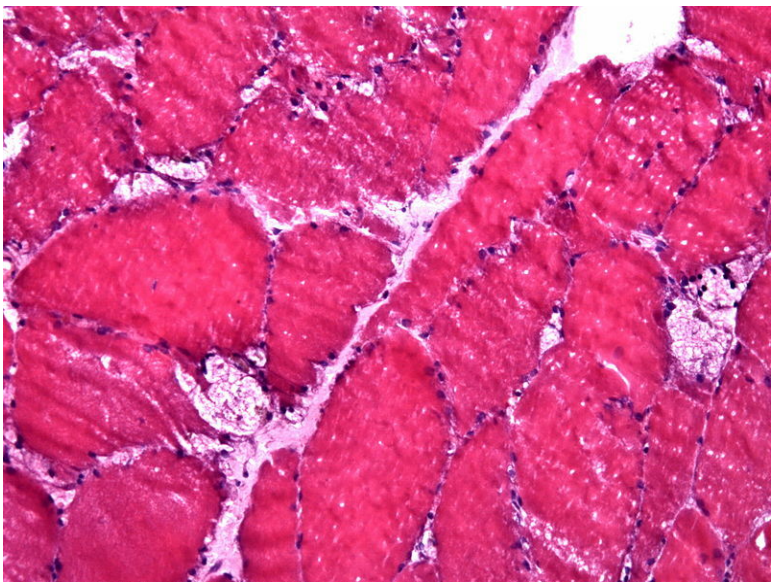
Solution to Question 6:

Pompe's disease results from a deficiency in the enzyme lysosomal alpha-glucosidase.

Pompe's disease is a type II glycogen storage disorder that results from a deficiency in the enzyme acid maltase/ lysosomal acid alpha-glucosidase. It is a rapidly progressive disorder that results in hypotonia and hepatosplenomegaly. Myocardial involvement helps to distinguish it from other similar glycogen storage disorders.

Hepatomegaly results from the ballooning of the lysosomes with glycogen. This creates a characteristic lacy cytoplasmic pattern. Cardiac and skeletal muscles will show enlargement with clear spaces in the cells, representing glycogen storage within the lysosomes. This disease classically has a poor prognosis, but enzyme replacement has helped to prolong survival in recent times.

A muscle biopsy with enlarged glycogen-containing vacuoles can be seen in the image below:



Other options:

Option A: Lactic acid dehydrogenase deficiency is not associated with any disorder.

Option B: Tarui's disease is characterized by a deficiency of muscle and erythrocyte phosphofructokinase 1. This results in abnormal glycogen metabolism and hence muscle cannot generate energy after exercise using glycogen reserves which leads to exercise intolerance.

Option C: Muscle glycogen phosphorylase deficiency is seen in McArdle's disease (type V glycogen storage disorder). Patients present with exercise-induced muscle cramping without elevated blood lactate levels which would normally be expected.

Solution to Question 7:

The thermic effect is highest in proteins.

Specific dynamic allowance (previously called the thermic effect of food): This refers to the increased heat production or increased metabolic rate following the intake of food (diet-induced

thermogenesis).

The values of SDA are

• 30% for proteins: This means that out of every 100 grams of proteins consumed, the energy available for doing useful work is 30% less than the calculated value - i.e 30% of the energy content in protein is used in its own metabolism.

• 15% for lipids, and

• 5% for carbohydrates.

Importance: It is a common experience that during hot weather following the consumption of a protein-rich meal, one feels hot and humid for a while. On the other hand, in cold weather, the same would provide a comfortable feeling.

The energy generated by the metabolism of the macronutrients is used for three energy-requiring processes that occur in the body:

• Resting metabolic rate

• Thermic effect of food (formerly termed specific dynamic action)

• Physical activity

Solution to Question 8:

Glycine is the most abundant amino acid(AA) in collagen and not phenylalanine.

Collagen is the most abundant protein in the animal world. It has a triple helical structure, forming a right-handed superhelix. A striking characteristic of collagen is the occurrence of glycine residues at every third position.

Proline and hydroxyproline confer rigidity on the collagen molecule. Hydroxyproline and hydroxylysine are formed by the post-translational hydroxylation of proline and lysine residues catalyzed by the enzyme prolyl and lysyl hydroxylase, whose cofactors are ascorbic acid (vitamin C) and α-ketoglutarate. Collagen is arranged in a quarter-staggered arrangement and further stabilized by covalent cross-links.

Solution to Question 9:

Ketone bodies are not utilized in the liver because it lacks the enzyme thiophorase.

Ketone bodies are synthesized in the liver mitochondria (by ketogenesis) and transported in the blood to the peripheral tissues. Here they are utilized by the following steps:

• β-hydroxybutyrate (the most predominant ketone body) is oxidized to acetoacetate by β-hydroxybutyrate dehydrogenase producing NADH.

• Acetoacetate is then activated to acetoacetyl CoA by transferring a CoA molecule from succinyl CoA by succinyl CoA-acetoacetyl CoA transferase (thiophorase).

• Acetoacetyl CoA is cleaved into two acetyl CoA molecules by thiolase and oxidized into CO_2 by the TCA cycle.

Thiokinase or Acyl CoA synthetase catalyzes the only energy-requiring step in fatty acid oxidation. In the presence of ATP and coenzyme A, thiokinase catalyzes the conversion of a fatty acid to acyl-CoA. Acyl-CoA is the active form of fatty acid. This step uses one high-energy phosphate and forms AMP and PPi.

When higher than normal ketone bodies are present in the blood or urine, it is called ketonemia or ketonuria, respectively. The overall condition is called ketosis. The metabolism of free fatty acids to produce ketone bodies is exaggerated in pathologic states such as starvation and diabetes mellitus, thus causing ketosis. The continued buffering and excretion of ketone bodies deplete the alkali reserve, causing ketoacidosis.

Solution to Question 10:

The alterations in DNA sequence can be detected by restriction fragment length analysis and pyrosequencing.

Restriction fragment length polymorphism (RFLP) is also called cleaved amplified polymorphic sequence (CAPS) assay. RFLP is a technique in which organisms may be differentiated by variations in their DNA sequence by restriction endonucleases. This technique involves cutting a particular region of DNA with known variability, with restriction enzymes, then separating the DNA fragments by agarose gel electrophoresis and determining the number of fragments and relative sizes.

Pyrosequencing is a synthesis type of approach of DNA sequencing. This technique employs four enzymatic reactions in a single tube to monitor DNA synthesis. Nucleotides are incorporated into the reaction and pyrophosphate (PPi) is released. PPi triggers a series of reactions resulting in the production of light, which is proportional to the amount of DNA and number of incorporated nucleotides. The generated light is detected and recorded by a detector system in the form of a peak signal, which reflects the activity of all four enzymes in the reaction.

The practical applications of recombinant DNA technology include:

• Gene mapping using techniques such as fluorescence in situ hybridization (FISH).

• Producing proteins such as:

• Interferons, tPA (tissue plasminogen activator)

• Insulin, growth hormone

• Hepatitis B vaccine

• Molecular analysis of disease, to detect gene variations and mutations.

• Restriction Fragment Length polymorphism (RFLP) and single nucleotide polymorphism (SNP)

• Microsatellite DNA polymorphisms

• Gene therapy and bone marrow transplantation

Flow cytometry is a laser-based method that analyzes the cells and cell components based on the presence of certain cell surface molecules which are named as per cluster of differentiation (CD)

nomenclature. It is very effective for the study of the immune system and its response to infectious diseases and cancer. It cannot detect the alterations in DNA sequence.

Fluorescent in situ hybridization (FISH) is a technique where cells are stained with fluorescent stains. It uses DNA probes that recognize sequences specific to particular chromosomal regions. It cannot detect the alterations in DNA sequence. FISH can be performed on prenatal samples, peripheral blood cells, touch preparations from cancer biopsies, and even fixed archival tissue sections. Uses include :

• Numerical abnormalities of chromosomes e.g., aneuploidy.

• Subtle microdeletions and rearrangements.

• Complex translocations that are not demonstrable by routine karyotyping.

• Gene amplification of HER2 in breast cancer or NMYC amplification in neuroblastomas.

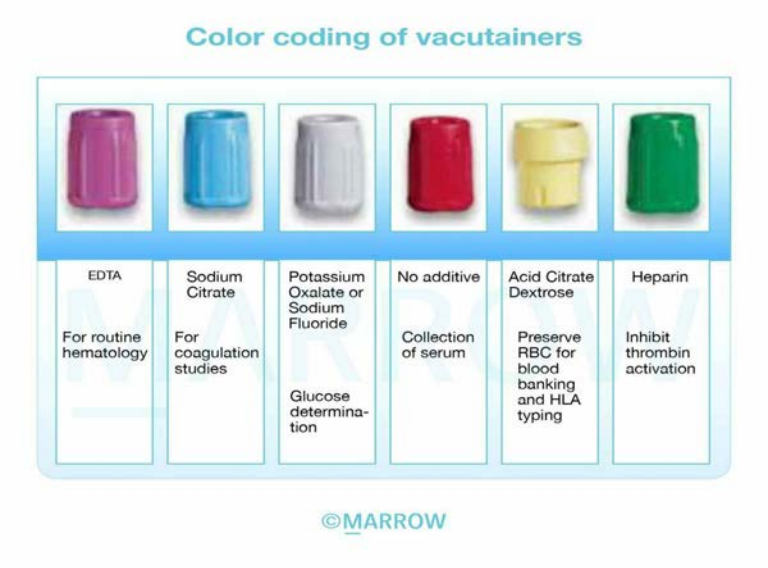
Solution to Question 11:

Light blue vacutainers contain the anticoagulant sodium citrate.

Citrated plasma generated from whole blood is commonly utilized in laboratory testing for hemostasis. The recommended procedure involves the collection of specimens in tubes that are filled with a solution containing 3.2% sodium citrate (109 mM). The appropriate ratio for this collection is 9 parts blood to 1 part anticoagulant. The primary objective of citrate is to effectively eliminate calcium ions, which play a crucial role in the process of blood coagulation.

The following image shows color coding of vacutainers with the anticoagulant used and their practical uses:

Vacutainer	Additive	Uses
Lightgrey	Sodiumfluorideand potassium oxalate	Blood glucose estimation
Light green	Lithium Heparin	Plasma testing
Light blue	SodiumCitrate	Coagulation tests (APTT and prothrombin time)

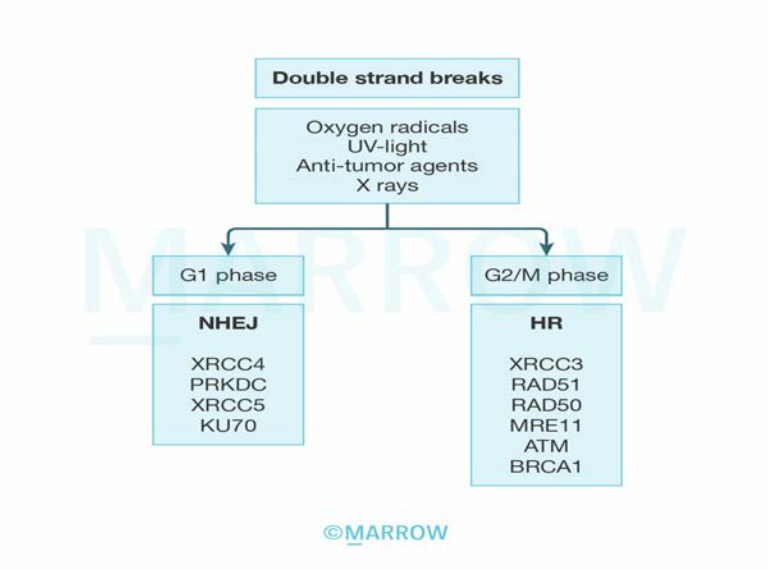


Solution to Question 12:

MSH2 is involved in mismatch repair and is not involved in the repair of double-stranded DNA breaks as the repair involves the correction of a single mismatch base pair e.g. C to A, instead of T to A.

DNA mismatch repair proteins function as spell checkers during DNA replication by correcting the incorrect pairing. In HNPCC, the proofreading function of the mismatch repair systems (majorly MLH1 and MSH2) is lost, leading to the accumulation of errors throughout the genome. The genomes of these patients show microsatellite instability, which is characterized by changes in the length of short repeats.

Double-strand breaks (DSBs) in DNA pose a significant concern. Genetic recombination events can give rise to chromosomal translocation, chromosomal breakage, and ultimately cellular demise. Double-strand breaks (DSBs) have the potential to undergo repair through two distinct mechanisms: homologous recombination and non-homologous end joining. Homologous recombination is observed in yeasts, whereas in mammals, non-homologous end joining predominates.



Non-homologous end-joining (NHEJ) is a mechanism by which a group of proteins mediates the recognition, processing, and direct ligation of the ends of two DNA fragments where a double-strand break in DNA has occurred. This is in contrast to homologous repair (HR), another mechanism, where an undamaged homologous DNA template is required to replace an adjacent damaged one.

The type of repair depends on the phase of cell cycles:

Other options:

Option A: The protein known as ataxia telangiectasia mutated (ATM) serves as a crucial kinase that triggers a wide range of cellular stress responses through its signalling activity. The activation of ATM is induced by DNA double-strand breaks (DSBs) and oxidative stress, resulting in the phosphorylation of a wide range of target proteins. Recent advancements in molecular biology have brought to light the participation of the ataxia telangiectasia mutated (ATM) protein in a range of cellular mechanisms triggered by DNA damage. These mechanisms encompass the repair of double-strand breaks (DSBs), the halting of cell cycle progression through checkpoint activation, the initiation of programmed cell death (apoptosis), and the cessation of transcriptional activity. The compromised precision of repair resulting from the combinational failure of stress responses leads to heightened sensitivity to ionizing radiation (IR) in ataxia-telangiectasia (A-T) cells.

Option B: CtIP which is a DNA repair protein involved in Homologous Repair whose function is dependent on phosphorylation at serine 327 as well as the recruitment of BRCA 1.

Option D: The Ku heterodimer, consisting of Ku70 and Ku80 subunits, plays a pivotal role in the nonhomologous end-joining (NHEJ) pathway, which is responsible for the repair of DNA double-strand breaks (DSBs). Ku protein mediates the binding of the damaged DNA fragment and orchestrates the recruitment of additional proteins to enable the subsequent processing and ligation of the broken DNA end.

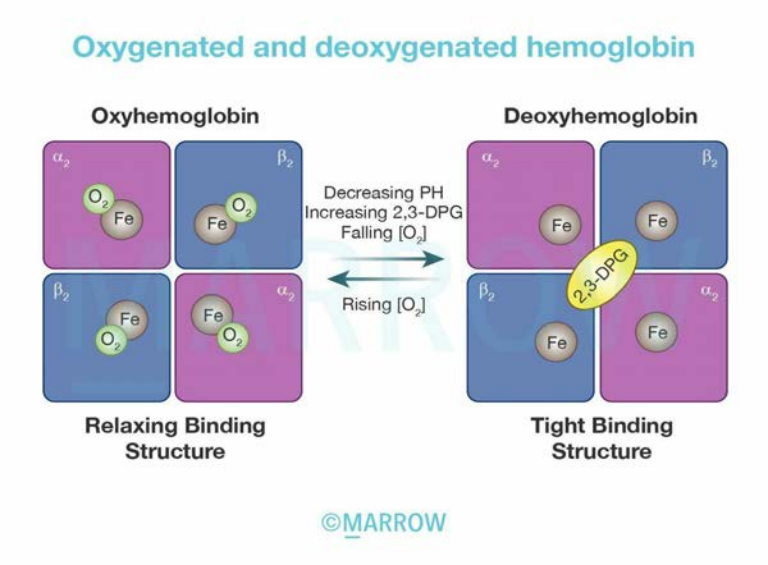
Phaseofthecellcycle	Repairmechanism
Go /G1 Phase	Nonhomologous End Joining Repair
S, G2, M Phase	Homologous Repair

Solution to Question 13:

2,3 bisphosphoglycerate binds to the globin chains of the hemoglobin while oxygen binds to the heme part of the hemoglobin.

A single unit of 2,3-BPG forms a complex with one tetrameric unit of deoxyhemoglobin within the central cavity of its four subunits. The centre pocket of this structure contains two -globin chains that are positively charged, such as histidine and lysine. Ionic bonds, also known as salt bridges, are established through the interaction between amino acids that carry a positive charge, specifically those found in globins, and phosphate groups that possess a negative charge, specifically those present in 2,3-BPG. The stabilization of deoxygenated haemoglobin (in its T-form) is achieved through the cross-linking of the α-chains by the binding of 2,3-BPG. Upon oxygenation of haemoglobin, the molecule 2,3-BPG is released from its binding site, resulting in the transformation of oxyhemoglobin into the R-form conformation.

A relaxed (R) configuration, exposes more O2 binding sites. The quaternary structure of haemoglobin determines its affinity for O2. In deoxyhemoglobin, the globin units are tightly bound in a tense (T) configuration, which reduces the affinity of the molecule for O2. When O2 is first bound, the bonds holding the globin units are released, producing a relaxed (R) configuration, which exposes more O2 binding sites. The net result is a 500-fold increase in O2. In tissues, these reactions are reversed, resulting in O2 dissociation.



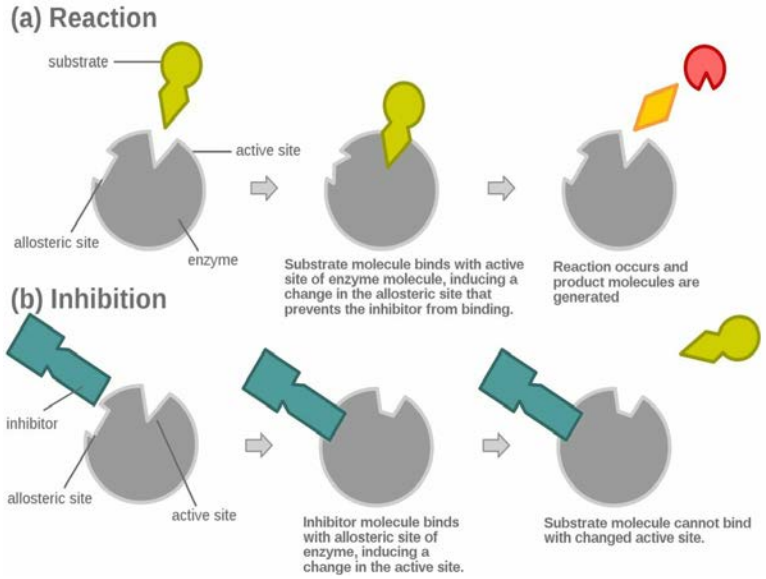
Solution to Question 14:

The substrate is complementary to the active site of the enzyme.

The Lock and Key concept was put forth by Emil Fischer. This model is the initial proposition aimed at elucidating the mechanism of an enzymatic catalytic process. Based on this concept, it can be inferred that the enzyme's structure or conformation exhibits a state of rigidity. The substrate effectively conforms to the binding site, which is now referred to as the active site, in a manner analogous to a key fitting precisely into its corresponding lock or a hand fitting snugly into a well-fitting glove. The active site of an enzyme can be described as a stiff and pre-configured template that selectively accommodates a certain substrate for binding.

The induced fit or Koshland theory states that the active site does not possess a firm and pre-determined conformation. The emerging active site exhibits the fundamental characteristics of the substrate binding site. The substrate's contact with the enzyme elicits a conformational change in the enzyme, leading to the establishment of a robust binding site for the substrate. Moreover, as a result of induced fit, the enzyme undergoes conformational changes that lead to the repositioning of the specific amino acids involved in the formation of the active site, hence facilitating the catalytic process. The induced fit model has garnered substantial empirical support through X-ray diffraction studies. Koshland's model additionally elucidates the mechanisms by which allosteric modulators and competitive inhibition exert their effects on enzymes.

The substrate strain theory states that the substrate experiences strain as a result of the conformational alteration generated by the enzyme. It is plausible that upon the binding of a substrate to the preexisting active site, the enzyme elicits a strain on the substrate. The presence of a stressed or strained substrate facilitates the generation of the desired product. The enzymatic action is believed to involve a combination of the induced fit model and substrate strain.



Other options:

Option A: The complementary active site of the enzyme binds to the substrate to form the product.

Option C: The active site of the enzyme is not complementary to the allosteric activator. Allosteric sites are separate and specific sites on the enzyme that are modulated with allosteric effect

modifiers and hence are complementary to them.

Option D: The active site of the enzyme binds to the substrate which form a transitional state which is unstable and later dissociates to form a product.

Solution to Question 15:

The microsomal cytochrome P450 system, located in the liver, facilitates the process of drug and foreign substance detoxification through hydroxylation processes that rely on the availability of NADPH.

Phase 1 reactions include oxidation, reduction, or hydrolytic reaction. CYPs- Cytochrome P family of enzymes play a major role in phase 1 reactions. Reactions carried out by phase 1 enzymes usually lead to the inactivation of a drug. The addition of functional groups does little to increase the water solubility of the drug but alters its biological properties.

The importance of NADPH is enumerated as follows:

• NADPH is needed for the reductive biosynthesis of fatty acids and steroids, hence HMP shunt is more active in lipogenesis tissues like adipose tissue and the liver.

• Along with Glutamate dehydrogenase helps in the synthesis of various amino acids.

• Maintaining reduced glutathione is critical for RBC membrane integrity. NADPH keeps haemoglobin's ferrous iron (Fe^{2+}) lowered to prevent methemoglobin (Fe^{3+}) buildup.

• High concentrations of NADPH are also required to maintain the transparency of the lens.

The cytochromes are a class of proteins that possess a conjugated heme group. The latter is comprised of a porphyrin ring containing an iron atom. The heme group present in cytochromes exhibits distinct characteristics when compared to the heme group observed in the structures of haemoglobin and myoglobin. The heme iron within cytochromes undergoes a cyclic process of oxidation (Fe^{3+}) and reduction (Fe^{2+}), playing a crucial role in facilitating electron movement throughout the electron transport chain (ETC). This stands in opposition to the heme iron found in haemoglobin and myoglobin, which remains in the ferrous (Fe^{2+}) form. The cytochromes were initially assigned the designations of a, b, and c based on the specific heme type they contained and their corresponding absorption spectra. Subsequent discoveries led to the identification of additional cytochromes, including c1, b1, b2, a3, among others.

Other options

Option A: Flavin adenine mononucleotide (FMN) is a phosphorylated form of riboflavin which functions as a cofactor for various enzymes. Some of these include as a cofactor for blue-light photoreceptors and oxidoreductases.

Option C: Flavin adenine dinucleotide (FAD) is nothing but phosphorylated riboflavin and is used in the electron transport chain and also is a cofactor for various enzymes. Some of these include oxidative phosphorylation, DNA repair, beta-oxidation of fatty acids as well as amino acid catabolism.

Option D: Nicotinamide adenine dinucleotide (NAD) consists of the vitamin B3 (niacin) and also serves as a coenzyme for various enzymatic reactions in the body. Some of these include oxidative phosphorylation (ATP production), DNA repair and intracellular calcium signalling.

Solution to Question 16:

It is the purine salvage pathway that is utilized by monoclonal antibodies in hybridoma technology.

Monoclonal antibodies refer to the antibodies produced by a group of lymphocytes that produce antibodies against a single antigen. These antibodies are produced by hybridoma technology.

In this technology, the B-lymphocytes of mice spleen are immunized with an antigen to produce a specific antibody. These specific antibody-producing B lymphocytes are then fused with myeloma cells that can multiply indefinitely.

The myeloma cells are deficient in the hypoxanthine-guanine-phosphoribosyltransferase (HGPRT) gene and do not produce immunoglobulins. Therefore, the resulting hybrid cell is producing antibodies against a single antigen indefinitely. These hybrid cells are cultured in a HAT medium (containing hypoxanthine, aminopterin, and thymidine) and the monoclonal antibodies are obtained. It is well-established that nucleotides present in DNA and RNA consist of purine and pyrimidine bases. The synthesis of these nucleotides can occur through either the De novo pathway or the salvage pathway. Consequently, the inclusion of aminopterin in the HAT medium effectively inhibits the De novo pathway, thereby rendering the synthesis of purine dependent on the salvage pathway. However, it should be noted that the salvage pathway exclusively takes place in the presence of the enzymes HGPRT and thymidine kinase. The hybridoma cell is uniquely capable of proliferating on the HAT medium due to its distinct composition. Specifically, the myeloma component of the hybridoma possesses the capacity for repetitive cellular division, while the plasma cell component contains the enzyme HGPRT. Consequently, the hybridoma cells can sustain growth and viability over an extended period when cultivated on the HAT medium.

Hybridoma technology is a method for producing large numbers of identical antibodies (monoclonal antibodies).

Hybridomas are somatic cell hybrids produced by fusing the antibody-forming spleen cells with myeloma cells. The resultant hybrid thus has both the antibody-producing ability of the B-cell and the ability to multiply indefinitely of the myeloma.

The following are the steps involved in hybridoma technology:

• Mice are immunized with an antigen.

• After several weeks of immunization, blood samples are obtained from mice for measurement of serum antibodies.

• When the antibody titer is high enough, mice are commonly boosted by injecting antigen without adjuvant, intraperitoneally or intravenously.

• Then the mice are euthanized and their spleens removed for in vitro hybridoma cell production.

• Fusing antibody-producing spleen cells, which have a limited life span, with myeloma cells (derived from an immortal tumour of lymphocytes) results in a hybridoma that is capable of unlimited growth.

• The cells are cultured in a medium containing hypoxanthine, aminopterin, and thymidine (HAT medium) which allows only the fused cells to survive in culture.

• Monoclonal antibodies are then harvested.

Applications of hybridoma technology

• Listing lymphocyte subpopulations

• Specific cell quantitative preparation

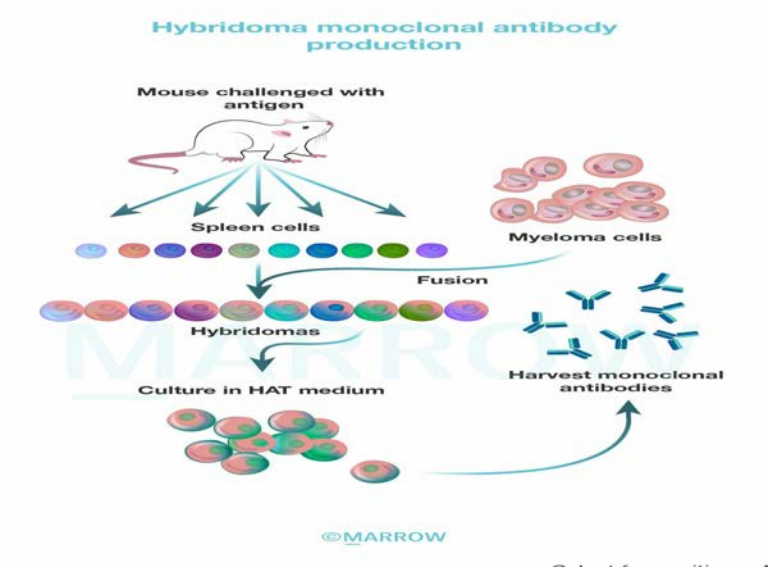
• As an immunosuppressant in therapeutic settings

• Blood component nephelometric assays

• ELISA testing

• Quantitative purification of antigens.

• Common therapeutic applications for monoclonal antibodies



Solution to Question 17:

Glycogen phosphorylase requires the presence of calcium to attain its fully activated state.

Glycogen phosphorylase is an enzyme required in glycogenolysis.

In the muscle: During muscle contraction → Ca++ is released → Ca++ binds to calmodulin forming Ca++-Calmodulin complex → activates phosphorylase kinase from b form (inactive form) without phosphorylation → significant Ca++ is required to activate glycogen phosphorylase.

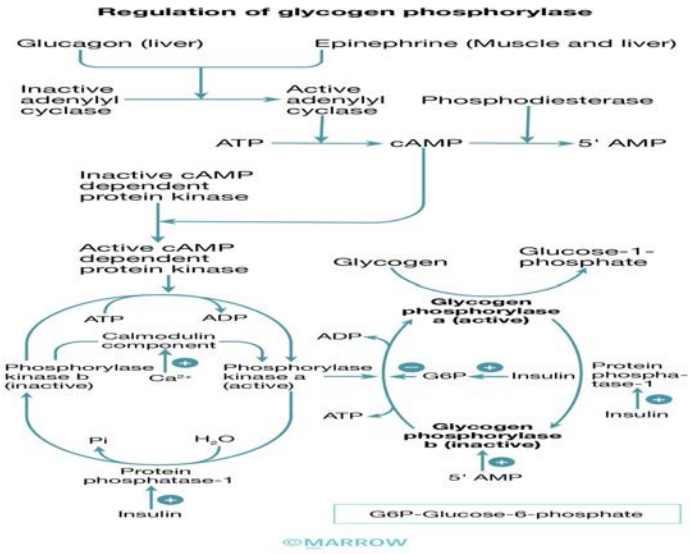
Hormonal regulation of glycogenolysis:

Glucagon (in liver) and epinephrine (in liver and muscle) acts via GPCR to activate adenylyl cyclase to catalyse synthesis of cAMP. cAMP dependent protein kinase activates phosphorylase kinase from inactive(b) to active(a) form, which in turn activates glycogen phosphorylase to active(a) form, hence leading to increased glycogenolysis. (Option D)

Option A: Insulin is a known inhibitor of glycogen phosphorylase which dephosphorylates the glycogen phosphorylase enzyme thus rendering it inactive.

Option B: Glucose 6 phosphate is also an inhibitor of glycogen phosphorylase which dephosphorylates it thus rendering it inactive.

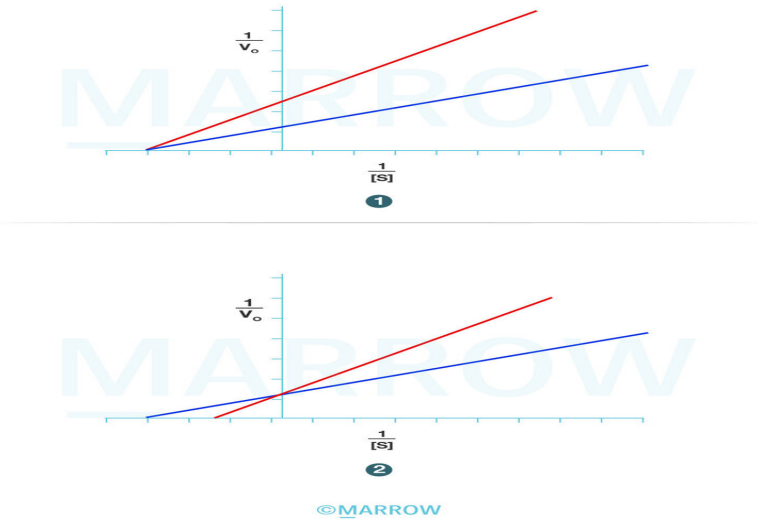
The regulation of glycogen phosphorylase is shown in the image below:



Biochemistry INI-CET 2024

Question 1:

The following Lineweaver-Burk plots depict enzymatic action in the presence of enzyme inhibitors. The enzyme action without inhibitor is represented by a blue line. What type of inhibitors are depicted in images 1 and 2?



a) 1- Uncompetitive inhibition 2- Competitive inhibition

b) 1- Noncompetitive inhibition 2- Competitive inhibition

c) 1- Competitive inhibition 2- Uncompetitive inhibition

d) 1- Competitive inhibition 2- Noncompetitive inhibition

Question 2:

FISH technique helps to identify all except?

a) Gene amplification

b) Deletion

c) Point mutation

d) Translocation

Question 3:

Which of the following micronutrients are associated with decreased sexual maturation and hypogonadism?

a) Zinc

b) Copper

c) Selenium

d) Iron

Question 4:

Which of the following is not a heme breakdown product?

a) Carbon Monoxide

b) Ferric / Fe 3+

c) ALA

d) Biliverdin

Question 5:

Which type of mutation results in the reversal to wild type of phenotype when the mutant gene is suppressed?

a) Deletion of mutated gene

b) Frameshift of mutated gene

c) Addition of another normal gene

d) Mutations in tRNA

Question 6:

Which of the following is not a post-transcriptional modification?

a) 5 prime capping

b) Methylation

c) Glycosylation

d) Endonuclease cleavage

Question 7:

Match the following conditions :

a) 1 - b, 2 -a, 3 -d, 4 -c

b) 1 -c, 2 -d, 3 -b, 4 -a

c) 1 -b, 2 -d, 3 -a, 4 -c

d) 1 -c, 2 - b, 3 -a, 4 -d

Question 8:

All are true statements regarding folate deficiency except

a) Increased levels of homocysteine and normal methylmalonic acid

b) Folate supplementation on diagnosis of pregnancy prevents neural tube defect

c) It is important to treat co-existing vitamin B12 deficiency before initiating folate therapy

d) Folate deficiency is commonly seen in children with hemolytic anemia

Question 9:

Congenital lactic acidosis is seen due to a defect in which of the following enzymes?

a) Pyruvate dehydrogenase

b) Branched chain ketoacid dehydrogenase

c) Transketolase

d) Isocitrate dehydrogenase

Question 10:

Which of the following is not associated with G6PD deficiency?

a) Equal incidence in males and females

b) Defective NADPH synthesis

c) Predisposes the patient to oxidative stress

d) Patient presents with hemolysis

Question 11:

Which of the following is not a neurotransmitter derived from aminoacids ?

a) Gamma amino butyric acid

b) Dopamine

c) 5 hydroxytryptamine

d) Creatine

Question 12:

Which of the following methods is used to test the blood taken from a neonate for metabolic disease screening?

a) Complete blood count

b) Tandem Mass Spectrometry

c) Next Generation Sequencing

d) ELISA

Question 13:

Familial hypercholesterolemia is a result of a defect in which of the following?

a) LDL receptor

b) Apo E

c) Apo CII

d) Apo B48

Question 14:

In a patient with Diabetes Mellitus, the liver produces more TG and VLDL. What is the cause of the same?

a) Decreased action of LPL with increased action of HSL

b) Decreased action of LPL with Decreased action of HSL

c) Increased action of LPL with increased action of HSL

d) Increased action of LPL with decreased action of HSL

Question 15:

Nutritional deficiency of Copper, required by lysyl oxidase which is an importent key step for formation for covalent cross linking in collagen synthesis, gives rise to which of the following condition?

a) Menke's disease

b) Scurvy

c) Ehlers Danlos syndrome

d) Scoliosis

Question 16:

Match the following with appropriate precursors

a) i-b, ii-d, iii-a, iv-c

b) i- c, ii-d, iii-a, iv-b

c) i- a, ii-d, iii-b, iv-c

d) i- b, ii-a, iii-d, iv-c

Question 17:

In the current scenario treatment for urea cycle disorder is available. Administration of amino acid phenylbutyrate can decrease ammonia formation. Which amino acid provides phenylbutyrate?

a) Arginine

b) Glutamate

c) Aspartate

d) Glycine

Question 18:

Which among the following are appropriate techniques for chromosomal aneuploidy?

a) i,ii,iii,iv

b) i,ii

c) ii,iii

d) iii,iv

Question 19:

Enzyme used in recombinant DNA technology are?

a) 1,2,3,4

b) 1,2,3

c) 2,3,4

d) 1,3,4

Answer Key

Question No.	Correct Option
1	b
2	c
3	a
4	c
5	d
6	c
7	b
8	d
9	a
10	a
11	d
12	b
13	a
14	a
15	a
16	a
17	b
18	a
19	c

Detailed Explanations

Solution to Question 1:

The Lineweaver-Burk plot in image 1 depicts non-competitive inhibition, and that in image 2 depicts competitive inhibition.

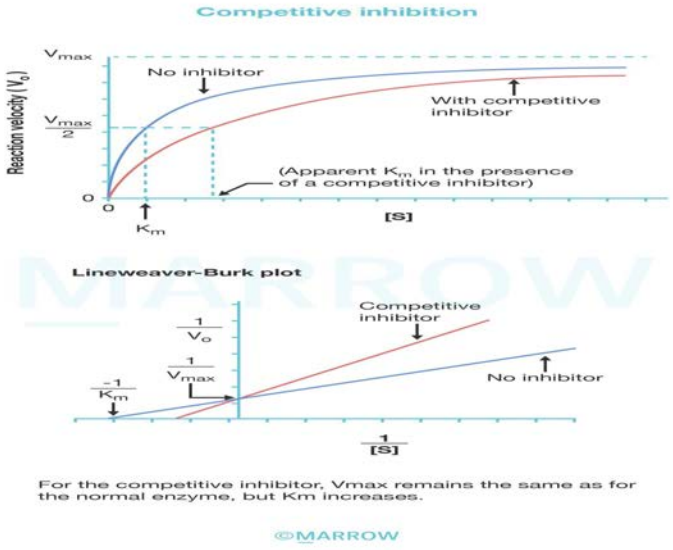
Important parameters in a reaction include:

• The affinity of the enzyme for its substrate, given by the Michaelis constant or Km. A low Km reflects a high affinity of the enzyme for substrate and vice versa. The value of Km is given by the substrate concentration at which the reaction velocity is equal to one-half Vmax. It does not change with changes in enzyme concentration.

• Vmax is the maximum velocity of a reaction.

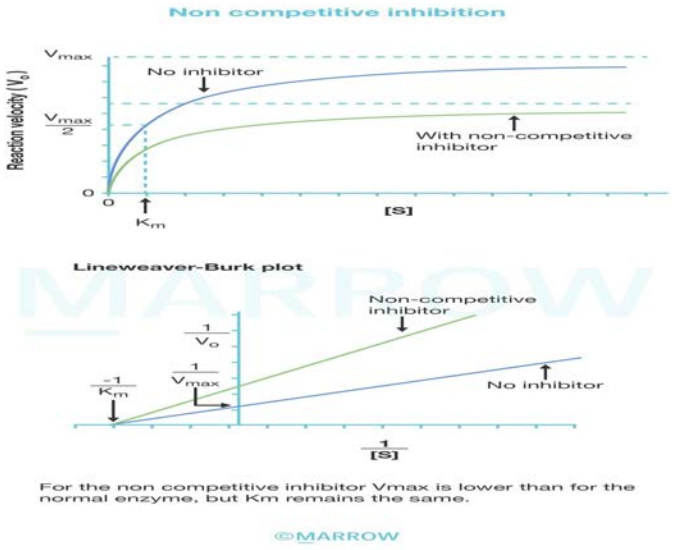
Competitive inhibition is when the inhibitor binds reversibly to the substrate-binding site and competes with the substrate for the active enzyme-binding site. This effect can be overcome by increasing the substrate concentration by which maximum velocity can still be achieved. Therefore, Vmax is unaltered in this type of inhibition. However, the concentration of the substrate required to achieve half of the maximum velocity is increased. Therefore, Km is increased in this condition.

In a Lineweaver-Burk plot, the addition of a competitive inhibitor causes plots with the same y-intercept (Vmax is unaffected) but different x-intercepts (due to increased Km).

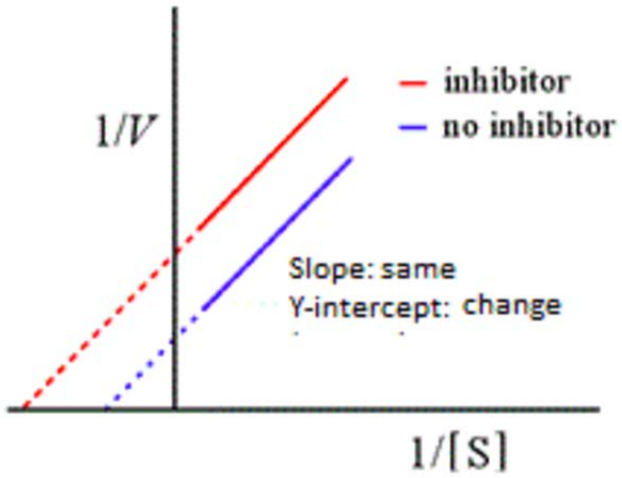


Noncompetitive inhibition is by binding of inhibitors to enzymes in locations remote from the active site. Increasing the concentration of the substrate does not overcome non-competitive inhibition. Thus, noncompetitive inhibitors decrease the Vmax of the reaction. They do not interfere with the binding of the substrate to the enzyme. Thus, the enzyme shows the same Km in the presence or absence of noncompetitive inhibitors.

In a Lineweaver-Burk plot, the addition of a non-competitive inhibitor causes plots with the same x-intercept (Km is unaffected) but different slopes and y-intercepts (due to decreased Vmax).



In uncompetitive inhibition, inhibitors bind with the enzyme-substrate intermediate complex and inhibit it. This leads to a decrease in both Vmax and Km.



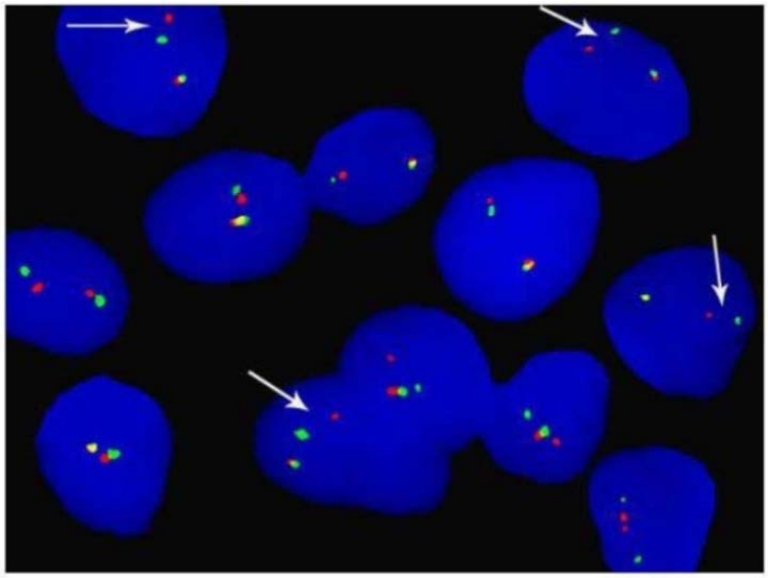
Solution to Question 2:

Fluorescent in situ hybridization (FISH) is not useful in identifying point mutation. Point mutations are identified by other means like sequencing studies and restriction fragment length polymorphism.

FISH is a method of molecular analysis of genetic lesions involving large deletions, duplications, or more complex rearrangements that are not readily amenable to detection using polymerase chain reaction or DNA sequencing approaches.

FISH uses DNA probes that recognize sequences specific to particular chromosomal regions. To perform FISH, large fragments of cloned genomic DNA spanning up to 200 kb are labeled with fluorescent dyes and applied to metaphase chromosome preparations or interphase nuclei. The probe hybridizes to its homologous genomic sequence and thus labels a specific chromosomal region that can be visualized under a fluorescent microscope.

FISH can be performed on prenatal samples, peripheral blood cells, touch preparations from cancer biopsies, and even fixed archival tissue sections. It is used to detect numeric abnormalities of chromosomes (aneuploidy), subtle microdeletions and complex translocations that are not demonstrable by routine karyotyping, and gene amplification (e.g., HER2 in breast cancer or NMYC amplification in neuroblastomas).



Solution to Question 3:

Zinc deficiency is associated with decreased sexual maturation and hypogonadism.

Zinc is the second most common trace element in the body after iron. As a component of zinc finger proteins, zinc regulates gene transcription and participates in nucleic acid metabolism, protein synthesis and thereby cell growth. Zinc is a major antioxidant being part of the enzyme superoxide dismutase.

Zinc is derived mainly from animal protein. Diets based on cereals, plants and legumes are associated with zinc deficiency due to dietary phytic acid decreasing the bioavailability of zinc.

Zinc is absorbed throughout the small intestine by a process of facilitated diffusion. Almost 90% of the total body zinc is localized in bone and skeletal muscle.

Deficiency -

• Poor physical growth is an important feature of zinc depletion in preschool and school-age children. Delayed sexual maturation and hypogonadism are prominent features of zinc deficiency in adolescents. Other features include anemia, anorexia, diarrhea, alopecia, impaired immune function and poor wound healing.

• Acrodermatitis enteropathica is an autosomal recessive disorder of severe zinc deficiency, caused by impaired intestinal absorption due to a defect in intestinal zinc transporter protein. It presents in early infancy with vesiculobullous, dry, scaly, or eczematous skin lesions chiefly in the periorificial and acral areas.

Normal requirements for children range between 3.5 and 5.0 mg/day. Acquired zinc deficiency stats can be treated with 0.5 to 1.0 mg/kg/day for several weeks. Malnourished children have much higher requirements of 2-4mg/kg/day.

Other options :

Option B - Copper deficiency results in microcytic, hypochromic anemia unresponsive to iron therapy, depigmentation of hair, neutropenia, neurological problems and osteoporosis. Disruption in copper transport is linked to Wilson's disease and Menke's disease.

Option C - Selenium deficiency is a cause of Keshan disease, a form of cardiomyopathy in young children seen in some regions of China. In combination with iodine deficiency, lack of selenium can result in myxedematous endemic cretinism.

Option D - Iron deficiency causes anemia, irritability, anorexia, pica, angular stomatitis, leg cramps and congestive heart failure.

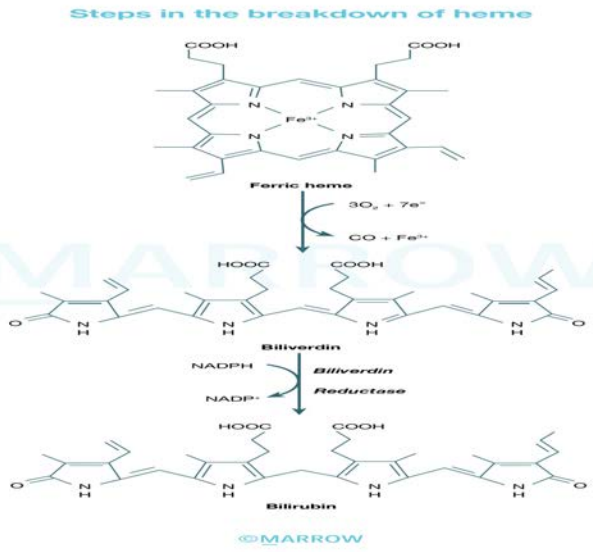
Solution to Question 4:

Aminolevulinic acid (ALA) is not a product of heme breakdown; rather it is an intermediate in the synthesis of heme molecules.

The process of heme breakdown occurs over a series of reactions. In the reticuloendothelial system of the liver, spleen and bone marrow, heme is degraded by microsomal heme oxygenase. It requires NADPH and cytochrome c. In this process, the alpha methenyl bridge of the heme molecule is liberated as carbon monoxide. The Fe+ liberated is oxidized to Fe3+++ and taken up by transferrin.

The linear tetrapyrrole formed is biliverdin (green pigment), which is further reduced to bilirubin (red-yellow pigment) by an NADPH-dependent biliverdin reductase. The bilirubin is transported in the plasma bound to albumin and is taken up by the liver, where it is conjugated with glucuronic acid to make it water-soluble, which is finally excreted in the bile.

The intestinal bacteria deconjugate the bilirubin, which is reduced to urobilinogen. It is further reduced to stercobilinogen, which is excreted through feces.



Solution to Question 5:

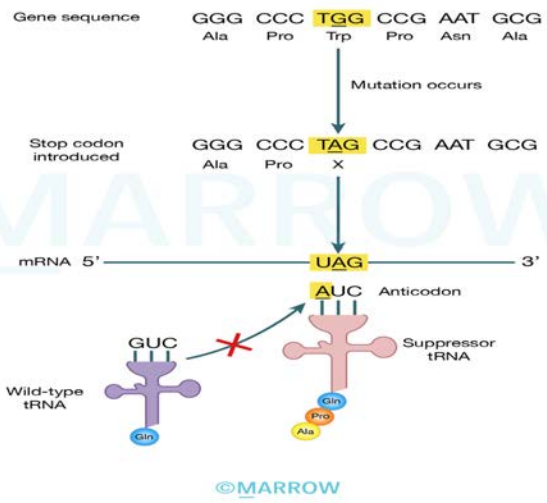
Mutations in tRNA are known to suppress the mutant gene and cause reversal to wild phenotype. Such mutations are called suppressor mutations.

Suppressor mutations are secondary mutations that alter the phenotypes caused by an existing mutation. This is not to be confused with reversion mutations in which the original mutation has been lost. Instead, suppressor mutations return the phenotype caused by the original mutation to a more wild-type phenotype despite the presence of the original mutation. The suppressor mutation's effect on the phenotype can vary from partial restoration to full restoration of the wild-type phenotype.

In prokaryotic and lower eukaryotic organisms, abnormally functioning tRNA molecules have been discovered that are themselves the results of mutations. Some of these abnormal tRNA molecules are capable of binding to and decoding altered codons, thereby suppressing the effects of mutations in the structural genes.

These suppressor tRNA molecules, usually formed as a result of alterations in their anticodon regions, are capable of suppressing certain missense mutations, nonsense mutations, and frameshift mutations. An example of suppressor mutation is illustrated below.

A primary mutation occurs changing the original codon sequence from UGG (Trp) to UAG (Stop). A secondary mutation occurs in the gene for a glutamine tRNA leading to the anticodon switch from a GUC to AUC. This mutant tRNA can recognize the UAG stop codon and insert glutamine in place of the stop, allowing translation to continue past the stop and suppressing the original mutation.



In the laboratory context, such suppressor tRNAs, coupled with mutated variants of aminoacyl-tRNA synthetases, can be utilized to incorporate unnatural amino acids into defined locations within altered genes that carry engineered nonsense mutations. The resulting labeled proteins can be used for in vivo and in vitro cross-linking and biophysical studies.

Solution to Question 6:

Glycosylation is not a post-transcriptional modification; it is a post-translational modification.

A primary transcript is the initial, linear, RNA copy of a transcription unit. The collection of all the primary transcripts synthesized in the nucleus by RNA polymerase II is known as heterogeneous nuclear RNA (hnRNA). The pre-mRNA components of hnRNA undergo extensive co- and posttranscriptional modification in the nucleus and become mature mRNA. These modifications usually include the following :

• Addition of a 5′ cap - This is the first of the processing reactions for pre-mRNA. The cap is a 7-methylguanosine attached to the 5′ terminal end of the mRNA and is resistant to most nucleases. Creation of the cap requires the removal of the γ-phosphoryl group from the 5′ triphosphate of the pre-mRNA, followed by the addition of guanosine monophosphate. Methylation of this terminal G occurs in the cytosol and is catalyzed by guanine-7-methyltransferase. Additional methylation steps may occur (options A and B).

• Addition of a 3′-poly-A tail - Most eukaryotic mRNA have a chain of 40 to 250 adenylates (adenosine monophosphates) attached to the 3′ end. This poly-A tail is added by the nuclear enzyme, polyadenylate polymerase. The poly-A tail terminates eukaryotic transcription. In addition, it helps stabilize the mRNA, facilitates its exit from the nucleus, and aids in translation.

• Splicing - Maturation of eukaryotic mRNA usually involves removal from the primary transcript of RNA sequences (introns) that do not code for protein (endonuclease cleavage). The remaining coding (expressed) sequences, the exons, are joined together to form the mature mRNA. The process of removing introns and joining exons is called splicing. The molecular complex that accomplishes these tasks is known as the spliceosome (option D).

Solution to Question 7:

The correct answer is option B: 1 -c, 2 -d, 3 -b, 4 -a

Von Gierke disease (type I glycogen storage disorder) occurs due to the deficiency of glucose-6-phosphatase enzyme in the liver, kidney, and intestinal mucosa. Patients present commonly by 3-4 months of age with hypoglycemia (leading to seizures), lactic acidosis, and hepatomegaly. Affected children often have a doll-like face with fat cheeks, relatively thin extremities, short stature, and a protuberant abdomen due to massive hepatomegaly. The kidneys are also enlarged, whereas spleen and heart are not involved. Laboratory findings include hypoglycemia, lactic acidosis, hyperuricemia, and hyperlipidemia.

Pompe's disease (type II glycogen storage disorder) occurs due to a mutation in alpha-1,4-glucosidase (also known as acid maltase), a lysosomal enzyme. A defect in this enzyme leads to the accumulation of glycogen in the lysosomes of peripheral, voluntary muscles and progresses to involve the cardiac muscle and diaphragm. Clinical features include hypotonia (floppy baby syndrome), cardiomyopathy, hepatomegaly, and failure to thrive. Myozyme can prevent worsening or can reverse cardiac and skeletal abnormalities.

Cori disease (type III glycogen storage disorder) occurs due to a deficiency of the glycogen debranching enzyme. The features of Cori disease include hypoglycemia, hepatomegaly, and hyperlipidemia but with normal blood lactate and uric acid levels. Muscle weakness and atrophy can also occur in these patients. Liver biopsy shows the accumulation of glycogen in the form of limit-dextrins (branched structures).

McArdle disease (type V glycogen storage disorder) typically presents during late childhood or in the second decade of life. The muscle glycogen phosphorylase enzyme deficiency interferes with ATP generation by glycogenolysis in the muscles. This causes muscle glycogen accumulation. Symptoms are exercise intolerance associated with muscle cramps. This leads to severe muscle damage resulting in a massive release of myoglobin in the blood.

1) Glycogen accumulation in liver and renal cells and lactic acidemia, associated with hypoglycemia	c) Von Gierk disease
2) Glycogen accumulation in lysosomes	d)Pompe disease
3) Exercise intolerance	b)McArdle disease
4) Accumulation of branched structures	a)Cori disease

Solution to Question 8:

Folate deficiency is seen in children with macrocytic anemia and not with hemolytic anemia.

Folic acid (vitamin B9) is the synthetic form of folate used in supplements and fortification of foods. Folic acid plays a key role in one-carbon metabolism, essential for the biosynthesis of several compounds. Tetrahydrofolate (THF), the reduced, coenzyme form of folate, receives one-carbon fragments from donors such as serine, glycine, and histidine and transfers them to intermediates in the synthesis of amino acids, purine nucleotides, and thymidine monophosphate (TMP), a pyrimidine nucleotide incorporated into DNA.

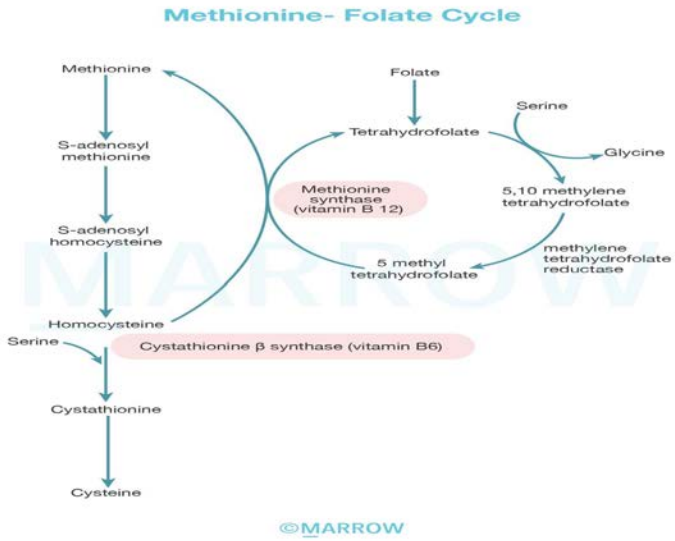
Leafy vegetables such as spinach, turnip, lettuce and fortified cereal products are rich sources.

Folate deficiency is caused by increased demand (e.g., pregnancy and lactation), poor absorption caused by pathology of the small intestine, alcoholism, or treatment with drugs (e.g., methotrexate) that are dihydrofolate reductase inhibitors. Children with hemolytic anemia have high folate requirements due to increased erythropoiesis predisposing them to deficiency (option B). Its manifestations are :

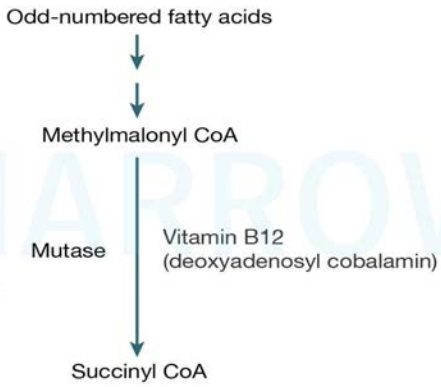
• Anemia - A primary result of folic acid deficiency is megaloblastic anemia, caused by diminished synthesis of purine nucleotides and TMP, which leads to an inability of cells to make DNA and, therefore, an inability to divide.

• Neural tube defects - Maternal deficiency of folate, during pregnancy, is implicated in neural tube defects. Periconceptional folate supplements, begun 1 month before conception and continued for 3 months after, are recommended to reduce the risk.

• Hyperhomocysteinemia - Folate, along with vitamin B12, is involved in converting homocysteine to methionine, as depicted below. Hence, folate deficiency results in increased levels of homocysteine.



However, levels of methylmalonic acid are normal. Methylmalonic acid levels are elevated in deficiency of vitamin B12, which is required as a coenzyme in the conversion of methylmalonyl CoA to succinyl CoA (option A).



Treatment: In patients with megaloblastic anemia, it is imperative to exclude and treat vitamin B12 deficiency before treating with folate. Otherwise the neurological signs of vitamin B12 deficiency may develop and progress irreversibly (option C). Deficiency is corrected using folic acid at a dose of 0.5-1mg/day orally for 3-4 weeks.

Solution to Question 9:

Congenital lactic acidosis is seen due to a defect in pyruvate dehydrogenase.

The major source of acetyl CoA for the tricarboxylic acid (TCA)cycle is the oxidative decarboxylation of pyruvate by the multienzyme pyruvate dehydrogenase complex (PDHC). The PDHC is a protein aggregate of multiple copies of three enzymes, pyruvate decarboxylase (E1), dihydrolipoyl transacetylase (E2), and dihydrolipoyl dehydrogenase (E3). Each catalyzes a part of the overall reaction.

A deficiency of the E1 component of the PDHC is the most common biochemical cause of congenital lactic acidosis. The deficiency results in a decreased ability to convert pyruvate to acetyl CoA, causing pyruvate to be shunted to lactate via lactate dehydrogenase. This creates particular problems for the brain, which relies on the TCA cycle for most of its energy and is particularly sensitive to acidosis. Symptoms include neurodegeneration, muscle spasticity, and, in the neonatal-onset form, early death. The inheritance pattern is X- linked dominant, with both males and females affected. Although there is no proven treatment for PDHC deficiency, dietary restriction of carbohydrates and supplementation with thiamine may reduce symptoms in select patients.

Other options :

Option B - Branched-chain ketoacid dehydrogenase deficiency results in maple syrup urine disease. There is defective oxidative decarboxylation of leucine, isoleucine and valine. The disease is characterized by feeding problems, ketoacidosis, changes in muscle tone, and coma.

Option C - Defective transketolase is a rare disorder of pentose phosphate metabolism with symptoms apparent in infancy including developmental delay and intellectual disability, delayed or absent speech, short stature, and congenital heart defects.

Option D - Isocitrate dehydrogenase is an enzyme of the TCA cycle which converts isocitrate to alpha-ketoglutarate. Defects in this enzyme are linked to carcinogenesis.

Solution to Question 10:

G6PD Deficiency does not have an equal incidence in males and females. It is an X-linked recessive (XLR) disorder, hence males are more affected than females.

Glucose-6-phosphate dehydrogenase (G6PD) deficiency causes congenital hemolytic anemia due to enzyme deficiency. G6PD is required to generate NADPH while oxidizing glucose-6-phosphate in the hexose monophosphate pathway (HMP). G6PD deficiency leads to reduced NADPH levels (option B) which then reduces the level of reduced glutathione. Reduced glutathione is required to protect the cells against oxidative stress to RBCs and hemolysis.

Clinically, most patients are asymptomatic. When exposed to triggers like fava beans, infections, drugs such as primaquine, chloroquine, sulfonamides/sulfones, dapsone, and nitrofurantoin patient develops:

• Episodic hemolysis, both intravascular and extravascular

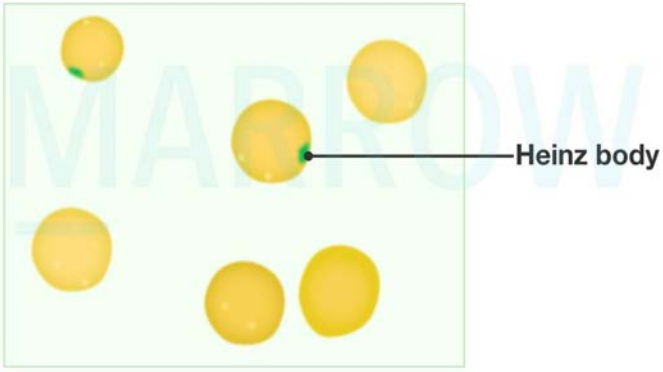
• Hemolytic anaemia

• Hemoglobinemia

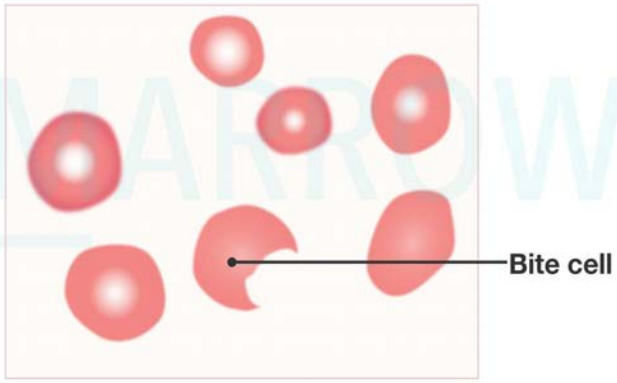
• Hemoglobinuria

Increased oxidative damage to RBCs leads to the formation of denatured precipitates known as Heinz bodies. These bodies can damage the RBC membrane leading to intravascular hemolysis. Additionally, when such RBCs pass through the splenic cords, macrophages pluck out these precipitates, giving them the characteristic appearance of bite cells.

The images below show the presence of Heinz bodies and bite cells.



©MARROW



Solution to Question 11:

Creatine is not a neurotransmitter derived from amino acids.

Creatine is an intermediate product in the process of formation of creatinine. The steps involved in the formation are as follows:

• The amidino group of arginine is transferred to glycine to form guanidoacetic acid. This step occurs in the kidneys and pancreas.

• Guanido acetic acid is methylated by S-adenosyl methionine to form creatine. This step occurs in the liver.

Creatine is phosphorylated to creatine phosphate by the enzyme creatine kinase, which is present in the muscle, brain and liver. The reaction needs hydrolysis of ATP. The stored creatine phosphate in the muscle serves as an immediate store of energy in the muscle. During muscle contraction, the energy is first derived from ATP hydrolysis. Thereafter, the ATP is regenerated by the hydrolysis of creatine phosphate. This is called the Lohmann's reaction.

The creatine phosphate may be converted to its anhydride, creatinine, which is excreted in the urine. Creatinine level in the blood is an indicator of renal function.

Other options :

Option A - Gamma amino butyric acid (GABA) functions in brain tissue as an inhibitory neurotransmitter. It is formed by decarboxylation of glutamate by L-glutamate decarboxylase.

Option B - Dopa is a precursor in the formation of the neurotransmitters dopamine, norepinephrine and epinephrine. It is formed by the hydroxylation of tyrosine by tyrosine hydroxylase.

Option C - 5 Hydroxytryptamine is an important neurotransmitter in the brain, where it functions as an antidepressant. It is derived from the amino acid tryptophan, in a process of hydroxylation followed by decarboxylation.

Solution to Question 12:

Tandem mass spectrometry is used to screen a blood sample for metabolic diseases.

Mass spectrometry is a very sensitive quantitative analytical technique used to measure a wide range of clinically relevant analytes. It identifies molecules based on their mass or molecular size. A sample is vaporized such that a positive charge is produced on the molecule. An electric field is applied so that particles move. At the same time, a magnetic field is applied, so the cations are deflected and hit on the detector. For molecules of identical charge, the time required for the molecule to reach the detector is inversely proportional to the mass of the molecule.

In tandem mass spectrometry, two mass spectrometers (MS) are arranged sequentially. The first MS separates big peptides, based on their mass. From this observation, the parent ion can be directed into the second MS. Here the ions collide with argon gas molecules and are broken into smaller ions. These daughter ions are detected and quantified by their mass spectrum in the second instrument.

Tandem MS is used to screen blood samples from newborns for the presence and concentrations of amino acids, fatty acids and other metabolites. Abnormalities in metabolite levels can serve as diagnostic indicators for a variety of genetic disorders like phenylketonuria.

Solution to Question 13:

Familial hypercholesterolemia occurs due to a defect in the LDL (low-density lipoprotein) receptor.

The primary function of LDL particles is to provide cholesterol to the peripheral tissues (or return it to the liver). They do so by binding to plasma membrane LDL receptors that recognize apo B-100.

After binding, the LDL–receptor complex is endocytosed. The pH of the endosome falls, which allows the separation of the LDL from its receptor. The receptors can be recycled, whereas the lipoprotein remnants in the vesicle are transferred to lysosomes and degraded by lysosomal acid hydrolases, releasing free cholesterol, amino acids, fatty acids, and phospholipids. These compounds can be reutilized by the cell.

Defects in the synthesis of functional LDL receptors cause a significant elevation in plasma LDL-C. Patients with such deficiencies have type IIa hyperlipidemia /familial hypercholesterolemia (FH). This autosomal dominant condition predisposes individuals to premature atherosclerosis and coronary artery disease.

Patients with homozygous FH must be treated aggressively to delay the onset and progression of CVD. Two drugs that reduce the hepatic production of VLDL and thus LDL, a small-molecule inhibitor of the microsomal TG transfer protein (MTP) and an antisense oligonucleotide to apoB, and an antibody that inhibits ANGPLT3 are approved and should be considered in patients who have insufficient response to statins and PCSK9 inhibitors. LDL apheresis should be considered in patients who have persistently elevated LDL-C levels despite drug therapy.

Other options :

Option B - Defects in apo-E lead to type III hyperlipoproteinemia / familial dysbetalipoproteinemia. It is characterized by defective clearance of chylomicron remnants and intermediate-density lipoproteins by the liver. This leads to hypercholesterolemia, xanthomas, and atherosclerosis.

Option C - Defective apo-C II results in type I hyperlipoproteinemia/ familial lipoprotein lipase deficiency. The resulting inactive lipoprotein lipase leads to slow clearance of chylomicrons and VLDL, and low levels of LDL and HDL. Patients present with eruptive xanthomas and acute pancreatitis.

Option D - Apo-B 48 is involved in the assembly of chylomicrons. Defects in this protein are not associated with familial hypercholesterolemia.

Solution to Question 14:

In a patient with Diabetes Mellitus, the liver produces more TG and VLDL, due to decreased action of LPL with increased action of HSL.

• Lipoprotein lipase (LPL): Enzyme responsible for hydrolyzing triglycerides (TG) in VLDL and chylomicrons into free fatty acids (FFAs) for storage or energy use in tissues.

• Hormone-sensitive lipase (HSL): Enzyme that breaks down stored triglycerides in adipocytes into free fatty acids and glycerol.

Insulin has an inhibitory effect on hormone-sensitive lipase (HSL). In diabetes, low insulin corresponds to an increase in HSL activity. This promotes the breakdown of lipids and a release of TG and free fatty acids from the adipose tissue.

Insulin induces the activity of lipoprotein lipase (LPL) which is present on the capillary walls. LPL promotes hydrolysis of TG and the degradation of the transport proteins, VLDL and chylomicrons. In diabetes, low insulin leads to decreased LPL activity which corresponds to an increase in VLDL and TG.

This results in increased production of triglycerides and VLDL in the liver.

Solution to Question 15:

Nutritional deficiency of copper, required by lysyl oxidase for formation for covalent cross linking in collagen synthesis, gives rise to Menke's disease.

Menke's disease is an X-linked recessive condition caused due to a mutation in the ATP7A gene on chromosome X. This causes impaired transport of dietary copper from the small intestine to the liver leading to low levels of copper-containing enzymes.

The final step of collagen synthesis involves the formation of covalent cross-links. This is done by the enzyme lysyl oxidase, a copper-containing protein. This is essential for the strength and rigidity of collagen. As a result of deficiency of copper in Menkes disease, this step of collagen synthesis is affected.

The patients presents with depigmented kinky hair, failure to thrive, neurodegenerative symptoms (loss of developmental milestones, truncal hypotonia, epilepsy), multiple fractures, anaemia due to ceruloplasmin deficiency, neutropenia, and recurrent infections.

Other Options:

Option B: Scurvy: Caused by vitamin C deficiency, leading to defective collagen synthesis due to impaired hydroxylation of proline and lysine.

Option C: Ehlers-Danlos syndrome: A group of genetic disorders affecting collagen structure or production.

Option D: Scoliosis: A structural deformity of the spine.

Solution to Question 16:

The correct matched sequence is : i-b, ii-d, iii-a, iv-c.

i. Melatonin – b. Tryptophan

Tryptophan is an essential amino acid and the precursor for the synthesis of melatonin, produced by the pineal gland. The process begins with tryptophan being converted into serotonin, and then serotonin is further converted into melatonin.

ii. Histamine – d. Histidine

Histamine is derived from the amino acid histidine. The conversion of histidine into histamine is catalyzed by the enzyme histidine decarboxylase. Histamine is involved in local immune responses, acts as a neurotransmitter, and plays a role in regulating gastric acid secretion.

iii. Norepinephrine – a. Tyrosine

Norepinephrine (noradrenaline) is synthesized from tyrosine. Tyrosine is first converted to L-DOPA by the enzyme tyrosine hydroxylase, and then L-DOPA is converted into dopamine. Finally, dopamine is hydroxylated to form norepinephrine. Norepinephrine is a neurotransmitter involved in the sympathetic nervous system's fight-or-flight response.

iv. Glutathione – c. Cystine

Glutathione is a tripeptide composed of glutamate, cystine, and glycine. The cystine component is crucial because it contains a thiol (-SH) group, which is responsible for the antioxidant properties of glutathione.

i. Melatonin	b. Tryptophan
ii. Histamine	d. Histidine
iii. Norepinephrine	a. Tyrosine
iv. Glutathione	c. Cystine

Solution to Question 17:

The amino acid that provides phenylbutyrate in the treatment of urea cycle disorders is glutamate.

Ammonia to Urea cycle: Ammonia gets converted to glutamate (non toxic form) through transamination. Glutamate is transported to the liver as glutamine (by glutamine synthase). In the liver, ammonia is released from glutamine, converting it to alpha keto glutatamte. The released ammonia enters the urea cycle.

In acetylation therapy, Phenylbutyrate (a prodrug) which is metabolized to phenylacetate. Phenylacetate combines with glutamine (a nitrogen-rich amino acid) to form phenylacetylglutamine. Phenylacetylglutamine is water-soluble and is excreted in the urine. This process helps trap excess nitrogen, bypassing the urea cycle.

Other drugs that can be used to achieve the same outcome (ammonia scavengers) include:

• Phenylacetate

• Benzoate

Other Options:

Option A and C: Arginine and Aspartate do not play a role in this specific reaction.

Option D: Glycine: The combination of benzoate and glycine forms hippuric acid, a non-toxic compound. When Benzoate is administered to the body, it acts as a nitrogen-scavenging agent. Hippuric acid is water-soluble and is excreted in the urine, effectively removing one nitrogen molecule from the body per molecule of hippuric acid formed. This mechanism is similar to how phenylacetate acts as a scavenger for glutamate.

Solution to Question 18:

In situ hybridization, Conventional cytogenetics, Sanger sequencing and Polymerase chain reaction are appropriate techniques for chromosomal aneuploidy.

Techniques to detect aneuploidy:

• In situ hybridization: Fluorescent In Situ Hybridisation (FISH) helps in the detection of specific genetic information using fluorescent probes. FISH is used to detect chromosomal aneuploidy, subtle microdeletions and rearrangements, complex translocations, and gene amplification.

• Conventional cytogenetics: This technique involves the study of chromosomes under a microscope, typically using methods like karyotyping, which arranges chromosomes by size, shape, and number. The analysis allows the identification of large chromosomal abnormalities, such as aneuploidy or structural changes.

• Sanger sequencing: DNA sequencing that uses chain-termination to identify the exact sequence of nucleotides in a DNA molecule. Simple Senger sequencing can detect aneuploidy only with massive parallel sequencing.

• Polymerase chain reaction: Polymerase chain reaction (PCR) is a rapid automated method for the amplification of specific DNA sequences (or genes). It can accurately quantify the target nucleic acid sequence within a sample. It is useful for determining somatic mutation with low allele frequency. Quantitative Fluorescence (QF) PCR is a method of rapid aneuploidy detection. It

is less expensive and allows simultaneous processing of large number of samples of FISH.

• Array Comparitive Genomic Hybridization: microarray based technique which can reveal imbalances across the genome.

• Multiplex Ligation Probe Amplification: to detect gene dosage.

Solution to Question 19:

Phosphatase, Terminal transferase and Crispr Cas9 are used in recombinant DNA technology.

Recombinant DNA technology is a technique where DNA from different sources is combined to create new genetic material. Applications of recombinant DNA technology include producing insulin, growth hormones, vaccines, gene therapy, and studying gene functions and disease mechanisms.

Phosphatase dephosphorylates 5′ ends of RNA and DNA. It is primarily used for the removal of phosphate groups pror to kinase labelling and it is also used to prevent self ligation.

Terminal transferase catalyzes the addition of nucleotides to the 3' terminus of a DNA molecule. It is used in homopolymer tailing.

CRISPR-Cas9 acts as an RNA-directed nuclease. It is a DNA editing/gene regulatory system. It involves two essential components: Cas9, an endonuclease that causes a double-stranded DNA break, allowing modifications to the genomic DNA to be made; and a synthetic single-guide RNA, or sgRNA, responsible for guiding Cas9 to its target.

Isomerase is a class of enzymes that catalyze the structural rearrangement of molecules, converting one isomer into another. Isomerase is not commonly used directly in recombinant DNA technology, it has broader applications. They are used in metabolic pathways and as biocatalysts in industrial processes.

Biochemistry NEET 2024

Question 1:

A patient underwent gastrectomy for gastric adenocarcinoma. Which of the following vitamins needs to be supplemented in this patient?

a) Vitamin B12

b) Vitamin B1

c) Vitamin A

d) Vitamin D

Question 2:

A 10-year-old child from a southern Indian state, hailing from a poor family, presents with rough and scaly skin. The child's diet lacks vegetables and fruits. After treatment with linseed oil, Vitamin A, and Vitamin B, the symptoms subsided. What is the most likely diagnosis?

a) Lichen planus

b) Erythroderma

c) Phrynoderma

d) Keratosis pilaris

Question 3:

A patient presents to the emergency department with severe abdominal pain, nausea, and vomiting. The laboratory results show serum triglyceride levels > 2000 mg/dl. Which deficiency could be contributing to the patient's condition?

a) Apolipoprotein C II

b) Apolipoprotein B48

c) Apolipoprotein B100

d) Apolipoprotein A I

Question 4:

After the age of 12, the boy had an intellectual disability. On examination, fingernail abrasions, excessive biting of lips, and increased levels of serum uric acid were observed. What is the likely diagnosis?

a) Hurler syndrome

b) Lesch-Nyhan disease

c) Hunter syndrome

d) Von Gierke syndrome

Question 5:

A neonate was brought with features of lethargy, and poor oral intake. On examination, a cataract was seen. Urine Benedict's test was positive but negative for Glucose. What will be the enzyme deficiency in this condition?

a) Hexokinase

b) Galactokinase

c) Galactose-1-phosphate uridyl transferase

d) Phosphofructokinase

Question 6:

A patient diagnosed with a rare homozygous recessive condition presented with ectopia lentis. In the peripheral smear, there was no megaloblastic anemia. Later, he was found to have elevated homocysteine levels in the blood. Which of the following supplementations will help the patient?

a) Thiamine

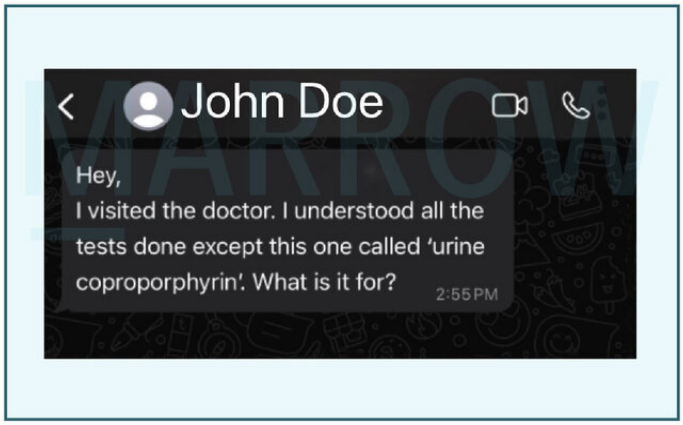
b) Pyridoxine

c) Biotin

d) Riboflavin

Question 7:

You received a text message from your friend JOHN DOE about occupational exposure after he visited his doctor as shown below. What is the test used to diagnose?



©MARROW

a) Anthracosis

b) Lead poisoning

c) Silicosis

d) Asbestosis

Question 8:

A 3-year-old child is brought to the OPD with complaints of persistent delayed developmental milestones, and hyperpigmented macular lesions on the body which are more pronounced on exposure to sunlight. What is the error in DNA multiplication?

a) Base excision repair

b) Nucleotide excision repair

c) DNA mismatch repair

d) Homologous recombination

Question 9:

A patient with a family history of coronary heart disease presented with tendon xanthomas. His lipid profile showed serum LDL to be 280 mg/dL and triglyceride levels was 398 mg/dl. What is the likely defect in this patient?

a) LDL receptor defect

b) LDL metabolism

c) VLDL metabolism

d) Lipoprotein lipase deficiency

Question 10:

Which food item among these is the primary source of thiamine in Indians?

a) 1

b) 2

c) 3

d) 4

Question 11:

A young female comes to the emergency department after ingesting 10 tablets of Phenobarbital. Which of the following components of the ETC is inhibited by this drug?

a) Succinate - Fe

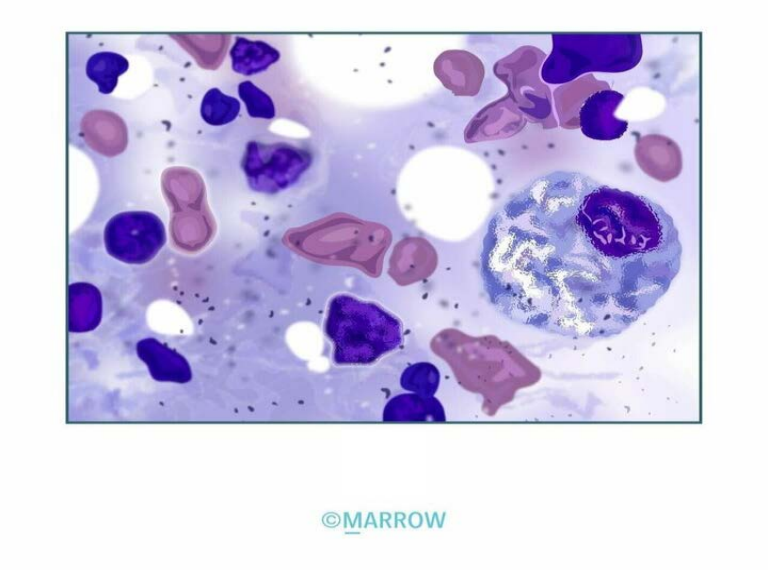
b) Cytochrome I-II

c) Complex I to Q

d) Complex IV

Question 12:

A child presents to you with bone pain, hepatosplenomegaly, and pancytopenia. A trephine biopsy aspirate shows the following finding. Which of the following is the most likely enzyme deficient in this patient?



a) Galactocerebosidase

b) Glucocerebrosidase

c) Sphingomyelinase

d) Alpha 1,4-glucosidase

Question 13:

A 32-year-old lady comes with complaints of erythematous scaly rash, loose stools, and cognitive dysfunction. The rash involved her forearm, neck, and face. She seems to have difficulty remembering things from the recent past. Her electrolytes are within normal range. She admits to having shifted to a corn-based diet due to economic reasons. Which of the following would improve her symptoms?

a) Oral Nicotinamide supplementation

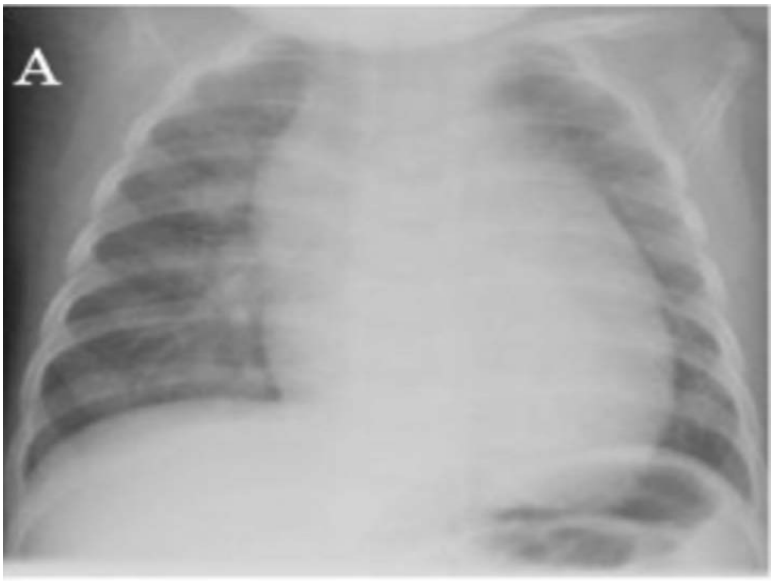
b) High dose of IV thiamine

c) High Dose Vitamin C

d) Stop corn diet

Question 14:

A 3-month-old child was brought to the clinic with a history of difficulty in feeding and failure to thrive. On examination, the child is floppy, 48 cm in length and weighs 2.8 kg. There is generalized hypotonia, macroglossia and hepatomegaly. The chest x-ray of the child is given below. What is the most likely diagnosis?



a) Ebstein's anomaly

b) Pompe's disease

c) Transposition of great arteries

d) Von- Gierke's disease

Question 15:

A patient presented with multiple yellowish raised plaques on eyelids, xanthomas on the achilles tendon. What is the likely cause for the patient's presentation?

a) Familial hypercholesterolemia

b) Tangier's disease

c) Xanthomatosis

d) Fabry's disease

Question 16:

A child presented to the OPD with complaints of fatigue and muscle weakness while exercising. Laboratory investigations found that LCFA oxidation was affected. A muscle biopsy was done which revealed the presence of fat vacuoles. What is the probable diagnosis?

a) LDL defect

b) LPL defect

c) Fatty acid synthase defect

d) Carnitine deficiency

Question 17:

A mother came back home to see her child suffering from difficulty breathing. The child had contact with rotenone while trying to bathe their pet. The child was taken to the emergency department and she later passed away. Inhibition of which of the following enzymes was the likely cause of her death?

a) Cytochrome c reductase

b) Succinate dehydrogenase

c) NADH-Q oxidoreductase

d) Cytochrome oxidase

Question 18:

A child suffering from phenylketonuria was started on necessary dietary modifications but the neurological symptoms persisted. Phenylalanine hydroxylase levels in the serum are normal. Which of the following enzymes is likely to be deficient in this case?

a) Tyrosine hydroxylase

b) Homogentisate oxidase

c) Tetrahydrobiopterin synthase

d) Dopa decarboxylase

Question 19:

Which micronutrient is most likely deficient in a patient with the radiographic findings given below along with anemia, neutropenia, depigmented hair and skin?

a) Iron

b) Zinc

c) Copper

d) Fluoride

Question 20:

A child presented with recurrent abdominal pain, vomiting, and diarrhea following ingestion of milk-based products. Which enzyme is likely to be deficient?

a) Lipase

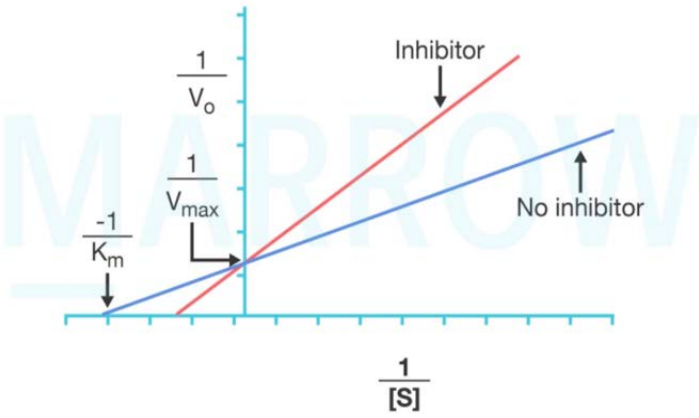
b) Maltase

c) Amylase

d) Lactase

Question 21:

In the given Lineweaver-Burk plot, the blue line represents the action of an enzyme, and the red line represents the action of the same enzyme in the presence of an inhibitor. What is the type of inhibition shown here?



©MARROW

a) Competitive inhibition

b) Non-competitive inhibition

c) Uncompetitive inhibition

d) Allosteric inhibition

Answer Key

Question No.	Correct Option
1	a

21	a

Detailed Explanations

Solution to Question 1:

A patient who has undergone gastrectomy for gastric adenocarcinoma needs to be supplemented with vitamin B12.

Vitamin B12 absorption is a complex process that relies on several factors. Intrinsic factor, a glycoprotein secreted by the parietal cells in the stomach, is essential for this process. Gastric acid and pepsin release vitamin B12 from dietary proteins, allowing it to bind with cobalophilin in the saliva. In the jejunum, cobalophilin is broken down, freeing vitamin B12 to bind with intrinsic factor. This complex is then absorbed in the distal ileum through specific receptors. Following gastrectomy, the production of intrinsic factor is impaired due to the removal of gastric tissue, making vitamin B12 absorption difficult. Therefore, vitamin B12 supplementation is necessary after gastrectomy to prevent deficiency.

Other complications of gastrectomy include:

• Nutritional deficiencies- Iron deficiency anemia (most common), Vitamin B12 deficiency, and osteoporosis

• Dumping syndrome: early and late

• Diarrhea

• Duodenal stump leak/blow out

• Bile reflux gastritis and esophagitis

• Gall stones

• Roux syndrome

Solution to Question 2:

The cutaneous lesions with rough and scaly skin, with dietary history stating lack of vegetables and fruits is suggestive of phrynoderma.

Phrynoderma are keratotic follicular papules commonly present over the elbows and knees. They can also extend to the shoulders, neck, back, thighs, buttocks, and abdomen. It is also known

as toad skin, due to the rough cone-shaped elevated papules. It can caused by deficiency of vitamins A, B complex, C, and E and essential fatty acids.

When it occurs due to vitamin A deficiency, it is associated with ophthalmic symptoms like xerophthalmia, night blindness, and Bitot's spots and cutaneous symptoms like xerosis, scaling, and acne.

Management includes nutritional improvement through diet, multivitamin supplementation, and treatment of the underlying cause.

Note: Linseed oil is rich in alpha-linolenic acid, which is an essential fatty acid.

The toad skin appearance of a child with phrynoderma is given below:

Other options:

Option A: Lichen planus is a papulosquamous lesion presenting as pruritic, purple, polygonal, planar, papules and plaques. These papules are often highlighted by white dots or lines called Wickham striae, which are created by areas of hypergranulosis. The characteristic lesions in lichen planus are shown below:

Option B: Erythroderma is a serious skin condition characterized by widespread redness (erythema) and scaling affecting more than 90% of the body's surface area. It is also known as exfoliative dermatitis and often results from underlying skin disorders, systemic diseases, or drug reactions.

Option D: Keratosis pilaris is an inherited abnormality of keratinization. It affects the follicular orifices leading to keratotic follicular plugging, perifollicular erythema, and follicular atrophy. It usually occurs during puberty. They present as small, keratotic papules on the extensor aspects of the limbs, particularly the arms which can lead to ingrowing of the hair. Treatment is purely reserved for cosmetic purposes.

Solution to Question 3:

The elevated triglyceride levels and symptoms of acute pancreatitis are likely related to a deficiency in apolipoprotein C II.

Apolipoprotein C2 is a lipoprotein lipase cofactor that catalyzes cleavage of chylomicrons. Defective apo C II results in type I hyperlipoproteinemia/ familial lipoprotein lipase deficiency. The resulting inactive lipoprotein lipase leads to slow clearance of chylomicrons and VLDL, and low levels of LDL and HDL. Patients present with eruptive xanthomas and acute pancreatitis.

Lipoprotein lipase is an extracellular enzyme that is present in the capillary walls of most tissues. It is chiefly synthesized by the adipose tissue, and cardiac and skeletal muscles. A deficiency of lipoprotein lipase or apo C-II leads to type 1 hyperlipoproteinemia or familial chylomicronemia which leads to an increased risk of acute pancreatitis.

Other options:

Option B: Apo B48 is involved in the assembly of chylomicrons. Defects in this protein are not associated with familial hypercholesterolemia.

Option C: Apo B100 binds low-density lipoprotein receptors. For the uptake of LDL, apo B100 acts as a ligand for the low-density lipoprotein receptor.

Option D: Apo A1 activates lecithin cholesterol acyltransferase (LCAT). LCAT is the enzyme present in HDL, which is activated by apo A1. LCAT converts free cholesterol (amphipathic) in HDL to cholesterol ester(hydrophobic). The initial discoidal shape now becomes spherical. This facilitates reverse cholesterol transport.

Solution to Question 4:

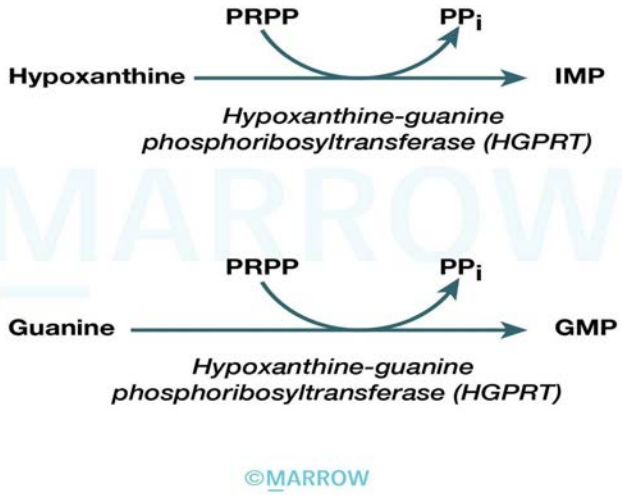
The above clinical scenario with findings showing self-mutilation and laboratory values of hyperuricemia is most likely suggestive of Lesch-Nyhan disease.

Lesch-Nyhan syndrome is an X-linked recessive disorder due to a complete deficiency of the hypoxanthine-guanine phosphoribosyltransferase (HGPRT). This deficiency results in an inability to salvage hypoxanthine or guanine leading to increased levels of phospho-ribosyl pyrophosphate (PRPP). Increased PRPP leads to increased purine synthesis, which is later degraded to uric acid. Increased hypoxanthine is also converted to uric acid.

The patients have intellectual disability, behaviors of self-injury like lip and finger biting, developmental delay, muscle dystonia, and extrapyramidal symptoms.

Diagnosis is made by the elevated levels of uric acid and by HGPRT enzyme assay.

The image given below shows the metabolism of hypoxanthine and guanine by HGPRT.



Orange diaper syndrome can be an early indicator of Lesch-Nyhan syndrome. At birth, individuals with Lesch-Nyhan syndrome typically appear asymptomatic, with normal prenatal growth and development. The condition is often first detected through the presence of orange-coloured crystals in the diaper, resulting from hyperuricemia. Since hyperuricemia is a common feature across all variants of HGPRT deficiency, which causes Lesch-Nyhan syndrome, predicting associated neurodevelopmental abnormalities requires enzyme activity testing.

Solution to Question 5:

The given clinical scenario of a neonate presenting with lethargy, and poor oral intake, with examination revealing a cataract and urine benedict's test was positive but negative for glucose, is suggestive of classical galactosemia and enzyme deficient is galactose-1-phosphate uridyl transferase.

Galactose-1-phosphate uridyl transferase deficiency leads to classical galactosemia. It is an autosomal recessive disorder. Normally, newborns receive up to 40% of their intake as lactose (glucose + galactose). The deficiency of this enzyme leads to an inability to convert galactose-1-phosphate to uridine diphosphate galactose. This leads to the accumulation of galactose 1-phosphate and causes injury to the kidney, liver, and brain.

Clinical features:

• Accumulation of galactose-1-phosphate in the liver causes liver damage & leads to hepatomegaly, vomiting, and convulsions.

• Accumulation of galactose-1-phosphate depletes the liver of inorganic phosphate leading to diminished ATP synthesis which affects gluconeogenesis resulting in hypoglycemia.

• Accumulation of galactose-1-phosphate in the nerves causes intellectual disability.

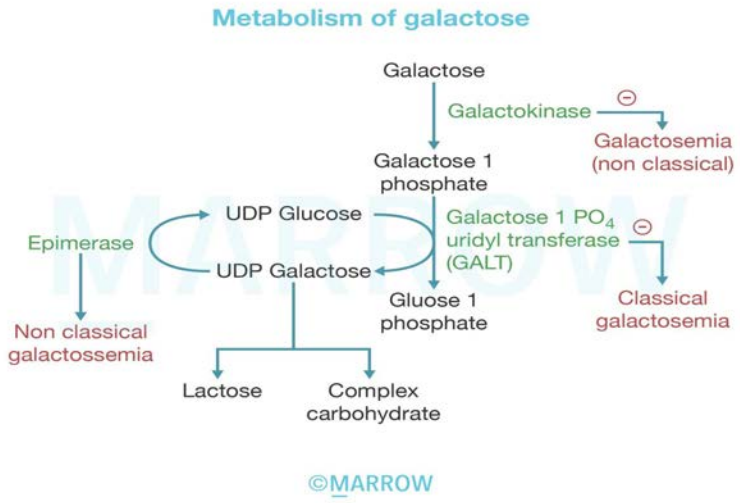
• Accumulation of galactitol in the lens causes oil-drop cataracts.

• Patients with galactosemia are at an increased risk of developing Escherichia coli neonatal sepsis.

In uridyl transferase deficiency, the epimerase is present in adequate amounts, so that the galactosemic individual can still form UDPGal from glucose. This explains how normal growth and development of affected children can occur despite the galactose-free diets.

Urinary reducing sugar (Benedict's test) and mucic acid test are positive. Direct enzyme assay using erythrocytes establishes the diagnosis.

Treatment is a galactose-free diet.



Other options:

Option A: Hexokinase is a glycolytic enzyme, involved in maintaining intracellular glucose concentration by catalysing the first step in glucose metabolism, i.e., phosphorylation of intracellular glucose. Its deficiency leads to hemolytic anaemia. Splenomegaly may be another presenting feature.

Option B: Galactokinase is the enzyme responsible for the conversion of galactose to galactose 1-phosphate. Only cataract is seen in the deficiency of this enzyme because galactose-1-phosphate is not formed. Hence no toxic effects of this compound are manifested.

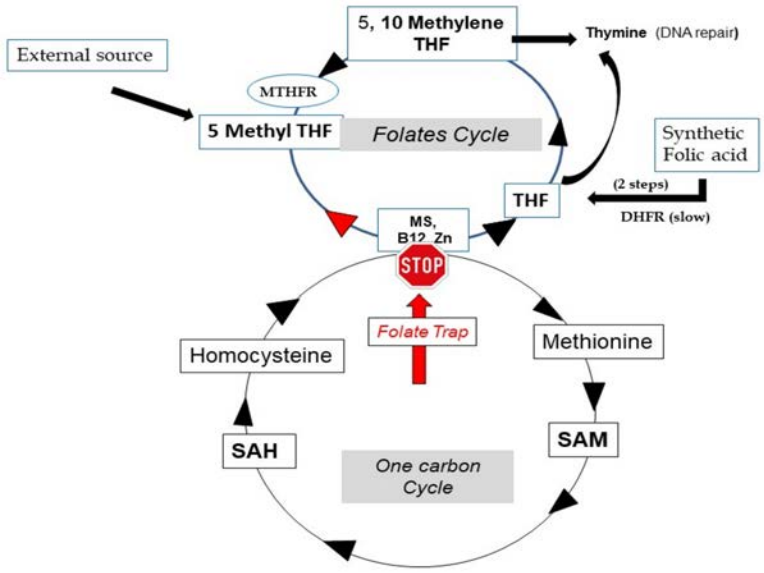
Option D: Phosphofructokinase is a key regulatory enzyme of glycolysis and is necessary for the ATP-dependent conversion of fructose-6-phosphate to fructose-1,6-diphosphate. Tauri's disease is type VII glycogen storage disorder that results due to the deficiency of phosphofructokinase.

Solution to Question 6:

The vitamin that can be used as supplementation in this patient with homocystinuria is pyridoxine (vitamin B6).

Classical homocystinuria is an autosomal recessive disease most commonly caused by a deficiency of the cystathionine β-synthase. The deficiency of this enzyme leads to an accumulation of homocysteine in the blood and a clinical syndrome of intellectual disability, subluxated ocular lenses, long and slender extremities, arachnodactyly, and arterial and venous thrombi. The skeletal features of homocystinuria often mimic Marfan syndrome. Folic acid and vitamin B12

deficiency can also lead to homocystinuria with megaloblastic anemia.



Demonstration of elevated total homocysteine in the blood confirms the diagnosis. 50% of the cases of homocystinuria are termed pyridoxine-responsive because large doses of pyridoxine can enhance the activity of deficient enzymes in these patients. Administration of large doses of pyridoxine (vitamin B6) restores the activity of the deficient enzyme in half of all cases of homocystinuria.

Folate supplementation is also added to overcome any folate deficiency that might occur due to increased conversion of homocysteine to methionine. For the other 50% of the patients, the treatment consists of methionine restriction and cysteine supplementation. In addition, betaine (methyl group donor), folate and vitamin B12 may be added.

Solution to Question 7:

The test for coproporphyrinogen levels is used as a screening test to diagnose lead poisoning.

Lead inhibits the enzymes delta-aminolevulinic acid (ALA) dehydratase and ferrochelatase, which are involved in heme synthesis. ALA is converted to porphobilinogen by ALA dehydratase, inhibited by lead. So, serum porphobilinogen levels are decreased in lead poisoning.

Laboratory findings include the following:

• An elevated serum lead level

• An elevated level of protoporphyrin in blood and elevated ALA and coproporphyrinogen in urine

• Microcytic anemia with basophilic stippling in peripheral smear due to ineffective heme synthesis

Clinical features of chronic lead poisoning include facial pallor, anemia, basophilic stippling of red cells, blue lines in the gums, and retinal stippling. In the later phase, the findings are colic abdominal pain, constipation, nerve palsy, encephalopathy, and disturbance of the genito-urinary and cardiovascular systems.

Diagnosis of lead poisoning:

Laboratory parameter	Value	Remarks
Coproporphyrin in urine	>150 mcg/L	Screening test- indicates exposure
Aminolevulinic acid (ALA) in urine	>5 mg/L	Indicates lead absorption
Lead in blood	>70 mcg/dL	Clinical symptoms appear
Lead in urine	0.8 mg/L	Indicates lead absorption
Basophilic stippling of RBCs		Sensitive indicator

Solution to Question 8:

The history points to a diagnosis of xeroderma pigmentosum. It is characterized by defective nucleotide excision repair.

UV radiation leads to pyrimidine dimerization in DNA strands, preventing further replication by DNA polymerase. The nucleotide excision repair mechanism corrects the dimer formation in DNA. Xeroderma pigmentosum (XP) is an autosomal recessive genetic disorder characterized by an inability to repair DNA pyrimidine dimers caused by UV exposure. This leads to clinical and cellular hypersensitivity to ultraviolet (UV) radiation.

In XP the skin is normal at birth and has a three-stage progression:

• Diffuse erythema, scaling, and freckle-like areas over the sun-exposed regions of the body at around 6 months of age.

• The second stage is characterized by poikiloderma. This results in skin atrophy, telangiectasias with mottled hyperpigmentation, and hyperpigmentation.

• In the third stage appearance of cutaneous malignancies like squamous cell carcinomas, malignant melanoma, basal cell carcinoma, and fibrosarcoma.

Most of the cases with XP have ocular manifestations. Initially, it appears as photophobia, conjunctivitis, ectropion, and symblepharon with ulceration. Accumulation of pyrimidine dimer causes corneal opacification and neovascularization. Ocular malignancies are common in the lids, conjunctiva, and cornea as they are exposed to as much as facial skin. XP is ultimately fatal, and early detection of the skin lesions and their management with prevention of UV ray exposures prolong life.

Solution to Question 9:

The clinical presentation with tendon xanthomas, elevated serum LDL and elevated serum triglycerides points to a diagnosis of familial hypercholesterolemia and is due to a defect in LDL

receptors.

Familial hypercholesterolemia (type IIa hyperlipoproteinemia) is an inherited disorder due to defects in LDL receptors. This defect causes a decrease in the uptake of LDL and cholesterol. As a result, the blood levels of both LDL and cholesterol are elevated. Such patients are at increased risk of developing atherosclerosis and coronary artery disease.

Features of FH:

• Painful polyarthritis and tendinitis are common.

• Physical findings seen are corneal arcus and tendon xanthomas over the Achilles tendon and the dorsum of the hands. Xanthomas are tumorous masses produced by foamy cell clusters (lipid-laden macrophages) found in the connective tissue of the skin and in tendons.

Diagnosis is done clinically based on hypercholesterolemia with

• LDL > 190 mg/dl,

• Family history of hypercholesterolemia and/or

• Premature coronary artery disease.

Treatment includes lifestyle changes, restriction of a fatty diet, and pharmacotherapy with statins in heterozygous FH patients.

Recent drugs for specific treatment of homozygous FH are:

• Lomitapide, a microsomal triglyceride transfer protein (MTP) inhibitor, and

• Mipomersen, an antisense oligonucleotide against apoB.

The image below shows Achilles tendon xanthoma and a plain lateral radiograph of both ankles showing bilateral symmetrical swellings (arrows) superior to the calcaneum respectively.

Note: Lipoprotein lipase (LPL) deficiency causes type I hyperlipoproteinemia due to defects in LPL or apo C-II. Eruptive xanthomas are seen. Chylomicrons and VLDL are elevated. LDL and HDL are low. There is no risk for coronary disease.

Solution to Question 10:

Among the various food items given on the plate, the primary source of thiamine (vitamin B1) in the Indian diet is option 4 i.e. chapati and rice.

The thiamine content in various foods in decreasing order are as follows:

• Gingelly seeds

• Groundnut

• Bengal gram

• Whole wheat

• Rice

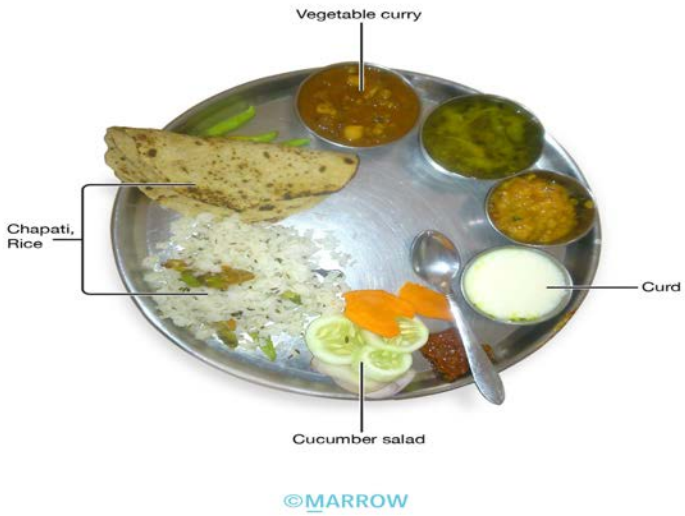
Gingelly (sesame) seeds have the highest content of thiamine.

Thiamine is lost from rice during the process of milling. As it is a water-soluble vitamin, washing, and cooking rice cause further losses. Hence, it is advisable to avoid highly polished rice and eat parboiled or under-milled rice.

Thiamine is essential for energy metabolism, particularly in carbohydrate processing. Its active form, thiamine diphosphate, acts as a coenzyme for three critical enzyme complexes: pyruvate dehydrogenase, α-ketoglutarate dehydrogenase, and branched-chain keto acid dehydrogenase. This coenzyme facilitates oxidative decarboxylation by forming a reactive carbanion that attaches to carbonyl groups like those in pyruvate, leading to the release of CO_2. Thiamine diphosphate is also vital for transketolase in the pentose phosphate pathway.

Thiamine triphosphate, another form of thiamin, helps regulate nerve function by activating chloride channels in nerve membranes.

A thiamine deficiency can cause several conditions such as beriberi, characterized by peripheral neuritis, which can also involve heart failure and edema. Additionally, thiamine deficiency can lead to Wernicke's encephalopathy and Korsakoff's psychosis, commonly associated with alcohol or drug abuse. The lack of thiamine impairs the conversion of pyruvate to acetyl-CoA, leading to increased levels of lactate and pyruvate in the blood, which can result in dangerous lactic acidosis, especially in those consuming high-carbohydrate diets.



Solution to Question 11:

Phenobarbital is a barbiturate that inhibits complex I to Q of the electron transport chain.

Complex I of the electron transport chain is NADH-Q oxidoreductase. It oxidizes NADH and reduces coenzyme Q. Phenobarbital inhibits complex I to Q so that the electrons will not be able to be transferred from NADH to coenzyme Q, which is the first step in the electron transport chain. As a result, the rate of oxygen consumption will decrease.

The electron transport chain (ETC) represents the final pathway through which electrons, originating from the oxidation of carbohydrates, fatty acids, and amino acids, are channeled toward a final reaction with oxygen to produce water and ATP. The ETC complexes are embedded in the inner mitochondrial membrane.

The oxidation of compounds by ETC complexes leads to the release of free energy. This is used to pump H+ to the intermembrane space. This results in the formation of a proton motive force that is used for the phosphorylation of ADP to ATP. Thus, oxidation is coupled with phosphorylation to generate ATP. NADH generates 2.5 ATP and FADH2 generates 1.5 ATP.

The table below summarizes the inhibitors of the electron transport chain.

Complexes of ETC	Inhibitors
Complex I:NADH-Q oxidoreductase	Piericidin A,phenobarbital, rotenone
Complex II:Succinate-Q reductase	TTFA (thenoyltrifluoroacetone), carboxin, malonate
Complex III:Q- Cyt c oxidoreductase	BAL (British anti-lewisite), antimycin A
Complex IV:Cyt c oxidase	Hydrogen sulfide, carbon monoxide, cyanide
Complex V:ATP Synthase	Atractyloside, oligomycin

Solution to Question 12:

The given clinical scenario of a child with bone pain, hepatosplenomegaly, and trephine biopsy showing Gaucher's cell with a characteristic crumpled tissue paper appearance is suggestive of Gaucher's disease. The deficient enzyme is glucocerebrosidase (also known as beta-glucosidase).

Gaucher's disease is an inborn error of metabolism caused due to a deficiency of beta-glucocerebrosidase. It is the most common lysosomal storage disorder and the mode of inheritance is autosomal recessive. There is an accumulation of lipid-laden macrophages in the spleen, liver, and other tissues.

There are three clinical subtypes - type I (chronic non-neuronopathic), type II (acute neuronopathic), and type III (intermediate). Clinical features include anemia, thrombocytopenia, hepatosplenomegaly, and neurological features depending on the subtype.

Gaucher's cells are formed as a result of the accumulation of massive amounts of glucocerebrosides within the phagocytes. The cells have a fibrillary cytoplasm and give a crumpled tissue paper appearance.

Solution to Question 13:

The given clinical features suggests the diagnosis of pellagra, due to her corn-based diet. Oral nicotinamide supplements can improve her symtpoms.

Niacin can be synthesized in the body from tryptophan. Two compounds, nicotinic acid and nicotinamide, have the biological activity of niacin. The nicotinamide ring of the coenzymes nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP) participate in oxidation/reduction reactions.

The initial symptoms of pellagra include loss of appetite, generalized weakness, irritability, abdominal pain, and vomiting. This is followed by bright red glossitis and a characteristic pigmented, scaly skin rash in sun-exposed areas. This rash is known as Casal’s necklace when it forms a ring around the neck.

The 4Ds of pellagra:

• Diarrhea

• Dermatitis

• Dementia, leading to

• Death

It is diagnosed by measuring urinary levels of 2-methyl nicotinamide and 2-pyridone.

Other options:

Option B: Thiamine (Vitamin B1) deficiency leads to conditions like beriberi and Wernicke-Korsakoff syndrome, which are characterized by symptoms such as muscle weakness, peripheral neuropathy, cardiovascular issues, and confusion. While cognitive dysfunction can result from thiamine deficiency, rash and loose stools do not fit with thiamine deficiency. Therefore, thiamine would not address the full spectrum of this patient's symptoms.

Option C: Vitamin C deficiency causes scurvy, which is associated with symptoms like bleeding gums, bruising, joint pain, and fatigue. Scurvy is not associated with a rash like the one described, nor does it typically cause cognitive dysfunction or diarrhea. Hence, high-dose vitamin C would not improve this patient's symptoms.

Option D: Corn-based diets are low in niacin and tryptophan, leading to pellagra over time, especially if the diet is not balanced with other niacin-rich foods. While stopping the corn-based diet could prevent further niacin deficiency, it will not immediately address the existing deficiency and symptoms like rash, diarrhea, and cognitive dysfunction. The patient would still need niacin supplementation to resolve the current symptoms.

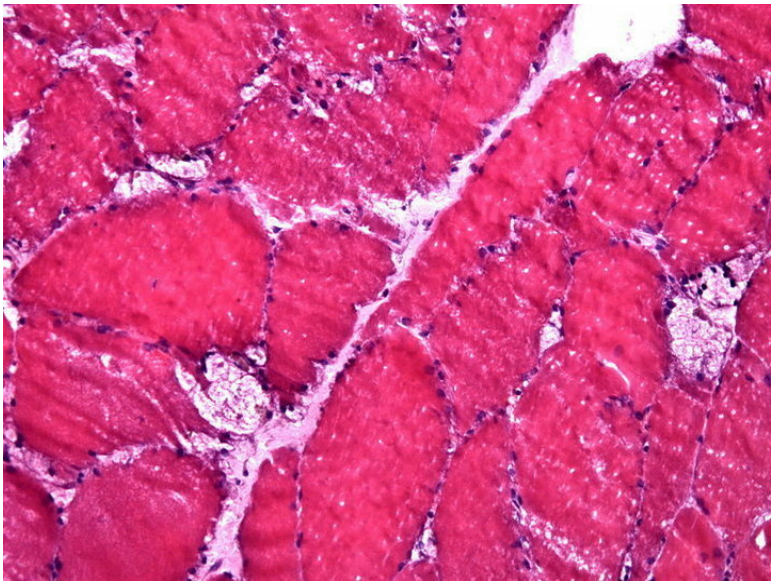
Solution to Question 14:

The child with a clinical history of difficulty feeding and failure to thrive with generalised hypotonia, macroglossia, hepatomegaly and chest x-ray findings of massive cardiomegaly suggest a diagnosis of Pompe's disease.

Pompe's disease is a glycogen storage disorder(type II) caused by a deficiency of lysosomal acid maltase (alpha-glucosidase) which leads to the accumulation of glycogen in the lysosomes of the liver (hepatomegaly), skeletal muscles in the form of large vacuoles (hypotonia and weakness), cardiac muscles (hypertrophic cardiomyopathy). The child generally dies by the age of 2 years due to cardiac failure. The adult form presents with muscle dystrophies.

Laboratory findings show elevated levels of serum creatine kinase (CK), aspartate transaminase (AST), alanine transaminase (ALT), and lactate dehydrogenase (LDH). Urine glucose tetrasaccharide, a glycogen breakdown metabolite, is a reliable biomarker for disease severity and treatment response. Treatment includes enzyme replacement therapy with recombinant enzyme a-glucosidase alfa (Myozyme).

Given below is the image of muscle biopsy showing glycogen-positive vacuoles.



Other options:

Option A- Ebstein's anomaly is the teratogenic effect of maternal lithium consumption which causes a cyanotic heart disease in the newborn with atrialization of the right ventricle and conduction defects. The chest X-ray will show a box-shaped enlargement of the right atrium and pulmonary oligemia.

Option C- Transposition of great vessels is cyanotic congenital heart disease where there is a switch in the position of two main arteries i.e. pulmonary artery and aorta. X-ray shows of egg-on-string appearance with pulmonary plethora.

Option D- Von Gierke disease occurs due to a deficiency of glucose-6-phosphatase. Patients present commonly in 3-4 months of age with hypoglycemia, lactic acidosis, hepatomegaly, growth retardation, hyperuricemia, and hyperlipidemia.

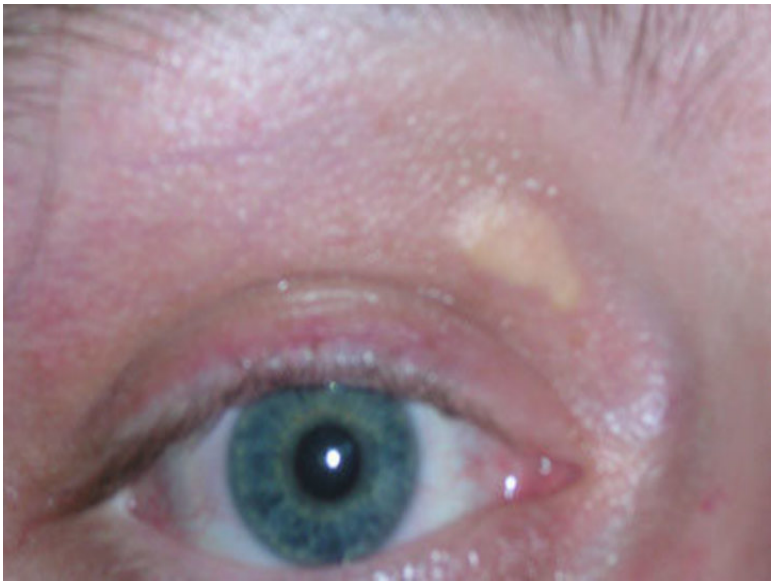
Solution to Question 15:

The clinical presentation with yellowish, raised plaques on eyelids, and tendon xanthomas points to a diagnosis of familial hypercholesterolemia (FH).

Familial hypercholesterolemia (type IIa hyperlipoproteinemia) is an inherited disorder due to defects in LDL receptors and Apo B100. This decreases the uptake of Low-density lipoprotein and cholesterol leading to their increased levels in the blood. The increased LDL accumulates in the blood vessels causing atherosclerosis (premature coronary artery disease)and in the Achilles tendon causing tendon xanthomas. Xanthomas are tumorous masses produced by foamy cell clusters (lipid-laden macrophages) found in the connective tissue of the skin and tendons. Patients can also have yellowish plaques around the eyes (Xanthelasma) and corneal arcus.

Treatment includes lifestyle changes, restriction of a fatty diet, and pharmacotherapy with statins in heterozygous FH patients.

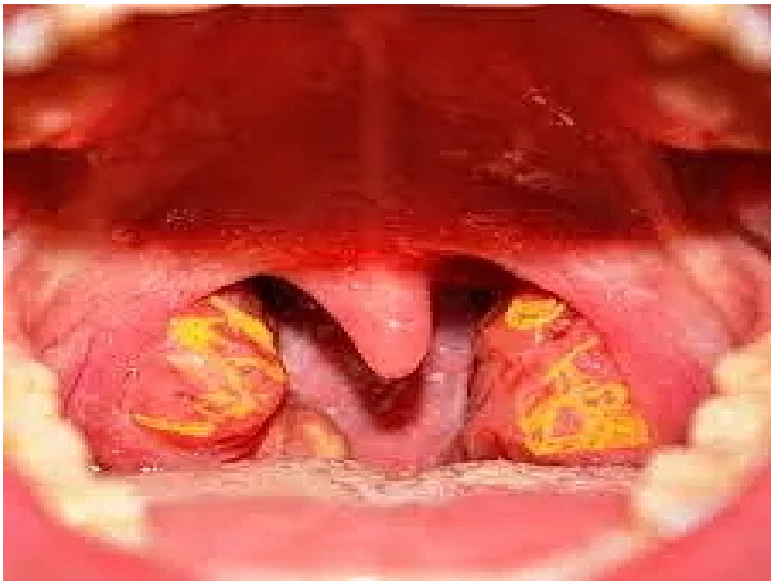
The images below show Achilles tendon xanthoma and xanthelasma respectively:



Other options:

Option B: Tangier's disease is a hypolipoproteinemia caused by a mutation of the ABCA1 gene. Enlarged orange tonsils are pathognomonic. Low HDL levels are seen. There is an increased risk for atherosclerosis.

The image below shows enlarged yellow-orange coloured tonsils in Tangier's disease.



Option C: Xanthomatosis is the deposition of lipids in various parts of the body like tendon xanthomas, xanthelasma, eruptive and tuberous xanthomas. This is a sign of underlying lipid metabolism disorders.

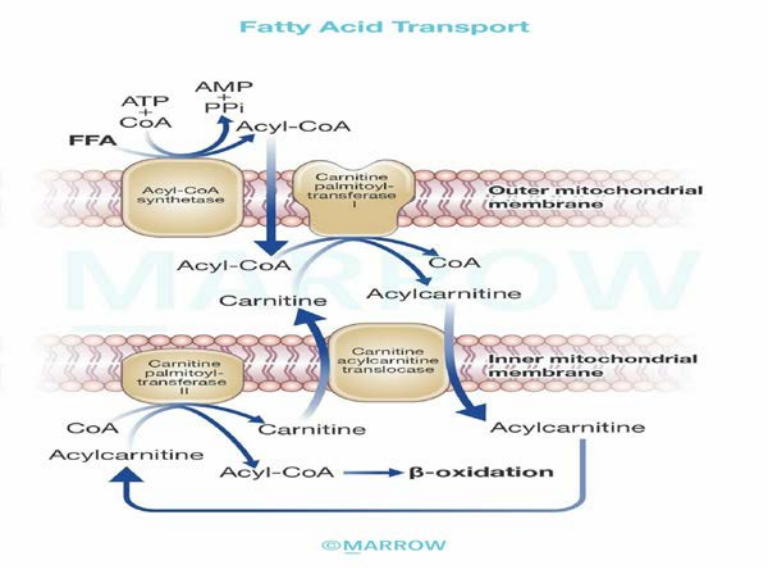
Option D: Fabry's disease is a lysosomal storage disorder with a defect in alpha-galactosidase. It causes angiokeratomas, hypohidrosis and characteristic Maltese cross deposits in urine.

Solution to Question 16:

The clinical scenario of a child with fatigue and muscle weakness on exercise with laboratory findings of LCFA oxidation deficiency and fat vacuoles on muscle biopsy suggests a diagnosis of carnitine deficiency.

Carnitine deficiency is a defect in fatty acid oxidation that leads to hypoketotic hypoglycemia and hyperammonemia. Carnitine transports activated LCFA (long chain fatty acyl CoA) from the cytoplasm to the mitochondria for beta-oxidation (as they cannot cross the mitochondrial membrane), carnitine deficiency impairs this transport causing accumulation of lipids (skeletal muscle weakness). This excess fatty acid inhibits the urea cycle causing hyperammonemia. Since beta-oxidation cannot occur, energy production is reduced, and there is hypoglycemia without a corresponding increase in ketone bodies (hypoketotic) during times of glucose depletion such as exercise.

The role of carnitine in the metabolism of fatty acids is demonstrated in the image below:



Clinical features of carnitine deficiency begin in childhood and include poor feeding, lethargy, liver dysfunction and hepatomegaly, hypotonia, and dilated cardiomyopathy. Treatment involves oral supplementation of carnitine.

Other options:

Option A: An increase in LDL can cause hyperlipoproteinemia, and reduced LDL can cause defective absorption of fat-soluble vitamins.

Option B: LPL is involved in hydrolysis of lipoproteins in the blood to free fatty acid and glycerol which are then taken up by the tissues. A defective LPL can cause type 1 familial chylomicronemia syndrome presenting as pancreatitis.

Option C: Fatty acid synthase is a multienzyme complex involved in fatty acid synthesis in the cytosol which when defective may impair energy production, essential fatty acids, and affect metabolic pathways. There is no accumulation of fat vacuoles since fatty acids are not synthesised.

Solution to Question 17:

In the given clinical vignette, inhibition of NADH-Q oxidoreductase by rotenone was the likely cause of breathlessness, followed by death in this child.

Rotenone inhibits complex I, thereby inhibiting the respiratory chain, so electrons cannot be transferred to oxygen. This halts ATP production, leading to an energy deficit in the cells, eventually causing cell death. The ETC constitutes four enzyme complexes:

• Complex I: NADH-Q oxidoreductase

• Complex II: Succinate-Q reductase

• Complex III: Q-cytochrome c oxidoreductase

• Complex IV: cytochrome c oxidase

Components of complex I are FMN and Fe-S complex. NADH-Q oxidoreductase catalyses the transfer of electrons from NADH to coenzyme Q, along with the transfer of four H+ across the membrane.

Solution to Question 18:

This child with phenylketonuria with neurological symptoms not improving despite dietary modifications and normal serum phenylalanine hydroxylase level is suggestive of tetrahydrobiopterin (BH4) synthase deficiency.

A diet low in phenylalanine (eg: tapioca) is the mainstay of treatment for classic phenylketonuria but may not be sufficient in BH4 deficiency where supplementation with BH4 and deficient neurotransmitter precursors (L-dopa) is required to overcome the block.

Phenylketonuria (PKU) is an inborn error of metabolism seen due to a defect in the enzyme phenylalanine hydroxylase (classic phenylketonuria) and less commonly, due to a defect in BH4 synthase (non-classical). These defects result in the impaired conversion of phenylalanine to tyrosine. The patient develops clinical features due to elevated levels of phenylalanine metabolites and decreased levels of tyrosine. The excess phenylalanine in the blood is metabolized to phenylpyruvate (positive ferric chloride) and phenylacetate (mousy odour) which are excreted in the urine. Infants appear normal at birth and gradually develop symptoms of hyperreflexia, seizures, hypopigmentation, low IQ, hyperactivity, and tremors.

Tandem mass spectroscopy is the investigation of choice. Guthrie test is a screening test that shows with absence of growth of Bacillus subtilis. The ferric chloride test is positive with the development of a transient blue-green colour.

Other options -

Option A: Tyrosine hydroxylase is the rate-limiting enzyme in the synthesis of epinephrine, converts tyrosine to DOPA, its deficiency does not cause phenylketonuria

Option B: Homogentisic acid oxidase converts homogentisic acid to maleylacetoacetic acid in the tyrosine degradation pathway and its deficiency causes alkaptonuria with a dark colour of urine on standing, bluish-black pigmentation in connective tissue (ochronosis) and arthritis.

Option D: Dopa decarboxylase is another enzyme involved in the synthesis of epinephrine. It converts DOPA to dopamine in the presence of vitamin B6. While enzymes involved in epinephrine synthesis cause neurological dysfunction, they do not cause phenylketonuria as such.

Solution to Question 19:

The given clinical features of anaemia and neutropenia, along with depigmented hair and skin and the radiological findings suggestive of pelkan spurs, trummerfeld zone, Frenkel's line, and Wimberger's ring sign point to the diagnosis of Menke's disease. Patients with this condition have low serum levels of copper.

Menke's disease or Menke-Kinky hair syndrome is an X-linked recessive condition caused due to a mutation in the ATP7A gene on chromosome X. This causes impaired transport of dietary copper

from the small intestine to the liver leading to low levels of copper-containing enzymes.

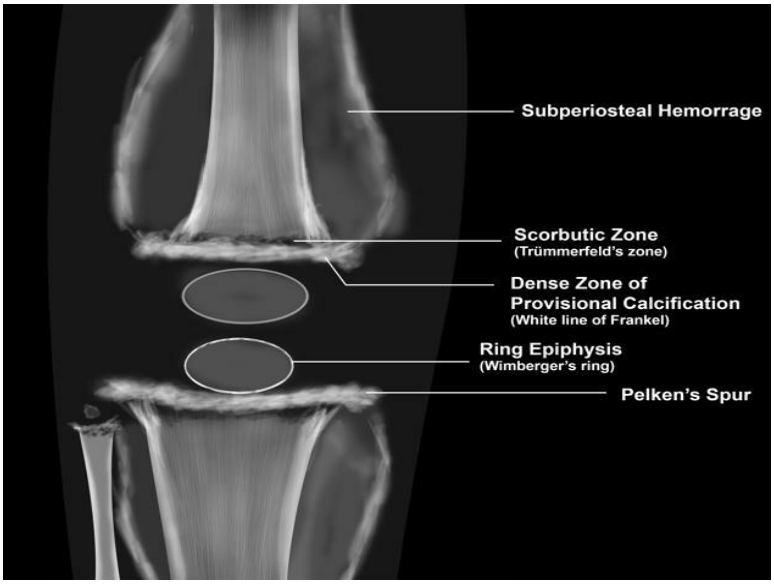
The final step of collagen synthesis involves the formation of covalent cross-links. This is done by the enzyme lysyl oxidase, a copper-containing protein. This is essential for the strength and rigidity of collagen. As a result of deficiency of copper in Menkes disease, this step of collagen synthesis is affected.

The patient presents with depigmented kinky hair, failure to thrive, neurodegenerative symptoms (loss of developmental milestones, truncal hypotonia, epilepsy), multiple fractures, anaemia due to ceruloplasmin and hephaestin deficiency (converts ferrous to ferric to be bound to transferrin), neutropenia, and recurrent infections.

Lab investigations show low serum copper (<65 µg/dL) and low ceruloplasmin(<20 mg/dl). The disease is fatal and has no curative treatment.

A variety of distinct anomalies that are representative of scurvy and acquired copper insufficiency can be seen on radiographs of people with menke's disease.

These include



Early administration of L-histidine and copper chloride injections may be beneficial.

Other options:

Option A: Iron deficiency causes iron deficiency anemia, and hair loss (telogen effluvium. It does not cause neutropenia, depigmentation of hair and skin, or bony abnormalities.

Option B: Zinc deficiency causes acrodermatitis enteropathica characterized by periorificial dermatitis, diarrhea, and alopecia.

Option D: Fluoride is essential for bone and teeth mineralization and its deficiency causes decreased bone-mineral density, osteoporosis, and tooth decay.

Solution to Question 20:

The given scenario indicates intolerance of milk-based products in this child, hence, the enzyme likely to be deficient is lactase.

Lactase is the enzyme that is responsible for breaking down lactose, a disaccharide found in milk and dairy products. When this enzyme is deficient, it can lead to the accumulation of lactose in the intestinal lumen where it is fermented by intestinal bacteria to lactate which produces symptoms of lactose intolerance, including recurrent abdominal pain, vomiting, and diarrhea after consuming lactose-rich food items. Lactase and maltase are present in the intestinal brush border.

Other options:

Option A- Lipases are involved in the hydrolysis of dietary triglycerides to free fatty acids and glycerol. It is deficient in exocrine pancreatic deficiency states such as chronic pancreatitis, cystic fibrosis, and Crohn's. Although it might also present with abdominal pain and diarrhea, the stools are foul-smelling(due to gut bacteria) and greasy due to the presence of fat (steatorrhea) and are also associated with fat-soluble vitamin deficiency.

Option B- Maltase breaks down maltose which is a disaccharide intermediate of starch breakdown.

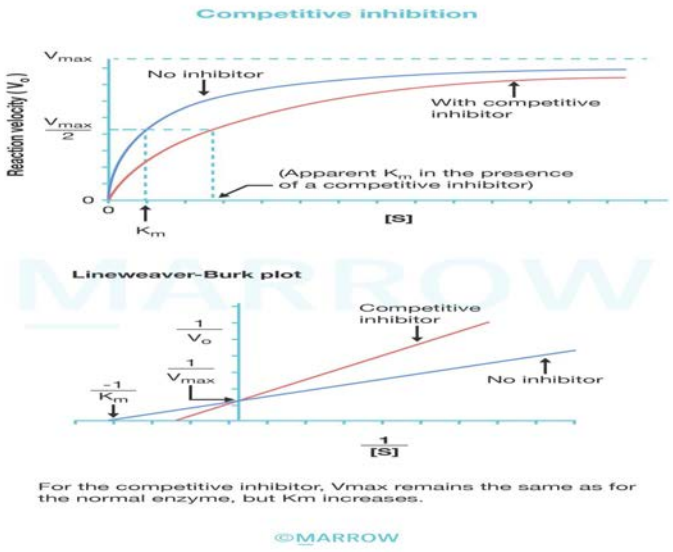
Option C- Amylase hydrolyses starch which is a glucose homopolymer and is present in germinating cereals, potatoes, legumes, and malt.

Solution to Question 21:

The given graph shows competitive inhibition, in which the value of Vmax remains constant and the Km value increases. The intercept on the y-axis remains unchanged while the intercept on the x-axis shifts close to zero forming a steeper slope.

Competitive inhibition is when the inhibitor binds reversibly to the substrate-binding site and competes with the substrate for the active enzyme-binding site. This effect of competitive inhibition can be overcome by increasing the substrate concentration by which maximum velocity can still be achieved. Therefore, Vmax (maximum velocity of the reaction) is unaltered in this type of inhibition. However, the concentration of the substrate required to achieve half of the maximum velocity is increased. Therefore, Km is increased in this condition.

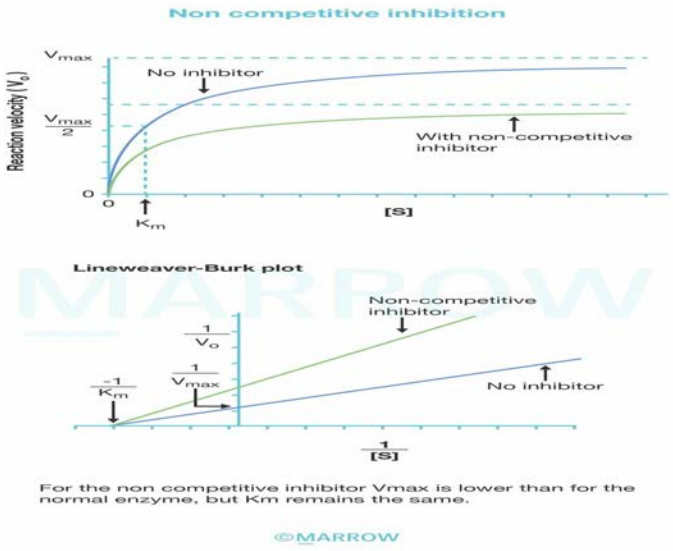
The graph below shows the changes in Vmax and Km in competitive inhibition.



Other options:

Option B: Non-competitive inhibition is by binding inhibitors to enzymes in locations remote from the active site. Increasing the concentration of the substrate does not overcome non-competitive inhibition. Thus, noncompetitive inhibitors decrease the Vmax of the reaction. They do not interfere with the binding of the substrate to the enzyme. Thus, the enzyme shows the same Km in the presence or absence of noncompetitive inhibitors.

The graph shows the changes in Vmax and Km in non-competitive inhibition.



Option C: In uncompetitive inhibition, inhibitors bind with the enzyme-substrate intermediate complex, and inhibit it. This leads to a decrease in both Vmax and Km. An example is the inhibition of placental alkaline phosphate (ALP) by phenylalanine.

Option D: In Allosteric inhibition, inhibitors bind to a site other than the active site i.e. allosteric site, and induce a conformational change (change in the shape of the active site unlike in non-competitive inhibition) thus, inhibiting the enzyme. ATP is an allosteric inhibitor of

Phosphofructokinase in glycolysis.

Pharmacology AIIMS 2017

Question 1:

How much drug will remain at the end of 6 hours when a patient is given 200 mg drug, 75 mg excreted in 90 min and if the drug follows first-order kinetics?

a) 50 mg

b) 30.5 mg

c) 12.5 mg

d) 6.25 mg

Question 2:

What is the most bactericidal anti leprotic drug amongst the given drugs?

a) Amoxicillin

b) Ciprofloxacin

c) Ofloxacin

d) Erythromycin

Question 3:

Which of the following is not true about P-glycoprotein?

a) Pgp stands for permeability glycoprotein

b) Also known as CD243

c) Also known as ABCB1

d) Also known as MDR2

Question 4:

For which of the following drugs, is absorption increased after a fatty meal?

a) Griseofulvin

b) Amphotericin B

c) Ampicillin

d) Aspirin

Question 5:

A patient with Prinzmetal angina is administered isosorbide mononitrate and is noticed to have symptomatic relief. What is the mechanism of action of nitrate in this case?

a) Endothelium independent coronary vasodilation

b) Reduced cardiac contractility

c) Increased left ventricular end diastolic volume

d) Decreased diastolic perfusion pressure

Question 6:

The drug of choice in anaphylactic shock is?

a) Adrenaline 0.5 mg 1/1000 IM

b) Adrenaline 1 mg 1/10000 IV

c) Atropine 3 mg

d) Adenosine 6 mg followed by 12 mg IV

Question 7:

What instruction do you give to a mother who is lactating for drug use?

a) No advice as most of drug are not present in breast milk

b) Give longer half-life drugs

c) Tell the mother to feed when it is least efficacious

d) To feed just before the next dose, when the plasma concentration of the drug would be the least

Question 8:

In a case of acute exacerbation of asthma, salbutamol was given, however, no improvement was noticed. Intravenous corticosteroids and aminophylline were given and the condition improved. What is the probable mechanism by which the corticosteroids would have improved the condition?

a) Corticosteroids increase bronchial responsiveness to salbutamol

b) Corticosteroids cause direct bronchodilatation when used with xanthines

c) Corticosteroids indirectly increase the effect of xanthines on adenosine receptor

d) Corticosteroids increase mucociliary clearance

Question 9:

Which of the following opioids is a partial agonist at mu and a full agonist at kappa receptors?

a) Pentazocine

b) Buprenorphine

c) Tramadol

d) Fentanyl

Question 10:

The drug of choice for insomnia in blind people is

a) Latanoprostene

b) Zerviate

c) Tasimelteon

d) Ramelteon

Question 11:

Dofetilide belongs to which class of anti-arrhythmic drugs?

a) Class I

b) Class II

c) Class III

d) Class IV

Question 12:

What is the mechanism of action of vancomycin?

a) Cell wall synthesis inhibition

b) Cell membrane inhibition

c) Peptide synthesis inhibition

d) 50s ribosome inhibition

Question 13:

The following table gives BP values before and after administration of drug 'X'. What would be the probable mechanism of action of drug 'X'?

		DRUG X
SBP	120	150
DBP	80	68
HR	72	86

©MARROW

a) α1 agonist and β1 agonist

b) M2 agonist and M3 agonist

c) α1 antagonist and β2 agonist

d) β1 agonist and β2 agonist

Question 14:

A patient requires Ceftriaxone 180 mg. You have a 2 ml syringe with 10 divisions per ml. The vial contains 500 mg/5ml of ceftriaxone. How many divisions in the 2 ml syringe will you fill to give 180 mg ceftriaxone?

a) 18

b) 1.8

c) 20

d) 2

Question 15:

The drug that decreases the size of prostate is:

a) Tamsulosin

b) Sildenafil

c) Finasteride

d) Flutamide

Question 16:

Which one of the following is a placebo?

a) Herbal medication with no effect known

b) Physiotherapy

c) Sham surgery

d) Cognitive behavioural therapy

Question 17:

A young male developed 5 episodes of loose stools 2 hours after eating in a restaurant. He is afebrile and has mild dehydration. What should be the treatment?

a) Ciprofloxacin and tinidazole

b) Only ciprofloxacin

c) Only ORS

d) Ciprofloxacin, tinidazole and ORS

Question 18:

Atropine is indicated in all of the following poisonings except _____.

a) Baygon

b) TIK 20

c) Parathion

d) Endrin

Question 19:

27-year-old female came for treatment of infertility to OPD. Bromocriptine was prescribed. What could be the possible reason?

a) Hyperprolactinemia

b) PCOD

c) Hypogonadotrophic hypogonadism

d) PID

Question 20:

Which is a mood stabiliser with an anti-suicidal role?

a) Carbamazepine

b) Lamotrigine

c) Lithium

d) Valproate

Question 21:

Which of the following is not an idiosyncratic reaction of carbamazepine?

a) Blurred vision

b) Agranulocytosis

c) Rash

d) Steven Johnson Syndrome

Question 22:

In a middle-aged diabetic patient with chronic kidney disease stage 5, which of the following drugs can be given safely without altering the dose?

a) Vildagliptin

b) Linagliptin

c) Saxagliptin

d) Sitagliptin

Question 23:

Which of the following drugs can be used as an antidote for fibrinolytic therapy?

a) Protamine

b) Streptokinase

c) Heparin

d) ε-Aminocaproic acid

Question 24:

A known epileptic patient on levetiracetam has been seizure-free for 2 years. But he develops agitation and anger issues interfering with his day-to-day activities as a result of the drug intake. Which of the following measures is to be taken next?

a) Slowly taper the drug over next 6 months

b) Continue levetriacetam since a 5 year seizure free interval is needed

c) Stop levetiracetam and start on a different anti-epileptic

d) Discontinue the drug as he is seizure free

Question 25:

A drug was given IV at a rate of 1.6mg/min. The clearance of the drug is 640ml/min. The half life of the drug is 1.8 hour. Calculate the plasma concentration of the drug at steady state.

a) 2.88mg/ml

b) 0.004mg/ml

c) 3.55mg/ml

d) 0.002mg/ml

Question 26:

Which of the following disease-modifying anti rheumatoid drug increases extracellular adenosine?

a) Methotrexate

b) Lefunamide

c) Sulphasalazine

d) Hydroxychloroquine

Question 27:

Composition of Lente insulin is:

a) 70% amorphous 30% crystalline

b) 70% crystalline 30% amorphous

c) Only 70% amorphous

d) Other name of NPH insulin

Question 28:

Mechanism of action of Oseltamivir as an antiviral agent is:

a) Inhibition of M2 receptor

b) Neuraminidase inhibition

c) Inhibition of RNA dependent DNA polymerase

d) Apoptosis of infected cells

Question 29:

A male patient who is suffering from a psychotic disorder is on antipsychotic, antidepressant and antihypertensive treatment. He suddenly developed tachycardia and chest tightness. On evaluation he had metabolic acidosis. ECG showed widened QRS complex and prolonged QT interval. Which of the following drugs is responsible for this?

a) Amitriptyline

b) Amlodipine

c) Chlorthalidone

d) Enalapril

Question 30:

You and your friend plan for a mountain trip for the day after. What medication would you advise him to help with his motion sickness?

a) Ranitidine tablet before start of trip

b) Dimenhydrinate before start of trip

c) Scopolamine patch the night before trip

d) Omeprazole the night before and before start of trip

Question 31:

A patient was treated for septicemia with norepinephrine infusion. Which of the following best explains the benefit of this drug?

a) Bradycardia

b) Tachycardia

c) Increases urine output

d) Increases mean arterial blood pressure

Question 32:

Which of the following suggests storage of drugs in tissue?

a) Excretion in saliva

b) Excretion in urine

c) Large volume of distribution

d) Small volume of distribution

Answer Key

Question No.	Correct Option
1	b
2	c
3	d
4	a

29	a
30	c
31	d
32	c

Detailed Explanations

Solution to Question 1:

In first order kinetics, a constant fraction of the drug is excreted in a given time.

Since 75 mg of 200 mg is excreted in 90 minutes, the fraction of drug excreted in each 90 mins is 75/200, which is 3/8. Thus, the fraction of the drug that remains in the body is 5/8.

There will be 4 cycles of excretion of the drug (6 hours = 360 mins, and 360/90 = 4). Thus, with a starting dose of 200mg, the drug remaining in the body after 4 hours will be:

200 x 5/8 x 5/8 x 5/8 x 5/8 = 30.5mg

Alternate way to calculate:

75 mg of 200 mg is excreted in 90 minutes, thus 75/200 = 0.375 is eliminated

After 90 minutes; 200 mg-75 mg = 125 mg remains.

The second 90 minutes (after 180 minutes) = 125 x 0.375 = 46.875 mg is eliminated, and 125-46.875 = 78.125 mg remains

The third 90 minutes (after 270 minutes) = 78.125 x 0.375 = 29.297 mg is eliminated, and 78.125-29.297 = 48.828 remains

The fourth 90 minutes (after 360 minutes) = 48.828 x 0.375 = 18.310 mg is eliminated, 48.828-18.310 = 30.518 mg remains after 6 hours.

Solution to Question 2:

Ofloxacin is the most bactericidal anti leprotic drug amongst the given drugs.

It exhibits high activity against M. leprae, and it is being used in alternative multidrug therapy (MDT) regimens in rifampicin-resistant cases. As a component of MDT, it has been found to hasten the bacteriological and clinical response.

Among the macrolides, clarithromycin has activity against leprosy bacilli and is used for alternative MDT in cases resistant to both rifampicin and fluoroquinolones. Azithromycin shows activity against Mycobacterium avium complex but not lepra bacilli.

Note: Rifampicin is the most potent bactericidal anti leprotic drug.

Solution to Question 3:

P-glycoprotein is also known as multidrug resistance protein 1 or MDR1 (not MDR2). It is also denoted by cluster of differentiation 243 (CD243).

P-glycoprotein (P-gp) is one of the first members of the ATP-binding cassette (ABC) transporter, which acts as an efflux membrane transporter. It is responsible for limiting cellular uptake and the distribution of xenobiotics and toxic substances. It is associated with multidrug resistance (MDR).

• Increased P-gp expression: Reduces the absorption of drugs that are substrates for P-gp

• Decreased P-gp expression: Leads to supratherapeutic plasma concentrations and drug toxicity

Solution to Question 4:

The absorption of griseofulvin is increased after a fatty meal.

Note: Fatty meals increase the rate of absorption of efavirenz to such an extent as to cause toxicity. Hence, efavirenz is recommended to be taken on an empty stomach.

Drug absorption reduced /delayed by food	Drug absorption increased by food
AmpicillinAspirinAtenololAzithromycinCaptoprilIndinavirIsoniazidRifampinSucralfateTetracyclineDoxycycline	AtovaquoneCarbamazepineChlorothiazideCefuroximeDiazepamGanciclovirLithiumMetoprololRitonavirHydralazineLumefantrine

Solution to Question 5:

The mechanism of action of nitrates in prinzmetal angina is endothelium-independent coronary vasodilatation.

Prinzmetal angina occurs due to vasospasm of the coronary arteries. Nitrates relax the smooth muscles of epicardial coronary arteries and relieve coronary artery spasm.

In the case of stable angina, the primary mechanism of action of nitrates is preferential dilatation of veins (by increasing cGMP). Venous dilatation leads to a decrease in the venous return to the heart (preload). This decreases the ventricular end-diastolic volume and thereby a decrease in myocardial oxygen consumption. The diastolic perfusion pressure (aortic blood pressure in diastole - left ventricular pressure in diastole) is increased.

Solution to Question 6:

Adrenaline 0.5 mg 1/1000 by intramuscular route (IM) is the drug of choice for treatment of anaphylactic shock. Hence it is the answer here.

In case the patient develops life threatening condition, adrenaline 0.25 mg IV is given.

Note : This is a controversial question. The following inference from journal may help to clarify the concept.

• As vasodilatation is the main pathological change early in anaphylaxis, this enables the subcutaneous or intramuscular absorption of adrenaline to be rapid and effective.

• Thus, when the disease is treated early and is progressing slowly, or venous access is difficult or the patient is unmonitored, intramuscular adrenaline has advantages in terms of safety and is usually effective.

• Later, when intravascular volume is depleted and shock occurs with a life threatening situation, or there is severe dyspnoea or airway compromise, the intravenous route is necessary to achieve optimal absorption.

Solution to Question 7:

Ideally, the mother should feed just before the next dose, when the plasma concentration of the drug would be the least.

• The drugs are present in breast milk in variable amount but lesser than in plasma of mother.

• Breastfeeding is advised at least 3-4 hours after drug intake so that plasma concentration is lesser and hence the concentration in the breast milk is also less.

Solution to Question 8:

Corticosteroids improved the condition by increasing the airway responsiveness to salbutamol.

Mechanism of action of corticosteroids in an acute asthma attack:

• Increases responsiveness to β-2 agonists

• Decreases mucous secretion

• Decreases inflammatory cell response.

Steroids increase the transcription of β-2 receptor genes and hence increases responsiveness to β-2 agonists.

β-2 agonists increase the effect of steroids by enhancing the action of glucocorticoid receptors.

Theophylline increases the effects of steroids by activating the enzyme histone deacetylase which is the target for steroids as well.

Note: As per recent GINA 2021 guidelines, aminophyllines are no longer preferred in the management of acute severe asthma due to their low efficacy and poor safety profile.

Solution to Question 9:

Pentazocine is a partial agonist at mu and a full agonist at kappa receptors.

Analgesia produced by pentazocine is predominantly mediated by the κ receptor.

Pentazocine is a mixed agonist-antagonist opioid agent. It is a full agonist at the κ receptor and a partial agonist or weak antagonist at the μ receptor

Note: Buprenorphine is a partial agonist at mu receptors but an antagonist at kappa receptors

Solution to Question 10:

The drug of choice for insomnia in blind people is tasimelteon.

Option A - Latanoprostene is used in primary open-angle glaucoma.

Option B - Zerviate is a cetirizine ophthalmic solution used in allergic conjunctivitis.

Option D - Ramelteon is a synthetic tricyclic analog of melatonin used in sleep onset difficulty insomnia.

Solution to Question 11:

Dofetilide belongs to class III of anti-arrhythmic drugs.

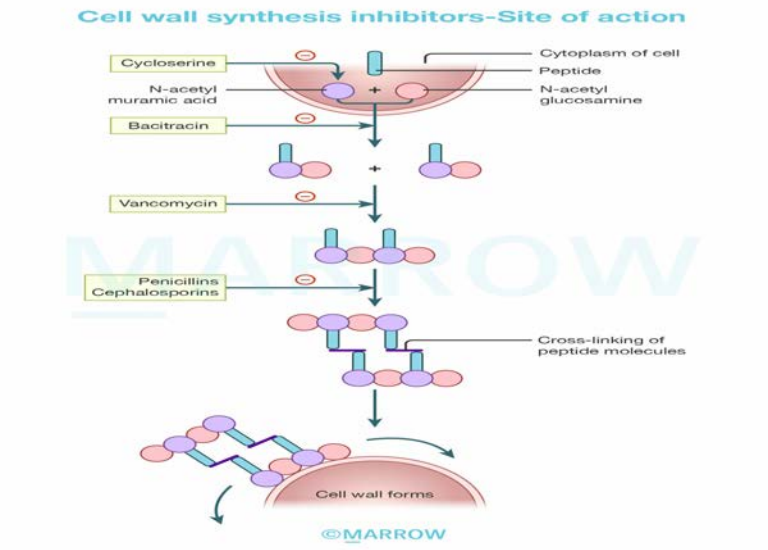
Solution to Question 12:

The mechanism of action of vancomycin is cell wall synthesis inhibition.

The bacterial cell wall has long chains of peptidoglycan and is cross-linked to each other by the action of the enzyme transglycosylase. Vancomycin is a glycopeptide group of antibiotics that binds to the D-alanyl-D-alanine terminus of the synthesized peptidoglycan. This inhibits the transglycosylase enzyme and prevents elongation and cross-linking of peptidoglycan. This leads to the weakening of the cell wall causing lysis.

It exhibits a time-dependant or concentration-independent killing of bacteria. It primarily acts on Gram +ve organisms which are resistant to other antibiotics such as methicillin-resistant staphylococcus and ampicillin resistant enterococci.

Lipoglycopeptides are a new generation of glycopeptide congeners which include telavancin, dalbavancin, and oritavancin. Dalbavancin and Oritovancin are administered as a single intravenous dose for skin and soft-tissue infections.



Solution to Question 13:

The probable mechanism of action of drug 'X' is β1 and β2 agonism.

According to the given table, systolic BP and heart rate is increased due to β1 agonistic effect, and diastolic BP is decreased by vasodilatation due to β2 action.

Option A: Action on α1 causes ↑ DBP

Option B: Action on M2 causes ↓ HR and action on M3 causes vasodilatation and reflex increase in HR. Hence there is no net effect on heart rate

Option C: α1 antagonism causes vasodilatation and ↓ DBP. β2 action causes vasodilatation and DBP ↓

Solution to Question 14:

• 500 mg of drug is in 5 ml and hence 100 mg in 1ml. Thus 180 mg in 1.8 ml

• 10 divisions for each ml

• 1 ml = 10 divisions

• Therefore, 1.8 ml = 10*1.8 = 18 Divisions

Solution to Question 15:

Finasteride reduces prostatic size.

Finasteride:

• It is a competitive inhibitor of 5α-reductase enzyme, thus inhibiting the conversion of testosterone into its active form DHT(Dihydrotestosterone) which is responsible for androgenic action in Prostate gland.

• It produces effect on long term use (nearly 6 months) by reducing prostatic epithelial cell proliferation thereby reducing the size of prostate and improves urine flow.

Tamsulosin is an α 1 Selective Antagonist which dilates prostatic urethra and hence produces immediate symptom relief in BPH. It has no effect on reducing size of the prostate.

Sildenafil acts by inhibiting phosphodiesterase-5 (PDE-5) and is used in the treatment of erectile dysfunction.

Flutamide is a Nonsteroidal Androgen Receptor antagonist with no hormonal activity. They are used for treatment of metastatic prostatic cancer in conjunction with GnRH agonists.

Solution to Question 16:

Sham surgery (placebo surgery) is a faked surgical intervention that omits the step thought to be therapeutically necessary.

Note: While option A may be considered a placebo due to there being no known effects, it is not certain as to whether all possible effects (known and unknown) have been considered. Hence,

weighing options A and C, the better option among the two would be C as sham surgery is a widely used placebo.

Solution to Question 17:

It is a case of acute diarrhea in an afebrile, stable patient which can be managed with ORS alone.

Management of diarrhea:

• Mild-moderate dehydration - ORS.

• Severe dehydration- IV fluids are given.

• Afebrile patient - No antibiotics are given.

• Febrile patient - empirical antibiotics. If only bacterial etiology is suspected, ciprofloxacin is given. If giardiasis is suspected, metronidazole or tinidazole are recommended.

Solution to Question 18:

Endrin is an organochloride pesticide that causes neurotoxicity. There is no antidote available and only symptomatic treatment is done.

Parathion and TIK20 are organophosphates and baygon is a combination of organophosphate and carbamate. For all of these, atropine is the drug of choice.

Solution to Question 19:

The patient is likely to be suffering from hyperprolactinemia.

Prolactin inhibits the secretion of GnRH, which leads to the decreased secretion of LH and FSH resulting in infertility. Bromocriptine acts on Dopamine D2 receptors to reduce prolactin secretion.

Solution to Question 20:

Lithium is a mood stabilizer with an antisuicidal role.

Maintenance treatment with lithium has shown to decrease the rate of suicide in mood disorders. Lithium was found to be better than other mood stabilizers such as carbamazepine, lamotrigine, and valproate.

Lithium is also used in recurrent depression with a cyclic pattern is controlled by either lithium or imipramine. It is also used to augment standard antidepressant response in acute major depression in those patients who have had an inadequate response to monotherapy.

Solution to Question 21:

Blurred vision is not an idiosyncratic reaction of carbamazepine.

Idiosyncratic blood dyscrasias with carbamazepine, include fatal cases of aplastic anaemia and agranulocytosis. The most common idiosyncratic reaction is an erythematous skin rash. It can rarely cause Steven Johnson Syndrome.

Solution to Question 22:

Linagliptin can be given safely without altering the dose for this patient.

Linagliptin is a dipeptidyl-peptidase-4 (DPP-4) inhibitor and is eliminated by the hepatobiliary route. Hence no dosage adjustment is needed in renal failure.

It is used in type 2 diabetes as monotherapy or as combination therapy with other drugs when metformin is not tolerated or contraindicated.

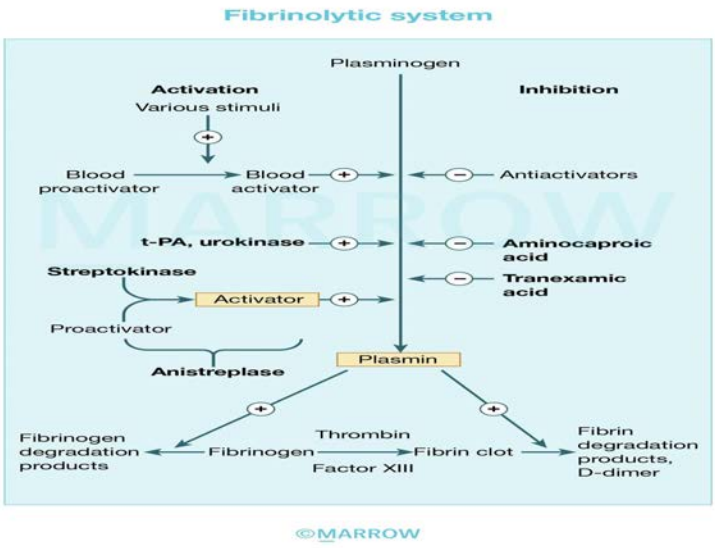
Other DPP-4 inhibitors like sitagliptin, vildagliptin, saxagliptin, alogliptin show renal elimination.

Solution to Question 23:

ε-Aminocaproic acid can be used as an antidote for fibrinolytic therapy.

It is a lysine analog that binds competitively to plasminogen, blocking plasminogen from binding to fibrin and the subsequent conversion to plasmin. This activity subsequently results in the inhibition of fibrinolysis.

It should not be given unless hemorrhage is life-threatening because it inhibits intrinsic fibrinolytic activity and can precipitate DIC. Fresh frozen plasma and cryoprecipitate may also be used to replenish fibrin and clotting factors.



Solution to Question 24:

The mood changes observed in the above patient must be due to an adverse effect of levetiracetam. Abrupt stoppage of the drug can result in rebound seizures. So the best management will be to slowly taper the drug over the next 6 months.

Adverse effects of levetiracetam:

- Somnolence
- Asthenia
- Ataxia
- Dizziness.
- Mood and behavioral changes
- Psychotic reactions (rare)

Solution to Question 25:

Plasma steady-state concentration is achieved when the amount of drug being administered equals the amount of drug being excreted from the body.

The amount of drug being administered = 1.6mg/min

Amount of drug being excreted = Clearance (CL) x Plasma concentration of the drug (C)

Clearance = 640ml/min

Therefore,

1.6mg/min = 640ml /min (clearance) x Plasma concentration of the drug

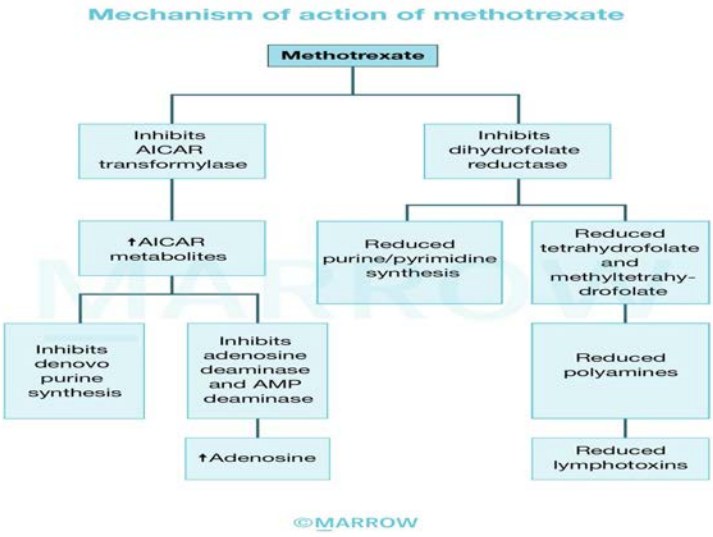
Hence,

Plasma concentration of the drug = 1.6 mg/min / 640 ml/min = 0.002 mg/ml.

Solution to Question 26:

Methotrexate is the disease-modifying anti rheumatoid drug that increases extracellular adenosine. Methotrexate's principal mechanism of action relates to inhibition of amino-imidazole carboxamide ribonucleotide (AICAR) transformylase and thymidylate synthetase.

AICAR accumulates intracellularly, competitively inhibits AMP deaminase, leading to an accumulation of AMP. The AMP is released and converted extracellularly to adenosine, which is a potent inhibitor of inflammation. As a result, the inflammatory functions of neutrophils, macrophages, dendritic cells, and lymphocytes are suppressed.



Solution to Question 27:

Lente insulin is an intermediate-acting insulin and is a combination of Ultralente and Semilente in the ratio of 7:3

Two types of insulin zinc suspensions have been produced. The one with large particles is crystalline and practically insoluble in water (Ultralente). It is long-acting. The other has smaller particles and is amorphous (Semilente), is short-acting. Their 7:3 ratio mixture is called 'Lente insulin' and is intermediate-acting.

Solution to Question 28:

Oseltamivir and zanamivir are neuraminidase inhibitors.

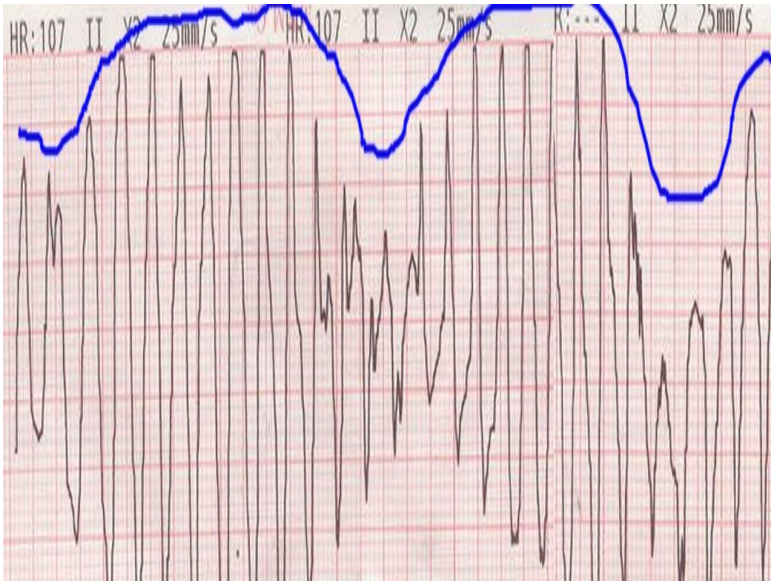
They competitively and reversibly interact with the enzyme sites to inhibit viral neuraminidase activity. This interferes with the release of the progeny from infected host cells, halting the spread of infection. Early administration is crucial.

Oseltamivir is given at a dose of 75 mg, twice a day for 5 days for the treatment of Influenza A and B. For prophylaxis, it is given at a dose of 75mg, once per day and continued for the duration of exposure.

Solution to Question 29:

The given clinical scenario is suggestive of torsades de pointes. Only amitriptyline causes this condition, among the above drugs.

Torsades de pointes (French: twisting of points) is a life-threatening form of polymorphic ventricular tachycardia with rapid asynchronous complexes and an undulating baseline on ECG.



Solution to Question 30:

In the above case, a scopolamine patch the night before the trip should be advised.

Treatment for motion sickness :

• Scopolamine patch- preferred, most effective.

• Do not give to children <10 years of age.

• Place patch behind the ears at least 4 hours before travel and replace every 72 hours as needed.

• Transdermal patch – Most effective

• Oral dose - 0.4–0.6 mg one hour before travel and then TID may be recommended.

• Cinnarizine – 30mg, 2 hours prior to travel, and 15mg TID as required. Not as effective as scopolamine. Moderately effective.

• Promethazine

• Other drugs (minimally effective):

• Cyclizine

• Dimenhydrinate

• Diphenhydramine

• Meclizine

PPI's / ranitidine / traditional ginger – all are ineffective.

Solution to Question 31:

The benefit of using noradrenaline in septicemia is that it increases the mean arterial blood pressure. It acts as a powerful peripheral vasoconstrictor and inotrope.

Noradrenaline causes a rise in both systolic BP and diastolic BP, resulting in a rise in the mean arterial blood pressure. This increases the organ perfusion in patients in septic shock or cardiogenic shock.

Another advantage of noradrenaline is that it does so without causing tachycardia, which is often a troublesome event with other inotropes in critical care.

Options A and B: The rise in mean arterial pressure causes reflex bradycardia which is not a major contributor to the treatment of septic shock.

Option C: Low-dose dopamine infusions and furosemide are used to increase urine output in critically ill patients.

Solution to Question 32:

Storage of drug in tissue suggests large volume distribution.

Drugs with small volume of distribution are confined to vascular component.

Drugs with large volume of distribution are in compartments like adipose tissue, muscle, bone.

Volume of distribution depends on:

• Lipid solubility

• pKa value of a drug

• Degree of plasma protein binding

• presence of tissue-specific transporters

• differences in regional blood flow.

Volume (V) = Dose administered I.V. / Plasma concentration

e.g., when 1000mg of drug is injected I.V. and plasma concentration of drug is 50mg/L,

- V=1000/50
- V=20L

Pharmacology AIIMS 2018

Question 1:

Which of the following is not a side effect of salbutamol?

a) Hypoglycemia

b) Hypokalemia

c) Tremors

d) Tachycardia

Question 2:

Which of the following drugs should be sold only on prescription from a registered medical practitioner?

a) Schedule M drugs

b) Schedule H drugs

c) Schedule J drugs

d) Schedule X drugs

Question 3:

The loading dose of a drug is governed primarily by:

a) Clearance

b) Volume of distribution

c) Plasma half life

d) Bioavailability

Question 4:

Therapeutic index is used for assessing which of the following factors?

a) Safety

b) Efficacy

c) Potency

d) Toxicity

Question 5:

Which of the following drugs causes flagellate pigmentation?

a) Bleomycin

b) Doxorubicin

c) Vincristine

d) Minocycline

Question 6:

Which is the anticoagulant of choice for the management of cancer-associated thromboembolism?

a) Unfractionated Heparin

b) Warfarin

c) Low molecular weight heparin

d) Dabigatran

Question 7:

Which of the following new drugs has been approved for the treatment of amyotrophic lateral sclerosis?

a) Edaravone

b) Piracetam

c) Dabrafenib

d) Trametinib

Question 8:

What is the drug of choice for scrub typhus during pregnancy and otherwise respectively?

a) Chloramphenicol, doxycycline

b) Doxycycline, doxycycline

c) Doxycycline, azithromycin

d) Azithromycin, doxycycline

Question 9:

Which of the following is an example of a GPCR?

a) Muscarinic

b) Nicotinic

c) GABA-A

d) Insulin

Question 10:

The package description of a drug states that 500mg of paracetamol is present in each unit of the tablet formulation, but in reality, each unit contains only 200mg. What is the terminology used to refer to these kinds of drugs?

a) Misbranded drug

b) Adulterated drugs

c) Spurious drugs

d) Counterfeit drugs

Question 11:

A patient presented to the casualty with signs of dehydration due to severe vomiting. The intern gave the patient a parenteral medication, following which the patient developed grimacing and abnormal posturing. What could have been the inciting drug for this reaction?

a) Atropine

b) Ranitidine

c) Metoclopramide

d) Domperidone

Question 12:

Identify the wrongly matched pair of antifungals with its mechanism of action:

a) Ketoconazole : Lanosterol-14-demethylase inhibition

b) Flucytosine : Inhibits microtubule synthesis and thus hinders mitosis

c) Terbinafine : Squalene epoxidase inhibition

d) Amphotericin B : Sequesters ergosterol

Question 13:

Which of the following parameters is used to assess the extent of drug absorption in a plasma concentration vs. time graph?

a) Tmax

b) Cmax

c) T1/2

d) Area under the curve

Question 14:

Which of the following routes of administration will not bypass hepatic first-pass metabolism?

a) Sublingual

b) Oral

c) Intravenous

d) Transdermal

Question 15:

For the action of heparin as an anticoagulant, availability of which of the following chemical substances is mandatory?

a) Thrombin

b) Plasmin

c) Antithrombin-III

d) Thrombomodulin

Question 16:

What is the bioavailability of a drug administered intravenously?

a) 10%

b) 100%

c) 50%

d) Variable

Question 17:

A drug solution containing 500 mg/5 ml of the drug is given to you. You are provided with a 2 ml syringe (having 10 divisions for each ml). How many divisions of the 2 ml syringe need to be administered to deliver 180 mg of the drug to a patient?

a) 1.8

b) 10

c) 14

d) 18

Question 18:

Which of the following is gametocidal to all the species causing malaria?

a) Primaquine

b) Chloroquine

c) Quinine

d) None

Question 19:

A drug label suggests storage in a 'cool' place. What is the temperature at which this drug is to be stored?

a) - 2 degree Celsius

b) 0 degree Celsius

c) 2-6 degree Celsius

d) 8-15 degree Celsius

Question 20:

A patient with AIDS was treated with zidovudine, lamivudine, indinavir, ketoconazole and cotrimoxazole. He developed nephrolithiasis, central obesity, hyperlipidemia and insulin resistance. Which of the drugs could have been the cause?

a) Ketoconazole

b) Indinavir

c) Lamivudine

d) Zidovudine

Question 21:

If carbamazepine is added to ongoing valproate therapy, what adverse effect is risked?

a) Pancreatitis

b) Thrombocytopenia

c) Hepatotoxicity

d) Hyperammonemia

Question 22:

What is the mechanism of action of dapsone, considering that it is used in the treatment of leprosy, fungal infections and, also for immunomodulatory actions?

a) Cell wall synthesis inhibitor

b) Folic acid synthesis inhibitor

c) Protein synthesis inhibitor

d) Cell membrane inhibitor

Question 23:

What is the mechanism of action of sodium nitroprusside?

a) Increased cAMP

b) Stimulation of guanylyl cyclase

c) Calcium channel blockage

d) K+ channel opener

Question 24:

Levothyroxine/liothyronine acts by binding to thyroid receptors. Thyroid hormone receptors belong to which of the following class of receptors?

a) Transmembrane receptor linked to tyrosine kinase

b) Nuclear receptor

c) Ion channel receptor

d) G protein coupled receptor

Question 25:

The Nobel Prize in Physiology or Medicine, 2018 was awarded to James P. Allison and Tasuku Honjo for which of the following discoveries?

a) Discovery of mechanisms of autophagy

b) Discoveries of molecular mechanisms controlling the circadian rhythm

c) Discovery of cancer therapy by inhibition of negative immune regulation

d) Discovery that mature cells can be reprogrammed to become pluripotent

Question 26:

Which of the following drugs does not require dose reduction in patients with renal failure?

a) Gentamicin

b) Vancomycin

c) Amphotericin B

d) Doxycycline

Question 27:

Which of the following drugs does not increase the risk of bleeding in patients undergoing warfarin therapy?

a) Cimetidine

b) Carbamazepine

c) Isoniazid

d) Amiodarone

Question 28:

Which of the following is used in acute mountain sickness?

a) Dexamathasone

b) Digoxin

c) Diltiazem

d) Acetazolamide

Question 29:

Which of the following anti-tubercular drugs is associated with ophthalmic toxicity?

a) Ethambutol

b) Isoniazid

c) Kanamycin

d) Rifampin

Question 30:

A patient with diabetic macular edema developed glaucoma. Which of the following drugs would you consider giving last?

a) Beta blocker

b) Alpha agonist

c) Pilocarpine

d) Prostaglandin analogues

Question 31:

What is the mechanism by which acetylcholine causes a decrease in the heart rate?

a) Delayed diastolic depolarization

b) Increase in plateau

c) Decrease in preload

d) Increase in afterload

Question 32:

Diamox is given to a patient with glaucoma. It is a non-competitive inhibitor of the carbonic anhydrase enzyme. Which of the following would be the effect of this drug?

a) Decrease in Vmax

b) Decrease in Km

c) Decrease in both Km and Vmax

d) No change in Vmax

Question 33:

Low apparent volume of distribution of drug indicates

a) Low t 1/2

b) Low bioavailability

c) Low efficacy

d) Not extensively distributed to tissues

Question 34:

An infant had a serum bilirubin level of 33 mg/dL. The mother might have taken which of the following drugs during the third trimester for this to occur?

a) Ampicillin

b) Co-trimoxazole

c) Azithromycin

d) Chloramphenicol

Question 35:

Lithium usage in pregnancy can lead to which of the following teratogenic effects?

a) Cardiac defects

b) Facial defects

c) CNS defects

d) Urogenital defects

Detailed Explanations

Solution to Question 1:

Hypoglycemia is not a side effect of salbutamol. It causes hyperglycemia.

The side effects of salbutamol are due to the stimulation of extrapulmonary β2 receptors. They are more common after oral or intravenous administration. The side effects seen are:

• Muscle tremor

• Tachycardia

• Hypokalemia

• Restlessness

• Hypoxemia

• Increase in free fatty acid, insulin, glucose, pyruvate, and lactate

Solution to Question 2:

Schedule H drugs should be sold only if the prescription is from a registered medical practitioner (RMP).

Important schedules under the “drugs and cosmetics act”:

• C and C1: Biological and special products

• F and F1: Bacterial vaccines

• G: Drugs that must be labelled with the word “caution” should not be taken without medical supervision

• J: List of diseases and ailments which a drug may not claim to prevent or cure

• M: Good Manufacturing Practices (GMP)

• P: Expiry period of drug formulations

• W: Drugs marketed under generic name only

• X: Psychotropic drugs requiring a special license for manufacture and sale

• Y: Requirements and guidelines on clinical trials, import, and manufacture of new drugs.

Solution to Question 3:

The volume of distribution of the drug determines the loading dose of the drug.

Loading Dose = Vol. of distribution x Desired steady state plasma concentration.

When the time to reach a steady-state is long, as it is for drugs with long half-lives, it may be desirable to administer a loading dose that promptly raises the concentration of drug in plasma to the target concentration.

Option A: Clearance is used to determine the maintenance dose.

Maintenance dose = Clearance x Desired Steady-state plasma concentration.

Options C and D: Plasma half-life primarily determines the frequency of dosing, while bioavailability determines the route of administration. Though bioavailability may affect the dose necessary, it will not be the primary factor considered during the calculation of the loading dose.

Solution to Question 4:

Therapeutic index is used to assess the safety of the drug administered.

Therapeutic index = TD50/ED50

• TD50 (Median toxic dose) = Dose required to produce a toxic effect in 50% of animals tested.

• ED50 (Median effect dose) = Dose required to produce a therapeutic effect in 50% of the individuals.

Option B: Efficacy is defined as the maximum effect produced by the drug. It expresses the effect produced by the receptors when bound by a certain drug.

Option C: Potency refers to the concentration (EC50) or dose (ED50) required to produce 50% of maximum effect where EC50 is the concentration of agonist resulting in a half-maximal response.

Option D: Median toxic dose is the dose required to produce a toxic effect in 50% of animals tested. Lethal dose is the dose required to kill 50% of animals tested.

Solution to Question 5:

Flagellate hyperpigmentation/flagellate erythema is a characteristic cutaneous reaction to treatment with bleomycin.

Clinical features include multiple linear streaks (erythematous or hyperpigmented) at sites of trauma and generalized pruritus.

Solution to Question 6:

The anticoagulant of choice for the management of cancer-associated thromboembolism is low-molecular-weight heparin (LMWH).

It is the preferred agent because of more bioavailability, lack of need for anticoagulant monitoring, and a long t1/2.

Venous thromboembolism (including deep vein thrombosis, pulmonary embolism, and splanchnic vein thrombosis), is a frequent complication of cancer and is the second-leading cause of death in cancer patients receiving chemotherapy.

Based on the results from the Comparison of Low-molecular-weight heparin vs. Oral anticoagulants for long-term anticoagulation in cancer patients with venous Thromboembolism (CLOT) Trial, all recent guidelines now advise LMWH for cancer-associated thromboembolism.

However, unfractionated heparin (UFH) can be used in patients with renal failure, and fondaparinux can be considered in patients with heparin-induced thrombocytopenia (HIT).

Solution to Question 7:

Edaravone was approved by the FDA for the treatment of amyotrophic lateral sclerosis (ALS).

It has free radical scavenging properties that may reduce oxidative stress. The exact mechanism of action is unknown. It is to be administered as an IV infusion with an initial treatment cycle of daily dosing for 14 days, followed by a 14-day drug-free period. Subsequent treatment cycles consist of dosing on 10 of 14 days, followed by a 14 day drug-free period.

The major adverse effect of edaravone is hypersensitivity because the infusion contains sodium bisulfite. Other adverse effects include bruising, gait disorder, and headache.

Tafinlar (dabrafenib) and Mekinist (trametinib), are both indicated as monotherapy in BRAF V600E/K (BRAF V600E mutation-positive) melanoma. They are approved for combined administration, for the treatment of anaplastic thyroid cancer (ATC) that cannot be removed by surgery or that has spread to other parts of the body (metastatic).

Piracetam is a nootropic agent (a drug that enhances cognitive function) that is used off-label to enhance memory. It is also used to treat myoclonus.

Solution to Question 8:

The drug of choice for a case of scrub typhus during pregnancy is azithromycin. For other patients the drug of choice is doxycycline.

An alternative treatment option in pregnant women and patients allergic to doxycycline is chloramphenicol.

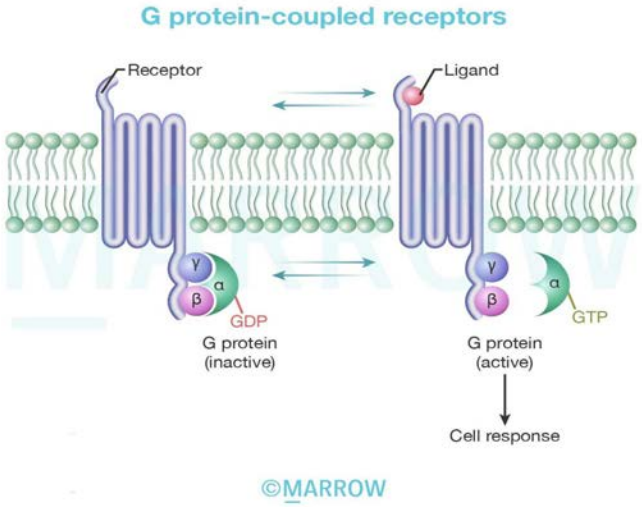
Solution to Question 9:

Muscarinic receptors are G-protein-coupled receptors among the given options.

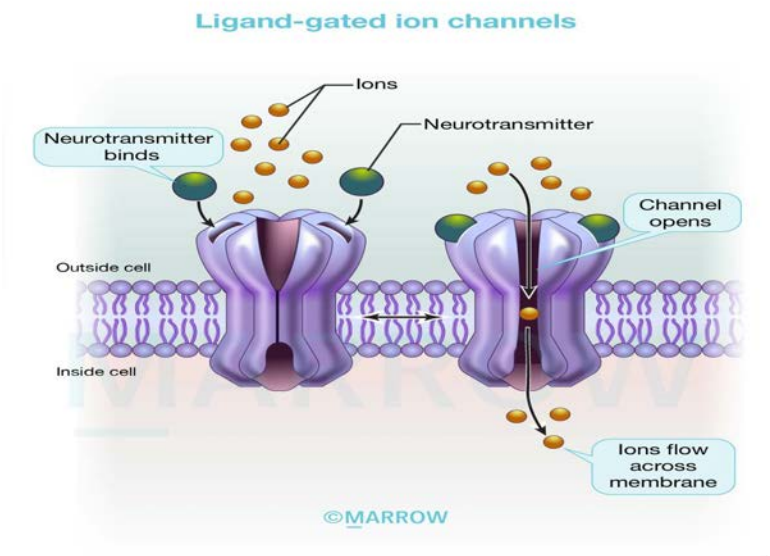
M1, M2, M3, M4, and M5 are the muscarinic Ach receptors.

• M1 and M3 act through Gq protein and activate IP3/DAG causing increased cytosolic calcium.

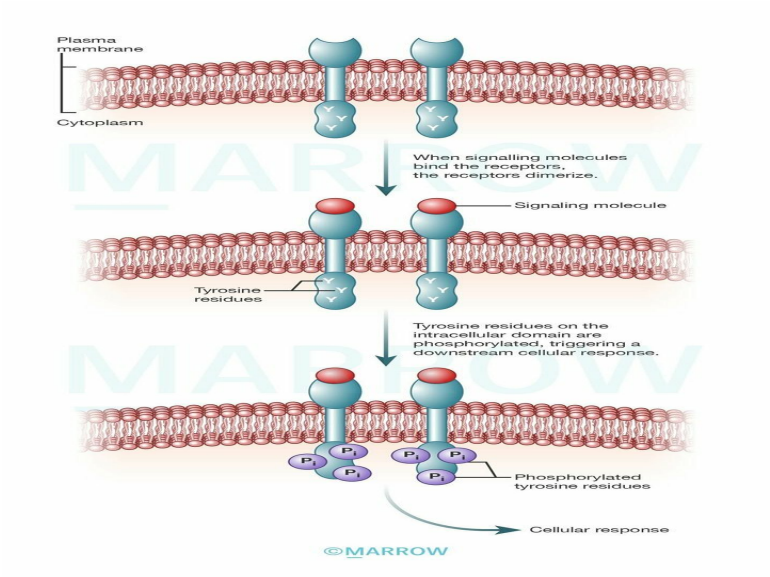
• M2 and M4 act through Gi protein and inhibit adenylyl cyclase causing increased potassium conductance.



Nicotinic receptors and GABA-A are examples of ion channel coupled receptors.



Insulin receptor is a tyrosine kinase receptor.



Solution to Question 10:

A drug stating that 500mg of paracetamol is present in each tablet, but contains only 200mg is a misbranded drug, according to the CDSCO (Central drugs standard control organization).

The drug and cosmetics act initially passed in 1940 and amended in 2016 provides a definition of misbranded, spurious, and adulterated drugs.

A drug is considered misbranded if it fulfills any of the following three conditions:

• If the appearance of the drug has been altered to conceal physical damage or make it appear of greater therapeutic value than it actually is (or)

• If it is not labeled in the prescribed manner (or)

• If the label or container of the drug makes a false or misleading claim about the drug. In this case, the packet states that there is 500 mg of paracetamol present as opposed to the 200 mg that is actually present.

A drug is considered spurious if it fulfills the following conditions:

• If the drug is imported under a name that belongs to another drug (or)

• If the drug is an imitation of another drug with the intent to deceive (or)

• If the label depicts a manufacturer that is either fictitious or a real company with no ties to the product (or)

• If it has been substituted wholly or in part by another drug or substance.

A drug is considered adulterated if it fulfills the following conditions:

• If it consists wholly or in part of any filthy, putrid, poisonous, or decomposed substance (or)

• If it has been manufactured under unsanitary conditions (or)

• If it bears a coloring other than the one prescribed (or)

• If it has been mixed with any substance that may reduce its quality or strength.

*Note: The term counterfeit drugs is a broad term and is used by the WHO. This may also be conceived to include misbranded, spurious, or adulterated drugs. However, the term misbranded drugs would be a more appropriate answer here since it is likely that the reference used is from CDSCO.

Solution to Question 11:

The given clinical scenario describes the adverse effects characteristic of metoclopramide. The most common adverse effects of metoclopramide involve the central nervous system because it crosses the blood-brain barrier (BBB) and blocks the central D2 receptors.

The adverse effects include:

• Restlessness

• Drowsiness

• Insomnia

• Anxiety

• Agitation

• Extrapyramidal effects - acute reaction with high doses and long-term therapy. (due to central dopamine receptor blockade)

• Dystonias

• Akathisia

• Parkinsonian features

• Tardive dyskinesia

Adverse events are more common among the elderly. Long-term use should be avoided unless absolutely necessary.

Solution to Question 12:

Flucytosine acts by inhibition of fungal DNA synthesis.

It is a pyrimidine antimetabolite. After uptake into fungal cells, fungal cytosine deaminase activates it to 5-fluorouracil, which is an anticancer drug. This is further converted into metabolites that inhibit thymidylate synthase which is necessary for DNA synthesis. Thus fungal DNA synthesis is inhibited. Mammalian cells are spared as they lack cytosine deaminase enzyme.

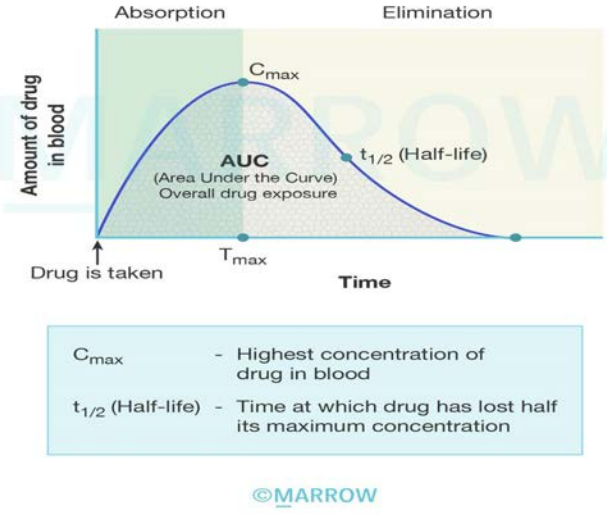
Flucytosine has clinically useful activity against (3C):

- Cryptococcus
- Candida species
- Agents causing chromoblastomycosis

Solution to Question 13:

The area under the curve of plasma concentration vs. time curve gives the extent of absorption, which is calculated by the trapezoidal rule.

The following image shows a plasma concentration vs. time graph:



Two drugs may have the same rate of absorption but a different extent of absorption or bioavailability.

The factors upon which the extent of drug absorption depends are:

• Lipophilicity - If too lipophilic (e.g., acyclovir), the drug is not soluble enough to cross the water layer adjacent to the cell.

• Hydrophilicity - If too hydrophilic (e.g., atenolol), the drug cannot cross the lipid cell membrane.

Solution to Question 14:

Hepatic first-pass metabolism occurs in drugs administered via the oral route.

When drugs are given orally, they are absorbed in the intestine and reach the liver through the portal vein. During this process, the drug is acted on by enzymes of the liver and intestine. Additionally, the liver may excrete part of the drug in the bile, further reducing the bioavailability. This is called the first-pass metabolism.

In all the other routes, the drug directly enters systemic circulation without reaching the liver.

Note: Bioavailability is the fraction of an administered dose of unchanged drug that reaches the systemic circulation. Hence, the bioavailability of a drug administered intravenously (I.V) is 100%. It is neither subjected to the first-pass metabolism as in the oral route nor does it depend on local factors as in subcutaneous, intramuscular, or transdermal.

Solution to Question 15:

Antithrombin-III is mandatory for the action of heparin as an anticoagulant. Reduced antithrombin levels can lead to resistance.

Heparin resistance refers to failure to achieve a therapeutic aPTT with daily doses of heparin of 35,000 units or more.

In true heparin resistance, there is an actual blunting of heparin's anticoagulant effect. This occurs due to:

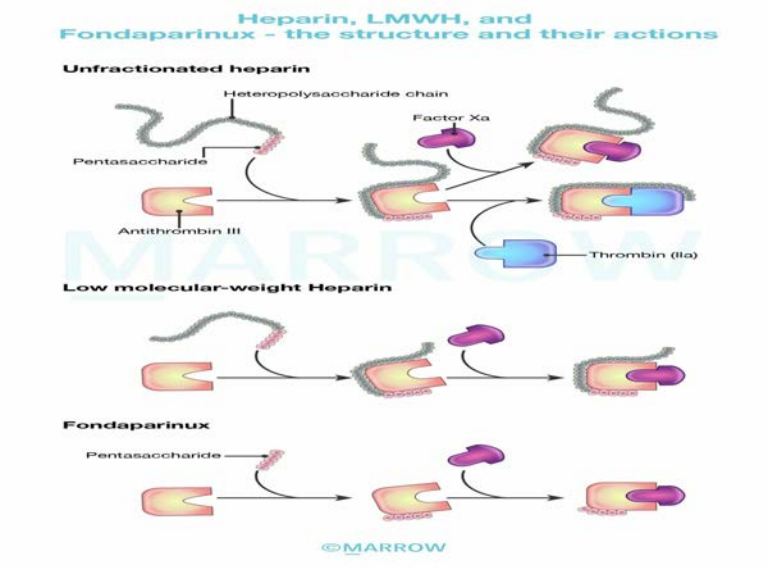
• Low ATIII levels (most common cause)

• Increased heparin-binding plasma proteins (acute phase reactants)

• Increased heparin clearance (e.g. due to splenomegaly in liver disease)

Low ATIII levels could be due to decreased synthesis (hereditary, hepatic failure), increased consumption (DIC, MAHA, or in a bypass circuit) or increased loss (nephrotic syndrome).

The dose of heparin has to be increased to achieve therapeutic aPTT. Severe antithrombin deficiency may require antithrombin concentrate as well.



Solution to Question 16:

The bioavailability of a drug administered intravenously (I.V) is 100%.

It is neither subjected to the first-pass metabolism as in oral route nor does it depend on local factors as in subcutaneous, intramuscular, or transdermal. In IV route, the drug is directly delivered to the systemic circulation and hence has the maximum availability for action at the intended site.

Bioavailability is the fraction of an administered dose of unchanged drug that reaches the systemic circulation. Hence, by definition, when a medication is administered intravenously, its bioavailability is 100%.

Intrathecal administration does not have a bioavailability of 100%.

Solution to Question 17:

Concentration of drug solution given = 500/5 ml or 100 mg/ml

-> 100 mg of drug in 1ml

i.e 180 mg of drug in "X" ml

-> X = 180/100 = 1.8 ml

So, 1.8 ml of the drug with 180 mg of the drug is to be given to the patient.

In the 2 ml syringe provided, each ml has 10 divisions i.e. each division corresponds to 0.1 ml.

So, for delivering 1.8 ml, 1.8/0.1= 18 divisions need to be administered.

Solution to Question 18:

Primaquine is gametocidal to all species causing malaria. It inhibits transmission of malaria.

The drugs with clinically important gametocidal activity (against all species) are:

• High activity:

• Artemisinins

• Primaquine

• Low to moderate activity:

• Chloroquine

• Quinine

• Atovaquone/proguanil

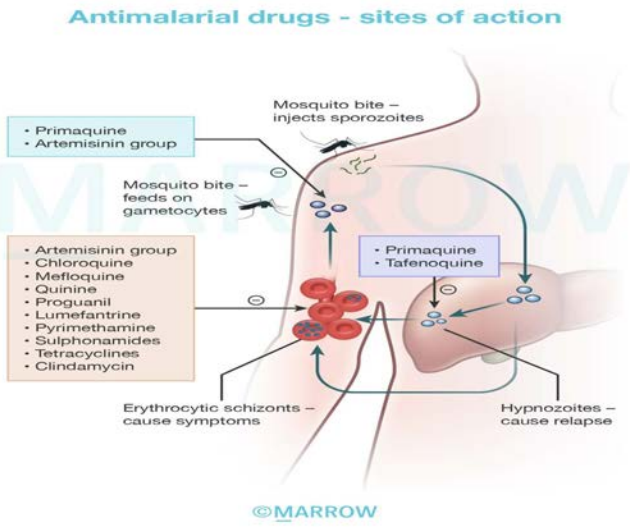
• No activity:

• Mefloquine

• Pyrimethamine

• Sulfadoxine

• Tetracycline



Solution to Question 19:

Storing at a cool place means to store at 8-15 degrees C.

Examples for drugs to be stored under cool temperature include insulin, nicorandil.

Label instructions	Temperature
Store frozen	-20oC
Keep cool	8-15oC
Store at room temperature	15-25oC

Solution to Question 20:

Indinavir, a protease inhibitor causes the above given adverse effects.

Patients being treated with protease inhibitors (e.g., indinavir) develop a syndrome involving the derangement of lipid metabolism. This causes changes in body fat distribution. Type 2 diabetes mellitus has also been reported. This is called HIV/HAART-associated lipodystrophy.

It is typically seen after 6–12 months of protease inhibitor therapy.

Solution to Question 21:

If carbamazepine is added to ongoing valproate therapy, it can result in hepatotoxicity.

A combination of valproate and carbamazepine increases hepatotoxicity. Valproic acid may inhibit carbamazepine clearance and increase steady-state carbamazepine blood levels.

Solution to Question 22:

The mechanism of action of dapsone is inhibition of folic acid synthesis.

Dapsone [4,4■diaminodiphenylsulphone (DDS)] is a structural analog of para-aminobenzoic acid (PABA) and a competitive inhibitor of dihydropteroate synthase in the folate pathway. It is weakly bactericidal and can cause mild hemolysis, and rarely anemia or psychosis.

DDS syndrome is a rare side effect of dapsone therapy in leprosy patients which starts after 5-6 weeks of starting dapsone and leads to exfoliative dermatitis, hepatosplenomegaly, lymphadenopathy, fever and hepatitis and may be fatal. It is also called 'five-week dermatitis'.

Solution to Question 23:

Sodium nitroprusside acts by stimulation of guanylyl cyclase.

Sodium nitroprusside releases nitric oxide which in turn stimulates guanyl cyclase. This activates cGMP secondary messenger which results in the relaxation of the smooth muscle.

Solution to Question 24:

Thyroid hormone receptors belong to the class of nuclear receptors.

Nuclear receptors are a family of ligand-regulated transcription factors that are activated by various lipid-soluble signals, including retinoic acid, thyroid hormone, and steroid hormones. They primarily function as transcription factors and directly interact with the genomic DNA to regulate gene expression.

Nuclear receptors can either remain anchored in the cytoplasm via chaperone proteins until freed by ligand-binding (e.g., steroid and vitamin D receptors) or can reside in the nucleus bound to specific DNA response elements even in the absence of ligand (e.g., thyroid hormone, PPARγ, and retinoic acid receptors).

Solution to Question 25:

The Nobel prize in Physiology or Medicine, 2018 was awarded to James P. Allison and Tasuku Honjo for the discovery of cancer therapy by inhibition of negative immune regulation.

Immune checkpoint inhibitors inhibit proteins that keep immune responses to cancer cells in check. When these proteins are blocked, the brake on the immune system is released and T cells are able to kill cancer cells more efficiently.

The Nobel prize 2018 in Physiology or Medicine was awarded to James P. Allison and Tasuku Honjo for their breakthrough work on unleashing the body's immune system to attack cancer, that has led to an entirely new class of these drugs and brought lasting remissions to many patients who had run out of options.

Solution to Question 26:

Doxycycline does not require dose reduction in renal failure. Doxycycline, minocycline, and glycylcyclines like tigecycline have fewer renal side effects.

Antibiotics causing acute kidney injury are as follows:

• Acute tubular necrosis:

• Amphotericin B

• Vancomycin

• Acyclovir

• Foscarnet

• Tenofovir

• Acute interstitial nephritis:

• Penicillin

- Cephalosporins
- Quinolones
- Rifampicin

Solution to Question 27:

Carbamazepine does not increase the risk of bleeding in patients undergoing warfarin therapy.

Warfarin is mainly metabolized by the CYP2C9 enzyme. Drugs that inhibit CYP2C9 enzyme reduce the metabolism of warfarin and thus, enhance the anticoagulant effect of warfarin and increase the risk of bleeding.

Drugs causing CYP2C9 inhibition:

- Amiodarone
- Azole antifungals
- Cimetidine
- Clopidogrel
- Cotrimoxazole
- Disulfiram
- Isoniazid
- Metronidazole

Solution to Question 28:

Acetazolamide is used in the treatment of acute mountain sickness for symptomatic relief. It can also be used for prophylaxis.

Solution to Question 29:

Ethambutol is associated with ophthalmic toxicity.

Optic neuritis resulting in decreased visual acuity and loss of ability to differentiate red from green is the most serious adverse effect of ethambutol. It is a dose-dependent adverse effect that can be unilateral or bilateral.

Tests of visual acuity and red-green discrimination before the start of therapy and periodically thereafter are recommended.

Solution to Question 30:

Prostaglandin analogs are the last drugs to be considered in this patient since macular edema is one of their side effects.

Adverse effects of PGF 2alpha analogs are:

• Blurring of vision

• Macular edema (especially in aphakic patients)

• Eyelash hypertrichosis

• Iris pigmentation (Heterochromia iridis)

• Peri-orbital fat depletion

Solution to Question 31:

The mechanism by which acetylcholine causes a decrease in the heart rate is by decreasing the diastolic depolarization.

The acetylcholine released from the vagal nerve acts on the M2 receptor (βγ subunit of G protein) on the SA node. This opens a special set of potassium channels causing an efflux of potassium (IKAch) which hyperpolarizes the SA node (Ih). The resultant current (Ih) slows the diastolic depolarization thereby causing bradycardia.

Solution to Question 32:

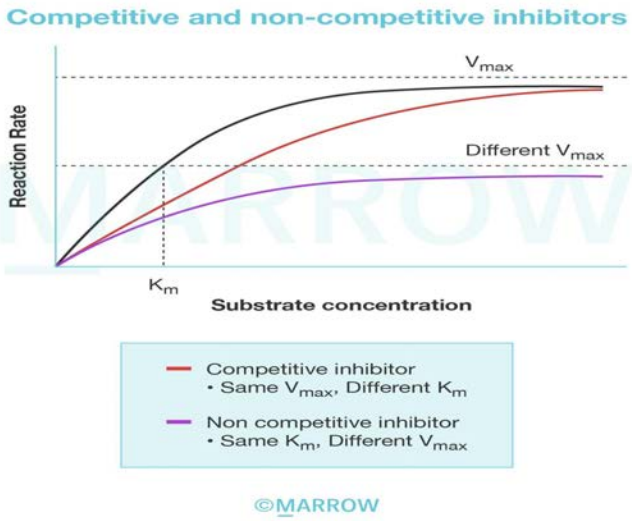
Non-competitive inhibitors cause a decrease in Vmax.

In non-competitive inhibition:

• The inhibitor binds to the adjacent site and not the catalytic site of the enzyme

• The catalytic property of the enzyme is reduced and hence Vmax is decreased

• The affinity of the enzyme is not altered and hence Km is unaltered



Solution to Question 33:

Low apparent volume of distribution of a drug indicates that it is not extensively distributed in the tissues.

Apparent Volume of distribution (Vd) = dose administered I.V/ plasma concentration E.g: If a 500 mg of drug A is given i.v (100% bioavailability) and the plasma concentration reached is 10 mg/ liter then the apparent volume of distribution (Vd) is 500/10= 50 liters.

But the normal blood volume is about 5 liters. A high Vd is due to accumulation of drug A in extravascular tissues resulting in low plasma concentration. Therefore, the apparent volume of distribution is an imaginary volume throughout which the drug is distributed if the plasma concentration remains the same throughout.

Option A: t1/2 relationship with volume of distribution (Vd) and clearance (Cl) is given by the formula t 1/2 = 0.693 x Vd /Cl. t1/2 is directly proportional to Vd but it is also inversely proportional to clearance. If a drug has a low volume of distribution but clearance is very low, t1/2 can still be high. So low Vd doesn't always imply low t1/2. So the best answer among the given options is D.

Option B and C: Low Vd does not indicate low bioavailability or low efficacy.

Solution to Question 34:

Cotrimoxazole is a combination drug consisting of trimethoprim and sulfamethoxazole, of which sulfamethoxazole is a sulfonamide. Sulphonamides displace bilirubin from plasma albumin, leading to elevation of serum bilirubin levels.

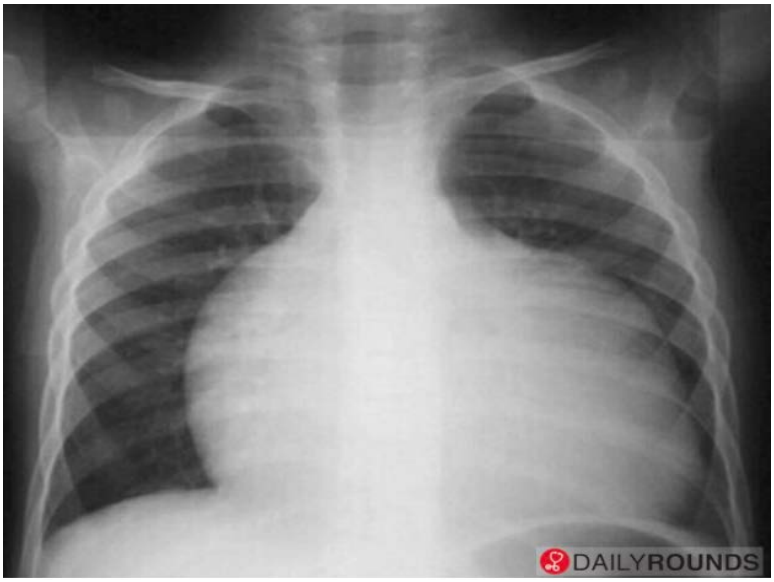
These drugs can cross the placenta and are secreted in milk and can therefore cause kernicterus in newborn infants if they are given to pregnant women near term or during lactation.

Solution to Question 35:

Lithium use in pregnancy can lead to cardiac defects.

Ebstein's anomaly is the specific cardiac defect with lithium use in pregnancy.

In Ebstein's anomaly, the radiological sign seen is a box-shaped heart.



Pharmacology AIIMS 2019 (May & Nov)

Question 1:

Which of the following is not an adverse effect of salbutamol?

a) Tachycardia

b) Tolerance

c) Hypokalemia

d) Hypoglycemia

Question 2:

Propranolol is drug of choice for:

a) Ulcerated infantile hemangioma

b) Lymphangioma circumscriptum

c) Capillary malformation

d) Pyogenic granuloma

Question 3:

CIostridium difficile associated diarrhea occurs maximally due to:

a) Lincosamides

b) Tetracyclines

c) Carbapenems

d) Macrolide

Question 4:

A 53 year old man is found to have stage 2 hypertension without any co morbidities. Which drug will you start?

a) Furosemide

b) Chlorthalidone

c) Spironolactone

d) Triamterene

Question 5:

Which of the following is a schedule X drug?

a) Halothane

b) Thalidomide

c) Ketamine

d) Colistin

Question 6:

LMWH is given by which route?

a) Intravenous

b) Subcutaneous

c) Intramuscular

d) Intradermal

Question 7:

A patient presents to the emergency department with diarrhea, sweating, excessive lacrimation, and salivation. His pulse rate is 55/min and his plasma cholinesterase level was 50U/mL. Which of the following can be used to treat this patient?

a) Neostigmine

b) Atropine

c) Epinephrine

d) Benztropine

Question 8:

What is pegloticase used for?

a) Chronic gout

b) Rheumatoid arthritis

c) Psoriatric arthritis

d) Paralytic ileus

Question 9:

Which of the following GPCRs does not act via the K+ channel?

a) Angiotensin 1 receptor

b) Muscarinic M2 receptor

c) Dopamine D2 receptor

d) Serotonin 5 HT1 receptor

Question 10:

Which of the following is not used in heart failure?

a) Trimetazidine

b) Sacubitril

c) Metoprolol

d) Nesiritide

Question 11:

Which of the following causes an increase in ACh release from the presynaptic neuron?

a) Potassium channel blocker

b) Sodium channel blocker

c) Calcium channel blocker

d) Chlorine channel blocker

Question 12:

Apart from mu-opioid receptors, on which other receptor does tramadol act?

a) Anticholinergic

b) 5HT1a inhibition

c) Serotonergic and norepinephrine reuptake inhibition

d) Antihistaminic

Question 13:

In which of the following conditions is non-pulsatile dosing of GnRH agonist not used?

a) Male infertility

b) Endometriosis

c) Precocious puberty

d) Prostate cancer

Question 14:

Which of the following cannot be used to decrease intraocular pressure in glaucoma?

a) Dexamethasone

b) Acetazolamide

c) Apraclonidine

d) Mannitol

Question 15:

Prucalopride is a _____.

a) 5HT2a agonist

b) 5HT2b agonist

c) 5HT4 antagonist

d) 5HT4 agonist

Question 16:

Z track technique is used for?

a) Administration of nicotine patches

b) Monitoring of carbamazepine therapy

c) Administration of long acting depot antipsychotics

d) Monitoring of lithium therapy

Question 17:

Tafenoquine is used in which of the following conditions?

a) Radical cure of plasmodium vivax

b) Prophylaxis of malaria in pregnancy

c) Treatment of severe falciparum malaria

d) Treatment of malaria in children <2 years

Question 18:

Which is not given in Wilson's disease?

a) Zinc

b) Penicillamine

c) Calcium citrate

d) Trientine

Question 19:

What dose of epinephrine is used in anaphylactic shock?

a) 1:10000 I.V. - 10 ml

b) 1:1000 I.M. - 0.5 ml

c) 1:1000 I.M. - 1 ml

d) 1:1000 I.V. - 0.5 ml

Question 20:

Which of the following is true about tedizolid?

a) Active against gram positive organisms

b) Poor oral bioavailability

c) Active against anaerobes

d) Causes peripheral neuropathy

Answer Key

Question No.	Correct Option
1	d
2	a
3	a

13	a
14	a
15	d
16	c
17	a
18	c
19	b
20	a

Detailed Explanations

Solution to Question 1:

Salbutamol in large doses can result in hyperglycemia, not hypoglycemia.

Option A: Tachycardia due to reflex sympathetic stimulation due to vasodilator action on β2 receptors and direct effect on cardiac β1 receptors (β2 selectivity is lost at high concentrations)

Option B: Tolerance occurs due to desensitization on long-term use

Option C: Hypokalemia due to direct effect on skeletal muscle uptake of K+ ions

Solution to Question 2:

Propranolol is the drug of choice in the management of infantile hemangioma complicated by ulceration or in symptomatic patients.

It acts by causing vasoconstriction, inducing apoptosis and inhibition of angiogenesis.

Solution to Question 3:

Clostridium difficile-associated diarrhea is mostly due to lincosamides such as clindamycin

Antibiotic-associated colitis is caused by Clostridium difficile infection due to the destruction of the normal gut microbial flora by the use of antibiotics. The antibiotics most frequently implicated include clindamycin, fluoroquinolones and broad-spectrum penicillins, and cephalosporins

Clostridium difficile infection occurs frequently in hospitals and nursing homes where antimicrobial use is high and the environment is contaminated by C. difficile spores.

Although all antibiotics can cause the condition, the most commonly implicated are:

• Clindamycin

• Third-generation cephalosporins (cefotaxime, ceftriaxone, cefuroxime, and ceftazidime)

• Fluoroquinolones (ciprofloxacin, levofloxacin, and moxifloxacin)

• Broad-spectrum penicillins

Solution to Question 4:

Chlorthalidone is one of the first choice drugs in the treatment of hypertension without any comorbidities.

First-choice drugs used in the treatment of hypertension in patients without any comorbidities include:

• Thiazide diuretics: Chlorthalidone is usually preferred to hydrochlorothiazide.

• Calcium channel blockers: Extended-release, long-acting dihydropyridines are preferred.

• ACE inhibitors: Captopril is preferred for the initiation of therapy. Enalapril and ramipril twice daily may also be used.

In the presence of any associated conditions or comorbidities, the first choice drugs for the treatment of hypertension would be as follows:

Conditions associated with hypertension	First choice drugs for hypertension
DiabetesChronic kidney disease with proteinuria	Inhibitors of renin-angiotensin system.
Angina	Beta-blockers or calcium channel blockers
Heart failure	ACE inhibitors and alpha+beta blockers such as carvedilol
Benign prostatic hyperplasia	α1Blockers
Pregnancy	Labetalol
Atrial fibrillation	Diltiazem and verapamil

Solution to Question 5:

Ketamine is a schedule X drug.

According to The Drugs and Cosmetics Act-1945,

Schedule X drugs are those that have high abuse liability and are to be sold with a valid prescription only.

A prescription in duplicate, separate license requirement, meticulous storage, and dispensing records must be maintained by the chemist.

Option B: Thalidomide is a schedule H drug.

Option D: Colistin is a schedule P drug.

Solution to Question 6:

LMWH is given by the subcutaneous route.

Heparin, low molecular weight heparin (LMWH), and fondaparinux are not absorbed through GI mucosa and must be given parenterally.

LMWH and fondaparinux are given subcutaneously.

Heparin can be given through intravenous infusion and subcutaneous routes.

Solution to Question 7:

The clinical features are suggestive of organophosphate poisoning and IV atropine is the treatment of choice.

The organophosphates commonly used as pesticides are anticholinesterases. Toxicity occurs by excessive inhalation of vapors, ingestion, or percutaneous absorption. It inhibits the

cholinesterase activity which results in an increase of acetylcholine, leading to cholinergic symptoms.

The predominant initial signs are of muscarinic excess which includes: (DUMBBELSS)

• Diarrhea

• Urination

• Miosis

• Bronchospasm

• Bradycardia

• Emesis

• Lacrimation

• Salivation

• Sweating

This may be followed by cognitive disturbances, convulsions, and neuromuscular blockade.

Treatment:

• Maintenance of vital signs particularly respiration

• Removal of clothing and washing of the skin

• IV atropine 2- 5 mg. If IV administration is not possible, then 2 mg IM every 5-10 minutes (till muscarinic symptoms disappear)

• Pralidoxime, a cholinesterase reactivator can also be used for treatment

Solution to Question 8:

Pegloticase is used in the treatment of chronic gout.

Pegloticase is a pegylated uricase (urate oxidase). It catalyzes the enzymatic oxidation of uric acid into allantoin, which is a more soluble and inactive metabolite.

It is used in the treatment of severe, refractory chronic gout or in cases where other urate-lowering therapies are contraindicated.

Solution to Question 9:

Angiotensin 1 receptor acts via Ca2+ channels. It does not act through second messengers via the K+ channel.

G-protein coupled receptors activate inwardly rectifying potassium channels and increase the permeability of the potassium ions causing hyperpolarisation of the cell. They are called G protein-coupled inwardly-rectifying potassium channels (GIRKs). These receptors include:

• M2 muscarinic

- A1 adenosine
- α2 adrenergic
- D2 dopamine
- 5HT1 serotonin
- Somatostatin receptors.

Solution to Question 10:

Trimetazidine is not used in heart failure.

Trimetazidine is a newer antianginal drug that is a pFOX inhibitor which partially inhibits the fatty acid oxidation pathway in the myocardium. This decreases the oxygen requirement of the heart.

Nesiritide (natriuretic peptide), sacubitril (neprilysin inhibitor) and metoprolol (beta-blocker) are used in the treatment of heart failure.

Solution to Question 11:

Potassium channel blockers cause an increase in ACh release from the presynaptic neuron.

Presynaptic potassium channel block promotes the activation of voltage-gated calcium channels. This leads to a release of acetylcholine in the neuromuscular junction.

Aminopyridines (K+ channel blockers) are used in the treatment of Lambert-Eaton myasthenic syndrome which helps to improve muscle strength.

Solution to Question 12:

Tramadol inhibits the reuptake of serotonin and norepinephrine, apart from its action on the mu-opioid receptor.

It is a synthetic codeine analog that is a mu-opioid receptor agonist.

Tramadol is a centrally acting analgesic used in the treatment of mild to moderate pain.

Solution to Question 13:

Pulsatile dose of GnRH agonist is used in the treatment of male infertility.

Pulsatile administration of GnRH agonists results in increased FSH and LH secretion and is used to treat male and female infertility.

Non-pulsatile or continuous dose of GnRH agonist results in suppression and decreased concentrations of gonadotropins LH and FSH. They are used in:

• Endometriosis

• Uterine fibroids

• Central precocious puberty

• Ca prostate

• Ca ovary and breast

• Controlled ovary stimulation

Solution to Question 14:

Dexamethasone is a long-acting glucocorticoid and is not used to decrease the intraocular pressure in glaucoma.

Acetazolamide, apraclonidine, and mannitol are used in lowering intraocular pressure in glaucoma.

Solution to Question 15:

Prucalopride is a specific 5HT4 receptor agonist which increases bowel movements.

It is approved for use in women with chronic constipation where other laxatives have failed to provide relief.

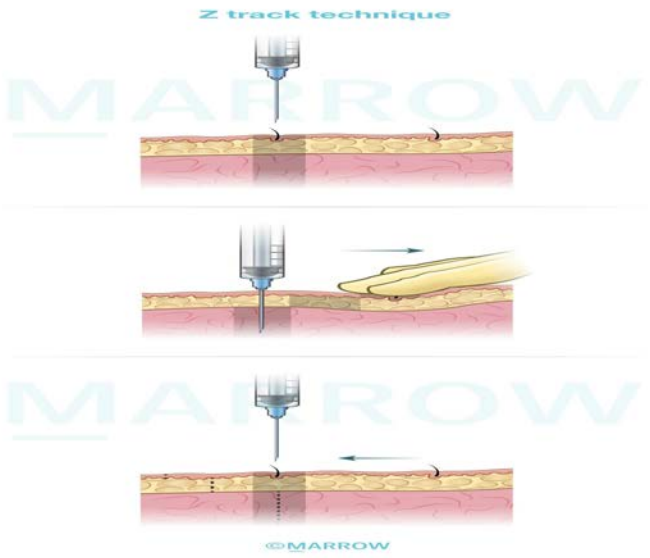
Solution to Question 16:

The Z-track technique is used for the intramuscular administration of long-acting depot antipsychotics.

Advantages:

• The 'Z-track' prevents leakage of the medication into the subcutaneous tissue and skin staining through the tract to the surface of the skin

• Pain intensity is also reduced



Solution to Question 17:

Tafenoquine is used in the radical cure of Plasmodium vivax. Total eradication of plasmodium species which includes clinical curative and hypnozoites phase are called radical cure.

Primaquine and tafenoquine (derivative of primaquine) have very high activity against the latent tissue forms (hypnozoites) of the species. It is primarily used for the chemoprophylaxis and radical cure of P. vivax and P. ovale infections.

Solution to Question 18:

Calcium citrate is not used in the treatment of Wilson's disease.

The drugs used in the management of Wilson's disease are:

Chelating agents: These drugs bind to copper to form complexes that get excreted in the urine. D-penicillamine and trientine are first-line drugs in symptomatic patients with hepatic diseases.

• D-penicillamine: It is the recommended drug due to its availability and cost-effectiveness as compared to trientine. Since it is an antagonist to pyridoxine, supplementation of pyridoxine is required. It can precipitate various adverse effects including aplastic anemia, myasthenia gravis, and membranous nephropathy. It can also worsen neurological symptoms

• Trientine: It is administered in those who cannot tolerate D-penicillamine

• Tetrathiomolybdate: It has been identified to be effective in patients with neuropsychiatric manifestation

Elemental zinc:

• Zinc blocks the intestinal absorption of copper by inducing metallothionein (endogenous chelator in enterocytes)

• It is commonly used as a maintenance therapy along with chelating agents. It can also be used as first-line therapy in pregnancy

Solution to Question 19:

Epinephrine (1:1000 solution) 0.5 ml via intramuscular route is preferred in the treatment of anaphylactic shock.

For intravenous use, 1:1000 adrenaline must be further diluted to 1:10,000 and should be used very cautiously as slow bolus.

There is a much greater risk of causing harmful side effects by either inappropriate dosage or misdiagnosis of anaphylaxis when using IV adrenaline. Hence, IM injection is preferred over intravenous (IV) bolus because it is faster in many situations and safer (lower risk of cardiovascular complications, such as severe hypertension and ventricular arrhythmias).

For intramuscular, subcutaneous, and inhalational (nebulization) routes of administration, 1:1000 dilution can be used.

In cardiac arrest, the 1:1000 adrenaline must be diluted to 1:10,000 for IV use. The recommended dose of epinephrine is 1mg = 10 mL of 1:10,000 solution IV administered every 3 to 5 minutes during resuscitation as per the CPR guidelines.

Epinephrine is also used in the treatment of hypotension, to induce local vasoconstriction to reduce the diffusion of local anaesthetics and to induce bronchodilation in asthma and COPD.

Solution to Question 20:

Tedizolid is active against gram-positive organisms.

Tedizolid belongs to the class of oxazolidinones. It has poor activity against most gram-negative bacteria and anaerobes. It inhibits protein synthesis by binding to the P site of the 50S ribosomal subunit.

It is used for the treatment of skin and soft tissue infections, respiratory tract infections caused by streptococci, and S. aureus including MRSA.

Common adverse effects include myelosuppression leading to anemia, leukopenia, thrombocytopenia, and pancytopenia.

Pharmacology AIIMS 2020 (May and Nov INI-CET)

Question 1:

All of the following are the uses of enteric-coated drugs except:

a) Protect the acid labile drug from gastric acidity

b) Protect the gastric mucosa from irritant effects of certain drugs

c) Prolongs the half life of the drug

d) Deliver drugs distal to stomach

Question 2:

A patient who was on antiepileptics for the management of seizure disorder started having visual disturbance. Evaluation reveals the contraction of the visual field. The drug responsible is likely to be?

a) Phenobarbitone

b) Vigabatrin

c) Ethosuximide

d) Levetiracetam

Question 3:

If a patient who is on metoprolol is started on verapamil, which of the following side effects would be seen?

a) Bradycardia with AV block

b) Torsades de pointes

c) Tachycardia

d) Ventricular fibrillation

Question 4:

The response on stimulation of muscarinic receptor is:

a) Erection

b) Ejaculation

c) Bronchodilation

d) Increased myocardial contractility

Question 5:

Rosuvastatin should not be combined with which of the following drugs?

a) Oxycodon

b) Clarithromycin

c) Adalimumab

d) Rivoraxaban

Question 6:

Which of the following is not a prodrug?

a) Proguanil

b) Sulindac

c) Primidone

d) Flurouracil

Question 7:

Which of the following topical antifungal has both anti-inflammatory effects and anti-pruritic action?

a) Ketoconazole

b) Sertaconazole

c) Luliconazole

d) Terbinafine

Question 8:

A patient is started on lithium therapy. Which of the following side effects should the patient be asked to watch out for to monitor for toxicity?

a) Malaise and sore throat

b) Vertigo and Diarrhoea

c) Fever

d) Breathlessness

Question 9:

A psychiatric patient was started on lithium for the management of bipolar disorder. To monitor the blood lithium levels, at what time interval should the blood sample be collected after the administration of lithium tablets?

a) After 24 hours

b) After 12 hours

c) After 6 hours

d) Immediately after taking tablets

Question 10:

Which of the following is a second line anti-tubercular drug?

a) Streptomycin

b) Ethionamide

c) Acyclovir

d) Vancomycin

Question 11:

Which of the following anti-tubercular drug is not bactericidal?

a) Isoniazid

b) Rifapentin

c) Thioacetazone

d) Kanamycin

Question 12:

Which of the following drugs do not need dose adjustment in renal failure?

a) Sitagliptin

b) Saxagliptin

c) Vildagliptin

d) Linagliptin

Question 13:

The antidote for fibrinolytic therapy is?

a) Urokinase

b) Dalteparin

c) Tranexamic acid

d) Alteptase

Question 14:

Which of the following is least likely to be useful in a patient with severe COVID-19?

a) Low molecular weight heparin

b) Oxygen

c) Favipiravir

d) Steroids

Question 15:

If codiene is coming to the market in combination with dextromethorphan as an anti-tussive, this combination _____

a) Should not be used due to risk of addiction

b) Can be used as both have different mechanism of action

c) Should not be used as it is irrational

d) Can be used to treat cough effectively

Question 16:

The normality of 2M HCl is ___ as 1M H_2SO_4.

a) Half

b) Twice

c) Same

d) 4 times

Question 17:

An elderly woman on treatment for migraine presents with chest pain. She has a previous history of angina/MI. Which of the following mechanism of the prescribed drug for migraine might have caused this presentation?

a) 5-HT antagonist

b) 5-HT agonist

c) Calcium Channel Blocker action

d) Nitric oxide mediated vasodilation

Question 18:

A patient presented with pelvic fracture and head trauma after a road traffic accident. He was given IV morphine for pain relief following which he developed respiratory difficulty. What could be the most likely cause?

a) Pelvic Fracture

b) CO_2 retention due to opioid use

c) Cerebral Edema

d) Pulmonary embolism

Question 19:

Which of the following antidepressants causes the least sexual dysfunction?

a) Fluoxetine

b) Venlafaxine

c) Mirtazapine

d) Imipramine

Question 20:

Which of the following statements is true about disulfiram?

a) When used with alcohol, the patients feels drowsy, with chest discomfort and respiratory depression

b) It is an anticraving drug

c) It can be initiated even in minimally motivated person

d) Its action persists up to 2-3 days after stopping the drug

Question 21:

Which of the following drugs promotes bone formation?

a) Calcitonin

b) Raloxifene

c) Bisphosphonates

d) Teriparatide

Question 22:

A known asthmatic patient with fever and sore throat was prescribed an antibiotic. Two days later he presents with a maculopapular rash. Which of the following drugs might have caused this?

a) Prednisolone

b) Salbutamol

c) Fexofenadine

d) Amoxicillin

Question 23:

What is the most common drawback of the given device?

a) Bacterial contamination

b) Does not provide multiple doses

c) Drug deposition in the oropharynx

d) Not portable

Question 24:

Which of the following statements is correct for a patient on high dose of penicillin and gentamicin?

a) TDM is done with penicillin because of narrow therapeutic index

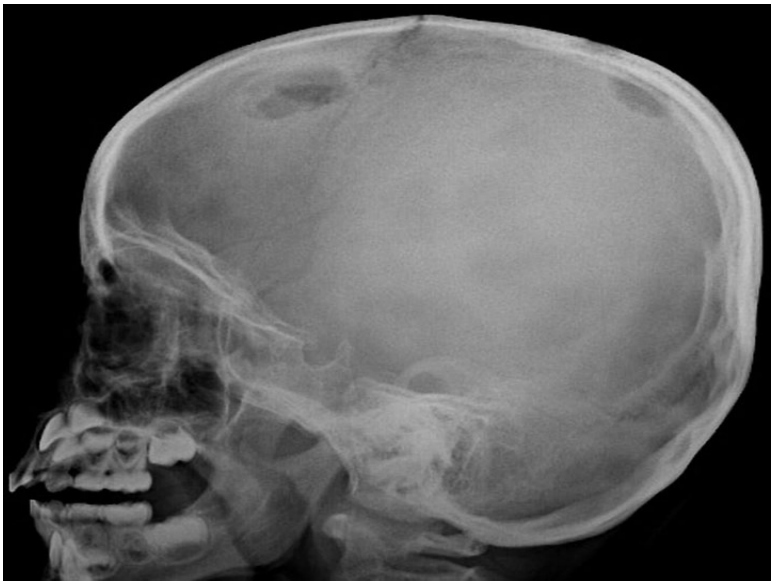
b) TDM is done with gentamicin because of narrow therapeutic index

c) TDM is done with both because of dangerous side effects

d) Both drugs do not need monitoring

Question 25:

A boy presents with pallor and lymphadenopathy, the X-ray of his skull is given below. Which of the following drug is not used for the management of the suspected diagnosis?



a) Cyclosporine

b) Methotrexate

c) Vinblastine

d) Vincristine

Question 26:

A patient was treated with TCA for a major depressive episode in the hospital for 4 weeks. What is the main concern while considering his discharge from the hospital?

a) Need for drug monitoring

b) ECG monitoring for arrhythmias

c) Suicidal risk

d) Sedation being the side effect

Question 27:

Which of the following drugs exacerbates myasthenia and is usually avoided in a patient with myasthenia gravis? 1. Lidocaine 2. Digene 3. Meropenem 4. Phenytoin

a) 1 and 2

b) 2 and 3

c) 1 and 3

d) 1 only

Question 28:

Which of the following drugs are used for absence seizures? A. Carbamazepine B. Valproate C. Ethosuximide D. Gabapentin

a) A, B and C

b) B and C only

c) B only

d) A, B and D

Question 29:

Match the following dilution of adrenaline and its use: A. 1:1000 B. 1:10000 C. 1:100000 1. Cardiac arrest 2. Anaphylaxis 3. Local anesthesia

a) A-1 B-2 C-3

b) A-2 B-1 C-3

c) A-3 B-2 C-1

d) A-1 B-3 C-2

Question 30:

Match the following bacteria with the drug of choice used for each.

a) A-1, B-3, C-4, D-2

b) A-2, B-1, C-4, D-3

c) A-3, B-4, C-1, D-2

d) A-4, B-1, C-2, D-3

Question 31:

Which of the following drug reduces mortality in COVID-19 patients? A. Dexamethasone B. Remdesivir C. Favipravir

a) B and C

b) A and B

c) Only A

d) A, B , C

Question 32:

Which of the following statements are true?

a) A and C

b) A, B and C

c) A and D

d) B, C and D

Question 33:

Which of the following is correct about the drugs used in Gout?

a) A, B & C

b) A, B, C & D

c) A & B

d) C & D

Detailed Explanations

Solution to Question 1:

Enteric coating of the drug does not prolong the half-life of the drug.

The half-life of a drug depends on the volume of distribution and rate of clearance from the blood. It is given by t1/2 = 0.693x Volume of distribution / Clearance.

The enteric coating can be done for the following reasons:

• Protection of active pharmaceutical ingredients, from the acidic environment of the stomach (e.g. enzymes and certain antibiotics).

• To prevent gastric distress or nausea from a drug due to irritation (e.g. sodium salicylate).

• For the delivery of drugs that are optimally absorbed in the small intestine to their primary absorption site in their most concentrated form.

• To provide a delayed-release component for repeat action.

• Required for minimizing the first-pass metabolism of the drug

Solution to Question 2:

The given patient has developed a contraction of the visual field which is a side effect of vigabatrin.

Solution to Question 3:

The patient will be prone to developing bradycardia and AV block.

Both ß-blockers and non-dihydropyridine calcium blockers have a propensity to slow down SA Node function and AV conduction. A combination of these drugs increases the risk further and is contraindicated. In contrast, propranolol has safely been used with the dihydropyridine group (nifedipine) of calcium channel blockers.

Solution to Question 4:

Erection is mediated by muscarinic receptors.

Erection results from parasympathetic action which is mediated via muscarinic/nicotinic receptors, whereas sympathetic action is mediated by adrenergic receptors.

Solution to Question 5:

Rosuvastatin should not be combined with clarithromycin.

Clarithromycin is a macrolide antibiotic and it can cause drug interactions because of its ability to inhibit organic anion-transporting polypeptides 1B1 and 1B3 (OATP1B1 and OATP1B3) which are involved in the excretion of statins like rosuvastatin and pravastatin.

Individuals taking rosuvastatin, pravastatin, or fluvastatin with clarithromycin had an increased risk of hospitalization for acute kidney injury, an increased risk of hyperkalemia and an increased risk of all cause mortality.

Solution to Question 6:

Among the given options primidone is not a prodrug.

Prodrugs are drugs that are in their pharmacologically inactive form. They are converted to their active forms by metabolism.

The prodrug may offer advantages over the active form in being more stable, having better bioavailability, or fewer side effects and toxicity. Some prodrugs are activated selectively at the

site of action. The given options are examples of prodrugs:

• Sulindac is a sulfoxide prodrug used in inflammatory diseases including osteoarthritis, rheumatoid arthritis, acute gouty arthritis, ankylosing spondylitis.

• Proguanil is a prodrug and its active metabolite is cycloguanil. It is used in the treatment and prevention of malaria.

• Fluro-uracil is a prodrug having the active metabolite as fluorouridine monophosphate

Solution to Question 7:

Sertaconazole has both anti-inflammatory effects and anti-pruritic action.

Sertaconazole inhibits the release of pro-inflammatory cytokines from activated immune cells.

Solution to Question 8:

Vertigo and diarrhoea are known side-effects of lithium therapy. Lithium therapy can cause side effects at both therapeutic and toxic levels.

Known significant side effects of lithium therapy include

• Polyuria-polydipsia

• Dry mouth

• Leukocytosis Headache

• Hand tremors

• Confusion

• Decreased memory

• Muscle weakness

• Hyperreflexia

• Muscle twitch

• Vertigo

• ECG changes

• Nausea & vomiting

• Diarrhoea

Other options:

No evidence of significant association with sore throat, fever or breathlessness has been documented with lithium therapy

Solution to Question 9:

The blood sample for serum lithium estimation is to be collected after a time interval of 10-12 hours from the previous dose of lithium.

Lithium is used in the management of bipolar disorder, mania, and has anti-suicidal properties. It has a narrow therapeutic index, and blood levels in excess of this may cause symptoms of toxicity. Therapeutic drug monitoring is done by measuring trough lithium levels 12 hours after the previous dose, at least 5 days after the initiation of the treatment with lithium.

Solution to Question 10:

Ethionamide is a second line anti-tubercular drug.

Ethionamide is structurally related to isoniazid and acts by inhibiting the mycolic acid synthesis. It is effective against bacilli resistant to other drugs and has been proved effective in infections due to atypical mycobacteria. It is effective against both intracellular as well as extracellular organisms.

The first line anti-tubercular drugs include: Isoniazid, Rifampicin, Pyrazinamide, Ethambutol

The second line drugs include fluoroquinolones, ethionamide, capreomycin, kanamycin, amikacin, cycloserine, thioacetazone.

Note: This is a recall question when ethionamide is a second-line among the given options, and streptomycin was a first line injectable drug.

Solution to Question 11:

Thioacetazone is not a bactericidal drug, it is bacteriostatic.

Thioacetazone is never used alone. It is only used as a combination with first-line TB medications, such as isoniazid and rifampicin. It is used primarily to prevent the development of bacteria that are resistant to first-line drugs and to treat patients infected with drug-resistant TB.

It should never be used in HIV patients as it can cause severe and fatal skin reactions.
Side-effects include gastrointestinal disturbances, blurring of vision, hemolytic anemia and urticaria.

Isoniazid is a first-line bactericidal drug that is active against both intracellular and extracellular bacilli.

Rifapentin is a rifampin congener having a similar mechanism of action. It is a bactericidal drug having a longer half-life than rifampin.

Kanamycin is bactericidal and is active against bacilli resistant to streptomycin, INH, and cycloserine.

Solution to Question 12:

Linagliptin does not require dose adjustment in patients with renal failure.

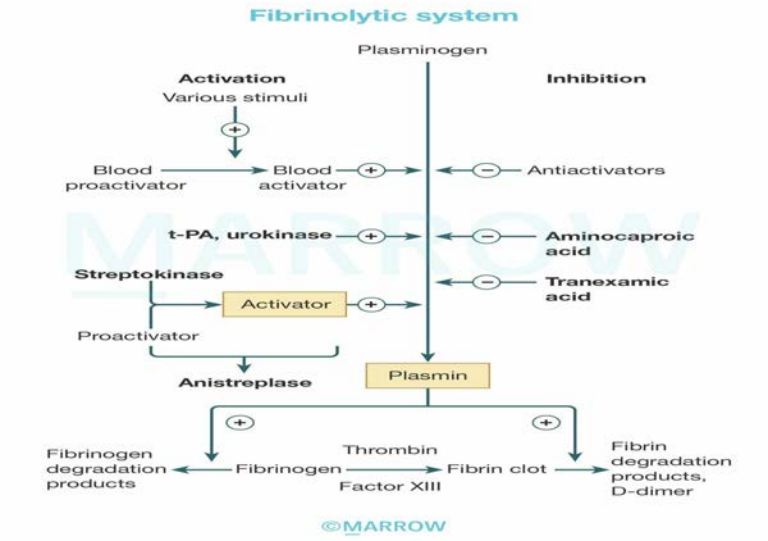
Linagliptin is a dipeptidyl-peptidase-4 (DPP-4) inhibitor. It is used in type 2 diabetes as monotherapy or in combination therapy when metformin is not tolerated or contraindicated. It binds extensively to plasma proteins and is cleared primarily by the hepatobiliary system. Hence, no dosage adjustment is needed in renal failure.

Other DPP-4 inhibitors (sitagliptin, vildagliptin, saxagliptin, alogliptin) show renal elimination and therefore require dose reduction in renal failure.

Solution to Question 13:

The antidote for fibrinolytic therapy is tranexamic acid.

Tranexamic acid is a lysine analogue that competitively bind to lysine binding sites on plasminogen and plasmin, and block their interactions with fibrin and thereby inhibiting fibrinolysis. It is given intravenously in trauma resuscitation, massive hemorrhage, and in women with postpartum hemorrhage.



Other options:

Option A (Urokinase) and D (Alteplase) are fibrinolytic drugs.

Option B: Dalteparin is low molecular weight heparin.

Solution to Question 14:

Favipiravir (inhibits viral RNA polymerase) was the first oral drug approved in India for restricted emergency use for the treatment of mild to moderate COVID-19 patients. It was not approved for

severe COVID-19.

Note: This is a question from INICET 2020, during which time Favipiravir had gained approval from DCGI for mild to moderate COVID. The current clinical management protocol for COVID-19 does not recommend Favipiravir.

Solution to Question 15:

It is an irrational drug combination and should not be given.

Codeine is an opioid analgesic having specific antitussive action while dextromethorphan is a centrally active NMDA receptor antagonist that may be effective as an antitussive. Both are centrally acting antitussives, and do not provide any added advantage when combined. Hence it is an irrational drug combination.

Rational fixed-dose combination drugs for the treatment of cough usually contain:

• A centrally acting anti-tussive (either codeine or dextromethorphan; not both), with

• Antihistamines, decongestants and expectorants.

Option A - Both of these drugs carry a risk of addiction, but it is not the reason to not give the drug. The main reason is that the combination is irrational.

Options B & D - Both codeine and dextromethorphan have different mechanisms of action and can treat cough effectively. However, the combination of two centrally acting antitussives does not provide any added advantage compared to using one drug alone. Hence, the combination is irrational.

Solution to Question 16:

The normality of 2M HCl is the same as 1M H_2SO_4.

Normality of a solution can be calculated from its molarity by multiplying it by its valence. Valence is the number of protons a salt releases in aqueous solution.

Here Valence of HCl is 1 while H_2SO_4 is 2.

Hence Normality of HCl = 2M x 1 = 2 N

similarly Normality of H_2SO_4 = 1M x 2 = 2N

Normality is defined as the number of gram equivalents dissolved per liter of solution. Where gram equivalents are the number of moles of a solute multiplied by its valence

Molarity is defined as the number of moles of a solute dissolved per liter of solution.

Solution to Question 17:

The patient may have been given sumatriptan, a 5-HT1b/1d receptor agonist which causes vasoconstriction and used in migraine. Thus, sumatriptan will worsen angina by causing coronary vasoconstriction.

Angina will be worsened if the O2 demand of the heart is increased or there is reduced blood flow to the already ischemic areas.

Solution to Question 18:

The most likely cause of respiratory difficulty in the given clinical scenario is CO2 retention due to opioid use, as the patient was administered morphine after head trauma.

Head injury is considered as a contraindication to morphine use because:

• Morphine retains CO2 that increases intracranial pressure (ICP) and adds to the already increased ICP.

• Therapeutic doses can result in marked respiratory depression.

• Interferes with the assessment of progress by causing miosis, vomiting, and altered mentation.

Solution to Question 19:

Among the given options mirtazapine causes the least sexual dysfunction.

Mirtazapine and mianserin block histamine H1 receptors and also have high antagonistic activity against 5HT2A, 5HT2C, and 5HT3 receptors. Sexual dysfunction is not a known side-effect of mirtazapine.

Due to its sedative effect, mirtazapine is used in depression with insomnia.

Option A: Fluoxetine is a selective serotonin reuptake inhibitor (SSRI) that can cause side effects like GI disturbances, sexual dysfunctions, may increase the risk of suicidal thoughts or behavior, risk of serotonin syndrome with MAOIs, and some CYP interactions. Vilazodone is an SSRI not associated with sexual dysfunction or weight gain.

Option B: Serotonin-norepinephrine reuptake inhibitors like venlafaxine have side effects that include nausea and dizziness, may increase the risk of suicidal thoughts or behavior, and can also cause sexual dysfunctions.

Option D: Tricyclic antidepressants like imipramine have side effects like orthostatic hypotension, weight gain, GI disturbances, sexual dysfunction, seizures, and irregular heartbeats.

The various drugs classes used in depression and anxiety are listed below

Class of drugs	Examples
Selective serotonin reuptake inhibitors (SSRI)	FluoxetineFluvoxaminParoxetineSertralineCitalopram
Serotonin-norepinephrine reuptake inhibitors	Venlafaxine, desvenlafaxineDuloxetineMilnacipran

Class of drugs	Examples
Tricyclic antidepressants	AmitriptylineImipramineNortriptylineDesipramineAmoxapine
Atypical antipsychotics	AripiprazoleOlanzapineQuetiapineRisperidone
Monoamine oxidase inhibitors (MAO)	IsocarboxazidSelegilinePhenelzine
Atypical antidperessants	BupropionTrazodoneMirtazapineMianserin

Solution to Question 20:

Disulfiram is used in behavioural modification technique for alcohol de-addiction. The principle of action is aversive conditioning.

Disulfiram is an irreversible inhibitor of both cytosolic and mitochondrial forms of aldehyde dehydrogenase. Ethanol consumption during disulfiram therapy can lead to increased concentrations of acetaldehyde. Increased acetaldehyde levels can cause flushing, pulsating headache, throbbing pain in head and neck, nausea, vomiting, rashes, respiratory difficulties, chest pain, autonomic manifestations and other aversive reactions.

Disulfiram can only be given to highly motivated individuals. Disulfiram should not be administered until the person has abstained from alcohol for at least 12 hours. The disulfiram-alcohol reaction may occur as long as 14 days after the last dose of disulfiram.

Disulfiram like reaction with alcohol ingestion is also seen with the following drugs:

• Metronidazole

• Sulfonylureas like chlorpropamide

• Cephalosporins like cefoperazone, cefamandole

Other modalities of treatment:

• Pharmacotherapy: Typically 5-10 days, treatment for detoxification: Benzodiazepine and chlordiazepoxide are the drugs of choice.

• Rehabilitation programs: Typically 28-day programs, learn about relapse prevention and identification of triggers.

• Maintenance phase: Baclofen, Acamprosate, Naltrexone, Topiramate, SSRI, Ondansetron

• Psychotherapy: Group therapy such as Alcoholics Anonymous

Solution to Question 21:

Teriparatide increases bone formation especially when given in low doses and intermittently.

Teriparatide is a recombinant preparation of parathyroid hormone.

The pharmacologic activity of teriparatide, which is similar to the physiologic activity of PTH, includes stimulating osteoblast function, increasing gastrointestinal calcium absorption, and increasing renal tubular reabsorption of calcium.

Although it may be more effective than bisphosphonates and estrogen, it has to be administered subcutaneously every day. Hence it is indicated mostly in severe osteoporosis.

Teriparatide increases the risk of osteosarcoma and it is contraindicated in conditions that cause high risk of osteosarcoma such as:

• Paget disease

• Prior h/o of radiotherapy

• Young adults with open epiphysis

• Unexplained elevated ALP

• Hypercalcemia

Option A: Calcitonin decreases bone resorption.

Option B: Raloxifene is a selective estrogen receptor modulator, which decreases bone resorption. It is used to prevent and treat osteoporosis in postmenopausal women.

Option C: Bisphosphonates like alendronate and etidronate decrease bone resorption.

Solution to Question 22:

Skin rashes of all types may be caused by allergy to penicillin.

Amoxicillin and ampicillin are aminopenicillins. The incidence of skin rashes appears to be highest following the use of ampicillin, at about 9%.

Amoxicillin is a close congener of ampicillin with the following features:

• Better oral absorption; food does not interfere with the absorption

• Incidence of diarrhea is less

• More active against penicillin-resistant pneumococci

Solution to Question 23:

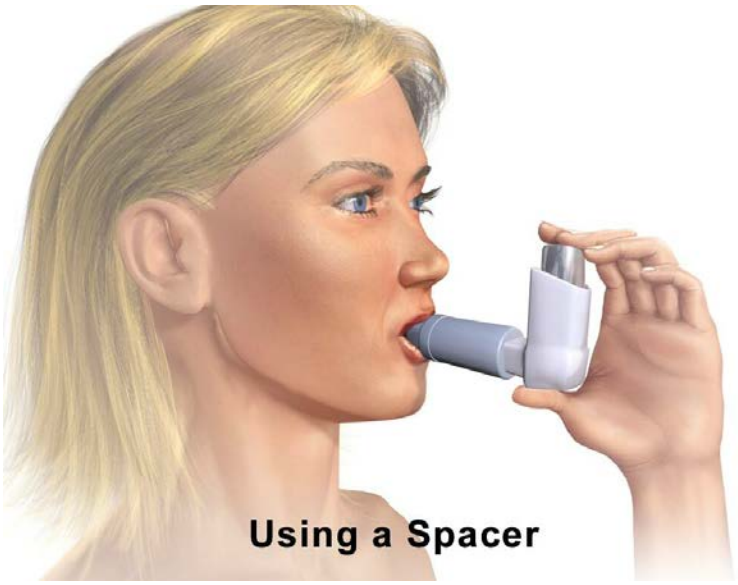
The given image shows a metered-dose inhaler (MDI). The most common side effect of this device is drug deposition in the oropharynx.

Most material inhaled using this device will be swallowed and absorbed, entering systemic circulation after undergoing the first-pass effect in the liver. Some drug will also be absorbed into the systemic circulation from the lungs.

The use of a large-volume spacer will reduce the amount of drug deposited in the oropharynx, thereby reducing the amount swallowed and absorbed from the GI tract, thus limiting the

systemic effects of the drug.

The given image shows the use of spacer with MDI:



Spacers reduce the velocity and size of particles entering the upper airways. This reduces the amount of drug that impinges on the oropharynx and increases the proportion of the drug inhaled into the lower airways.

Spacer devices are useful in delivering inhaled drugs to small children, as young as 3 years of age, who are not able to use a pMDI (pressurized MDI), as seen in the image below:

Pressurized metered-dose inhalers: Drugs are propelled from a canister in the pMDI with the aid of a propellant. These devices are convenient, portable, and typically deliver 50–200 doses of the drug.

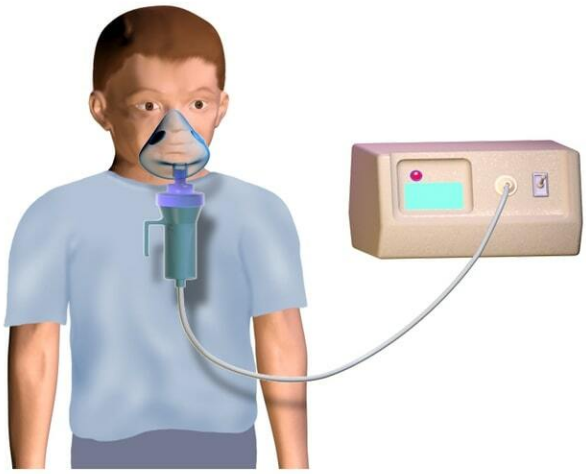
Dry powder inhalers: Drugs may also be delivered as a dry powder using devices that scatter a fine powder dispersed by air turbulence on inhalation. Children less than 7 years of age find it difficult to use a DPI. DPIs have been developed to deliver peptides and proteins, such as insulin,

systemically but have proved to be problematic because of the consistency of dosing.

The given image shows various types of dry powder inhalers:

Nebulizers: Two types of nebulizers are available. Jet nebulizers are driven by a stream of gas (air or oxygen), whereas ultrasonic nebulizers use a rapidly vibrating piezoelectric crystal and thus do not require a source of compressed gas.

The nebulized drug may be inspired during tidal breathing, and it is possible to deliver much higher doses of the drug as compared to pMDI. Nebulizers are therefore useful in treating acute exacerbations of asthma and COPD, for delivering drugs when airway obstruction is extreme (e.g., in severe COPD), for delivering inhaled drugs to infants and small children who cannot use the other inhalation devices, and for giving drugs such as antibiotics when relatively high doses must be delivered.



Using a Nebulizer

Solution to Question 24:

Gentamicin is an aminoglycoside antibiotic that requires therapeutic drug monitoring (TDM) as it has a narrow therapeutic index. It is nephrotoxic and ototoxic (predominantly vestibular effects).

The threshold for toxicity for gentamicin is the plasma concentration of 2 μg/mL, the maximum recommended for prolonged exposure.

Aminoglycoside antibiotics act by binding to the 30s ribosome and inhibiting protein synthesis. Their ability to cause misreading of DNA templates and the formation of aberrant proteins that get incorporated into bacterial cell membranes makes them bactericidal agents.

Common ototoxic drugs are:

• Antibiotics - aminoglycosides (gentamicin > tobramycin > amikacin > neomycin), erythromycin, tetracyclines.

• Chemotherapeutic agents - cisplatin, bleomycin, nitrogen mustards.

• High dose aspirin, acetaminophen, NSAID's

• Antimalarials - quinine, quinidine

• Phosphodiesterase-5 inhibitors - sildenafil

Solution to Question 25:

The given clinical scenario and the X-ray of the skull are suggestive of Langerhans Cell Histiocytosis. Vincristine is not used in the management of this condition.

Following are skeletal and radiological manifestations of Langerhan's cell histiocytosis:

Skull:

• Solitary or multiple punched-out lytic lesion without sclerotic rim.

• Double contour or beveled edge appearance (hole within a hole sign).

• Button sequestra representing residual bone.

• Geographic skull.

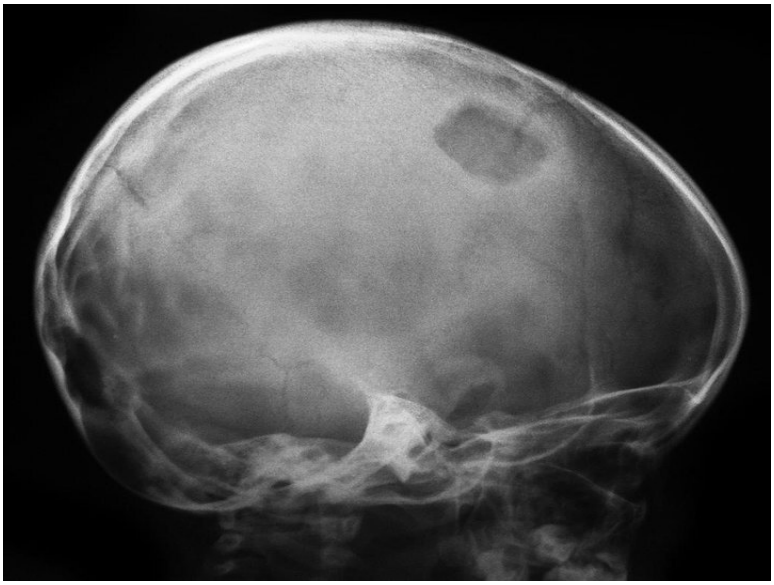
Mandible:

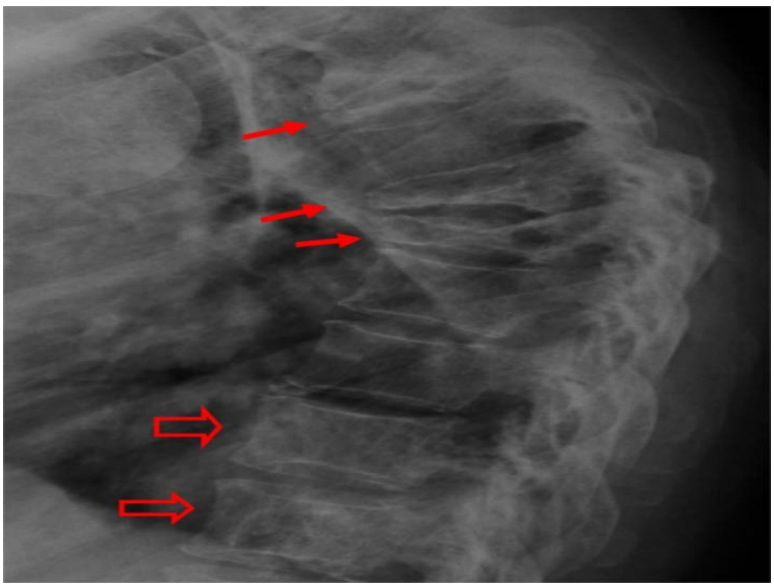
• Floating tooth: loss of lamina dura.

Spine:

• Vertebra Plana: Most common cause of vertebra plana in children; mostly seen in thoracic spine.

Skull in LCH, Vetebra plana:





Solution to Question 26:

Suicidal thoughts or behavior are a side effect of TCAs. Therefore, the attendants of the patient should be warned regarding this when a patient gets discharged after being treated with TCAs for a major depressive episode.

Tricyclic antidepressants (TCAs) are drugs that act by inhibiting the reuptake of noradrenaline and serotonin from the synaptic clefts.

The side effects of TCAs are due to blockade of other receptors:

• Muscarinic M receptors- constipation, dry mouth, arrhythmia

• Histamine H1 receptors- sedation

• 5HT receptors - weight gain due to increased appetite

• Alpha1 receptors - postural hypotension.

The various classes of drugs used in depression and anxiety are listed below:

Class of drugs	Examples
Selective serotonin reuptake inhibitors (SSRI)	FluoxetineFluvoxaminParoxetineSertralineCitalopram
Serotonin-norepinephrine reuptake inhibitors	VenlafaxineDesvenlafaxineDuloxetineMilnacipran
Tricyclic antidepressants	AmitriptylineImipramineNortriptylineDesipramineAmoxapine
Atypical antipsychotics	AripiprazoleOlanzapineQuetiapineRisperidone
Monoamine oxidase inhibitors (MAO)	IsocarboxazidSelegilinePhenelzine
Atypical antidepressants	BupropionTrazodoneMirtazapineMianserin

Solution to Question 27:

Lidocaine can exacerbate myasthenia gravis and should be avoided in patients with this disease. Also, digene is an antacid, that contains magnesium hydroxide as one of its active ingredients, which may exacerbate myasthenia.

Drugs that may aggravate myasthenia gravis are

• Antibiotics like aminoglycosides, quinolones, and macrolides

• Beta-blockers

• Botulinum toxin

• Local anaesthetics

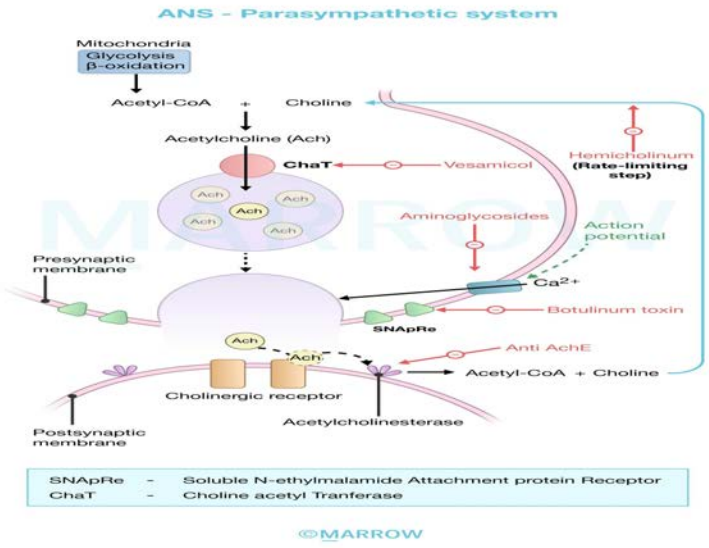
• Magnesium

• Non–depolarising muscle relaxants

• Penicillamine

• Quinine derivatives

Aminoglycosides have to be avoided in a patient with myasthenia gravis. It blocks Ca^{2+} mediated exocytosis of acetylcholine from the presynaptic membrane in the neuromuscular junction. The decrease in ACh levels aggravates myasthenia gravis. Aminoglycosides can also have a direct inhibitory effect on post-synaptic acetylcholine receptors.



Solution to Question 28:

Ethosuximide and Valproate are effective for the treatment of absence seizures. However, between these 2 drugs, Ethosuximide would be a better first-line treatment choice for uncomplicated typical absence seizures followed by Valproate. Atypical absence seizures respond well to valproate.

Typical absence seizures are characterized by sudden, brief lapses of consciousness without loss of postural control. There is no postictal confusion. The following subtle motor signs may accompany the episodes

• Rapid blinking of the eyelids

• Chewing movements

• Small-amplitude clonic movements of the hands

Hyperventilation has a tendency to provoke the absence seizures.

NOTE: In a typical absence seizure, Ethosuximide is the first-line therapy for it and acts by blocking the calcium channel.

Mechanism of action of some common antiepileptics:

Mechanism of action	Antiepileptics
Sodium-channel blockers	PhenytoinCarbamazepine, OxcarbamazepineEslicarbazepineLamotrigineTopiramateFelbamateValproateRufinamideLevetiracetam
Calcium-channel blockers	ValproateLamotrigineEthosuximide

Mechanism of action	Antiepileptics
GABAAreceptor modulators	BenzodiazepinesPhenobarbitalFelbamatePrimidoneTopiramateCarbamazepine, OxcarbamazepineStiripentolClobazam
GABA uptake inhibitors	TiagabineVigabatrin
NMDA receptor antagonist	Felbamate
AMPA/Kainate receptor antagonist	PhenobarbitalTopiramatePerampanel
HCN channel activity enhancers	Lamotrigine
Inhibitors of brain carbonic anhydrase	AcetazolamideZonisamideTopiramate
Potassium-channel openers	RetigabineTopiramate

Solution to Question 29:

A-2 B-1 C-3

Epinephrine (1:1000 solution) 0.5 ml I.M. is preferred in the treatment of anaphylactic shock.

In cardiac arrest, the 1:1000 adrenaline must be diluted to 1:10,000 for IV use.

Adrenaline in a concentration of 1: 50,000 to 1: 200,000 is added to local anesthetics for:

• Reducing the systemic absorption

• Prolonging the duration of action

• Providing a more bloodless field for surgery

1:1000 dilution can be used for intramuscular, subcutaneous and inhalational (nebulization) route of administration. For intravenous use, 1:1000 adrenaline must be further diluted to 1:10,000 and used cautiously.

IM injection is preferred over intravenous (IV) bolus because it is faster in many situations and safer (ie, lower risk of cardiovascular complications, such as severe hypertension and ventricular arrhythmias). There is a much greater risk of causing harmful side effects by inappropriate dosage or misdiagnosis of anaphylaxis when using IV adrenaline.

Epinephrine is also used in the treatment of hypotension, to induce local vasoconstriction to reduce the diffusion of local anaesthetics, to induce bronchodilation in asthma and COPD.

Note: . The recommended dose of epinephrine is 1mg = 10 mL of a 1:10,000 solution administered IV every 3 to 5 minutes during resuscitation as per the CPR guidelines. For nebulization, 1:1000 adrenaline is commonly used.

Solution to Question 30:

A-2, B-1, C-4, D-3

Vancomycin is Drug Of Choice for Methicillin-Resistant Staphylococcus aureus (MRSA) (should be used only if other drugs are resistant).

Metronidazole is the drug of choice for anaerobic infections caused by Bacteroides.

Uses of metronidazole include:

• Giardiasis

• Trichomoniasis

• Amoebiasis

• Bacterial vaginosis

• treatment of pseudomembranous colitis.

Meropenem is used in infections caused by ESBL producing bacteria like Klebsiella.

Carbapenems are not hydrolyzed by ESBL (extended-spectrum beta-lactamases). Therefore, carbapenems like imipenem, meropenem, ertapenem are resistant to hydrolysis by extended-spectrum beta-lactamases and are indicated in the treatment of infections caused by ESBL producing bacteria. ESBL is most prevalent among gram-negative organisms like Klebsiella and E. coli.

Penicillins like amoxicillin, ampicillin can be used in H. influenzae infections.

Solution to Question 31:

Among the given options, only dexamethasone is shown to reduce mortality in severe covid19 cases.

Patients with severe COVID-19 can develop a systemic inflammatory response that can lead to lung injury and multisystem organ dysfunction. It has been proposed that the potent anti-inflammatory effects of corticosteroids might prevent or mitigate these deleterious effects and help reduce mortality.

In severe cases, Dexamethasone is administered at doses of 6mg IV/PO once daily for 10 days or until hospital discharge. If dexamethasone is not available, then, equivalent doses of other corticosteroids, like prednisone, methylprednisone, or hydrocortisone may be used.

Other options:

• There is no evidence that favipiravir reduces mortality. It reduces duration of hospitalisation in mild to moderate disease.

• In a recent update, WHO recommended against the use of remdesivir in hospitalized patients, regardless of disease severity, as there is no evidence that it improves survival.

Solution to Question 32:

Statements A, B and C are true.

A. Morphine used in pulmonary edema

B. Pethidine used in biliary colic

C. Indomethacin is used in headache

Aspirin can also cause damage to the stomach and intestinal lining leading to the development of erosions or ulcers. Erosions may cause further complications like bleeding and perforations.

Note: Unlike Morphine, Pethidine/Mepiridine can be used for pain management in biliary colic as it has no effect on the tone of sphincter of Oddi.

Solution to Question 33:

Gout is a metabolic disease associated with hyperuricemia.

The drug of choice is an acute attack of gout is NSAIDs (Non-steroidal anti-inflammatory drugs) like indomethacin or the drug colchicine, but they are poorly tolerated and should not be used in elderly patients with chronic kidney disease.

Indomethacin is commonly used in the initial treatment of gout. In addition to inhibiting prostaglandin synthase, indomethacin and other NSAIDs also inhibit urate crystal phagocytosis

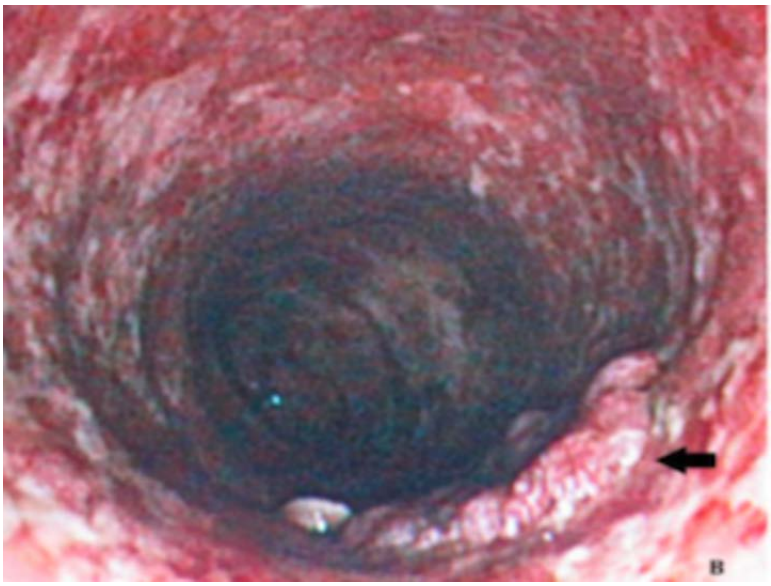
Intraarticular steroids like triamcinolone or methylprednisolone can also be given.

Aspirin is not used because it causes renal retention of uric acid at low doses. It is uricosuric only at higher doses that are poorly tolerated.

Pharmacology NEET 2018

Question 1:

A colonoscopy of an elderly patient revealed brownish pigmented lesions as shown below. He admitted to chronic laxative abuse. Which of the following laxatives is most likely to cause this condition?



a) Bran

b) Psyllium

c) Senna

d) Methylcellulose

Question 2:

A patient who is on treatment for angina, presents to you with erectile dysfunction. You decide against prescribing sildenafil because the patient is being treated with _____

a) Calcium channel blockers

b) Beta blockers

c) Nitrates

d) ACE inhibitors

Question 3:

An example of a bacteriostatic drug is _____

a) Aminoglycoside

b) Vancomycin

c) Metronidazole

d) Linezolid

Question 4:

The antiviral drug having dual antiviral activity against HIV and HBV is:

a) Enfuviritide

b) Abacavir

c) Emtricitabine

d) Ritonavir

Question 5:

The replacement dose of hydrocortisone for chronic adrenal insufficiency is (in mg/day):

a) 10

b) 12

c) 20

d) 5

Question 6:

Which of the following is the drug of choice for scrub typhus?

a) Doxycycline

b) Azithromycin

c) Chloramphenicol

d) Ciprofloxacin

Question 7:

Which of the following drugs is associated with QT prolongation?

a) Lignocaine

b) Quinidine

c) Magnesium sulfate

d) All of the above

Question 8:

Sacubitril is a new drug approved for chronic heart failure. The mechanism of action of sacubitril is:

a) Angiotensin II inhibitor

b) ACE inhibitor

c) Renin inhibitor

d) Neutral endopeptidase inhibitor

Question 9:

Coagulation profile monitoring is needed in therapy with which of the following drugs?

a) Fondaparinux

b) Enoxaparin

c) Dabigatran

d) Lepirudin

Question 10:

Which of the following antihypertensives are not used in pregnancy?

a) Alpha methyldopa

b) Hydralazine

c) Propranolol

d) Labetalol

Question 11:

Which of the following atypical antipsychotics has the highest risk of galactorrhea?

a) Iloperidone

b) Risperidone

c) Clozapine

d) Aripiprazole

Question 12:

When the pH = pKa of a drug, which of the following statements is true?

a) Concentration of the drug is 50% ionic and 50 % non-ionic

b) Concentration of the drug is 90% ionic and 10% non-ionic

c) Concentration of the drug is 75% ionic and 25 % non-ionic

d) Concentration of the drug is 25% ionic and 75 % non-ionic

Question 13:

Corticosteroid indicated for the stimulation of fetal lung maturation in preterm labor is?

a) Hydrocortisone

b) Triamcinolone

c) Methylprednisolone

d) Betamethasone

Question 14:

What is the site of action of amphotericin B in fungi?

a) Nucleic acid

b) Ribosome

c) Cell membrane

d) Cytoplasm

Question 15:

Which of the following acts by causing both decreased bone resorption and increased bone formation?

a) Strontium ranelate

b) Ibandronate

c) Teriparatide

d) Calcitonin

Question 16:

Which is the drug used for refractory intractable rheumatic chorea?

a) Probenecid

b) Diazepam

c) Haloperidol

d) Sodium valproate

Question 17:

What is basiliximab?

a) IL-1 receptor antagonist

b) Anti-CD3 antibody

c) IL-2 receptor antagonist

d) TNF inhibitor

Question 18:

Which of the following conditions can be treated with pirenzepine?

a) Asthma

b) Peptic ulcer disease

c) Glaucoma

d) Hypertension

Question 19:

Which of the following antimicrobials is effective against an organism producing extended-spectrum beta-lactamases?

a) Amoxicillin - clavulanic acid

b) Penicillin

c) Piperacillin - tazobactam

d) Ceftriaxone

Question 20:

Which of the following inhibits the synthesis of glucocorticoid?

a) Mifepristone

b) Flutamide

c) Finasteride

d) Metyrapone

Question 21:

Isosorbide dinitrate is indicated for congestive heart failure in combination with which of the following vasodilators?

a) Minoxidil

b) Hydralazine

c) Nimodipine

d) Nitrendipine

Question 22:

What is the mechanism of action of colchicine?

a) Inhibits synthesis of uric acid

b) Promotes excretion of uric acid

c) Inhibits xanthine oxidase enzyme

d) Binds to tubulin and inhibits granulocyte migration

Question 23:

Which of the following statements is true about prasugrel?

a) It acts as an P2 Y12 agonist

b) It is 10 times less potent than clopidogrel

c) It is a pro drug

d) Omeprazole interferes in its activation to an active metabolite

Question 24:

Apixaban belongs to which of the following class of drugs?

a) Antifibrinolytic

b) Factor Xa inhibitor

c) Oral direct thrombin inhibitor

d) Parenteral direct thrombin inhibitor

Answer Key

Question No.	Correct Option
1	c
2	c
3	d

Detailed Explanations

Solution to Question 1:

The above colonoscopy image depicts a brownish moiré pattern that is indicative of melanosis coli. Chronic use of anthraquinone laxatives like senna and cascara sagrada can cause melanosis coli.

Bisacodyl is also implicated in causing melanosis coli.

Solution to Question 2:

The patient would be on nitrates for angina and thus should not be prescribed sildenafil as sildenafil causes dangerous potentiation of nitrate action resulting in severe hypotension.

The combination of the two drugs has a synergistic action on the intracellular cGMP levels that can result in uninhibited vasodilation and a precipitous fall in blood pressure. Hence, the use of sildenafil is a contraindication when on nitrates.

Solution to Question 3:

Linezolid is an example of a bacteriostatic drug.

Primarily bacteriostatic drugs	Primarily bactericidal drugs
SulfonamidesErythromycinTetracyclinesClindamycinChloramphenicolLinezolidEthambutol	Penicillins,CephalosporinsAminoglycosidesVancomycinPolypeptidesCiprofloxacinRifampinMetronidazoleIsoniazidCotrimoxazolePyrazinamide

Solution to Question 4:

Antiviral drug having dual antiviral activity against HIV and HBV is emtricitabine.

It is a nucleoside reverse transcriptase inhibitor similar to lamivudine. It has activity against HIV-1, HIV-2, and HBV.

Solution to Question 5:

The replacement dose of hydrocortisone for chronic adrenal insufficiency is 20 mg/day.

The treatment of chronic adrenal insufficiency (not in crisis) requires glucocorticoid replacement at a dose that replaces the physiologic daily cortisol production. This is achieved by administering an oral replacement dose of 15-25mg Hydrocortisone.

A midpoint dose of 20mg is given in 2-3 divided doses: 10mg + 5mg + 5mg.

Half the daily dose should be administered to all patients in the morning. This is to follow the normal circadian rhythm.

Solution to Question 6:

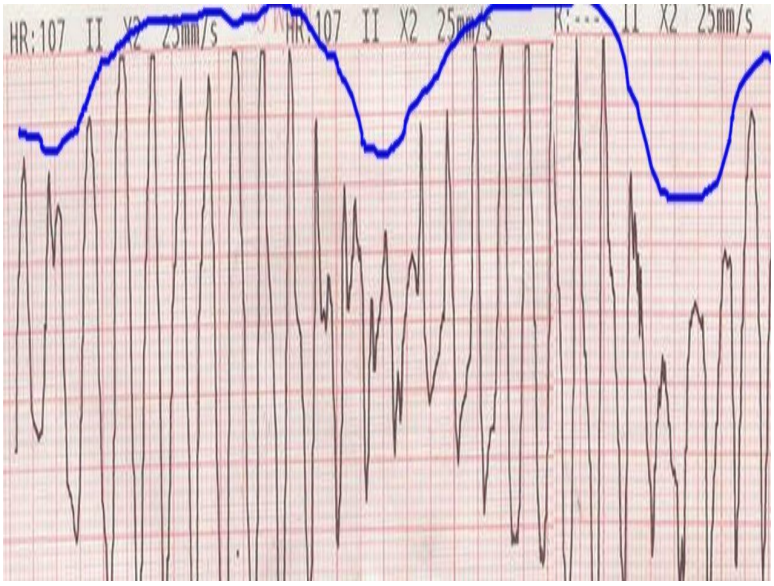
Doxycycline is the drug of choice for scrub typhus.

Azithromycin, chloramphenicol, or rifampin can be administered as alternatives in patients allergic to doxycycline and in pregnancy.

Solution to Question 7:

QT prolongation is seen with quinidine.

It causes torsades de pointes, a life-threatening form of polymorphic ventricular tachycardia.



Solution to Question 8:

Sacubitril is a neutral endopeptidase (neprilysin) inhibitor.

Sacubitril is a prodrug that is activated to sacubitrilat. It can inhibit the enzyme neprilysin (neutral endopeptidase), which is responsible for the degradation of atrial and brain natriuretic peptides (reduction of blood volume). Therefore, it increases the levels of atrial and brain natriuretic peptides and lowers blood pressure.

In 2015, the FDA approved the use of sacubitril in combination with valsartan, at a ratio of 1:1, for the treatment of chronic heart failure.

Solution to Question 9:

Coagulation profile monitoring is needed for lepirudin.

Lepirudin is a direct irreversible thrombin inhibitor and its most adverse reaction is bleeding. The risk of bleeding can be reduced by implementing an appropriate monitoring and dose adjustment strategy. Thus, coagulation profile monitoring is required for lepirudin.

However, enoxaparin, fondaparinux, and dabigatran do not bind to endothelium or many plasma proteins and thus, the response to these drugs at the usual doses is consistent from patient to patient. Hence, monitoring is not required.

Solution to Question 10:

Propranolol is a non-selective beta-blocker and is not safe for use during pregnancy.

Antihypertensives to be avoided in pregnancy:

• ACE inhibitors, ARBS

• Diuretics

• Nonselective beta-blockers

• Nitroprusside

Antihypertensives found to be safe in pregnancy:

• Hydralazine

• Methyldopa

• Dihydropyridine CCBs: should be stopped before labor as they weaken the uterine contractions

• Cardioselective beta-blockers and those with intrinsic sympathomimetic activity: may be used as a last choice

Solution to Question 11:

Among atypical antipsychotics, risperidone and paliperidone have the highest risk of galactorrhea.

The adverse effect occurs due to their higher D2 blocking potency.

Solution to Question 12:

When the pH = pKa of a drug, the concentration of the drug is 50% ionic and 50% non-ionic.

pKa is defined as the pH at which a drug exists as 50% ionized (hydrophilic) and 50% unionized (lipophilic).

For e.g., phenobarbitone is an acidic drug with a pKa of 7.2. At a pH of 7.2, 50% will be unionized. In a more basic plasma (pH=7.4), a lesser fraction (around 40%) will be unionized.

Small changes in pH near pKa of a drug may cause large variations in the degree of ionization.

Solution to Question 13:

Betamethasone is indicated for the stimulation of fetal lung maturation in preterm labor.

As compared to cortisol, betamethasone binds to maternal proteins less and has less placental metabolism. This allows increased transfer to the fetus. Additionally, infants exposed to betamethasone are less likely to require postnatal resuscitation. 2 doses of 12 mg each are administered 18-24 hours apart when the delivery is anticipated before 34 weeks of gestation.

Dexamethasone, another long-acting glucocorticoid is also indicated. It has benefits such as less risk of intraventricular hemorrhage and a shorter length of stay in the NICU.

Solution to Question 14:

The site of action of amphotericin B in fungi is the cell membrane.

Amphotericin B binds to the ergosterol in the cell membrane of fungi and forms pores or channels. They increase the permeability of the membrane to ions and cause leakage of cytosolic molecules. This leads to a loss of integrity of the cell membrane and causes fungicidal effects.

Recent evidence suggests that the amphotericin B sequesters ergosterol from lipid layers, much like a sponge, resulting in fungal cell death.

Solution to Question 15:

Strontium ranelate acts by both decreased bone resorption and increased bone formation.

It is generally reserved for severe osteoporosis. Due to an increased incidence of myocardial infarction and other cardiovascular events, the use is restricted in all the approved regions.

Option B- Ibandronate which is a bisphosphonate, decreases bone resorption only.

Option C- The pharmacologic activity of teriparatide, which is similar to the physiologic activity of PTH, includes stimulating osteoblast function, increasing gastrointestinal calcium absorption, and increasing renal tubular reabsorption of calcium.

Option D- Calcitonin also decreases bone resorption.

Solution to Question 16:

The drug used for refractory intractable rheumatic chorea is sodium valproate, as it doesn't have extrapyramidal side effects.

Sydenham's chorea is characterized by involuntary, purposeless, jerky movements which mainly affect the head and upper limbs. In the tongue, it is visible as the characteristic darting movements.

Medications used to treat Sydenham chorea are:

• Mild cases - Providing a calm environment.

• Severe cases:

• Dopamine antagonists - haloperidol, pimozide

• Antiepileptic medications - sodium valproate, carbamazepine.

• Severe, refractory cases - Steroids (thought to be immune-mediated)

• IV immunoglobulins, plasmapheresis - limited studies, decreased efficacy (not currently recommended)

Solution to Question 17:

Basiliximab exhibits a high affinity towards IL-2 receptor and inhibits it. It is an anti- CD-25 monoclonal antibody.

It has a short plasma half-life of 1 week. It is used to prevent transplant rejection reactions. Its adverse effects are anaphylactic reactions & opportunistic infections.

Solution to Question 18:

Pirenzepine is used for treating gastric ulcers. It is a selective M1 anticholinergic drug. It decreases gastric acid secretions at doses that have little effect on salivation or heart rate.

Solution to Question 19:

Piperacillin-tazobactam is an antimicrobial that is effective against organisms producing extended-spectrum beta-lactamases.

Extended-spectrum beta-lactamase (ESBL) enzyme produced by bacteria causes resistance to most of the penicillins, cephalosporins (third and fourth generation), and monobactams. ESBL is most prevalent among gram-negative organisms like Klebsiella and E. coli.

ESBL can be inhibited by combining beta-lactamase inhibitors like clavulanic acid or tazobactam. Carbapenems and quinolones have inherent activity against ESBL.

Note: As piperacillin has greater activity against Klebsiella and other gram-negative organisms than amoxicillin, piperacillin-tazobactam can be considered as a better option in this question.

Solution to Question 20:

Metyrapone inhibits the synthesis of glucocorticoids by inhibiting steroid 11β-hydroxylase reversibly.

It is used to test the hypothalamic-pituitary feedback pathway in the diagnosis of Cushing syndrome.

Solution to Question 21:

Isosorbide dinitrate (ISDN) is indicated in combination with hydralazine for CHF.

Hydralazine is a direct vasodilator and its mechanism of action is not known. It also reduces nitrate tolerance.

The combination of ISDN and hydralazine showed mortality benefits in a specific group of population (African-Americans).

Solution to Question 22:

Colchicine acts by binding to tubulin and inhibits granulocyte migration.

Colchicine produces its anti-inflammatory effects by binding to the intracellular protein tubulin. This prevents the polymerization of tubulin into microtubules which is necessary for leukocyte migration and phagocytosis. Inhibition of microtubule formation prevents granulocyte migration and also arrests cell division at G1 phase.

Solution to Question 23:

Prasugrel is a prodrug.

It acts as an irreversible ADP (P2 Y12) antagonist and is converted into its active metabolite by CYP3A4 and CYP2B6. Since omeprazole is an inhibitor of CYP2C19, it does not interfere with its activation.

It is 10-times more potent than clopidogrel and has a more rapid onset of action because of better absorption and more predictable metabolic activation.

Solution to Question 24:

Apixaban, a novel oral anticoagulant (NOAC), is a factor Xa inhibitor that is used in the treatment of VTE (venous thrombo embolism)/DVT and in its prophylaxis after major orthopedic surgeries.

Direct factor Xa inhibitors:

• Rivaroxaban

• Apixaban

• Edoxaban

• Betrixaban

Parenteral direct thrombin inhibitors:

• Bivalirudin

• Argatroban

• Desirudin

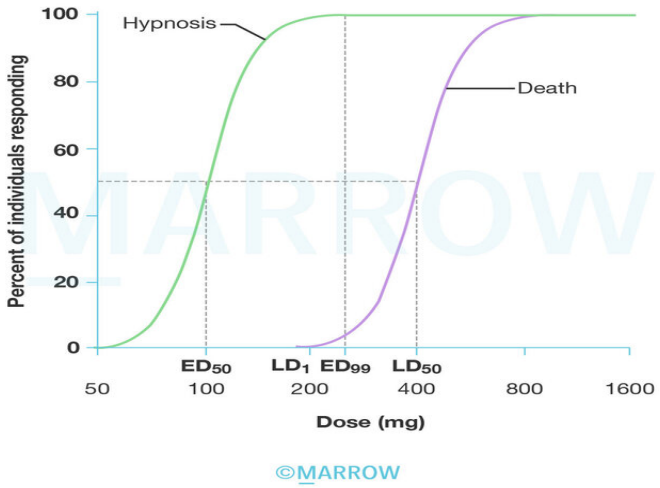
Oral direct thrombin inhibitor—Dabigatran is the only oral direct thrombin inhibitor available for clinical use.

The FDA recently approved the drug Apixaban for a new indication. The drug is now used to reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation.

Pharmacology NEET 2019

Question 1:

Calculate the therapeutic index of a drug whose dose-response curves are plotted as shown below:



a) 1

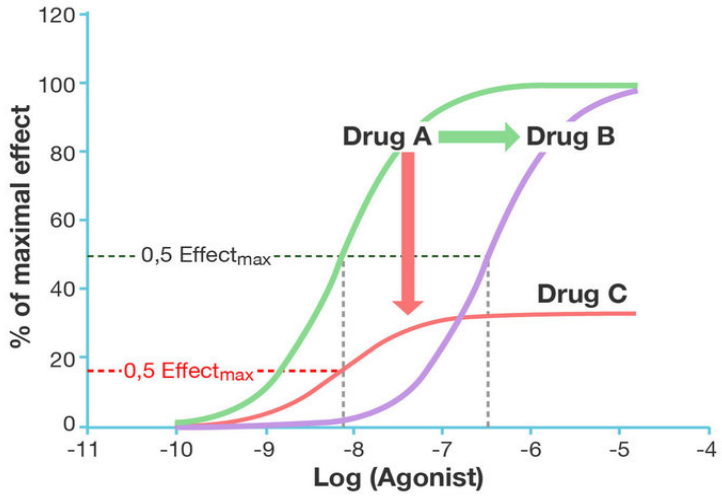
b) 2

c) 4

d) 8

Question 2:

Which of the following statements is true regarding the dose-response curve shown in the image below?



a) C is competitive antagonist

b) C is more potent than A

c) B is more potent than A

d) B is competitive antagonist

Question 3:

Which of the following antiglaucoma medications is unsafe in infants?

a) Timolol

b) Brimonidine

c) Latanoprost

d) Dorzolamide

Question 4:

Apparent volume of distribution of a drug is very high (6L/kg). Which of the following is true regarding the distribution of that drug?

a) Highly bound to plasma proteins

b) Confined to vascular compartment

c) Sequestered in body tissues

d) Both A and B

Question 5:

Which of the following phases of a clinical trial is also referred to as efficacy trial?

a) Phase 1

b) Phase 2

c) Phase 3

d) Phase 4

Question 6:

Which of the following is an oral factor Xa inhibitor?

a) Bivalirudin

b) Dabigatran

c) Rivaroxaban

d) Enoxaparin

Question 7:

What is the drug of choice for diphtheria carrier state?

a) Amoxicillin

b) Erythromycin

c) Rifampicin

d) Tetracycline

Question 8:

What is the mechanism of action of oseltamivir and zanamivir?

a) DNA polymerase inhibition

b) Protein synthesis inhibition

c) Nucleotide analogue

d) Neuraminidase inhibition

Question 9:

Which of the following is a synthetic PGF2 alpha derivative used as an abortifacient?

a) Dinoprost

b) Dinoprostone

c) Misoprostol

d) Carboprost

Question 10:

Which of the following drugs causes activation of K+-ATP channels?

a) Nicorandil

b) Molsidomine

c) Isosorbide dinitrate

d) Nitroglycerin

Question 11:

Most effective antiemetic for chemotherapy-induced vomiting is_____.

a) Domperidone

b) Tegaserod

c) Granisetron

d) Doxylamine

Question 12:

True statement about teduglutide is :

a) It is a GLP- 2 analogue

b) It's half life is 6 - 8 hours

c) It is administered orally

d) It is recommended for patients with colorectal cancer

Question 13:

Cisatracurium is preferred over atracurium because?

a) It has rapid onset of action

b) It has less depressant action on heart

c) It has short duration of action

d) It causes less release of histamine

Question 14:

Which one of the following drugs inhibits neutrophil recruitment?

a) Montelukast

b) Sodium cromolyn

c) Colchicine

d) Febuxostat

Question 15:

Which of the following fluoroquinolones has maximum bioavailability?

a) Ciprofloxacin

b) Levofloxacin

c) Gatifloxacin

d) Norfloxacin

Question 16:

What is the mechanism of triazoles?

a) Interferes with DNA and RNA synthesis

b) Inhibition of ergosterol synthesis

c) Forms pores in fungal membranes

d) Inhibits epoxidation of squalene in fungi

Question 17:

A dermatologist wants to prescribe acitretin to a patient with psoriasis. Which of the following statements is false regarding the drug?

a) Contraindicated in persons with hyperlipidemia

b) It can cause increased sensitivity to sunlight

c) Female patients should avoid getting pregnant for 6 months after therapy

d) Acitretin has a half life of about 50 hours

Question 18:

Cilastatin is administered to prolong the action of which of the following drugs?

a) Meropenem

b) Imipenem

c) Cefazolin

d) Piperacillin

Question 19:

What is the drug used to differentiate myasthenia gravis from cholinergic crisis?

a) Obidoxime

b) Edrophonium

c) Donepezil

d) Atropine

Question 20:

Which of the following is true about pegylated-filgrastim?

a) Duration of action is shorter than normal filgrastim

b) Added advantage is that it can be taken orally

c) It should not be administered in sickle cell patients

d) It is not effective in the treatment of severe neutropenia

Question 21:

The best approach in the treatment of chronic SIADH is _____

a) Tolvaptan

b) Reducing fluid intake to <500 ml per day

c) Demeclocycline

d) Fludrocortisone

Question 22:

Intravenous mannitol is used in ____?

a) Pulmonary edema

b) Congestive cardiac failure

c) Acute kidney injury with anuria

d) Glaucoma

Question 23:

Which of the following carbapenems has increased risk of causing seizures?

a) Meropenem

b) Imipenem

c) Etrapenem

d) Doripenem

Question 24:

Which of the following helps in maintaining the patency of ductus arteriosus?

a) PGF2α

b) PGE1

c) PGH2

d) PGI2

Answer Key

Question No.	Correct Option
1	c

2	d
3	b
4	c
5	b
6	c
7	b
8	d
9	d
10	a
11	c
12	a
13	d
14	c
15	b
16	b
17	c
18	b
19	b
20	c
21	a
22	d
23	b
24	b

Detailed Explanations

Solution to Question 1:

The therapeutic index is 4.

In the above graph,

Median lethal dose (LD50) = 400

Median effective dose (ED50) = 100

Therapeutic index (TI) = LD50/ED50.

Hence,

Therapeutic index (TI) = 400/100 = 4

Clinically, the therapeutic range bound by the dose that produces the minimal therapeutic effect and the dose that produces the maximal acceptable adverse effect is more relevant.

Solution to Question 2:

In the above image, drug B is a competitive antagonist.

In competitive antagonism, the DRC is shifted to the right whereas in non-competitive antagonism the DRC is flattened.

Thus in the above image Drug B is the Competitive antagonist while drug C is the non-competitive antagonist.

Potency:

• It is defined as the amount of drug needed to produce a given response.

• A highly potent drug evokes a given response at low concentrations and vice-versa.

• The more the curve is on the left in a dose-response curve (DRC), the greater is its potency.

• Thus, in the above image, the potency is drug A > drug C > drug B.

Efficacy:

• It is defined as the maximum effect produced by the drug.

• It expresses the effect produced by the receptors when bound by a certain drug.

• In the log dose-response curve, the perpendicular height represents the drug efficacy.

• Thus, in the above image, the efficacy is drug A = drug B > drug C.

Solution to Question 3:

The use of brimonidine is unsafe in infants. It is an alpha-2 agonist that can cross the blood-brain barrier. This may result in CNS depression and apnoea in neonates. Therefore it is contraindicated in children less than 2 years.

α2 agonists, through the activation of G-protein coupled receptor activation, inhibit the activity of adenylate cyclase. This reduces cAMP and hence reduces aqueous humor production by ciliary action.

Solution to Question 4:

In the present case, the volume of distribution of the drug is 6L/kg (420 L in a normal adult with reference weight 70kg) which is very high when compared to the total body water of 42L. Therefore, it can be implied that the drug is having high sequestration in tissues.

The apparent volume of distribution (Vd) is an imaginary volume throughout which the drug is distributed if the plasma concentration remains constant throughout.

Vd = Dose administered IV/ plasma concentration

The difference in the volume of distribution based on drug type:

• Low Vd

• Restricted to the intravascular compartment

• Seen in drugs with high molecular weight (e.g., heparin) or high protein binding (e.g., warfarin - 9.8L)

• Medium Vd

• Lipid insoluble drugs (e.g., gentamicin - 20L) do not enter the cells and are distributed in the extracellular fluid volume

• Small water-soluble molecules (e.g., ethanol - 42L) are distributed in the total body water

• High Vd

• Sequestered and accumulated in the tissues

• Small lipophilic molecules (e.g., chloroquine - 13000L)

Solution to Question 5:

Efficacy and appropriate dose range is the main aim of phase 2 of clinical trials. It is evaluated on a small group of patients with the target disease.

Phase II of clinical trials involve a small group of patients (50-500). Most of the new drugs will be administered for the first time in patients with the target disease. The study is designed to obtain proof of concept (potential of the drug to treat the disease) and dose-ranging study (provides input for choosing the most appropriate dose for phase 3 studies).

Phase 3 studies are also known as pivotal studies as they establish treatment benefits.

Solution to Question 6:

Rivaroxaban is an oral direct factor Xa inhibitor. They represent a new class of oral anticoagulant drugs that do not require monitoring.

This group of drugs inhibit factor Xa in the final common pathway of clotting [conversion of Prothrombin (Factor II) to thrombin (Factor IIa)]. They are given as fixed doses and have a rapid onset of action.

Oral direct factor Xa inhibitors are indicated in:

• Prevention of embolic stroke in patients with atrial fibrillation (without valvular heart disease)

• Venous thromboembolic disease (VTE)

• Postoperative thromboprophylaxis in patients undergoing hip and knee arthroplasty

Solution to Question 7:

The drug of choice for diphtheria carrier state is erythromycin.

Erythromycin for 7 days is very effective for eradicating the diphtheria carrier state or acute infections.

Solution to Question 8:

Oseltamivir and zanamivir are neuraminidase inhibitors.

They competitively and reversibly interact with the enzyme sites to inhibit viral neuraminidase activity. This interferes with the release of the progeny from infected host cells, halting the spread of infection.

Early administration hastens the resolution of symptoms if given within 48 h of infection. Oseltamivir is given at a dose of 75 mg, BD for 5 days for the treatment of Influenza A and B.

For prophylaxis, it is given at a dose of 75mg, OD and continued for the duration of exposure.

Solution to Question 9:

Carboprost is a 15-methyl synthetic derivative of PGF2 alpha. It is used as an abortifacient and in refractory PPH.

Options A: Dinoprost is a natural PGF2 alpha preparation.

Option B: Dinoprostone is natural PGE2 preparation.

Option C: Misoprostol is a synthetic PGE1 analog. Gemeprost is also a synthetic PGE1 analog.

Solution to Question 10:

Nicorandil causes activation of K+-ATP channels. This leads to the hyperpolarization of the smooth muscle cells leading to vasodilatation.

It also has nitrate like cGMP dependent action. Nicorandil dilates both arteries and veins leading to a decrease in afterload and preload of the heart.

Molsidomine, isosorbide dinitrate, and nitroglycerin are nitrates. They do not act on K-ATP channels.

Solution to Question 11:

Among the given options, the most effective antiemetic for chemotherapy-induced vomiting is granisetron.

Granisetron is a 5HT3 receptor antagonist. They are the most effective drugs for the treatment of chemotherapy-induced and post-operative nausea and vomiting.

Palonosetron is a second-generation 5HT3 antagonist that has the highest affinity for 5HT3 receptors and has the maximum potency. It is also the longest acting that makes it effective in delayed emesis associated with chemotherapy. Palonosetron has minimal/no propensity to cause QT interval prolongation.

Solution to Question 12:

Teduglutide is a GLP-2 analogue.

It has been recently approved for the treatment of short bowel syndrome. Teduglutide binds to enteric neurons and endocrine cells, stimulating the release of a number of hormones such as insulin-like growth factor, this stimulates mucosal epithelial growth and enhances fluid absorption.

The drug has a t1/2 of 1–2 hours and is administered subcutaneously once daily. It can potentially cause bowel cancer, therefore it is not recommended for patients with active malignancies.

Note: GLP-1 analogs are used for the treatment of Type II diabetes mellitus.

Solution to Question 13:

Cisatracurium is preferred over atracurium because it causes less release of histamine.

Other options:

Option A- Cisatracurium has a slower onset of action

Option B and C- Both atracurium and cisatracurium have similar duration of action and cardiac action.

Solution to Question 14:

Colchicine inhibits neutrophil (granulocyte) recruitment.

Colchicine acts by preventing the polymerisation of microtubules by binding to tubulin. This reduces neutrophil recruitment to inflamed tissue and also decreases the secretion of chemotactic factors by activated neutrophils, thus reducing the inflammatory response overall.

Colchicine is used in gout and Mediterranean fever.

Solution to Question 15:

Levofloxacin and ofloxacin have the maximum bioavailability among fluoroquinolones. Hence, intravenous and oral doses are the same for these drugs.

Solution to Question 16:

Triazoles act by inhibition of ergosterol synthesis.

The azole group inhibits the fungal cytochrome P450 enzyme called 14-α-sterol demethylase and results in an impairment of conversion of lanosterol to ergosterol. This results in the depletion of membrane ergosterol.

Azole antifungals are of two types:

• Imidazoles - clotrimazole, ketoconazole, luliconazole

• Triazoles - itraconazole, fluconazole, voriconazole, posaconazole and isavuconazole

Solution to Question 17:

Female patients should avoid conception for 3 years after discontinuing acitretin treatment to prevent retinoid-induced embryopathy.

Acitretin is approved for use in the cutaneous manifestations of psoriasis.

Absolute contraindications:

• Pregnant women

• Women who are planning to get pregnant

• Breastfeeding

Relative contraindications:

• Leukopenia

• Alcoholism

• Hyperlipidemia

• Hypercholesterolemia

• Hypothyroidism

• Significant hepatic or renal disease

Note: Female patients should avoid conception for 1 month after discontinuation of isotretinoin.

Solution to Question 18:

Cilastatin is administered to prolong the action of imipenem.

Imipenem is rapidly hydrolyzed by the enzyme renal dehydropeptidase. It is administered with cilastatin, a reversible inhibitor of dehydropeptidase to inhibit the breakdown and prolong the action of imipenem.

Meropenem is not hydrolyzed by renal dehydropeptidase. Cilastatin administration is not necessary with meropenem.

Solution to Question 19:

The drug used to differentiate myasthenia gravis from a cholinergic crisis is edrophonium.

Muscle weakness is a common presentation in patients with myasthenia gravis and cholinergic crisis (excessive dose of anti-ChE drugs). Intravenous injection of edrophonium improves muscular weakness in a patient with myasthenia gravis and not in a case of cholinergic crisis.

The test used for this differentiation is known as the edrophonium test.

Initially, 2 mg is administered; if improvements of symptoms do not occur within 45 seconds, an additional 8 mg can be administered. Improvement of strength is a positive test for myasthenia gravis.

Solution to Question 20:

Patients with sickle cell anemia should not receive pegylated filgrastim as it can trigger a sickle cell crisis.

Filgrastim is a recombinant human G-CSF (granulocyte colony-stimulating factor). The pegylated forms of filgrastim, pegfilgrastim, and lipefilgrastim, are longer-acting forms. It is administered subcutaneously or by slow intravenous infusion only.

Indications of recombinant G-CSF:

• Severe neutropenia after autologous hematopoietic stem cell transplantation

• Severe neutropenia after high dose cancer chemotherapy

• Severe congenital neutropenias

• Neutropenia of patients with AIDS receiving zidovudine

Solution to Question 21:

The best approach in the treatment of chronic SIADH is the oral administration of a vaptan like tolvaptan, which is a selective V2 receptor antagonist. This increases urinary water excretion by blocking the antidiuretic effect of AVP.

Other treatment options for chronic SIADH include:

• Fluid intake < 500 ml/day

• Demeclocycline

• Fludrocortisone

Increased thirst is a frequently observed characteristic of hyponatremia in SIADH. Fluid restriction is usually a burden to the patient. It is unreliable, impractical, and slow to work. As thirst is particularly difficult to suppress, water restriction in SIADH frequently leads to non-compliance in the long run. Vaptans would be especially suited for the treatment of these patients. Serum sodium concentrations are also corrected by vaptans and hence, vaptans substantially improve the quality of life in these patients.

Solution to Question 22:

Intravenous mannitol is used for the treatment of acute attacks of glaucoma.

Uses of mannitol are:

• To reduce cerebral edema and intracranial pressure

• Enhancement of urinary excretion of salicylates, barbiturates, bromides, and lithium

• Diagnosis of bronchial hyperreactivity (inhalation)

• Antihemolytic urological irrigation during transurethral procedures

• Treatment of acute attacks of glaucoma.

Solution to Question 23:

Imipenem is the carbapenem that is associated with an increased risk of causing seizures, especially when high doses are given to patients with CNS lesions.

Excretion of imipenem is mainly renal and dosage modification is required to avoid seizures in renal failure patients.

Solution to Question 24:

Prostaglandin E1 (PGE1) maintains the patency of ductus arteriosus (PDA). This is used in term neonates with underlying cyanotic congenital heart disease awaiting surgical intervention as they have duct-dependant circulation.

Indomethacin and Ibuprofen are the NSAID indicated for closing the ductus arteriosus in premature infants and neonates.

Pharmacology NEET 2020

Question 1:

Which of the following is an inhibitor of DNA synthesis?

a) 6-mercaptopurine

b) Mitomycin

c) Actinomycin

d) Asparaginase

Question 2:

A patient on lithium therapy developed hypertension. He was started on thiazides for hypertension. After few days, he developed coarse tremors and other symptoms suggestive of lithium toxicity. Explain the likely mechanism of this interaction.

a) Thiazide inhibits the metabolism of lithium

b) Thiazides act as an add on drug to lithium

c) Thiazides increase the tubular reabsorption of lithium

d) Thiazides cause water loss therby increase lithium levels

Question 3:

Which of the following should not be prescribed with theophylline?

a) Erythromycin

b) Cefotaxime

c) Cotrimoxazole

d) Amoxicillin

Question 4:

Which of the following drugs gets deposited in cornea?

a) Leflunamide

b) Chloroquine

c) Methotrexate

d) Sulfasalazine

Question 5:

A patient was prescribed an antipsychotic drug following which he developed parkinsonism. Which of the following drugs■ can be given?

a) Trihexiphenidyl

b) Entacapone

c) Rasagiline

d) Pramipexole

Question 6:

Which of the following antiarrhythmic drugs is contraindicated in a patient with interstitial lung disease?

a) Amiodarone

b) Sotalol

c) Quinidine

d) Lignocaine

Question 7:

Which of the following drugs acts by inhibiting the late sodium current in the heart?

a) Ivabradine

b) Ranolazine

c) Trimetazidine

d) Fasudil

Question 8:

A patient with diabetes and COPD developed post-operative urinary retention. Which of the following drugs can be used for short-term treatment of the condition?

a) Tamsulosin

b) Bethanechol

c) Terazosin

d) Methacoline

Question 9:

Which of the following drugs is used for the treatment of motion sickness?

a) Cetrizine

b) Promethazine

c) Misolastin

d) Loratidine

Question 10:

Which of the following is not a prokinetic?

a) 5HT4 agonist

b) Dopamine antagonist

c) Motilin

d) Diphenylmethane

Question 11:

Which of the following is used in the first-line management of postmenopausal osteoporosis?

a) Estrogen

b) Bisphosphonates

c) Raloxifene

d) Combined oral contraceptives

Question 12:

What is the mechanism of resistance by lactamases■ to β-lactam antibiotics?

a) Alteration of penicillin binding protein

b) Degradation of antibiotics

c) Drug efflux

d) Alteration in 50s ribosome structure

Question 13:

A female patient is on first-line pharmacological therapy for bipolar disorder for 6 months. She is fasting for a few days due to religious reasons and presented with seizures, coarse tremors, confusion, and weakness of limbs. Which of the following investigations should be done to help diagnose her condition?

a) Serum potassium level

b) Serum lithium level

c) ECG

d) MRI

Question 14:

Pegloticase is used in management of:

a) Chronic gout

b) Rheumatoid arthritis

c) Psoriatric arthritis

d) Calcium pyrophosphate dihydrate crystal deposition (CPPD)

Question 15:

Which of the following is an inhibitor of RNA synthesis?

a) 5-Fluorouracil

b) Rifampicin

c) Nitrofurantoin

d) Novobiocin

Question 16:

Which of the following fluoroquinolone is not given in liver disease?

a) Ofloxacin

b) Levofloxacin

c) Pefloxacin

d) Lomefloxacin

Question 17:

Theophylline causes diuresis by:

a) Adenosine antagonism

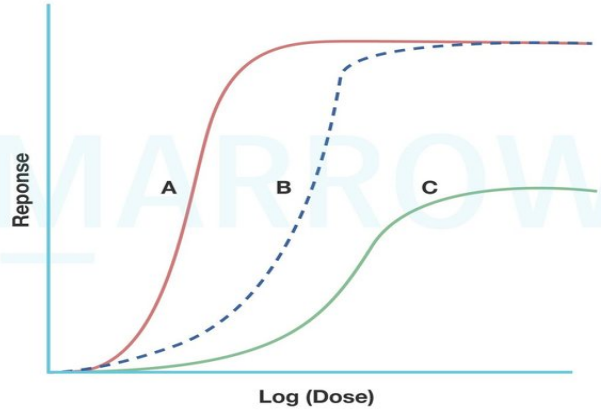
b) PDE 4 inhibition

c) Beta 2 agonism

d) PDE 3 inhibition

Question 18:

The graph below shows the relationship between the log(dose) and the response of three drugs, A, B, and C. Which of these drugs has the highest potency?



a) A

b) B

c) Both A and B

d) C

Question 19:

A patient presented with biliary colic. The intern has administered an analgesic, following which the pain got aggravated. Which of the following could be responsible for the aggravation of the patient's symptoms?

a) Morphine

b) Diclofenac

c) Nefopam

d) Etoricoxib

Question 20:

A patient with gout develops hypertension. The uric acid level was found to be elevated. Which of the following is not administered?

a) Hydrochlorothiazide

b) Atenolol

c) Enalapril

d) Prazosin

Question 21:

Voriconazole is not effective against which of the following?

a) Candida albicans

b) Mucormycosis

c) Candida tropicalis

d) Aspergillosis

Question 22:

A patient who was diagnosed with ADPKD was prescribed tolvaptan. After a few weeks, he presented with dry mouth and increased thirst. What is the likely cause?

a) Increased free water clearance

b) V2 receptor agonism

c) Increased renal cAMP levels

d) Increase in urine osmolality

Detailed Explanations

Solution to Question 1:

6-Mercaptopurine is an inhibitor of DNA synthesis.

6-Mercaptopurine is inactive in its parent form. It must be metabolized by hypoxanthine-guanine phosphoribosyltransferase to form monophosphate nucleotide

6-thioinosinic acid. This inhibits several enzymes of de novo purine nucleotide synthesis.

Option B- Mitomycin acts as an alkylating agent and crosslinks DNA. It also generates free radicals which damage DNA.

Option C- Actinomycin causes single-strand breaks in DNA. It blocks RNA transcription as well.

Option D- L-Asparaginase causes the breakdown of asparagine and thus interferes with protein synthesis.

Solution to Question 2:

Thiazides act by increasing the tubular reabsorption of lithium.

Thiazide use is accompanied by sodium loss which is compensated in a few days by increased reabsorption of Na+ in the proximal tubule.

The kidney handles both lithium and Na+ in the same way. Thus, along with Na+ reabsorption, there will be an increase in the reabsorption of lithium also, resulting in decreased excretion of lithium.

Solution to Question 3:

Erythromycin should not be prescribed with theophylline.

Theophylline is mainly metabolized by CYP1A2 in the liver. Erythromycin inhibits CYP1A2 and thereby decreases the clearance of theophylline.

Factors decreasing the clearance of theophylline are:

• Drugs - erythromycin, cimetidine, ciprofloxacin, allopurinol, fluvoxamine, zileuton, zafirlukast

• Congestive heart failure

• Liver disease

• Pneumonia

• Viral infection and vaccination

• High-carbohydrate diet

• Old age

Solution to Question 4:

Chloroquine, an anti-malarial drug may get deposited in the cornea leading to corneal opacity.

Ocular toxicity of chloroquine:

• Short-term therapy - blurring of vision and diplopia, reversible on stoppage of drug.

• Long-term use (high-dose):

• Keratopathy

• Pigmentary retinopathy

• Optic atrophy

Hydroxychloroquine has lower ocular toxicity compared to chloroquine.

Drugs causing corneal opacity:

• Amiodarone

• Phenothiazine

• Indomethacin

• Chloroquine

Long-term treatment with these drugs can cause a whorl-like opacity in the corneal epithelium called cornea verticillata. It is also seen in Fabry's disease.

Solution to Question 5:

Trihexyphenidyl is the drug of choice for drug-induced parkinsonism. It is a central anticholinergic.

Drug-induced parkinsonism is a condition caused by certain drugs having D2 antagonistic action (typical antipsychotics). The decrease in dopaminergic activity results in an unbalanced cholinergic activity. Anticholinergics act by restoring the balance.

Solution to Question 6:

Amiodarone is contraindicated in a patient with interstitial lung disease.

The most serious adverse effect during chronic amiodarone therapy is pulmonary fibrosis, which can be rapidly progressive and fatal. Underlying lung disease, doses of 400 mg/day or more, and recent pulmonary insults such as pneumonia appear to be risk factors for this condition.

Amiodarone is a class III antiarrhythmic drug.

The side effects of amiodarone include:

• Pulmonary fibrosis

• Hypotension, depressed ventricular function

• Torsades de pointes

• Corneal microdeposits

• Hepatotoxicity

• Neuropathies

• Photosensitivity

• Thyroid dysfunction

Solution to Question 7:

Ranolazine acts by inhibiting the late sodium current in the heart.

Late sodium current (INa) facilitates entry of calcium via the sodium-calcium exchanger. Inhibition of INa, therefore, reduces the intracellular calcium concentration which in turn reduces the diastolic tension, cardiac contractility and work.

At higher doses, it may also modify the fatty acid oxidation, which improves the efficiency of cardiac oxygen utilization.

It is used in the prophylaxis of angina.

Solution to Question 8:

Tamsulosin is the drug used to relieve the symptoms in cases of postoperative urinary retention in a patient with COPD.

It is also efficacious in the treatment of benign prostatic hyperplasia (BPH) with little effect on blood pressure.

Option B: Bethanechol is the drug of choice to relieve the symptoms in cases of postoperative urinary retention. However, it can cause bronchoconstriction in patients with COPD. Hence tamsulosin is the best answer here.

Option C: Terazosin is an $\alpha 1$ receptor antagonist, used in the treatment of benign prostatic hyperplasia (BPH).

Option D: Methacholine is a muscarinic agonist but acts specifically on bronchial smooth muscle causing its contraction. It is available as an inhalational agent and is used for the diagnosis of bronchial hyper-reactivity in patients who do not have clinically apparent asthma.

Solution to Question 9:

Promethazine is used for motion sickness. It is an antihistaminic agent that acts as an antagonist of H1 receptors. It also has central anticholinergic activity that is responsible for its antiemetic action.

Solution to Question 10:

Diphenylmethane is not a prokinetic agent. Its derivative (Bisacodyl) is used as a laxative.

Prokinetic agents are the drugs that increase GI motility and transit of material in the GI tract. These agents include:

• Dopamine receptor antagonists- metoclopramide and domperidone

• Serotonin receptor agonists- cisapride and prucalopride

• Motilin

• Macrolide antibiotics mimicking motilin - erythromycin

• Miscellaneous agents:

• Sincalide (C-terminal octapeptide of CCK)

• Camicinal (motilin receptor agonist)

• Relamorelin (ghrelin receptor agonist)

• Velusetrag and naronapride (5HT4 agonists)

Solution to Question 11:

Bisphosphonates are used in the first-line management of postmenopausal osteoporosis.

Bisphosphonates are analogs of pyrophosphates. They specifically inhibit bone resorption and thus are very effective for the treatment of postmenopausal osteoporosis.

Bisphosphonates concentrate at sites of active remodeling. They remain in the matrix until the bone is remodeled. Then, they are released in the acid environment of the resorption lacunae and induce apoptosis in osteoclasts.

Classification of bisphosphonates (mainly based on potency):

First-generation:

• Etidronate (least potent)

• Clodronate

• Tiludronate

Second-generation: 10-100 times more potent than the first generation

• Alendronate

• Pamidronate

• Ibadronate

Third-generation: 10,000 times more potent than the first generation

• Risedronate

• Zoledronate

Solution to Question 12:

Resistance by lactamases is through the degradation of antibiotics.

The bacterial cell wall is made of heteropolymeric peptidoglycan that confers mechanical stability. The β-lactam antibiotics inhibit the last step in peptidoglycan synthesis by acylating the transpeptidase via cleavage of the –CO–N– bond of the β-lactam ring. These transpeptidase targets are collectively called Penicillin Binding Proteins (PBPs)

Beta-lactamases are enzymes produced by certain bacteria that inactivates β-lactam antibiotics by hydrolysis of the β-lactam ring in their structure.

The resistance to penicillins and other beta-lactam antibiotics can be conferred through one of the four mechanisms:

• Inactivation of antibiotic by lactamases

• Modification of target PBPs

• Impaired penetration of drug to target PBPs

• Antibiotic efflux

Solution to Question 13:

The clinical features given in the question are most likely suggestive of lithium toxicity, and hence serum lithium levels should be measured to confirm it.

Lithium is a mood stabilizer with a very narrow therapeutic index and is the first line of management in bipolar disorder.

The kidney handles both lithium and Na+ in the same way via ENac channel. Thus during fasting/dehydration, along with Na+ reabsorption in renal tubules, there will be an increase in the reabsorption of lithium leading to lithium toxicity.

Lithium has a very narrow therapeutic index of 0.8-1.2 mEq/L. The severity of lithium toxicity is often divided into the following three grades:

A fine tremor is common in patients taking lithium at therapeutic doses. Therapeutic lithium tremor is generally symmetric, limited to the arms, and nonprogressive. The tremor from lithium toxicity is coarser and more disabling, may also affect the legs, and occurs with other symptoms of toxicity. Other adverse effects include mental confusion, hypothyroidism, nephrogenic diabetes insipidus, and edema.

As lithium is readily dialyzed, lithium overdose or toxicity is treated with hemodialysis.

*Note - Serum Na+ levels are significant with respect to lithium toxicity, where as serum potassium levels becomes significant in digoxin toxicity. Hypokalemia increases the risk of digoxin toxicity.

Grade	Sr. lithium concentration(in mEq/L)	Symptoms
Mild symptoms	1.5-2.5	nausea, vomiting,tremor, and fatigue
Moderate intoxication	2.5-3.5	confusion, agitation, delirium, tachycardia, and hypertonia

Grade	Sr. lithium concentration(in mEq/L)	Symptoms
Severe intoxication	>3.5	coma,seizures, hyperthermia, and hypotension

Solution to Question 14:

Pegloticase is used in the treatment of chronic gout.

Pegloticase is a pegylated uricase (urate oxidase). It catalyzes the enzymatic oxidation of uric acid into allantoin, which is a more soluble and inactive metabolite.

It is used in the treatment of severe,refractory chronic gout or in cases where other urate-lowering therapies are contraindicated.

Solution to Question 15:

Rifampicin is an inhibitor of RNA synthesis. It binds to the beta subunit of DNA dependent RNA-polymerase (rpoB) to form a stable drug-enzyme complex. The binding suppresses the chain formation in RNA synthesis.

Option A: 5-Fluorouracil inhibits thymidylate synthesis.

Option C: Nitrofurantoin produces highly reactive intermediates that cause DNA damage

Option D: Novobiocin is a potent inhibitor of bacterial DNA gyrase.

Solution to Question 16:

Pefloxacin is mainly metabolized in the liver and hence avoided in patients with liver disease.

Quinolones with primarily hepatic metabolism include moxifloxacin, pefloxacin, and trovafloxacin (withdrawn from the market due to hepatotoxicity).

Quinolones primarily excreted by the kidneys include ciprofloxacin, levofloxacin, norfloxacin, lomefloxacin, and ofloxacin.

Solution to Question 17:

The diuretic effect of theophylline is due to blockade of adenosine (A1) receptors.

Theophylline is a methylxanthine drug that acts by:

• Inhibition of phosphodiesterase enzyme (PDE). PDE3 inhibition causes relaxation of bronchial smooth muscle and PDE4 inhibition causes inhibition of the release of cytokines and chemokines

which further leads to a decrease in immune cell migration and activation.

• Blockade of adenosine receptors, which inhibits bronchoconstriction. However, blockade of A1 receptors in the glomerular afferent arteriole and PCT causes diuresis.

• Activating enzyme histone deacetylase-2, which is responsible for its anti-inflammatory action

Solution to Question 18:

Drug A has the highest potency.

Potency:

• It is defined as the amount of drug needed to produce a given response. A highly potent drug evokes a given response at low concentrations and vice-versa.

• The more the curve is on the left in a dose-response curve (DRC), the greater is its potency.

• Thus, in the above image, the potency is Drug A >Drug B> Drug C.

Efficacy:

• It is defined as the maximum effect produced by the drug. It reflects the capacity of the drug to activate a receptor and produce the response.

• In the log dose-response curve, the perpendicular height represents the drug efficacy.

• Thus, in the above image, the efficacy is Drug A = Drug B > Drug C.

• Drugs having a similar pharmacological effect can have different efficacies e.g furosemide and metolazone are both diuretics but furosemide has greater efficacy than metolazone.

Solution to Question 19:

Morphine is the analgesic which could be responsible for the aggravation of the patient's symptoms.

It causes constriction of the sphincter of Oddi causing an increase in fluid pressure in the common bile duct and gall bladder.

Note: Pethidine causes lesser spasm of the sphincter of Oddi and can be used in biliary colic.

Solution to Question 20:

Hydrochlorothiazides are not given to this patient.

Gout is a metabolic disease associated with hyperuricemia.Thiazides increase direct urate reabsorption in the proximal renal tubules and are associated with elevated serum uric acid levels and may precipitate gout. Hence, hydrochlorothiazides are not used to treat hypertension in gout patients.

Solution to Question 21:

Voriconazole is not effective against mucormycosis.

Mucormycosis is treated by amphotericin B. Posaconazole can also be used. However, other azoles are not effective against this fungus.

Voriconazole is the drug of choice for the treatment of aspergillosis. It can also be used for Candida species (including glabrata and krusei), Scedosporium and Fusarium.

Solution to Question 22:

Tolvaptan causes increased free water clearance, which causes dehydration. Hence, the patient may present with dry mouth and increased thirst.

Tolvaptan is a vasopressin V2 receptor antagonist. Decreased binding of vasopressin to the V2 receptor in the kidney lowers the adenyl cyclase activity leading to decreased intracellular cAMP. Decreased cAMP concentrations prevent the fusion of aquaporin 2 containing vesicles with the plasma membrane, leading to an increase in urinary water excretion (free water clearance), and a decrease in urine osmolality.

The common side effects of tolvaptan include:

• dehydration

• hypernatremia

• hypovolemia

• liver injury

Tolvaptan is used to delay disease progression in patients with ADPKD.

Pharmacology INI-CET 2021

Question 1:

Which of the following is false about the selection of essential drugs?

a) Adequate safety profile needs to be established

b) Cost to benefit has to be considered

c) Fixed drug combination is preferred over single drugs

d) Disease prevalence is considered

Question 2:

A 34-year-old man with hypertension is diagnosed with stage 4 chronic kidney disease, with eGFR of <30. His doctor wants to prescribe a thiazide diuretic. Which of the following can be given?

a) Chlorothiazide

b) Chlorthalidone

c) Metolazone

d) Hydrochlorothiazide

Question 3:

A patient who was diagnosed with epilepsy was put on retigabine TDS. Now phenytoin is being added. Which of the following changes should be made to retigabine?

a) Increase the dose

b) Decrease the dose

c) Stop the drug

d) Stop retigabine and start on carbamazepine

Question 4:

A patient with history of ischemic stroke was started on clopidogrel. However, she had another attack of stroke after 6 months. Which of the following is likely to be responsible for

the failure of clopidogrel in this patient?

a) Downregulation of CYP2C19

b) Downregulation of CYP2D6

c) Upregulation of CYP1A1

d) Downregulation of CYP2E1

Question 5:

Which of the following can be given for long term management of obesity?

a) Liraglutide

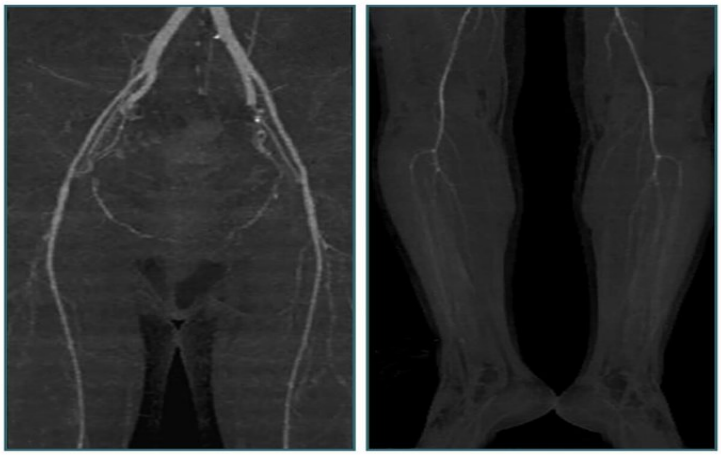
b) Metformin

c) Sibutramine

d) Fenfluramine

Question 6:

An HIV-positive woman on ART was prescribed ergotamine for a migraine attack 4 days back. She presented with complaints that she is unable to feel her legs from the mid-thigh to her toes, for the past two days. The angiography image is given below. What is the likely diagnosis?



a) Atherosclerosis

b) Ergotism

c) Polyradicular neuropathy

d) Herniated disc

Question 7:

Topiramate is used for

a) Treatment of migrane

b) Treatment of Lennox Gastaut syndrome

c) Prophylaxis of ADHD

d) Treatment of dementia

Question 8:

Which of the following is incorrectly matched?

a) Andexanet alfa: Edoxaban

b) Andexanet alfa: Rivaroxaban

c) Idarucizumab : Dabigatran

d) Ciraparantag: Fondaparinux

Question 9:

Inhaled Nitric oxide is approved for treatment of

a) Labile hypertension

b) Pulmonary hypertension

c) Treatment of resistant migraine

d) Resistant Parkinson's disease

Question 10:

Nivolumab is used as a checkpoint inhibitor in

a) Retinoblastoma

b) Medulloblastoma

c) Pleuropulmonary blastoma

d) Hodgkin's lymphoma

Question 11:

Paradoxical bronchoconstriction seen with ipratropium bromide is due to all except

a) Hypertonic saline

b) EDTA

c) Benzalkonium chloride

d) Prejunctional M2 receptor blockade

Question 12:

Antimicrobial combinations are used in all except

a) Gonorrhea

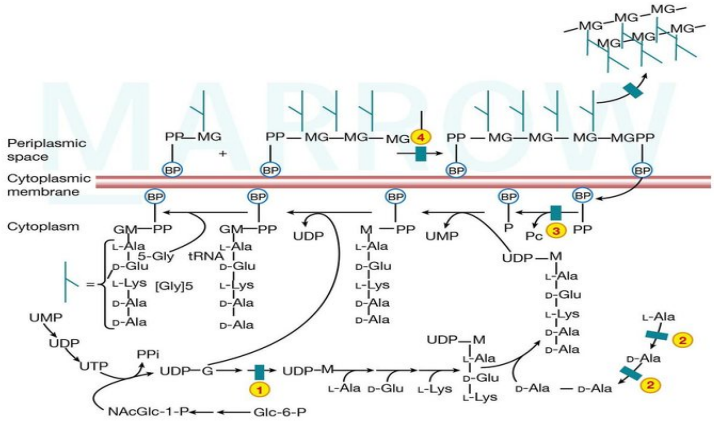
b) Tuberculosis

c) Intra abdominal infections

d) Malaria

Question 13:

Which of the following steps does Vancomycin act on?



©MARROW

a) 1

b) 2

c) 3

d) 4

Question 14:

What would happen to the half-life and plasma concentration of a drug which follows first-order kinetics, if the dose is doubled?

a) Half-life doubles and plasma concentration remains the same

b) Half-life remains the same and plasma concentration doubles

c) Half-life and plasma concentration remains the same

d) Half life and plasma concentration doubles

Question 15:

Which of the following is not an off-label use of risperidone?

a) OCD

b) Dementia

c) PTSD

d) Bipolar disorder

Question 16:

The elimination rate constant of a drug is 0.05/hr. What is its half-life?

a) 20.8 hours

b) 6.9 hours

c) 13.8 hours

d) 9.8 hours

Question 17:

A patient is on phenytoin for a seizure disorder. He was prescribed sucralfate 4 times a day for peptic ulcers. What should be the minimum duration of time between consumption of these drugs?

a) 30 minutes

b) 60 minutes

c) 90 minutes

d) 120 minutes

Question 18:

Category A, B, C, D, X in drug classification are indicative of which of the following?

a) Safety in pregnancy

b) Dose adjustment in renal failure

c) Cost ratio from cheap to expensive

d) As per safety or therapeutic index

Question 19:

Identify the false statement regarding suicidal inhibition.

a) The inhibitor can bind with any site resulting in suicidal inhibition

b) The binding of the enzyme to the substrate analogue is irreversible

c) They are enzyme specific and used in rational drug design

d) The inhibitor forms a product with the enzyme and the product inhibits it

Question 20:

The dose at which dopamine acts on beta 1 receptors is ____.

a) 2-10 mcg/kg/min

b) <2 mcg/kg/min

c) 10-20 mcg/kg/min

d) >20 mcg/kg/min

Question 21:

Which of the following is the incorrect statement regarding clomiphene citrate?

a) Causes monofollicular development

b) Inhibits negative feedback on GnRH

c) Causes endometrial thinning

d) Can be used with gonadotropin

Question 22:

What is the mechanism of action of remdesivir?

a) RNA-dependent DNA polymerase inhibition

b) RNA-dependent RNA polymerase inhibition

c) Fusion inhibition

d) Entry inhibition

Question 23:

Administration of which of the following drugs would increase the bioavailability of saquinavir?

a) Ritonavir

b) Vitamin C

c) Cimetidine

d) Ganciclovir

Question 24:

The table below gives the AUC of drug B alone and that of drug B when combined with another drug A. If the ■ value is <0.01, then which of the following statements is true?

a) Drug A decreases intestinal absorption of Drug B

b) Drug A reduces first pass metabolism of Drug B

c) Drug A increases the metabolism of Drug B

d) Drug A increases renal elimination of Drug B

Question 25:

What is the mechanism of action of cyclosporine?

a) Inhibition of calcineurin

b) AMP kinase stimulation

c) IMP dehydrogenase inhibition

d) Dihydro-orotate dehydrogenase inhibition

Question 26:

Anionic and weakly acidic drugs bind to which of the following?

a) Albumin

b) Globulin

c) Lipoprotein

d) Alpha-1 glycoprotein

Question 27:

A 14-month-old boy was diagnosed with Hemophilus influenza meningitis. The initial treatment plan was to start on ampicillin but later was shifted to ceftriaxone. What could be the probable reason?

a) Hemophilus alters penicillin binding protein sites, hence resistant to ampicillin

b) Easier to administer IV ceftriaxone than IV ampicillin

c) Cotrimoxazole is the drug of choice, but patient is allergic to sulfa drugs

d) Hemophilus produces beta lactamase, hence resistant to ampicillin

Question 28:

A patient who is a known case of cirrhosis of the liver presents with abdominal distension and swelling of the lower limbs. The preferred diuretic for this patient would be

a) Triamterene

b) Eplerenone

c) Chlorthalidone

d) Furosemide

Question 29:

Which of the following is the most effective drug in smoking cessation?

a) Varenicline

b) Buspirone SR

c) Nicotine gum

d) Rimonabant

Question 30:

A patient who was on warfarin therapy for atrial fibrillation is prescribed a cephalosporin antibiotic for the treatment of a lower respiratory tract infection. He reports back to the hospital after having developed hemarthrosis. Which of the following cephalosporins is likely to have caused this?

a) Cefixime

b) Cefoperazone

c) Ceftobiprole

d) Ceftazidime

Question 31:

Which of the following is a novel anti-depressant?

a) Lurasidone

b) Vilazodone

c) Asenapine

d) Blonanserin

Question 32:

A 57-year-old man was brought to the hospital with complaints of dizziness and breathlessness. During his physical examination, you notice the following discolouration over his face. He is presently being treated with amiodarone, metoprolol, verapamil, lisinopril, and amlodipine. Which of the following drugs is most likely responsible?

a) Amiodarone

b) Amlodipine

c) Metoprolol

d) Verapamil

Question 33:

Which of the following is a centrally acting opioid antitussive?

a) Ambroxol

b) Diphenoxylate

c) Levopropoxyphene

d) Levorphanol

Question 34:

The anti-epileptic drugs which can also be used for the treatment of neuropathic pain are

a) 1, 2 and 3

b) 1, 2 and 4

c) 1, 3 and 4

d) 2 and 4 only

Question 35:

A breast cancer patient post-chemotherapy developed a low-grade fever with anemia and leukocytopenia (<4000/cm3; DNC: 30). Which of the following antibiotics will not be used in the empirical management of this patient?

a) Cefepime

b) Piperacillin-Tazobactam

c) Linezolid

d) Meropenem

Answer Key

Detailed Explanations

Solution to Question 1:

Fixed drug combinations are not preferred over single drugs while selecting essential drugs.

Criteria for selection of essential medicines as per WHO:

• There should be adequate data on the safety and efficacy of the drug.

• The drug should be available in a form where its quality including bioavailability and stability on storage is assured.

• The choice of the drug depends on the pattern of prevalent diseases, financial resources, availability of trained personnel and facilities, genetic, demographic, and environmental factors.

• The cost-benefit ratio is an important factor.

• Pharmacokinetic properties of the drug and the local manufacture and storage facilities are also considered.

• Essential drugs should preferably be single compounds.

• Fixed combinations are used only when the dosage of each component meets the requirement of the population in which it is used. It should also have the advantage in safety, therapeutic effect, adherence, and prevention of drug resistance when compared to single compounds.

• The selection of essential drugs is a continuous process and changes are to be made with developments in public health and the availability of better drugs.

• The selection should be based on rationally developed treatment guidelines.

Note:

In 1977 WHO brought the first "Model List of Essential Drugs". India made its "National Essential Drug List" in 1996 and revised the list in 2011 and renamed it as "National List of Essential Medicines". The latest edition of WHO Model List of Essential Drugs is the 21st edition published in 2019.

Solution to Question 2:

The thiazide diuretic that can be used as an antihypertensive in this patient with chronic kidney disease is metolazone.

In patients with chronic renal failure, thiazide diuretics are ineffective. But metolazone, despite being a thiazide diuretic, is effective as antihypertensives in patients with chronic renal failure.

Metolazone is useful even in severe renal failure (GFR of ~15 mL/min). It has an additive action when combined with loop diuretics like furosemide. It also has an additional proximal tubular action (thiazides mainly act on DCT). It is commonly used for edema and is occasionally used as an antihypertensive.

Diuretics in hypertension:

Thiazides are the diuretics of choice for uncomplicated hypertension.

Mechanisms of antihypertensive action:

• Decreases plasma and ECF volume by diuresis thereby decreasing cardiac output

• Even when the compensatory mechanisms restore the Na+ levels and plasma volume, a low BP is maintained by a reduction in total peripheral resistance.

• This reduction in total peripheral resistance is due to the persistence of a small sodium and volume deficit even after compensation. The decreased intracellular sodium is responsible for increased compliance of the vessel wall and a reduced response to constrictor stimulus.

Advantages of thiazide as an antihypertensive:

• It can be given as once a day dose and has a flat dose-response curve.

• Decreased incidence of postural hypotension and relative freedom from CNS side effects

• No tolerance

• No fluid retention

• Decreased risk of osteoporotic fractures due to its hypocalciuric action

• Low cost

• Effectiveness in isolated systolic hypertension

Thiazides are ineffective both as antihypertensive and diuretic in patients with chronic renal failure.

High ceiling diuretics: Furosemide is the prototype drug in this class and it is a weaker antihypertensive agent than thiazides. They are given in hypertension only in the presence of the following complications:

• Chronic renal failure - As thiazides are ineffective

• Coexisting refractory congestive heart failure

• Resistance to combination regimen with thiazides

• Marked fluid retention with the use of potent vasodilators.

Potassium-sparing diuretics - They are only used in combination with thiazides to prevent the loss of potassium.

Side effects of diuretics include hypokalemia, carbohydrate intolerance, dyslipidemia, and hyperuricemia.

Solution to Question 3:

The dose of retigabine should be increased when phenytoin is added because phenytoin can decrease the plasma concentration of retigabine when given together.

Retigabine is also known as ezogabine. Metabolism of the drug occurs by glucuronidation and acetylation. Its half-life is about 7-11 hours and hence requires thrice-daily dosing. When it is administered with phenytoin or carbamazepine there may be a reduction in the plasma concentration of the drug. So the dose of retigabine should be increased when given along with these drugs.

It is a potassium(K+) channel opener that enhancer transmembrane potassium currents mediated by the KNCQ family of ion channels. It was approved as an adjunctive agent for focal onset seizures of patients above 18 years. But because of its adverse effects like retinal abnormalities and blue pigmentation, the production of the drug was discontinued by the manufacturer.

Other drug interactions of phenytoin:

It is an inducer of the enzymes CYP2C8/9, CYP3A4/5, and other CYPs. It is also an inhibitor of CYP2C9/19.

• Phenobarbitone can inhibit the metabolism of phenytoin. But the overall interaction is unpredictable as both the drug enhance each other's degradation by enzyme induction.

• Phenytoin and carbamazepine induce each other's metabolism.

• Valproate increases the level of unbound phenytoin by displacing the protein-bound form and decreasing its metabolism.

• Phenytoin increases the metabolism of steroids, oral contraceptives, doxycycline, theophylline, etc by enzyme induction.

• It produces competitive inhibition of warfarin metabolism. (Increased risk of bleeding when given together)

• Drugs like chloramphenicol, warfarin, isoniazid, and cimetidine can inhibit the metabolism of phenytoin and cause its toxicity.

• Sucralfate decreases the absorption of phenytoin by binding to it in the gastrointestinal tract.

Solution to Question 4:

Downregulation of CYP2C19 is responsible for the failure of clopidogrel in this patient.

Clopidogrel is a prodrug and its metabolic activation occurs in the liver. It is bioactivated by the CYP2C19 enzyme. If there is downregulation of this enzyme it will cause a decrease in the efficacy of clopidogrel and can lead to thrombotic events like stroke. Drugs that inhibit CYP2C19 can also decrease the antiplatelet effect of clopidogrel. Proton-pump inhibitors may cause inhibition of CYP2C19 and when they are given in combination there would be a decrease in the efficacy of clopidogrel.

Therapeutic uses: Clopidogrel is used to reduce the rate of stroke and myocardial infarction. It also decreases the rate of deaths in patients with recent myocardial infarction or stroke. Other uses are acute coronary syndrome and peripheral arterial disease.

Adverse effects: Increased risk of bleeding especially when given with an anticoagulant or aspirin. Rarely thrombotic thrombocytopenic purpura can occur.

CYP2C19: Common drugs that are metabolized include omeprazole, phenytoin, diazepam, and propanolol. Inducers of the CYP2C subfamily are rifampicin and carbamazepine. Omeprazole is an inhibitor.

Other options:

CYP2D6: Drugs metabolized include SSRIs, tricyclic antidepressants, antiarrhythmic drugs, beta-blockers, and opiates. It is inhibited by quinidine and it will prevent the formation of morphine from codeine. Hence quinidine decreases the analgesic effect of codeine.

CYP1A1/2: It metabolizes few drugs like theophylline, paracetamol, caffeine and carbamazepine. It plays an important role in the activation of procarcinogens. Inducers are rifampicin, carbamazepine, polycyclic hydrocarbons, charbroiled meat, and cigarette smoke.

CYP2E1: It is involved in the oxidation of alcohol, halothane, and minor metabolism of other drugs. It is important to note that it is involved in the formation of hepatotoxic N-acetyl benzoquinone imine from paracetamol. Chronic alcoholism is responsible for the induction of this enzyme.

Solution to Question 5:

Liraglutide is used in the long-term management of obesity.

Mechanism of action:

• Increase glucose-mediated insulin release

• Lowers the glucagon levels

• Delays gastric emptying

• Decreases feeding by stimulating GLP-1 receptors in the arcuate nucleus of the hypothalamus.

It is a GLP-1 analog used as a parenteral hypoglycemic agent and anti-obesity drug. It is administered subcutaneously. It is used as an adjuvant in patients who are not achieving glycemic control with oral agents. It can be also added with basal insulin.

It is found to decrease the risk of cardiovascular death, nonfatal myocardial infarction, and stroke in patients with type 2 diabetes and cardiovascular disease.

Adverse effects: Nausea, vomiting, diarrhea, or constipation. It should not be given in patients with a personal or family history of MEN syndrome or medullary carcinoma of the thyroid.

Other options:

Metformin: It belongs to the biguanides class of oral hypoglycemic agents. It is used as a first-line agent in the management of type 2 diabetes and it acts by reducing hepatic glucose production. It is also used to treat infertility in PCOD patients. IT is usually not associated with weight gain and in some cases, it may cause mild weight reduction.

Sibutramine: It has both serotonergic and noradrenergic action. It is also an anorectic agent with a similar mechanism of action to fenfluramine. But due to severe adverse effects, US-FDA has banned its use.

Fenfluramine: It is a serotonergic anorectic agent. It reduces food-seeking behavior due to increased serotonergic transmission in the hypothalamus. The use of is not recommended now by the US-FDA due to its severe side effects.

Solution to Question 6:

The clinical features and the CT angiography image showing diffuse symmetrical luminal narrowing of the lower limb vessels are suggestive of ergotism.

In this case, a patient on antiretroviral therapy is given ergotamine. HIV protease inhibitors used in ART like ritonavir, lopinavir, etc are potent inhibitors of the CYP3A4 enzyme. This enzyme is responsible for the metabolism of ergot compounds. Hence inhibition of this enzyme leads to decreased metabolism of ergotamine. This causes the accumulation of toxic levels of ergotamine in the patient and leads to ergotism.

Ergotamine is a partial agonist and antagonist at alpha-adrenergic, 5HT1; and 5HT2 receptors. It produces sustained vasoconstriction, vasomotor center depression, and visceral smooth muscle contraction.

Adverse effects: Nausea, vomiting, and abdominal pain may be seen. Vasoconstriction caused by the drug is responsible for most of the adverse effects. These are usually seen with long-term therapy with higher doses.

• It may precipitate or aggravate angina pectoris or myocardial infarction due to coronary insufficiency.

• Some patients develop cold, numb, and painful extremities.

• Leg claudication may be seen

• Gangrene of the extremities

Contraindications for ergotamine:

• Peripheral vascular disease

• Coronary artery disease

• Uncontrolled hypertension

• Sepsis

• Pregnancy

• Liver and kidney diseases

Solution to Question 7:

Topiramate is used in the treatment of Lennox-Gastuat syndrome.

Uses of topiramate:

• In newly diagnosed focal and primary generalized epilepsy in adults and children

• As monotherapy for refractory focal epilepsy and generalized tonic-clonic seizures

• Treatment of tonic-clonic seizures in patients with Lennox-Gastuat syndrome

• It is also used in the prophylaxis of migraine(not for treatment)

• It can be given as monotherapy for children of 10 years or more. But if used as adjunctive therapy it can be used in children as young as 2 years.

Mechanism of action: It reduces voltage-gated sodium currents in the cerebellar granule cells. It also activates a hyperpolarizing potassium current, enhances GABAA receptor currents, and limits the activation of the AMPA-kainate subtype of glutamate receptors. It also produces weak inhibition of the carbonic anhydrase enzyme.

Pharmacokinetics: Only 10-20% is bound to plasma proteins and the drug is largely excreted unchanged in the urine. Half-life is about 1 day. Topiramate is found to decrease the plasma concentrations of oral contraceptives, hence a higher dose of OCPs should be given along with topiramate.

Adverse effects:

• Somnolence, weight loss, fatigue, and nervousness are commonly seen

• It can precipitate renal calculi. It may be due to the weak carbonic anhydrase inhibition.

• Cognitive impairment

Solution to Question 8:

Ciraparantag is a reversal agent for all direct anticoagulants and is not useful with fondaparinux which is an indirect factor Xa inhibitor.

Ciraparantag, andexanet alfa, and idarucizumab are all reversal agents of direct anticoagulants.

Ciraparantag: It is considered as a potential reversal agent against all direct anticoagulants including dabigatran, rivaroxaban, edoxaban, apixaban, LMWH, and heparin. This drug is in the early stages of development.

Andexanet alfa: It is a recombinant analog of factor Xa and is proposed for reversal of oral factor Xa inhibitors like rivaroxaban, edoxaban, and apixaban. It rapidly reverses the action of these drugs and restores thrombin generation.

Idarucizumab: It is a licensed monoclonal antibody that specifically acts as a reversal agent for dabigatran. It has a 350 times higher affinity for dabigatran than thrombin. Hence it forms a complex with dabigatran and is excreted by the kidneys.

If a patient on direct oral anticoagulants like dabigatran, rivaroxaban, edoxaban, and apixaban presents with life-threatening bleeds and the reversal agents are not available then other options are the administration of prothrombin complex concentrate, activated prothrombin complex concentrate, or recombinant factor VII-A. Hemodialysis is useful in severe bleeding due to dabigatran.

Other reversal agents for anticoagulants:

• Protamine sulphate - Heparin

• Vitamin K - Warfarin

Note:

Andexanet alfa has received US-FDA approval in May 2018 as a reversal agent for rivaroxaban and apixaban.

Solution to Question 9:

Inhaled nitric oxide (NO) is used in the management of pulmonary hypertension.

The only FDA-approved therapeutic indication of inhaled nitric oxide is in persistent pulmonary hypertension of the newborn. It has the ability to selectively dilate pulmonary vasculature. Hence it can be used in conditions with increased pulmonary vascular resistance.

It is proposed for the:

• Long-term management of pulmonary artery hypertension(PAH) and other forms of pulmonary hypertension

• Rescue therapy for severely hypoxemic patients with or without pulmonary hypertension

Diagnostic indications:

• In heart failure patients and infants with congenital heart disease during cardiac catheterization to evaluate pulmonary vasoreactivity.

• In determining the diffusion capacity across the alveolar-capillary unit. It is considered superior to carbon dioxide in this because it has a greater affinity for hemoglobin and higher water solubility at body temperature.

Mechanism of action:

It activates soluble guanylyl cyclase and produces cGMP, which then activates cGMP-dependent protein kinase. This leads to the activation of multiple regulatory mechanisms that decrease intracellular calcium and cause vasodilation in precapillary resistance arterioles.

Adverse effects:

• Methemoglobinemia at higher concentrations.

• It can worsen left ventricular performance in patients with an already impaired left ventricular function.

Solution to Question 10:

Nivolumab is used as a checkpoint inhibitor in Hodgkin's lymphoma.

FDA approved uses of nivolumab:

• Advanced melanoma

• Advanced non-small cell lung cancer(NSCLC) that are previously treated

• Renal cell carcinoma

• Advanced head and neck cancers

• Refractory/relapsed classical Hodgkin's lymphoma

Nivolumab is a checkpoint inhibitor that blocks the interaction between PD-1 and its ligands. It is a fully human monoclonal IgG4 antibody. It has a good response rate in patients with pretreated solid tumors and hematological malignancies. Similar effectiveness is also seen with pembrolizumab which is also an anti-PD-1 monoclonal antibody.

Adverse effects:

• In melanoma patients rash is a commonly seen side effect

• fatigue, dyspnea, musculoskeletal pain, cough, decreased appetite, and constipation can be seen in advanced squamous NSCLC patients

• Pneumonitis, colitis, nephritis, hepatitis, and renal dysfunction are also seen

Important note:

The FDA on May 2021 has approved the use of nivolumab in patients having completely resected esophageal or gastroesophageal junction cancers with residual pathologic disease who have received neoadjuvant chemoradiotherapy.

Solution to Question 11:

Paradoxical bronchoconstriction with ipratropium bromide is seen with a hypotonic nebulizer solution and not hypertonic saline.

Paradoxical bronchoconstriction with ipratropium bromide is seen especially when given by a nebulizer and may be due to the following factors:

• Hypotonic nebulizer solution

• Antibacterial additives like benzalkonium chloride and EDTA

• It may be also due to prejunctional M2 receptor blockade on the cholinergic nerves present in the airway. These prejunctional M2 receptors normally inhibit acetylcholine release into the synapse. So their blockade can cause increased Ach release and bronchoconstriction.

Paradoxical bronchoconstriction is not reported with tiotropium bromide or any other long-acting muscarinic antagonists. Tiotropium is selective for M3 and M1 receptors and therefore less likely

to produce prejunctional M2 receptor blockade.

Other adverse effects of inhaled muscarinic antagonists:

• A bitter taste is seen with ipratropium

• Nebulization with ipratropium bromide may precipitate glaucoma in elderly patients. This is due to the direct effect of the drug on the eyes and can be easily prevented by using a mouthpiece instead of a facemask.

• Long-acting agents can cause dryness of the mouth.

• In elderly patients, urinary retention may be seen occasionally.

Solution to Question 12:

Gonorrhea is not managed by antimicrobial combinations. According to the latest CDC guidelines, single-agent therapy with ceftriaxone is the preferred treatment for gonococcal infections.

Single-dose of 500mg intramuscular(IM) ceftriaxone is given for gonorrhea. It is important to note that the previous guidelines that recommended dual therapy with ceftriaxone and azithromycin are no longer preferred.

Monotherapy with ceftriaxone is given when concurrent chlamydia infection is ruled out by molecular testing. If this is not done then presumptive treatment for chlamydia should be given along with the treatment of gonorrhea. According to CDC guidelines, 100mg doxycycline twice daily for 7 days is given as presumptive treatment of chlamydia in nonpregnant individuals.

Other options:

Tuberculosis: Multidrug therapy is given in tuberculosis for proper cure and to prevent the selection of drug-resistant mutants. ATT regimen is given in detail in the pearl attached.

Intraabdominal infections: It is usually polymicrobial and can result in an intraabdominal abscess or secondary peritonitis. These are managed with either single-agent or combination therapy. Broad-spectrum agents with gram-negative cover such as meropenem or piperacillin-tazobactam can be used alone. Combination therapy with metronidazole and other agents like ciprofloxacin, cefepime, etc are used as empirical agents in intraabdominal infections.

Malaria: It is also treated with antimicrobial combinations. In plasmodium vivax and ovale malaria, schizontocides like chloroquine are combined with agents that attack the hypnozoites like primaquine for radical cure. Primaquine is also given in combination with Artemisinin combined therapy(ACT) for plasmodium falciparum infections as a gametocidal agent. Treatment regimens are given in the pearl attached.

Solution to Question 13:

Vancomycin acts on step 4 in the given image.

Mechanism of action of vancomycin: It is a cell wall synthesis inhibitor. It binds to the D-Ala-D-Ala terminus of the newly formed peptidoglycan pentapeptide and inhibits the transglycosylase enzyme. This would prevent further elongation of the peptidoglycan and its cross-linking.

Vancomycin is a bactericidal agent for gram-positive organisms. It is also active against many gram-positive anaerobes like Clostridium difficile. Resistance against vancomycin in enterococci is due to the alternation in its binding site where D-Ala is replaced by D-Lactate.

Clinical uses:

• Parenteral vancomycin is given for bloodstream infections and endocarditis caused by MRSA.

• Vancomycin plus gentamicin is given as an alternative regimen for enterococcal endocarditis with penicillin allergy.

• In combination with other agents for suspected meningitis or meningitis due to penicillin-resistant pneumococcus.

• Oral vancomycin is given for Clostridium difficile colitis.

Adverse effects:

• Injection site phlebitis

• Nephrotoxicity

• "Redman" syndrome due to histamine release following infusion

Other options:

Fosfomycin inhibits step 1 in the image. It acts at a very early stage in cell wall synthesis and inhibits the cytoplasmic enzyme enol pyruvate transferase. This would block the addition of phosphoenolpyruvate to UDP-N-acetylglucosamine. This prevents the formation of UDP-N-acetylmuramic acid which is the precursor N-acetylmuramic acid. N-acetylmuramic acid is a component of the bacterial cell wall and hence cell wall synthesis is inhibited.

Cycloserine inhibits step 2 in the image. It is a structural analog of D-alanine and inhibits the enzymes alanine racemase that converts L-alanine to D-alanine and d-alanyl-d-alanine ligase. This would thereby inhibit the incorporation of D-alanine into the peptidoglycan pentapeptide. It is mainly used in the management of tuberculosis where there is resistance to the first-line agents.

Bacitracin inhibits step 3 in the image. It is a cell wall synthesis inhibitor that interferes with dephosphorylation in the cycling of the lipid carrier which transfers peptidoglycan subunits to the growing cell wall. It is only given for topical application because of its severe nephrotoxicity when given systemically.

Note:

Beta-lactam antibiotics prevent cross-linking by inhibiting the transpeptidases. (Last step in the images)

Solution to Question 14:

In this case, the half-life remains the same, and the plasma concentration doubles.

Half-life is constant in drugs following first-order kinetics irrespective of the dose as a constant fraction of the drug is eliminated per unit time.

The plasma concentration of the drug increases when the dose given is increased. In this case, as the drug dose is doubled plasma concentration is also doubled.

Solution to Question 15:

Risperidone is FDA approved for the treatment of bipolar affective disorders.

Uses of risperidone:

• Long-term management of psychosis and schizophrenia.

• Maintenance therapy in mania bipolar disorders.

• Management of irritability associated with autism.

Off-label uses of risperidone:

• Management of psychotic symptoms in delirium and dementia.

• Obsessive-compulsive disorders.

• Post-traumatic stress disorders.

Risperidone is an atypical antipsychotic that shows both D2 and 5 HT2 receptor blockade. It also has an affinity for alpha 1, alpha 2, and H1 receptors. It produces a more potent D2 blockade than clozapine. Hyperprolactinemia is an important adverse effect. It is also associated with an increased risk of stroke in elderly patients. At low doses, extrapyramidal side effects are less.

Solution to Question 16:

The half-life of the given drug is 13.8 hours.

The half-life of a drug or t1/2 is the time taken for the plasma concentration to be reduced by 50%. The elimination rate constant or k value of a drug reflects the fraction of drug removed from the body compartment per unit of time.

The half-life of a drug and its elimination rate constant are inversely proportional to each other. They are represented by the equation:

k t1/2 = 0.693

Therefore, t1/2 = 0.693/ k

The given value for elimination rate constant ■ is 0.05, therefore the half-life of the given drug would be:

0.693/ 0.05 = 13.8

Therefore, the half-life of the drug would be 13.8 hours.

Solution to Question 17:

The minimum duration of time between the consumption of phenytoin and sucralfate should be 120 minutes.

Sucralfate, in an acidic environment (pH < 4) acts by producing a viscous, sticky polymer that adheres to ulcer craters and epithelial cells for up to 6 hours after a single dose. This viscous layer produced in the stomach leads to inhibition of absorption of other drugs, like phenytoin, digoxin, cimetidine, ketoconazole, and fluoroquinolone antibiotics. Therefore, sucralfate should be taken after a gap of at least 2 hours / 120 minutes after the administration of phenytoin.

Constipation is the most common side effect of sucralfate. It should be avoided in patients with renal failure who are at risk of aluminium overload. Aluminum-containing antacids should not be combined with sucralfate in these patients. As the viscous gel produced by sucralfate is sticky, it may eventually lead to bezoar formation.

It is generally used for prophylaxis of peptic ulcers, but rarely so because of its side effects and its risks outweigh its benefits.

Solution to Question 18:

Category A, B, C, D, X in drug classification are indicative of their safety in pregnancy.

The united states food and drug administration (FDA) system for teratogenic potential attempts to quantify teratogenic risk from category A (safe) to category X (definite human teratogenic risk).

Category A: The possibility of fetal harm is remote and studies in women have failed to demonstrate any evidence of risk to the fetus. Examples: doxylamine, folic acid, levothyroxine.

Category B: Either animal-reproduction studies have not demonstrated a fetal risk, but there are no controlled studies in pregnant women, or animal-reproduction studies have shown an adverse effect that was not confirmed in controlled studies in pregnant women. Example: Amoxicillin, loratadine, ondansetron.

Category C: Either studies in animals have revealed adverse effects on the fetus, that is, teratogenic or embryocidal but there are no controlled studies in women, or studies in women and animals are not available. These drugs should be given only if the potential benefit justifies the potential risk to the fetus. Example: fluconazole, metoprolol, sertraline.

Category D: Though there is evidence of human fetal risk, the benefits from use in pregnant women may be acceptable despite the risk, for example, if the drug is needed in a life-threatening situation or for a disease for which safer drugs cannot be used or are ineffective. Example: lisinopril, lithium, phenytoin.

Category X: There is evidence of fetal risk based on human or animal experience and the risk of the use of the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindicated in women who are or may become pregnant. Example: methotrexate, simvastatin, warfarin.

Solution to Question 19:

The false statement regarding suicidal inhibition is the inhibitor can bind with any site resulting in suicidal inhibition.

In suicidal inhibition, the inhibitor can only bind with the active site of an enzyme and is unreactive outside the confines of the enzyme's active site.

The enzyme inhibition helps to modify the rate of reactions it catalyzes and this inhibition can either be reversible or irreversible. Reversible inhibitors bind to enzymes through non-covalent bonds. Irreversible inhibitors usually bind to an enzyme through covalent bonds and do so strongly so that it can no longer dissociate.

Suicide inhibitors are a category of irreversible inhibitors also called mechanism-based inhibitors. They are specialized substrate analogs that contain a chemical group that reacts with the catalytic machinery of the target enzyme. In these types of inhibitors, the substrate analog irreversibly ties up with the binding site of an enzyme, deceiving the enzyme by concealing its functional group resulting in the formation of a highly reactive molecule, which brings about self-inactivation of the enzyme.

Suicide inhibitors bind to the enzyme by means of covalent bonds; they are enzyme-specific and unreactive outside the confines of the enzyme’s active site.

An example of this would be the binding of clavulanic acid to the active site of beta-lactamases in bacteria. Clavulanic acid mimics the structure of a beta-lactam antibiotic and forms a covalent adduct with the β-lactamase active site. This leads to a rearrangement that creates a much more reactive derivative, which is subsequently attacked in its active site to irreversibly acylate the enzyme and inactivate it. Thus, amoxicillin and clavulanic acid are combined to overcome bacterial resistance to amoxicillin alone.

The development of clavulanic acid to target beta-lactamase-producing bacteria is also an example of the rational design of drugs. Rational design of drugs refers to the ability to predict the appropriate molecular structure of a drug on the basis of information about its biological receptor.

Solution to Question 20:

The dose at which dopamine acts on β-1 receptors is 2-10 mcg/kg/min.

The systemic effects of dopamine vary with its concentration in the body.

When administered at an infusion rate of 2-5 mcg/kg/min, it directly stimulates cardiac β receptors. This enhances myocardial contractility and is useful in the management of cardiogenic shock.

At doses of 5-15 mcg/kg/min and above, it stimulates α adrenergic receptors. This causes peripheral arterial and venous vasoconstriction.

At lower doses of <2 mcg/kg/min, it directly stimulates both D1 and D2 receptors. The D1 receptors in renal and mesenteric blood vessels are the most sensitive: i.v. infusion of low dose of DA dilates these vessels subsequently, causing increased renal blood flow and increased urine output.

The clinical indications of dopamine include cardiogenic and vasodilatory shock, congestive cardiac failure and symptomatic bradycardia unresponsive to atropine or pacing.

The major side effects are:

• Severe hypertension (especially when taken with nonselective β-blockers)

• Ventricular arrhythmias

• Cardiac ischemia

• Tissue ischemia/gangrene (high doses/extravasation into tissues)

Solution to Question 21:

The incorrect statement regarding clomiphene citrate is that it causes monofollicular development; rather, it causes multi follicular development.

Clomiphene is an unequal mixture of two isomers, enclomiphene and zuclomiphene. Zuclomiphene is a non-steroidal compound closely resembling an estrogen, blocks the negative inhibitory feedback of estrogens on the hypothalamus, causing a surge of gonadotropins (FSH, LH), which leads to ovulation. The continued flow of FSH encourages multiple follicular development which is relatively common.

Being an anti-estrogen, it causes thickening of cervical mucus and thinning of the endometrium.

Clomiphene citrate (CC) is used for the treatment of absent or irregular ovulation due to hypothalamic-pituitary dysfunction associated with normal levels of endogenous estradiol; the patient must be treated repeatedly until pregnancy is achieved since the normal cyclic ovulatory function does not usually resume. Clomiphene citrate has no effect on patients with ovarian or pituitary failure. Ovulation induction with clomiphene citrate and a gonadotropin like FSH increases the likelihood of multiple concurrent ovulations.

Side effects of CC include hot flushes and some nausea. However, it is usually very well tolerated.

Solution to Question 22:

The mechanism of action of remdesivir is inhibition of the enzyme RNA-dependent RNA polymerase.

Remdesivir is an adenosine nucleotide prodrug. It distributes into cells where it is metabolized to form remdesivir triphosphate (RDV-TP). It binds to the viral RNA-dependent RNA polymerase and inhibits viral replication by prematurely terminating RNA transcription.

Remdesivir (under Emergency Use Authorization) is used in the treatment of COVID-19. It may be considered in patients with moderate to severe disease, requiring supplemental oxygen, within 10 days of onset of the illness.

Dose: 200 mg IV on day 1 followed by 100 mg IV daily for 4 days (total 5 days).

The following are contraindications to the use of remdesivir:

• Renal or hepatic dysfunction (eGFR <30 ml/min/m2; AST/ALT >5 times upper limit of normal) (Not an absolute contraindication)

• Pregnant or lactating females

• Patients <12 years of age

• Patients who are not on oxygen support or in-home settings

Remdesivir can cause gastrointestinal symptoms, elevated transaminase levels, increased prothrombin time, and hypersensitivity reactions. Hence, liver function tests and prothrombin time should be obtained before and during treatment with remdesivir.

Other options:

Option A- RNA-dependent DNA Polymerase / reverse transcriptase inhibitors prevent the conversion of viral RNA into proviral DNA. They help to prevent infection of susceptible cells but do not eradicate the virus from cells that are integrated with proviral DNA. Examples: zidovudine, lamivudine, stavudine, tenofovir, didanosine, zalcitabine, and emtricitabine. These are drugs used to manage HIV infection.

Options C and D- Entry/fusion inhibitors include enfuvirtide and maraviroc. Enfuvirtide inhibits the fusion of viral and cell membranes mediated by gp41 and CD4 interactions. Maraviroc is a chemokine receptor antagonist and binds to host cell CCR5 receptor to block binding of viral gp120. They are also used to manage HIV infection.

Solution to Question 23:

Administration of ritonavir would increase the bioavailability of saquinavir.

Saquinavir is an HIV protease inhibitor that inhibits replication of both HIV-1 and HIV-2. It is metabolized predominantly by the hepatic enzyme CYP3A4. Inhibition of CYP3A4 results in an increase or a boost in the concentration of saquinavir. Ritonavir is one such drug that inhibits CYP3A4. Therefore combining it with a protease inhibitor like saquinavir results in:

• Enhanced bioavailability

• Inhibition of systemic clearance

• Inhibition of first-pass metabolism, and

• Longer half-life of the co-administered HIV protease inhibitor.

This allows for a reduction of drug dose and dosing frequency of saquinavir.

All protease inhibitors except for nelfinavir are predominantly metabolized by CYP3A4. Therefore, the administration of CYP3A4 inhibitors like ritonavir or cobicistat can increase the bioavailability of these protease inhibitors. This phenomenon is known as boosting protease inhibitors by CYP inhibitors. The dosage of ritonavir, when given as a booster drug, is 100 to 200mg once or twice daily.

Other options :

Option B: Vitamin C / Ascorbic acid is a water-soluble vitamin that can actually reduce the steady-state concentration of protease inhibitors. It increases the absorption of dietary iron.

Option C: Cimetidine is a histamine 2 receptor antagonist which is used to promote gastric and duodenal ulcer healing. It is used in the management of gastroesophageal reflux disease. It also inhibits CYPs, but only ritonavir and cobicistat are used for boosting protease inhibitors.

Option D: Ganciclovir is a guanine nucleoside analogue which has inhibitory activity against all herpes viruses, especially cytomegalovirus (CMV).

Solution to Question 24:

Drug A reduces the first-pass metabolism of Drug B.

The area under the plot of plasma concentration of a drug versus time after dosage is called the area under the curve or AUC. It can be used as a measure of the bioavailability of a drug and to calculate its clearance rate from the body.

Bioavailability refers to the extent to which an administered dose of the drug reaches its site of action; if the metabolic and excretory capacity of the intestine or liver for the drug is large, bioavailability is reduced substantially and this is called the first-pass metabolism whereas bioavailability is increased if intestinal absorption of the drug is increased.

The greater the AUC, the greater is the bioavailability of the drug.

In the question, is observed that when drug A was given along with drug B, the total AUC has increased (820 seconds ± 124 seconds) when compared to the AUC when drug B is administered alone (570 seconds ± 127 seconds).

The null hypothesis for the above question would be that drug A doesn't increase the AUC for drug B and for this to be true, ■ value should be >0.05.

As given ■ value is <0.01, it is significant and the null hypothesis is rejected, which means that drug A has indeed increased the AUC for drug B.

This indicates increased bioavailability of drug B when administered with drug A, which shows that drug A has either increased the intestinal absorption of drug B or has reduced its first-pass metabolism.

Other options:

Option A: If drug A decreased the intestinal absorption of drug B, this would mean that the AUC for drug B, when administered with drug A, would be reduced. This is due to decreased bioavailability of drug B when given with drug A.

Option C: If drug A increases the metabolism of drug B, this would lead to a shorter t1/2 and duration of action of drug B, thereby decreasing the AUC for when drug B and drug A are given together.

Option D: If drug A increased the elimination of drug B, the AUC for drug B when given with drug A would be reduced due to reduced duration of action of drug B.

Solution to Question 25:

The mechanism of action of cyclosporine is inhibition of calcineurin activity.

Calcineurin is a calcium/calmodulin-dependent phosphatase required for the induction of T cell lymphokine production and proliferation. Cyclosporine is an immunomodulatory drug

that inhibits calcineurin activity by forming a complex with cyclophilin, a cytoplasmic-receptor protein present in target cells, to form a cyclosporine-cyclophilin complex. This drug-receptor complex specifically and competitively binds to and inhibits calcineurin, a calcium and calmodulin-dependent phosphatase. This in turn, inhibits the translocation of a family of transcription factors (NF-AT), leading to reduced transcriptional activation of cytokine genes for interleukin (IL)-2, tumour necrosis factor (TNF)-alpha, IL-3, IL-4, CD40L, granulocyte-macrophage colony-stimulating factor, and interferon-gamma. Ultimately, the proliferation of T lymphocytes is reduced, resulting in immunomodulation.

Its uses are :

• In solid organ transplantation, to treat organ rejection in kidney, liver, and heart allogeneic transplants.

• In patients with rheumatoid arthritis, when the disease has not adequately responded to methotrexate.

• It is approved to treat amyotrophic lateral sclerosis (ALS or Lou Gehrig disease) and its variants.

• In nephrotic syndrome, to treat focal segmental glomerulosclerosis not responding to corticosteroids.

Adverse effects of cyclosporine include a decrease in glomerular filtration rate (GFR) and metabolic disturbances like hypomagnesemia, hyperkalemia, dyslipidemia, gynecomastia, hypertrichosis; neurotoxicity in the form of convulsions. There is an increased risk of developing skin and lymphoproliferative malignancies in cyclosporine-treated psoriasis patients.

Other options:

Option B: AMP kinase is stimulated by metformin, a first-line orally administered drug in the management of type-2 diabetes mellitus.

Option C: IMP dehydrogenase is inhibited reversibly by the drug mycophenolate mofetil, which is indicated in the prophylaxis of transplant rejection.

Option D: Dihydro-orotate dehydrogenase is inhibited by leflunomide, a pyrimidine synthesis inhibitor indicated for the management of rheumatoid arthritis in adults.

Solution to Question 26:

Anionic and weakly acidic drugs bind to albumin.

After being distributed in the circulating blood, drugs bind to serum proteins to varying degrees. Among serum proteins, albumin and alpha-1 acid glycoprotein play important roles in protein binding for many drugs, which affects their distribution in the body.

Albumin is a major carrier of and binds to acidic drugs like phenytoin, NSAIDs. Whereas, α-1 acid glycoprotein binds basic drugs like lignocaine,disopyramide, quinidine and propranolol.

Importance of plasma protein binding:

Conditions resulting in acute phase reaction response leading to elevated levels of alpha-1 acid glycoprotein like Crohn's disease, myocardial infarction, arthritis, cancer, etc. enhance binding of basic drugs. Conditions causing hypoalbuminemia result in decreased binding sites for acidic

drugs.

When a drug is bound to the plasma proteins, it is kept in the blood, while the unbound (free) drug can produce a therapeutic effect, be metabolized, or excreted. In the majority of the drugs, this does not have a significant effect, but in drugs with a narrow therapeutic index like warfarin, it is clinically relevant as excessive free warfarin can produce toxicity.

Many drugs displace other drugs from their protein binding sites. This may cause an increase in the pharmacological effect of the displaced drug.

A drug bound to a plasma protein cannot cross membranes and this bound fraction of a drug is also not available for metabolism or glomerular filtration which can make the drug long-acting.

Other options:

Option B- Globulins are of three types - α,β, and γ-globulins. Globulins bind glucocorticoids and progesterone in the blood.

Option C- Lipoproteins like VLDL, LDL can bind anti-cancer drugs like 5-fluorouracil and doxorubicin.

Solution to Question 27:

The probable reason why the drug to be administered was changed from ampicillin to ceftriaxone is because Hemophilus produces beta-lactamase and hence, is resistant to ampicillin.

A considerable percentage of isolates of Hemophilus influenzae produce beta-lactamase, rendering them resistant to ampicillin, a beta-lactam antibiotic. However, these strains are still sensitive to second and third-generation cephalosporins.

In H. influenzae, the resistance to ampicillin and other β-lactam antibiotics is generally due to the production of a β-lactamase. In the case of β-lactamase-negative ampicillin-resistant strains, resistance is due to the presence of altered penicillin-binding proteins.

Ceftriaxone is a third-generation cephalosporin that is effective against Hemophilus Influenzae and considerably resistant to beta-lactamase. It has a very long half-life which permits once-daily dosing of the drug. Because of the efficacy of third-generation cephalosporins in the therapy of meningitis caused by Hemophilus Influenzae type b, ceftriaxone administered at the rate of 50 mg/kg/dose given 12th hourly should be a part of the initial empirical therapy.

Vancomycin combined with a third-generation cephalosporin like ceftriaxone is the recommended empirical antibiotic regimen in a suspected case of meningitis, beyond the neonatal period.

Solution to Question 28:

The preferred diuretic for this patient with cirrhosis presenting with abdominal distension and lower limb swelling is eplerenone.

Eplerenone is a mineralocorticoid receptor/aldosterone antagonist. High doses of mineralocorticoid receptor/aldosterone antagonists decrease total body sodium in cirrhotic patients with ascites by natriuresis.

Patients with liver cirrhosis have a decreased effective arterial blood volume because of splanchnic vasodilatation. This stimulates the renin-angiotensin-aldosterone system and results in hyperaldosteronism. This causes increased sodium and water retention and leads to the development of ascites. This also contributes to resistance to loop diuretics.

Normally, aldosterone (AL) enters the cells of the late distal tubule and collecting ducts by diffusion and binds to a specific mineralocorticoid receptor (MR) in the cytoplasm. This AL-MR complex mediates Na+ reabsorption, which drives the secretion of K+ and H+into the tubules.

Eplerenone competitively blocks this MR, preventing it from binding with aldosterone. The net effect is sodium diuresis and potassium retention. It is a potassium-sparing diuretic. Other mineralocorticoid receptor antagonists include spironolactone, canrenone, potassium canrenoate.

Some clinical uses of MR antagonists are -

• Hypertension due to primary hyperaldosteronism

• Edema associated with liver cirrhosis, congestive cardiac failure, chronic kidney disease

• They may reduce mortality in patients with myocardial infarction

Hyperkalemia is the major side effect of MR antagonists, the risk being greater in patients with renal disease or those already taking ACE inhibitors. Other important side effects are gynecomastia and decreased libido due to the anti-androgenic effect of spironolactone but eplerenone does not cause gynecomastia and decreased libido.

Other options :

Option A- Triamterene directly inhibits renal epithelial sodium channels (ENaC) in the late distal tubule and collecting duct. It is a potassium-sparing diuretic and is generally used along with other diuretics in the treatment of hypertension and edema. Triamterene is metabolized in the liver, hence triamterene toxicity may be enhanced in patients with hepatic disease. It is used in the management of Liddle syndrome.

Option C- Chlorthalidone is a thiazide-like diuretic. It inhibits Na+-Cl- symporter in the early distal tubule and increases the excretion of sodium and chloride. Thiazide diuretics may be used for the treatment of hypertension, heart failure, nephrolithiasis due to idiopathic hypercalciuria, and nephrogenic diabetes insipidus.

Option D- Furosemide is a loop diuretic. It acts by inhibiting the Na+-K+-2Cl- symporter in the thick ascending limb of the loop of Henle resulting in increased excretion of sodium and chloride. It also has mild carbonic anhydrase inhibitory activity and also increases urinary excretion of bicarbonate and phosphate. Cirrhotic patients are often resistant to loop diuretics due to decreased secretion of the drug into tubular fluid and high aldosterone levels. Furosemide may be given along with eplerenone, but the best answer here is eplerenone since aldosterone antagonists are the main therapy for cirrhotic edema.

Solution to Question 29:

Varenicline is the most effective drug in smoking cessation.

Nicotine is the principal constituent of tobacco responsible for its addictive behaviour. One of the newest agents introduced to aid in smoking cessation is varenicline.

Varenicline works by blocking the effects of nicotine on the brain. It blocks α-4, β-2 nicotinic acetylcholine receptor subtypes and varenicline inhibits dopaminergic activation produced by smoking through their partial agonism, and decreases the craving and withdrawal syndrome that occurs with cessation attempts. It prevents nicotine stimulation of the mesolimbic dopamine system associated with nicotine addiction, thus helping to occlude the "rewarding" effect of smoking.

Varenicline is prescribed only to patients 18 years or older. Varenicline is taken orally and the dose taken is 0.5 mg once daily on days 1 to 3, increased to 0.5 mg twice daily on days 4 through 7 and 1 mg twice daily after day 8 for 11 weeks. Therapy should start one week before the target quit date. It can be continued for another 12 weeks (1 mg BD) to maintain abstinence.

The adverse effects include nausea, which can be mitigated by starting at lower doses and gradually increasing the dose. Other symptoms include disturbed sleep, sleepwalking, agitation, drowsiness, and constipation and may also increase the risk of pancreatitis. Varenicline has also been implicated in specific skin syndromes such as Stevens-Johnson syndrome, erythema multiforme, and photosensitivity. Varenicline can cause renal failure and kidney stones, thus renal function must be monitored.

The FDA has issued a warning about mood and behavioral changes associated with its use, and there is some evidence of increased cardiovascular risk.

Other options:

Option B: Buspirone sustained release is a partial agonist at 5HT receptors but affinity for D2 receptors may also be present. Its effects are slow onset, over a couple of weeks and is used in the management of generalised anxiety states.

Option C: Nicotine gum has nicotine which is an agonist at Nn type nicotinic cholinergic receptors and is also advised for smoking cessation along with psychotherapy. However, varenicline was more effective when compared with single■product nicotine replacement therapy (NRT) and was similarly effective compared with combination NRT.

Option D: Rimonabant is an inverse agonist at cannabinoid receptor CB1 which decreases neurotransmitter release at GABAergic and glutamatergic synapses; its usage for smoking cessation and treat obesity was stopped after serious side effects notably severe depression and increased risk of suicide. However, it continues to be used off-label for smoking cessation.

Solution to Question 30:

The cephalosporin antibiotic most likely to have caused hemarthrosis in this patient on warfarin therapy is cefoperazone.

Cephalosporins containing a methylthiotetrazole (NMTT) group can prolong the prothrombin time. This results in clinically significant bleeding in patients already on anticoagulant therapy or having vitamin K deficiency.

This is because NMTT cephalosporins inhibit the enzyme vitamin K epoxide reductase in the liver, which is the key enzyme for vitamin K-dependent carboxylation, a posttranslational modification that is essential for the biological functions of coagulation factors.

NMTT group containing cephalosporins include latamoxef, cefmenoxime, cefoperazone, cefotetan, cefamandole.

Vitamin K epoxide reductase is also the target of anticoagulants like warfarin. Oral administration of vitamin K can prevent this problem.

Solution to Question 31:

Vilazodone is the novel antidepressant.

The antidepressant effect of vilazodone is due to its enhancement of serotonergic activity in the CNS through selective inhibition of serotonin reuptake. It binds with high affinity to the serotonin reuptake site but not to the norepinephrine or dopamine reuptake site. As a result, vilazodone potently and selectively inhibits the reuptake of serotonin.

Vilazodone is also a partial agonist at serotonergic 5-HT1A receptors; the result of this activity on serotonergic transmission also plays a role in its antidepressant effect.

Thus it offers a novel combination of selective serotonin reuptake inhibition (SSRI) and serotonergic (5-HT1A) receptor partial agonist activity. Because of these characteristics, vilazodone has been termed a serotonin partial agonist–reuptake inhibitor (SPARI).

Vilazodone is never combined with a monoamine oxidase (MAO) inhibitor or given within 14 days of discontinuing or initiating MAO inhibitor therapy due to the serious risk of serotonin toxicity.

Other options:

Option A: Lurasidone is a second-generation antipsychotic that is a 5-HT2A and D2 receptor antagonist. it is used in the treatment of schizophrenia and bipolar depression (as monotherapy or as an adjunct).

Option C: Asenapine is a second-generation antipsychotic which is also a 5-HT2A and D2 receptor antagonist, used in the management of schizophrenia and acute mania.

Option D: Blonanserin is a second-generation antipsychotic, which acts as an antagonist at D2, D3, and 5-HT2A receptors. Blonanserin has a low affinity for 5-HT2C, adrenergic α1, histamine H1, and muscarinic M1 receptors, but displays a relatively high affinity for 5-HT6 receptors. It is used in the management of schizophrenia.

Solution to Question 32:

The image shows grey-blue discoloration over this patient's face and the drug responsible for this is amiodarone.

Long-term treatment with amiodarone is responsible for skin pigmentation. Elderly men are at an increased risk of developing this.

Ultraviolet light reacts with amiodarone and its metabolites to cause local vasodilatation. This increases the diffusion of amiodarone and its metabolites, resulting in their deposition in the tissues, causing pigmentation. Therefore, it is usually seen in sun-exposed areas.

Cessation of amiodarone, avoiding exposure to sunlight using sunscreen cream is recommended.

Amiodarone is an iodine-containing compound that is structurally related to thyroid hormone. It is a class III antiarrhythmic drug, which increases the duration of an action potential by blocking potassium channels. It thereby increases the time taken for repolarization. It also prolongs the refractory period and suppresses abnormal automaticity. It also has weak calcium channel blocking, sodium channel blocking, and adrenergic blocking actions.

It is used to maintain normal sinus rhythm during atrial fibrillation and prevent recurrent ventricular tachycardia.

Adverse effects of amiodarone:

• Prolonged usage of amiodarone causes interstitial lung disease.

• Heart blocks, bradycardia and QT prolongation

• Hyperthyroidism or hypothyroidism

• Corneal micro-deposits and vortex keratopathy, optic neuropathy

Drug interactions of amiodarone

• Causes digoxin toxicity by decreasing its renal clearance.

• Increases concentration of quinidine and procainamide

• Potentiates the anticoagulant effect of warfarin when given simultaneously

Solution to Question 33:

Levopropoxyphene is a centrally acting opioid antitussive.

Levopropoxyphene is an opioid derivative that is a strong and partial μ receptor agonist that helps to reduce the cough reflex and therefore, is used in the management of acute debilitating cough. The usual antitussive dose is 50–100 mg every 4 hours. It has no analgesic activity. However, it is known to cause some sedation.

Other options:

Option A: Ambroxol is derived from bromhexine. It is a mucoactive agent that helps alter the viscoelastic properties of mucus and increase mucociliary clearance, thereby providing relief in productive cough. It is commonly available as intramuscular or intravenous, lozenges, syrups, or tablets.

Option B: Diphenoxylate is an opioid agonist that is structurally similar to meperidine. It is used in the treatment of acute, chronic, and traveler's diarrhea. Upon administration, it undergoes de-esterification to difenoxin, which is its active metabolite. Its side effects include constipation, toxic megacolon, paralytic ileus and can give rise to CNS depression in children.

Option D: Levorphanol is a synthetic opioid that is also a 5HT/Norepinephrine reuptake inhibitor and an NMDA receptor antagonist which is chiefly used in the management of moderate to severe pain and has a relatively rapid onset of action. Its side effects include delirium and hallucinations.

Solution to Question 34:

The anti-epileptic drugs which can also be used for neuropathic pain are 1, 2, and 4 which are pregabalin, carbamazepine and gabapentin respectively.

Pregabalin is an anti-epileptic drug that acts by binding to α2δ, a protein that is a subunit of voltage-gated calcium channels and causes a decrease in glutamate release at excitatory synapses. It is used in the management of neuropathic pain associated with diabetic peripheral neuropathy, spinal cord injury or postherpetic neuralgia.

Gabapentin is an anti-epileptic drug that, like pregabalin, acts by binding to α2δ protein. It is used in the management of neuropathic pain due to postherpetic neuralgia in adults.

The binding of gabapentin and pregabalin, also called "gabapentinoids" due to their structural similarity to GABA, to calcium channel subunit a2δ protein, is considered to mediate the anti-convulsant effects of gabapentin and pregabalin. They are used in focal onset seizures with or without progression to bilateral tonic-clonic seizures when used in addition to other anti-epileptic drugs.

Carbamazepine is an iminostilbine derivative. It blocks voltage-activated sodium channels, slowing their rate of recovery and limiting the repetitive firing of action potentials. It is used in the treatment of:

• Generalized, focal-to-bilateral and idiopathic tonic-clonic seizures

• Focal seizures

• Neuropathic pain associated with trigeminal and glossopharyngeal neuralgias.

Lamotrigine is an anti-folate agent whose mechanism of action is similar to that of carbamazepine i.e. it delays the recovery from inactivation of recombinant sodium channels. It also inhibits the release of glutamate by acting directly on the sodium channels. Therefore, when used concurrently with carbamazepine, is associated with toxicity in some patients due to increase in 10,11- epoxide of carbamazepine. It is useful in the management of:

• Focal and secondarily generalized tonic-clonic seizures in adults

• Lennox-Gastaut syndrome - a childhood disorder characterized by multiple type seizures, mental retardation, and refractoriness to anti-seizure medication.

Solution to Question 35:

Linezolid cannot be used in this patient as bone marrow suppression is a side effect of this drug and hence it can worsen the post-chemotherapy bone marrow suppression in this patient.

Linezolid can cause myelosuppression which can present as anemia, thrombocytopenia, leukopenia, and pancytopenia. It is commonly associated with thrombocytopenia and is seen 7-10 days following administration. This is usually reversed on discontinuation of the drug.

Other adverse effects of linezolid:

• It inhibits mitochondrial protein synthesis and may lead to peripheral neuropathy, optic neuritis, and lactic acidosis in patients receiving the drug for longer durations.

• It can cause serotonin syndrome when coadministered with adrenergic or serotonergic drugs like SSRIs due to its nonspecific MAO inhibition.

It is a protein synthesis inhibitor of the class oxazolidinones. It mainly acts against gram-positive organisms. It is approved for the treatment of the following conditions:

• Skin and skin structure infections by staphylococcus(Both MRSA and MSSA) and streptococcus.

• Community-acquired pneumonia due to streptococcus pneumoniae.

• Nosocomial pneumonia due to staphylococcus aureus.

Other options:

Cefepime: It is a fourth-generation antipseudomonal cephalosporin. It is useful in enterobacter and pseudomonas infections that are resistant to other cephalosporins.

Piperacillin-Tazobactam- It is a combination of piperacillin which is a ureidopenicillin and tazobactam which is a beta-lactamase inhibitor. It is useful in various infections including nosocomial infections, intraabdominal infections, pneumonia, and UTI. It is highly effective against E Coli and Klebsiella.

Meropenem: It belongs to the carbapenem group of beta-lactam antibiotics. They are more active against gram-negative organisms. Coadministration of cilastatin is not required with this drug. (Cilastation should be coadministered with imipenem as imipenem is sensitive to renal peptidase degradation)

Pharmacology NEET 2021

Question 1:

A female patient on oral contraceptive pills (OCP) was diagnosed to have tuberculosis and started on antitubercular therapy (ATT). She was advised to use an additional barrier method of contraception. What is the reason for this advice?

a) Teratogenic

b) Failure of ATT

c) Rifampicin decreases OCP metabolism

d) Rifampicin induces OCP metabolism and cause failure

Question 2:

A 35-year-old chronic hypertensive woman visits the outpatient department for pre-conceptional counseling. Which of the following anti-hypertensives should she discontinue?

a) Labetalol

b) Calcium channel blockers

c) Angiotensin-converting enzyme inhibitors

d) Alpha methyldopa

Question 3:

A pregnant woman was prescribed indomethacin. Which of the following effects does the drug have on the fetus?

a) Premature closure of ductus arteriosus

b) Keeps ductus arteriosus patent

c) Closure of fossa ovalis

d) Premature closure of ductus venosus

Question 4:

Which of the following can be prescribed in case of an open angle glaucoma with bronchial asthma?

a) Timolol

b) Gemeprost

c) Latanoprost

d) Mannitol infusion

Question 5:

As a medical practitioner in India, how will you prescribe alprazolam to a patient?

a) 1 mg OD before bedtime for 7 days

b) 1/2 mg HS for 7 days

c) 0.5 mg BD for 7 days

d) 0.5 mg daily before bedtime for 7 days

Question 6:

A patient started on antihypertensive presented with the following picture. Which of the following drugs is the most likely cause?

a) Lisinopril

b) Nifedipine

c) Atenolol

d) Clonidine

Question 7:

A patient on aspirin presented with occult blood in the stool. This is due to inhibition of____ by aspirin

a) Phospholipase A2

b) Thromboxane

c) Phospholipase C

d) Phospholipase D

Question 8:

A 60-year-old postmenopausal female patient with a previous history of Colle's fracture came with complaints of lower backache. On evaluation, her T score was -2.5. Which of the following statements are false about the management of her condition?

a) Teriparatide should be started before supplementing with bisphosphonates

b) Bisphosphonates are not given for more than a year

c) Calcium requirement is 1200 mg per day

d) Oral vitamin D3 is given along with oral calcium

Question 9:

A patient presented with a history of multiple episodes of vomiting. He was given an intravenous drug, and later, he developed abnormal movements. Which of the following can be used to treat him?

a) Hyoscine

b) Cyproheptadine

c) Levodopa

d) Benzhexol

Question 10:

What formula is the dosing rate of a drug based on?

a) Clearance / plasma concentration

b) Clearance x plasma concentration

c) Clearance x loading dose

d) Clearance / loading dose

Question 11:

A patient on digoxin, potassium chloride, clarithromycin, atenolol, and triamterene developed atrial fibrillation with controlled ventricular rate. Serum digoxin levels were raised. Which of his medications is responsible for the same?

a) Potassium chloride

b) Clarithromycin

c) Atenolol

d) Triamterene

Question 12:

What is the mechanism of action of methotrexate in osteosarcoma?

a) Analog of UMP

b) Competitive inhibitor of DHFR

c) Blocks purine synthesis

d) Blocks pyrimidine synthesis

Question 13:

What should not be consumed by patients with bacterial vaginosis and trichomoniasis on metronidazole?

a) Grapefruit juice

b) Alcohol

c) Benzodiazepine

d) MAOI/SSRI

Question 14:

A patient with chronic kidney disease underwent a nephrectomy. Which of the following can be administered as a postoperative analgesic in this patient?

a) Naproxen

b) Indomethacin

c) Diclofenac

d) Acetaminophen

Question 15:

A patient with renal insufficiency presented with very low urine output, pedal edema, headache and BP 160/90. Which anti-hypertensive can be administered?

a) Aliskiren

b) Chlorthalidone

c) Amlodipine

d) Prazosin

Question 16:

Which of the following interleukin (IL) is inhibited by tocilizumab?

a) IL-6

b) IL-2

c) IL-4

d) IL-5

Answer Key

Question No.	Correct Option
1	d
2	c
3	a
4	c
5	d

6	a
7	b
8	b
9	d
10	b
11	b
12	b
13	b
14	d
15	b
16	a

Detailed Explanations

Solution to Question 1:

Rifampicin is a potent cytochrome P450 (CYP450) enzyme inducer. When given along with oral contraceptive pills(OCP) it would induce the metabolism of OCPs leading to contraceptive failure. This is the reason for the patient being advised to use an additional method of contraception.

Important enzyme inducers are:

• Barbiturates

• Phenytoin

• Carbamazepine

• Rifampicin

• Cigarette smoking

• Chronic alcoholism

Important drugs that inhibit CYP450 isoenzyme are:

• Macrolide antibiotics

• Azole antifungals

• Chloramphenicol

• Omeprazole

• Selective serotonin reuptake inhibitors (SSRIs)

• HIV protease inhibitors

• Cimetidine

• Ciprofloxacin

• Metronidazole

Solution to Question 2:

Angiotensin-converting enzyme (ACE) inhibitors should be discontinued in pregnancy as they can cause hypoplasia of organs, growth retardation, and fetal loss.

ACE inhibitors cause reduced perfusion and oligohydramnios leading to fetal growth retardation, calvarium maldevelopment, hypoplasia of lungs and kidneys, and limb contractures.

Antihypertensive drugs to be avoided in pregnancy:

• ACE inhibitors and Angiotensin receptor blockers(ARB) - Can cause growth retardation and fetal damage.

• Diuretics - Can decrease uteroplacental perfusion

• Nonselective beta-blockers

• Sodium nitroprusside - It is contraindicated in eclampsia.

Antihypertensive drugs that can be used in pregnancy:

• Labetalol - Combined $\alpha + \beta$ blocker

• Nifedipine - Dihydropyridine calcium channel blocker. It is useful in preeclampsia but should be stopped before labor as they weaken the uterine contractions.

• Methyldopa

• Hydralazine

Note:

Thiazide diuretics like hydrochlorothiazide are considered to be safe in pregnancy and are useful in the management of chronic hypertension in pregnant women.

Solution to Question 3:

Indomethacin can cause premature closure of ductus arteriosus if given to a pregnant woman.

Indomethacin is approved for the closure of persistent ductus arteriosus in premature infants. It is given intravenously. One of its limiting factors is the development of renal toxicity in neonates.

Indomethacin is a nonselective COX inhibitor. It has anti-inflammatory, analgesic, and antipyretic properties. It can be used in the management of conditions like rheumatoid arthritis, gouty arthritis, osteoarthritis, ankylosing spondylitis, etc. But its use is limited due to the high rate of intolerance and availability of safer agents.

Adverse effects: Diarrhea with ulcerative bowel lesions, acute pancreatitis, and hepatitis are seen. Frontal headache is the most frequent CNS effect. Dizziness, light-headedness, vertigo, and mental confusion can occur. Neutropenia, thrombocytopenia, and rarely aplastic anemia can also occur.

Note:

Prostaglandin analogs are indicated in the maintenance of patency of the ductus arteriosus.

Solution to Question 4:

Latanoprost can be given in a case of open-angle glaucoma with bronchial asthma.

Latanoprost is a PGF2α analog and it is not associated with systemic side effects like bronchospasm and hence can be given for asthmatic patients. Prostaglandin analogs are the first choice drugs for open-angle glaucoma.

Mechanism of action: It reduces intraocular pressure by altering the ciliary muscle tension and improving the outflow of the aqueous humor.

Advantages of latanoprost:

• Good efficacy

• Once-daily application

• Absence of systemic side effects

Disadvantage: High cost

Adverse effects:

• Blurring of vision

• Iris pigmentation

• Thickening and darkening of eyelashes

• Macular edema can occur especially in aphakic patients.

Other options:

Option A- Timolol is a non-selective beta-blocker used topically in glaucoma. It is associated with systemic effects by absorption through the nasolacrimal duct and can cause life-threatening bronchospasm in asthmatics and COPD patients. Hence they are not given in in this case.

Option B- Gemeprost is a PGE1 analog used for the termination of early pregnancy.

Option D- Mannitol infusion is given for acute congestive glaucoma and not for open-angle glaucoma. It causes decongestion of the eye by its osmotic action.

Solution to Question 5:

The correct method of prescribing alprazolam is 0.5mg daily before bedtime for 7 days.

The drugs are prescribed in generic names legibly and preferably in capital letters. The prescription should have details to identify the patient and medication that needs to be dispensed and the therapeutic purpose. The use of abbreviations, especially Latin is discouraged. The dosage should be written in metric measure.

Guidelines for drug prescription:

The parts of an ideal prescription are as follows.

• Date

• Name and address of the doctor

• Superscription(Rx symbol)

• Information about the patient

• Name and dose of the drug prescribed(Inscription)

• Dispencing directions to the pharmacist(Subscription)

• Instructions for the patient

• Signature of the doctor

Solution to Question 6:

The image shows edema over the lips and face and its occurrence following intake of an antihypertensive is suggestive of drug-induced angioedema. Lisinopril being an ACE inhibitor is most likely to be responsible for this condition.

Angioedema with ACE inhibitors:

In very few patients(0.1%-0.5%), ACE inhibitors cause rapid swelling in the nose, throat, mouth, glottis, larynx, lips, or tongue. Once the drug is stopped symptoms improve drastically over hours. Angioedema of the intestine can occur very rarely.

ACE inhibitor-associated angioedema is a class effect, and patients who develop this adverse event should not be prescribed any other drugs within the ACE inhibitor class.

Other adverse effects of ACE inhibitors:

Hypotension - A sudden fall in blood pressure can occur following the first dose of ACE inhibitors.

Cough - It can produce a bothersome dry cough due to the accumulation of bradykinin, substance P, or prostaglandins in the lungs. The cough usually disappears within 4 days of the stoppage of the drug.

Hyperkalemia due to K+ retention can occur.

Acute renal failure can occur with ACE inhibitors in patients with bilateral renal artery stenosis, stenosis of the artery to a single remaining kidney, heart failure, or volume depletion due to diarrhea or diuretics.

It should be discontinued in pregnant women as it can cause developmental defects.

It can also cause maculopapular skin rash in some cases.

Other options:

Option B: Nifedipine is a calcium channel blocker. Common adverse effects include headache, flushing, and dizziness. Peripheral edema may rarely occur.

Option C: Atenolol is a beta 1 selective antagonist. Bradycardia, fatigue, cold extremities are common adverse effects. CNS side effects like nightmares and depression are less frequent with atenolol than other beta-blockers.

Option D: Clonidine is an alpha-2 adrenergic agonist. The main adverse effects of clonidine are dry mouth and sedation. Bradycardia and sexual dysfunction are other effects.

Solution to Question 7:

Aspirin causes inhibition of cyclooxygenase-1(COX-1) which would inhibit the formation of thromboxane A2. Thromboxane A2 is an inducer of platelet aggregation and is a potent vasoconstrictor. Hence inhibition of its formation is responsible for the bleeding complications of aspirin.

Aspirin is a noncompetitive, irreversible inhibitor of the cyclooxygenase(COX) enzyme. It is a nonselective COX inhibitor and inhibits both COX-1 and COX-2.

Uses of aspirin:

• Analgesic and antipyretic uses.

• Acute rheumatic fever

• Rheumatoid arthritis

• Post myocardial infarction and stroke due to its antiplatelet action.

• Prevention of preeclampsia

Adverse effects:

Nausea, vomiting, epigastric discomfort, and increased occult blood in stools are seen with analgesic doses(0.5-2g/day). Antiinflammatory doses(3-5g/day) can produce salicylism characterized by dizziness, tinnitus, vertigo, hyperventilation, reversible loss of hearing and vision, etc. It can cause elevation of liver enzymes and hepatic damage. Hypersensitivity reactions are also seen.

Reye's syndrome is a rare condition that can occur when salicylates like aspirin are given in children having viral infections like influenza.

Solution to Question 8:

Bisphosphonates are given for periods of more than one year (Option B is false). In this case, as the patient is having a history of osteoporotic fracture, teriparatide can be given before bisphosphonates.

Pharmacologic management of osteoporosis:

Bisphosphonates: These are pyrophosphate analogs that act by directly inhibiting bone resorption. The antiresorptive action is mainly due to its direct inhibitory effect on osteoclasts. It causes osteoclast apoptosis as well as the prevention of hydroxyapatite dissolution. Long-term bisphosphonates therapy is given for durations of 3-5 years, depending on the fracture risk of the

patient. Since they are associated with osteonecrosis of the jaw and atypical femur fractures, a drug holiday may be advised after long-term management.

Teriparatide is a recombinant PTH analog that has an anabolic effect on bone homeostasis by increasing osteoblastic activity. It increases bone mineral density and decreases the risk of fractures in postmenopausal women. Indications of teriparatide therapy include the history of osteoporotic fracture, multiple risk factors for fracture, intolerance, or failure of previous osteoporosis therapy. It is only approved for 2 years of use. Clinical trials that used teriparatide prior to bisphosphonate have been proven effective.

Denosumab is a human monoclonal antibody with a mechanism of action similar to that of osteoprotegerin (OPG). It binds to RANK Ligand (RANKL), thereby inhibiting its binding to the RANK receptor of the surface of osteoclasts. This prevents RANK receptor activation and subsequent bone resorption.

Selective estrogen receptor modulators (SERMs) - Estrogen has a protective effect that prevents accelerated bone loss. This is carried out by reducing the bone resorption effects of parathyroid hormone (PTH). Keeping in line with these effects, osteoporosis prevention in postmenopausal women has been attributed to the use of SERMs such as raloxifene. It acts as an estrogen agonist on the bone and liver.

Calcium and Vitamin D supplementation: Calcium supplementation in the elderly suppresses bone turnover and improves bone mineral density. 1200mg of calcium is daily required in adults of more than 50 years of age. Vitamin D supplementation with 400-800IU/day improves intestinal calcium absorption, suppresses bone remodeling, and improves bone mineral density.

Solution to Question 9:

Benzhexol should be used in the management of this patient. The development of abnormal movements following an anti-emetic injection suggests that the antiemetic used in this case is probably metoclopramide.

Metoclopramide is a dopamine receptor antagonist used as a prokinetic and anti-emetic agent. It can produce extrapyramidal side effects and dystonia is seen acutely following intravenous injections. Anticholinergics like benzhexol (trihexyphenidyl) are used in the management of these side effects. Benzhexol is a centrally-acting anticholinergic agent. It acts by restoring the cholinergic balance in the striatal interneurons.

Extrapyramidal side effects of metoclopramide are commonly seen in children and young adults with higher doses. Acute dystonia occurs after intravenous administration, while parkinsonian-like symptoms develop weeks after therapy. It is managed with the discontinuation of metoclopramide and with anticholinergics or antihistaminics. Irreversible tardive dyskinesia can occur with chronic treatment.

Other adverse effects:

It can cause galactorrhea by its dopamine antagonism. Methemoglobinemia can occur if used in infants.

Other options:

Option A: Hyoscine (scopolamine): It is a muscarinic receptor antagonist used in the management of motion sickness and vomiting.

Option B: Cyproheptadine is an H1 receptor antagonist used in the management of various allergy-related conditions like allergic rhinitis, anaphylaxis, urticaria, etc.

Option C: Levodopa is the precursor of dopamine and it is given in combination with carbidopa for the management of parkinsonism.

Solution to Question 10:

The formula for drug dosing rate is clearance x plasma concentration.

The equation for dose rate given here is based on steady-state concentration. When a drug is given repeatedly at short intervals it will accumulate in the body until the elimination of the drug matches its input. So steady-state concentration is the plasma concentration at which the drug elimination and drug input balance each other.

Steady-state concentration(Cpss) = Dose rate / Clearance

From this equation dose rate for a target steady-state plasma concentration is calculated as

Dose rate = Clearance(CL) x target plasma concentration(Cpss)

Solution to Question 11:

Elevated serum digoxin levels and the development of atrial fibrillation with controlled ventricular rate are suggestive of digoxin toxicity. Clarithromycin when given along with digoxin can cause digoxin toxicity.

P-glycoprotein pumps play a major role in the elimination of digoxin. Drugs that inhibit P-glycoprotein can thereby decrease the elimination of digoxin and lead to digoxin toxicity. Macrolide antibiotics like clarithromycin and erythromycin are inhibitors of the P-glycoprotein. So clarithromycin when given along with digoxin can cause digoxin toxicity.

Other drugs that inhibit P-glycoprotein are - Amiodarone, quinidine, verapamil, diltiazem, cyclosporine, itraconazole, propafenone, and flecainide.

Digoxin is one of the cardiac glycosides which is derived from the digitalis plant and used clinically.

It inhibits Na+/K+ ATPase, a membrane-bound transporter to increase intracellular sodium. As a result, there is less expulsion of calcium from the cell by sodium-calcium exchanger (NCX). Increased calcium inside the myocyte leads to an increase in cardiac contractility.

The most common cardiac manifestations of digitalis toxicity include atrioventricular junctional rhythm, premature ventricular depolarizations, ventricular bigeminy, ventricular tachycardia, and second-degree AV blockade.

Factors that increase the risk of digoxin toxicity are:

• Hypercalcemia

• Hypomagnesemia

• Hypokalemia- It increases the binding of the digoxin to the Na+/K+ ATPase pump.

• Drugs causing hypokalemia- loop and thiazide diuretics, amphotericin B, corticosteroids

• Drugs that decrease digoxin elimination (inhibitors of P-glycoprotein)

• Renal failure

• Hypothyroidism

Triamterene, atenolol, and potassium chloride cause hyperkalemia, and therefore do not cause digoxin toxicity.

Solution to Question 12:

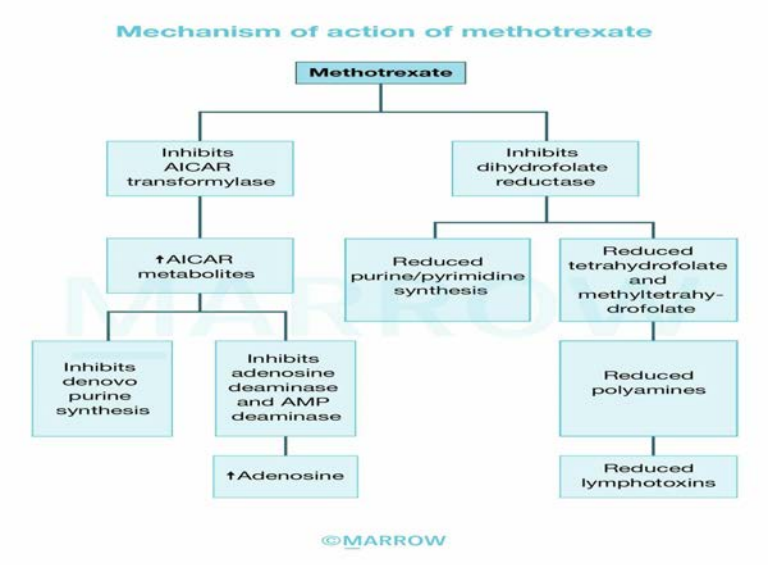
The anticancer activity of methotrexate is by inhibition of dihydrofolate reductase (DHFR).

Methotrexate belongs to the antimetabolite class of anticancer drugs. The antifolate action of the drug is responsible for its anti-cancer properties.

Mechanism of action:

It is a folic acid analog and binds to the active catalytic site of dihydrofolate reductase(DHFR). This would inhibit the formation of tetrahydrofolate(THF) which is needed for purine nucleotides, thymidylate, and the amino acids serine and methionine. This would interfere with the production of DNA, RNA, and important cellular proteins.

Low doses of methotrexate are used in the management of rheumatic diseases. It is due to the inhibition of amino-imidazole carboxamide ribonucleotide (AICAR) transformylase and thymidylate synthetase. This results in increased levels of adenosine that inhibits inflammation.



Adverse effects:

Common side effects are nausea and mucosal ulcers. Others include anemia, leukopenia, stomatitis, GI ulcerations, and alopecia. Dose-related hepatotoxicity is also seen. The GI effects and hepatotoxicity can be reduced by the use of leucovorin or folinic acid.

Solution to Question 13:

Alcohol should not be consumed by a patient on metronidazole. Metronidazole produces a disulfiram-like reaction. If the patient consumes alcohol during or within 3 days of therapy, they may experience abdominal distress, vomiting, headache, and flushing.

Disulfiram and disulfiram-like reactions:

Disulfiram inhibits the aldehyde dehydrogenase(ALDH) activity and thereby increases the concentration of acetaldehyde in the blood. When a person treated with disulfiram consumes alcohol he or she would develop symptoms of acetaldehyde poisoning. The symptoms are:

- Flushing
- Pulsating headache
- Nausea and vomiting
- Sweating
- Tachycardia
- Hypotension
- Orthostatic syncope
- Vertigo
- Blurred vision

Certain drugs can also produce disulfiram-like reactions if alcohol is consumed along with these drugs. Patients should be warned not to use alcohol along with these drugs. The drugs include:

- Metronidazole
- Tinidazole
- Cefoperazone
- Sulfonylureas

Solution to Question 14:

Acetaminophen can be given as an analgesic for the patient as it is the least nephrotoxic among the given options.

Analgesia in CKD patients:

Acetaminophen is considered a safer non-narcotic analgesic in chronic kidney disease (CKD) patients. For more severe pains opioid analgesics like tramadol or fentanyl are used.

Even though acetaminophen is considered safe, with chronic high dosage it can also become nephrotoxic.

NSAIDs like naproxen, indomethacin, diclofenac, etc are not used in CKD patients because of their direct nephrotoxic effects. In healthy normal individuals, NSAIDs have little effect on renal function and blood pressure. But in conditions where the regulatory systems are impaired as hypovolemia, congestive heart failure, hepatic cirrhosis, chronic kidney disease, or other conditions where the renin-angiotensin system is activated, renal function by the formation of prostaglandins are very important.

NSAIDs cause impairment of prostaglandin-induced inhibition of chlorine reabsorption and antidiuretic hormone action. This will cause salt and water retention. It also inhibits COX-2 derived prostaglandins which regulate the renal medullary blood flow and would lead to a rise in blood pressure, increased cardiovascular thrombotic events, and cardiac failure. It can also cause electrolyte abnormalities like hyponatremia and hyperkalemia.

Solution to Question 15:

The antihypertensive that can be given in this case is chlorthalidone. The patient in this case is having renal insufficiency but there is no proteinuria mentioned in the question stem. So among the given options, the thiazide diuretic chlorthalidone can be administered as antihypertensive in this patient.

Management of hypertension in chronic kidney disease(CKD):

ACE inhibitors or ARBs are considered the first-line drugs in patients with proteinuria. These agents effectively reduce blood pressure, proteinuria and prevent kidney decline. Calcium channel blockers can be added if necessary.

For patients who do not have proteinuria, there is no established first-line therapy. One or two of the following drugs can be used:

• Thiazides/thiazide-like diuretics

• ACE inhibitors or ARBs

• Calcium channel blockers

In patients presenting with fluid retention or fluid overload, thiazide diuretics such as chlorthalidone and hydrochlorothiazide are recommended for management. In CKD stages 1 to 3 (GFR >=30ml/min), thiazides are recommended, while loop diuretics such as bumetanide, furosemide are used in stages 4-5 (GFR < 30ml/min).

Other options:

Option A: Aliskiren is a direct renin inhibitor. It effectively lowers blood pressure, reduces albuminuria, and limits left ventricular hypertrophy.

Option C: Amlodipine is a calcium channel blocker. A common side effect of amlodipine is the production of peripheral edema.

Option D: Prazosin is a selective α1 antagonist. It is generally not used as an initial agent to treat hypertension, except in symptomatic prostatism or nightmares linked to posttraumatic stress disorder. Headache is one of the side effects of prazosin.

Solution to Question 16:

Tocilizumab inhibits IL-6.

Tocilizumab is a newer humanized antibody. It binds to the soluble, membrane-bound IL-6 receptors and inhibits IL-6 mediated signaling. IL-6 can cause T-cell activation, acute-phase protein synthesis, and stimulation of inflammatory processes in diseases like rheumatoid arthritis.

Uses:

• Rheumatoid arthritis - It is a biological DMARD and is indicated in adult patients having moderate to severe disease with inadequate response to one or more DMARDs.

• Juvenile idiopathic arthritis - It can be given for active systemic juvenile idiopathic arthritis(SJIA) or polyarticular juvenile idiopathic arthritis(PJIA) in patients of 2 years of age or more.

Adverse effects:

Common adverse effects include upper respiratory infections, hypertension, headache, and elevation of hepatic enzymes. It is also associated with serious infections including TB and opportunistic infections. Neutropenia and reduction in platelet count can also occur.

Other options:

Option B- IL-2 receptor inhibitors are daclizumab, basiliximab. They are used as immunosuppressive agents following renal and heart transplants.

Option C- IL-4 receptor inhibitor is dupilumab. They have been shown to reduce exacerbations in asthma.

Option D- IL-5 inhibitors are mepolizumab, reslizumab, benralizumab. They have been shown to reduce exacerbations in asthma.

Pharmacology INI-CET 2022

Question 1:

The extent of drug absorption is represented by:

a) Tmax

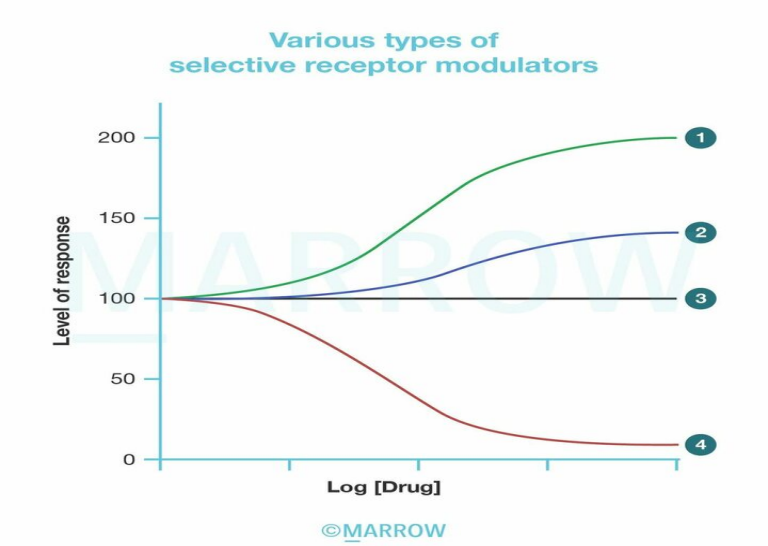
b) Area under the curve

c) Cmax

d) t1/2

Question 2:

Which of the following statement is correct regarding the given graph?



a) Drug 1 represents agonist and drug 2 represents inverse agonist

b) Drug 3 represents agonist and drug 4 represents inverse agonist

c) Drug 1 represents agonist and drug 4 represents inverse agonist

d) Drug 2 represents partial agonist and drug 3 represents inverse agonist

Question 3:

Which among the following drugs is the new FDA approved immune check point inhibitor for carcinoma endometrium?

a) Nivolumab

b) Pembrolizumab

c) Trastuzumab

d) Ipilimumab

Question 4:

Which of the following is not an immune checkpoint inhibitor?

a) Nivolumab

b) Pembrolizumab

c) Atezolimumab

d) Cetuximab

Question 5:

NAPQI is the metabolite of which of the following drug toxicity?

a) Aspirin

b) Paracetamol

c) Diclofenac

d) Ketorolac

Question 6:

Identify the correct match, regarding the drug and its adverse effect.

a) Hydralazine - heart failure

b) Atenolol - hemolytic anemia

c) Aliskiren - hypokalemia

d) Verapamil - constipation

Question 7:

A lady who had undergone mastectomy for breast cancer is being treated with tamoxifen. How long should it be stopped for before she can conceive?

a) 1 month

b) 3 months

c) No need to stop

d) Can be stopped and conceived soon after stopping

Question 8:

A young boy with a history of multiple blood transfusions presents with bone pain for the past 6 months. A peripheral smear showed sickle-shaped RBCs. Which of the following drugs are not used in the treatment of his condition?

a) Bebtelovimab

b) Voxelotor

c) Hydroxyurea

d) L-glutamine

Question 9:

The half-life of letrozole is:

a) 45 hours

b) 70 hours

c) 90 hours

d) 120 hours

Question 10:

Identify the false statement about eicosanoids.

a) Synthesized from arginine

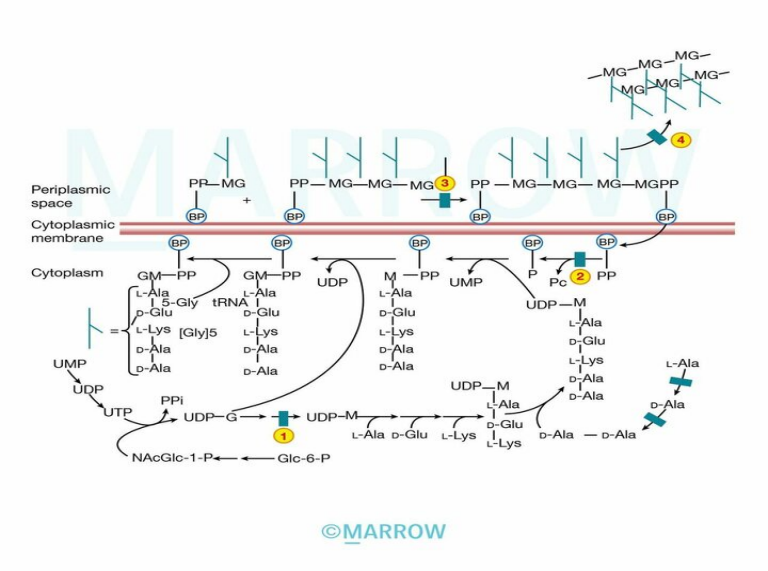
b) Synthesized from arachidonic acid

c) Prostaglandins have 5 carbon ring

d) Synthesized in platelets

Question 11:

The given diagram shows the steps in bacterial cell wall formation. Identify the site of action of beta-lactam antibiotics.



a) 1

b) 2

c) 3

d) 4

Question 12:

Phospholipase C acts via which of the following G protein-coupled receptors?

a) Gs

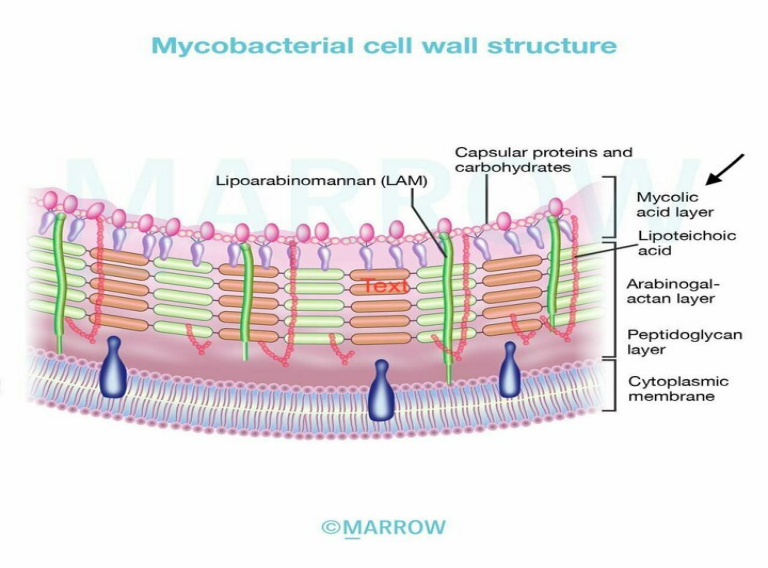
b) Gi

c) Gq

d) Go

Question 13:

A patient was diagnosed with pulmonary tuberculosis and was started on first-line antitubercular drugs. Which of the following drug acts by inhibiting the synthesis of the marked layer shown in the image?



a) Isoniazid

b) Rifampicin

c) Pyrazinamide

d) Ethambutol

Question 14:

A man was brought to the emergency room after poisoning with an unknown substance. Muscarinic poisoning was suspected and he was treated for the same. What is the possible presenting feature which led to the diagnosis?

a) Mydriasis

b) Diuresis

c) Muscle fasciculations

d) Bradycardia

Question 15:

A 29-year-old lady came to psychiatry OPD with symptoms of hypomania. There is a past history of maniac episode. Now, she is planning to conceive. Which drug should be avoided for being highly teratogenic to the fetus?

a) Valproate

b) Lithium

c) Oxcarbazepine

d) Olanzapine

Question 16:

True statement regarding the administration of 5 alpha-reductase inhibitors is/are:

a) 1, 2, 3

b) 1, 3, 4

c) 1, 4

d) 2, 3

Question 17:

The manufacturer of a drug company labels a drug as having 500 mg paracetamol. On quantitative analysis of the drug, it actually contained only 200 mg of paracetamol. What is this type of drug called?

a) Spurious drug

b) Adulterated drug

c) Unethical drug

d) Misbranded drug

Question 18:

Which of the following anti-diabetic drugs is associated with the increased risk of fractures?

a) Rosiglitazone

b) Liraglutide

c) Voglibose

d) Canagliflozin

Question 19:

The active metabolite of cyclophosphamide is:

a) N - hydroxy cyclophosphamide

b) 4 - hydroxy cyclophosphamide

c) 4 - acetyl cyclophosphamide

d) N - acetyl cyclophosphamide

Question 20:

Urinary alkalinization will be most useful in toxicity of which of the following drugs?

a) Beta blockers

b) Calcium channel blockers

c) Acetaminophen

d) Aspirin

Question 21:

A hospital is conducting a study to check the efficacy of statins in multiple centers. There are 4-5 patients per center and half of the patients receive the drug and the other half receive the placebo. Neither the patients nor clinicians know which drug is being administered. What phase of the clinical trial describes the above scenario?

a) Phase 1

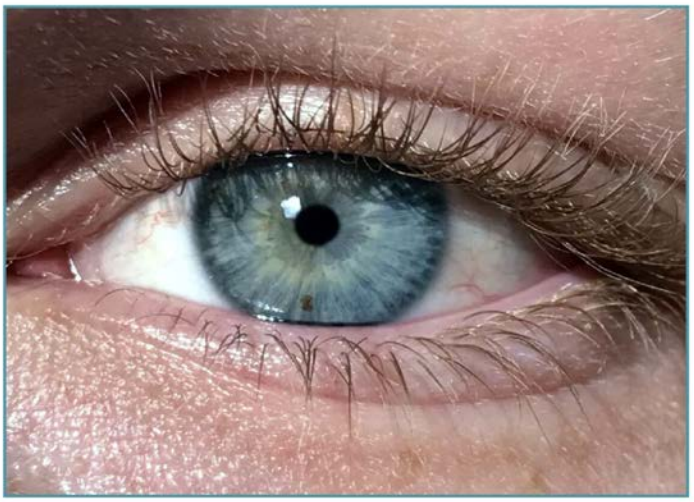
b) Phase 3

c) Phase 2

d) Phase 4

Question 22:

A patient who is a known addict is brought to the hospital with the intoxication of an agent. An ocular examination shows the following finding. Which of the following is true regarding this condition?



a) This action can be reversed by phenylephrine.

b) It cannot be reversed by levallorphan.

c) It is caused by activation of the Edinger-Westphal nucleus.

d) Tolerance develops due to long-term use.

Question 23:

Match the following drugs in Column A with their contraindications in Column B.

a) A-1, B-3, C-2, D-4

b) A-4, B-1, C-3, D-2

c) A-2, B-4, C-1, D-3

d) A-3, B-2, C-4, D-1

Question 24:

Which of the following statements is true regarding memantine?

a) 1, 2, 3, 4

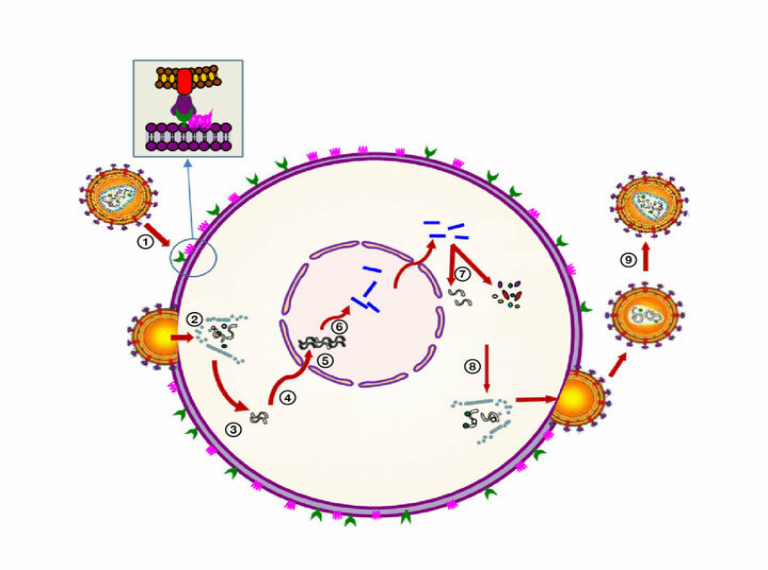
b) 1, 2

c) 3, 4

d) 1, 2, 3

Question 25:

The image below shows the life cycle of a virus. Which of the following drugs acts at step 5?



a) Raltegravir

b) Enfuvirtide

c) Tenofovir

d) Zidovudine

Question 26:

Which of the following statements is correct regarding clinical trials?

a) New drug application is done after phase 4

b) Phase 4 is also called post-marketing surveillance

c) Phase 3 is always double-blinded

d) Phase 2 is done on healthy individuals

Question 27:

Match the following teratogenic drugs with their teratogenic effects.

a) 1-a, 2-b, 3-c, 4-d

b) 1-c, 2-d, 3-a, 4-b

c) 1-d, 2-a, 3-d, 4-c

d) 1-d, 2-c, 3-b, 4-a

Question 28:

A young man sustained a scorpion sting 2 hours ago. On examination, his blood pressure is 108/ 60 mm Hg; HR, 72 beats/minute, and respiratory rate, 32 breaths/minute. He also complains of breathlessness. How do you manage this patient?

a) Metoprolol

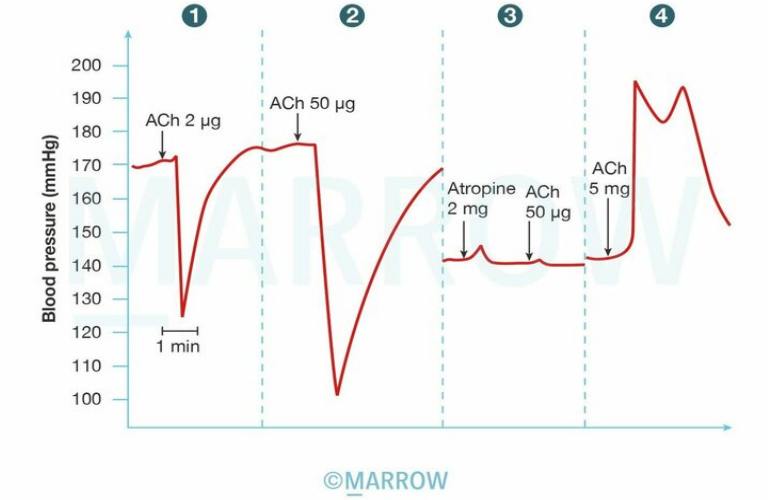
b) Ivabradine

c) Prazosin

d) Frusemide

Question 29:

An experiment is being conducted on a cat spine to study the effect of acetylcholine. The blood pressure is recorded at each intervention and is shown below. What does phase 4 in the graph indicate?



a) Muscarinic action of acetylcholine

b) Potentiation of acetylcholine

c) Antagonism of acetylcholine

d) Nicotinic action of acetylcholine

Question 30:

A patient who is a known case of HIV is started on combined active antiretroviral therapy (cART). After 5 months of treatment, he develops hyperpigmentation in the palms and soles. What is the most likely drug causing this?

a) Nelfinavir

b) Emtricitabine

c) Abacavir

d) Zidovudine

Question 31:

Dorzolamide is a _____.

a) Topically applied sulfonamide antibacterial

b) Topical ocular carbonic anhydrase inhibitor

c) Second-generation sulfonylurea

d) Opioid receptor agonist

Question 32:

A patient with erectile dysfunction is given sildenafil. The penile erectile function is found to be improved after the therapy. Which of the following mediates the action of sildenafil?

a) cAMP

b) cGMP

c) Calcium

d) Phosphatidyl glycerol and inositol phosphate

Question 33:

Match the following diuretics in column A to their site of action in column B.

a) A-2, B-3, C-1, D-4

b) A-3, B-4, C-2, D-1

c) A-1, B-2, C-4, D-3

d) A-4, B-1, C-3, D-2

Question 34:

Alkalinization of urine will be helpful in the removal of _____.

a) Weakly basic drugs

b) Strong electrolytes

c) Polar drugs

d) Weakly acidic drugs

Question 35:

All of the following side effects are more commonly seen with carbamazepine than oxcarbazepine, except_____.

a) Hypotension

b) Hyponatremia

c) Rash

d) Elevated levels of gamma glutamyl transpeptidases

Question 36:

Match the following drugs with the targets of their actions.

a) A-2, B-3 , C-1 , D-4

b) A-4, B-3 , C-1 , D-2

c) A-3, B-4 , C-2 , D-1

d) A-4, B-3 , C-2 , D-1

Question 37:

A patient is brought with altered sensorium and seizures. Attender shows the laboratory report which reveals elevated transaminases. Which of the following can be used in this condition?

a) Midazolam

b) Diazepam

c) Alprazolam

d) Oxazepam

Question 38:

The lipid profile of a patient who suffered from acute coronary syndrome is given below. What drug can be used to treat this condition?

a) Fenofibrate 160 mg

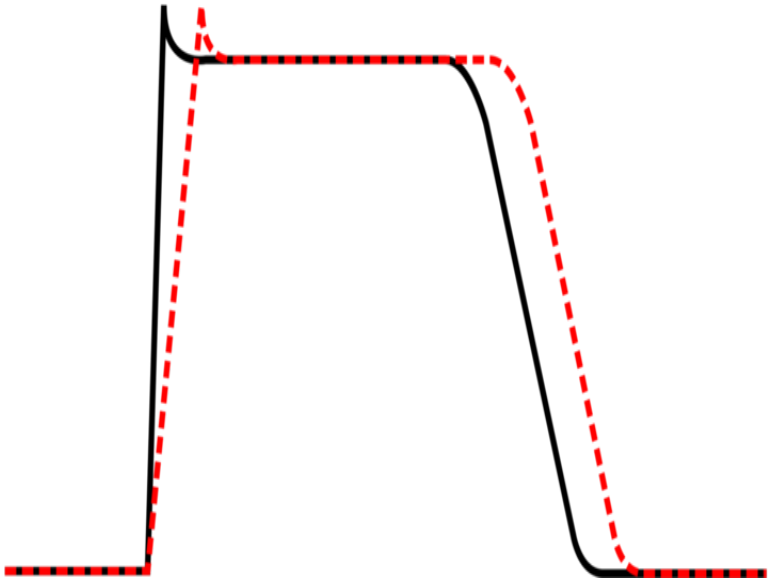
b) Rosuvastatin + Fenofibrate

c) Rosuvastatin 10 mg

d) Atorvastatin 80 mg

Question 39:

An anti-arrhythmic drug is shown to have the following effect. It is effective in both atrial and ventricular arrhythmias. Identify the drug.



a) Tocainide

b) Propranolol

c) Quinidine

d) Lignocaine

Question 40:

Which among the following is the false statement regarding statins?

a) Although HMG-CoA reductase inhibitors substantially reduce the risk of cardiovascular events, there is mild increase in lipoprotein a (Lpa) levels.

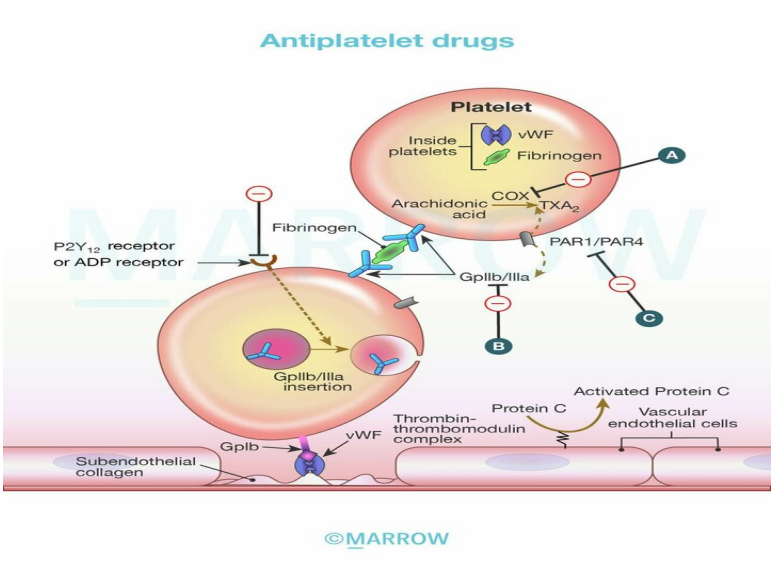
b) These drugs should not be stopped even in severe conditions like injury, surgery, etc.

c) They can be given with verapamil and other enzyme inhibitors.

d) With the long term use, there is slight increase in the incidence of type 2 diabetes mellitus.

Question 41:

Identify the drugs marked as A, B, and C.



a) A - Aspirin, B -Vorapaxar, C - Prasugrel

b) A - Aspirin, B - Eptifibatide, C - Vorapaxar

c) A - Aspirin, B - Eptifibatide, C - Prasugrel

d) A - Aspirin, B - Prasugrel, C - Eptifibatide

Question 42:

Which of the following is false regarding disulfiram?

a) Only 3

b) 1, and 3

c) 1, 3, and 4

d) 2, 3, and 4

Question 43:

G6PD can manifest with which of the following drugs?

a) Primaquine

b) Chloroquine

c) Penicillin

d) Tetracycline

Question 44:

Choose the correctly matched pairs regarding the drugs used in schizophrenia:

a) 1,3

b) 1,4

c) 1,2,4

d) 1,2,3,4

Question 45:

A patient presented with a lesion, as shown in the image below. She is an immunocompromised patient currently on HAART. What are the systemic antifungal drugs that can be added along with the HAART in this patient?

a) Inj. Amphotericin B 4-8 weeks, followed by oral itraconazole

b) Inj. Amphotericin B 8 weeks, followed by oral posaconazole

c) Inj. Fluconazole, followed by oral fluconazole

d) Inj. Amphotericin B, followed by flucytosine

Question 46:

A patient who is on treatment for hyperlipidemia develops gallstones. What is the mechanism of action of the causative drug that was given to this patient?

a) Inhibits HMG CoA reductase

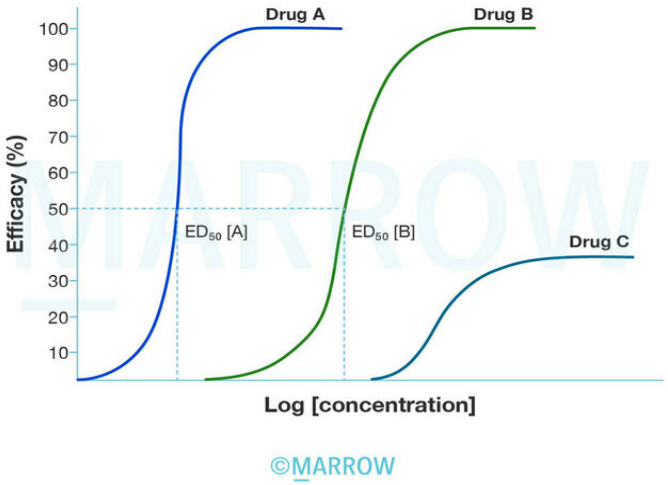
b) Activates PPAR alpha

c) Binds to deoxycholic acid

d) Decreases VLDL

Question 47:

The dose-response curve for three drugs in the same tissue is shown in the image below. Which of the following statements is true?



a) Efficacy of drug A is more than that of drug B.

b) Potency of drug B is more than that of drug A.

c) Drug A & drug B are agonists.

d) Drug C is a non-competitive antagonist.

Question 48:

Which of the following drugs is a β2 agonist?

a) 1, 2, 3

b) 4, 3, 2, 1

c) 1, 2

d) 3, 4

Question 49:

What is the mechanism of action of sildenafil?

a) Inhibition of 5α-reductase

b) Inhibition of phosphodiesterase-5

c) Release of nitrous oxide radicals

d) Blockage of voltage-gated calcium channels

Question 50:

Choose the correct options regarding the route of administration and bioavailability.

a) A,B,D

b) A,C,D

c) A and C

d) A and D

Question 51:

A hypertensive patient on medication presents with the lab values as shown below. Which of the following drugs should be stopped?

a) Amlodipine

b) Metoprolol

c) Losartan

d) Furosemide

Question 52:

Which of the following is the most effective oral drug in smoking cessation?

a) Varenicline

b) Cevimeline

c) Muscarine

d) Atropine

Question 53:

Match the following antiarrhythmic drugs with their mechanism of action:

a) 1-d, 2-b, 3-a, 4-c

b) 1-a, 2-c, 3-d, 4-b

c) 1-a, 2-d, 3-b, 4-c

d) 1-d, 2-c, 3-a, 4-b

Question 54:

Which of the following drugs increases trabecular outflow?

a) Timolol

b) Netarsudil

c) Brimonidine

d) Acetazolamide

Question 55:

Finasteride is used to treat male-pattern baldness acts by inhibiting which of the following enzymes?

a) Aromatase

b) 17-hydrolase

c) 5-alpha reductase

d) Phosphodiesterase

Question 56:

Rituximab is a:

a) Polyclonal antibody which acts against CD20

b) Polyclonal antibody which acts against CD50

c) Monoclonal antibody which acts against CD20

d) Monoclonal antibody which acts against CD50

Question 57:

A new drug application is filed after which phase of clinical trials?

a) 4

b) 3

c) 2

d) 1

Answer Key

Detailed Explanations

Solution to Question 1:

The extent of drug absorption is represented by the area under the curve.

The rate and extent of absorption of a drug from dosage form administered by any route refer to the bioavailability of a drug. Bioavailability is determined by the concentration-time curve in blood or by its excretion in urine. The area under the blood concentration-time curve (AUC) is proportional to the dose and the extent of bioavailability of a drug.

Bioavailability is defined as the fraction of unchanged drug that reaches systemic circulation. It can be represented by the formula:

Bioavailability(F) = Quantity of drug reaching systemic circulation/ Quantity of drug administered.

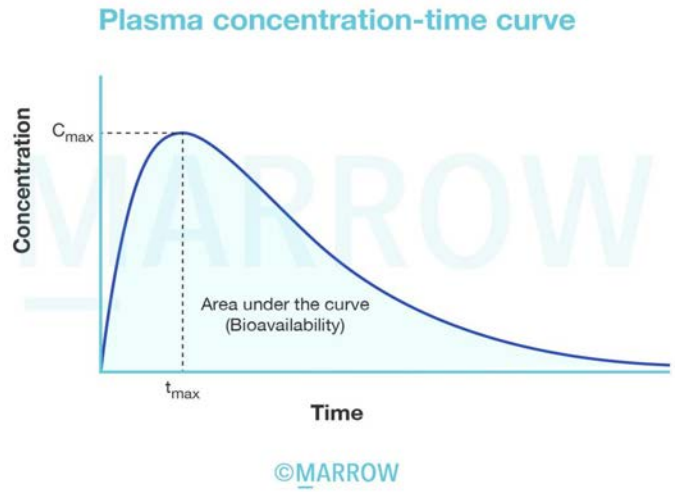
Bioavailability depends on two factors:

• Absorption

• 1st pass metabolism

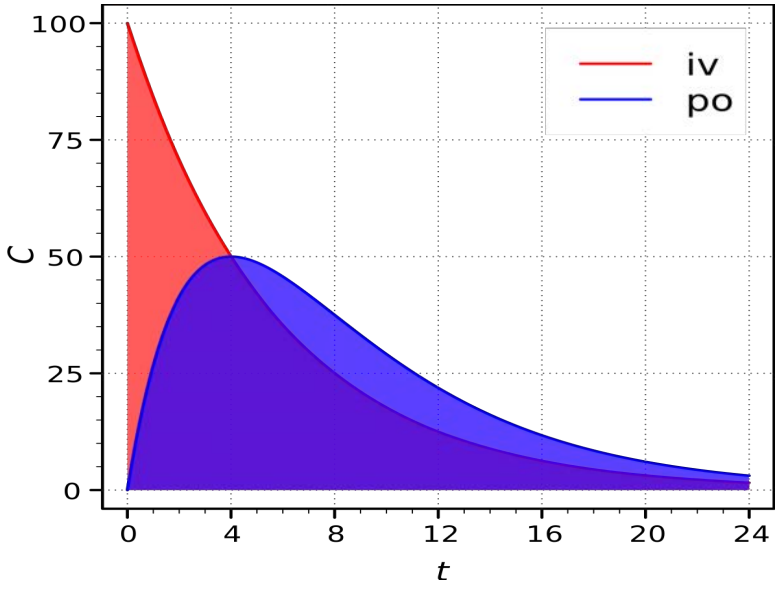
The area under the plot of plasma concentration of a drug versus time after dosage is called the area under the curve or AUC. It can be used as a measure of the bioavailability of a drug and to calculate its clearance rate from the body.

The image given below shows the AUC (bioavailability) in a plasma concentration-time curve:



Bioavailability of drug injected intravenously is 100%, but it is lower after oral ingestion because of incomplete absorption and first-pass metabolism in the intestinal wall/liver.

The image below shows the difference between the bioavailability of drugs injected intravenously(iv) and orally(PO). Note the area under the respective curves is shaded in red and blue colours which represent the absorption of the drug.



Solution to Question 2:

The correct statement is Drug 1 represents agonist and drug 4 represents inverse agonist.

Graph 1 represents the agonist: An agonist is an agent which initiates the normal physiological response when combined with a receptor.

Example: Salbutamol is a beta-2 receptor agonist.

Graph 2 represents a partial agonist: An agent which produces a submaximal or partial effect when combined with a receptor.

Example: Buprenorphine and butorphanol are partial agonists at opioid receptors.

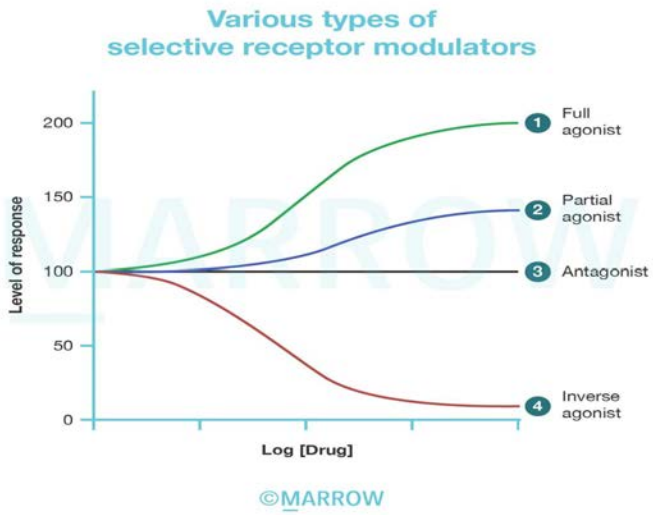
Graph 3 represents the antagonist: An agent which blocks or reduces the action of an agonist on a receptor, but does not have any effect of its own.

Example: Naltrexone and naloxone are antagonists at opioid receptors

Graph 4 represents an inverse agonist: An agent which activates a receptor to produce an effect in the opposite direction to that of the agonist.

Example: β-Carboline is an inverse agonist at benzodiazepine site of GABA-A receptor.

The image given below shows action of various types of selective receptor modulators.



Solution to Question 3:

The new FDA-approved immune checkpoint inhibitor for carcinoma endometrium is pembrolizumab.

Pembrolizumab acts by inhibiting programmed death receptor - 1 (PD-1) and was used for the treatment of advanced melanoma. Now, the FDA has approved the use of pembrolizumab for any cancer with mismatch repair (MMR) deficiency or high microsatellite instability (MSI-H).

On March 21, 2022, the food and drug administration approved pembrolizumab, as a single agent, for patients with advanced endometrial carcinoma that is microsatellite instability-high (MSI-H) or mismatch repair deficient (dMMR), as determined by an FDA-approved test.

Other options:

Option A: Nivolumab is an immune checkpoint inhibitor that acts by inhibiting programmed death receptor - 1 (PD-1) and is used for the treatment of advanced melanoma and relapsed/refractory classical Hodgkin lymphoma.

Option C: Trastuzumab is a monoclonal antibody that inhibits the HER2 receptor. It is used in the treatment of HER2-positive breast cancer.

Option D: Ipilimumab is a monoclonal antibody that binds to cytotoxic T lymphocyte–associated Protein 4 (CTLA-4) and is approved for the treatment of late-stage melanoma.

Solution to Question 4:

Cetuximab is not an immune checkpoint inhibitor. Cetuximab is a monoclonal antibody against epidermal growth factor receptor(EGFR). It is used for the treatment of colon cancer and head and neck squamous cell cancer.

Other options.

Option A: Nivolumab is an immune checkpoint inhibitor. It acts by inhibiting programmed death receptor - 1 (PD-1) and is used for the treatment of advanced melanoma and classical Hodgkin lymphoma.

Option B: Pembrolizumab is an immune checkpoint inhibitor. It acts by inhibiting programmed death receptor - 1 (PD-1) and is used for the treatment of advanced melanoma. In 2021, approval was granted for the treatment of patients with endometrial carcinoma that progressed after systemic treatment, in combination with lenvatinib.

Option C: Atezolimumab is an immune checkpoint inhibitor. It acts by inhibiting programmed death-ligand - 1 (PDL-1) and is used for the treatment of non-small cell lung cancer.

Important note:

The FDA on May 2021 approved the use of nivolumab in patients having completely resected esophageal or gastroesophageal junction cancers with residual pathologic disease who have received neoadjuvant chemoradiotherapy.

Solution to Question 5:

N-acetyl-p-benzoquinone imine (NAPQI) is a metabolite of paracetamol drug toxicity.

Paracetamol is an analgesic and antipyretic with weak anti-inflammatory action. It is mainly metabolized in the liver by conjugation with glucuronic acid and sulfate and is excreted in the urine.

At toxic doses, the glucuronide and sulfate conjugation pathway becomes saturated. The metabolites of paracetamol get converted into NAPQI. NAPQI is highly reactive and causes enzymatic dysfunction in the liver. Normally, minor amounts of NAPQI produced in our body are rapidly eliminated by conjugation with reduced glutathione(GSH) and then excreted into the urine.

Therefore, paracetamol toxicity is treated with N-acetyl cysteine(NAC), which replenishes GSH. NAC thereby helps in the excretion of NAPQI from the body. N-acetyl cysteine is an anti-oxidant and functions by detoxifying NAPQI.

Paracetamol poisoning is the most common cause of liver failure necessitating transplantation.

The maximum dose of acetaminophen that can be given is 4 g/day.

Solution to Question 6:

The correct match is verapamil causes constipation.

Verapamil is a calcium channel blocker used for the treatment of paroxysmal supraventricular tachycardia, atrial fibrillation, and atrial flutter. Bradycardia and constipation are the important side effects of verapamil.

Other options:

Option A: Hydralazine is a vasodilator used in the treatment of heart failure, and hypertensive emergencies, especially preeclampsia. The drug is used as a combination pill containing isosorbide dinitrate (BiDil) in the treatment of heart failure. The important side effect of hydralazine is drug-induced lupus.

Option B: Atenolol is a cardioselective beta-1 blocker used in the treatment of angina and hypertension. Atenolol doesn't cause hemolytic anemia.

Option C: Aliskiren is a direct renin inhibitor used as an alternative antihypertensive drug for those who do not respond or do not tolerate 1st line drugs. The side effect of aliskiren is hyperkalemia and not hypokalemia.

Solution to Question 7:

In a post-mastectomy patient undergoing therapy with tamoxifen, it should be stopped for 3 months before she can conceive.

Tamoxifen is a selective estrogen receptor modulator (SERM) and is used as a chemotherapeutic agent in receptor positive breast cancer patients to prevent recurrence after surgery. It is the drug of choice in pre-menopausal women. It has an agonistic action on the endometrium, leading to an increased risk of endometrial cancers (2 fold risk). Hence, it is not used in post-menopausal women.

It is contraindicated in pregnancy due to teratogenic effects such as craniofacial abnormalities and reproductive tract abnormalities. For the same reason, it has to be stopped for 3 months (due to long half-life) prior to conceiving. It is also stopped during lactation as it is secreted in breast milk. Other complications of tamoxifen include deep vein thrombosis, pulmonary embolism, and hot flashes.

Other breast cancer risk reduction techniques:

• Lifestyle modification: Low-calorie diet, daily exercise, no smoking, no drinking, etc.

• More frequent screening with mammogram +/- MRI

• Chemoprevention: Preferred in women >35 years of age in patients who are ER/PR positive. Given for 5-10 years.

• SERMS (selective estrogen receptor modulators) - Tamoxifen and raloxifene. These have adverse effects.

• Aromatase Inhibitors (AIs): They are used only in post-menopausal women.

• Risk-reduction surgeries: preferred in patients with BRCA1/2 mutations or patients with first-degree relatives with breast cancers. Provides >90% risk-reduction. preferred in patients who have completed their family.

• Bilateral mastectomy

• Salpingo-oophorectomy: Best results when done < 40 years of age.

Solution to Question 8:

Bebtelovimab is not used in the treatment of sickle cell disease. The clinical features of multiple blood transfusions, bone pain, and sickle cells on peripheral smear are suggestive of sickle cell disease.

Bebtelovimab is the new monoclonal antibody used for the treatment of COVID-19. It works by binding to the spike protein of the COVID-19 virus. It has been found useful in reducing the risk of hospitalization or death. Bebtelovimab retains the activity against the omicron variant.

Other options:

Option B: Voxelotor is an inhibitor of hemoglobin S polymerase and stabilizer of sickle cell hemoglobin (HbS) that is used in the therapy of sickle cell disease.

Option C: Hydroxyurea improves fetal haemoglobin (HbF) and is the primary drug for controlling HbS in sickle cell disease. Thus improving the oxygen-carrying capacity of the blood. Hydroxyurea also inhibits the enzyme ribonucleotide reductase (RNR), which is a rate-limiting step in the biosynthesis of DNA. This property of hydroxyurea is used in the treatment of various cancers, and myeloproliferative disorders like chronic myelogenous leukemia, and polycythemia.

Option D: L-glutamine is a naturally occurring amino acid with antioxidant properties.
It increases the availability of reduced glutathione which may lessen oxidative damage in sickle red blood cells.

Solution to Question 9:

The half-life of letrozole is 45 hours.

Letrozole is a reversible aromatase inhibitor. It is a non-steroidal compound that inhibits the aromatization of estrogen thereby causing estrogen depletion. Letrozole is rapidly absorbed with 99.9% oral bioavailability and has a t½ of around 41 hours.

Letrozole is used as the first-line drug for estrogen-positive breast cancer following mastectomy in post-menopausal women.

Adverse effects of letrozole are due to the depletion of estrogen. The commonly seen adverse effects are hot flashes, vaginal dryness, nausea, diarrhea, dyspepsia, accelerated bone loss, and

thinning of hair.

Solution to Question 10:

A false statement about eicosanoids is they are synthesized from arginine. Eicosanoids are synthesized from arachidonic acid (Option B)

Eicosanoids are the most universally distributed autocoids in the body. Prostaglandins, thromboxanes, and leukotrienes comprise eicosanoids. Every cell is capable of synthesizing one or more eicosanoids. Platelets primarily synthesize thromboxanes (Option D).

Eicosanoids are synthesized from arachidonic acid. Arachidonic acid is derived from membrane phospholipids. The release of arachidonic acid (AA) from the membrane phospholipids is mainly mediated by phospholipase A.

AA is metabolized by cyclooxygenases to produce prostaglandins and lipoxygenases to produce leukotrienes and lipoxins.

Inhibitors of metabolism of arachidonic acid:

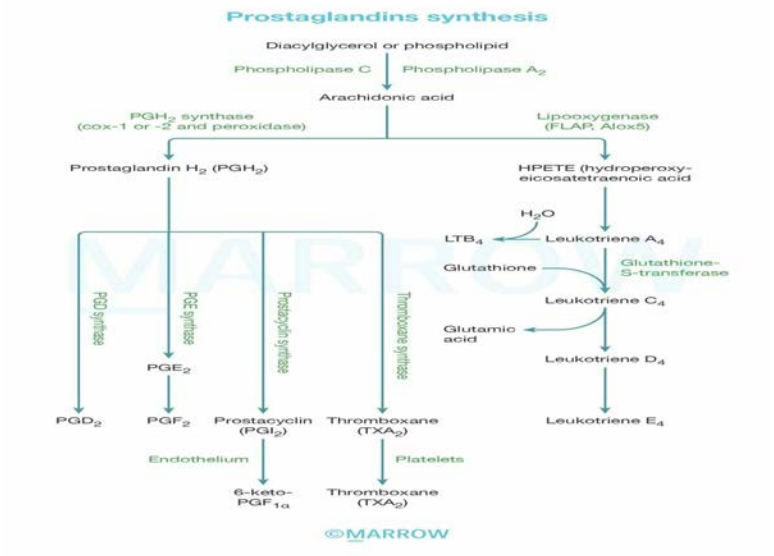
• Corticosteroids cause inhibition of prostaglandin synthesis by inhibiting phospholipase A2.

• Non-steroidal anti-inflammatory (NSAIDs) drugs inhibit the synthesis of prostaglandins by inhibiting the enzyme cyclooxygenase.

• Zileuton inhibits the enzyme lipoxygenase thereby decreasing the synthesis of leukotrienes.

Chemically, all prostaglandins are considered to be derivatives of prostanoic acid, having a five-carbon ring (Option C).

The image given below shows the synthesis of various eicosanoids from arachidonic acid:



Solution to Question 11:

Beta lactams act on step 4 in the given image.

Mechanism of action of beta-lactams: They are the cell wall synthesis inhibitor. The β-lactam antibiotics inhibit this last step in peptidoglycan synthesis. They inhibit the enzyme transpeptidase which is required for cross-linking of the peptidoglycan chain. Transpeptidases cleave the terminal D-alanine of the peptide chains and form cross-linkages between them. This cross-linking provides rigidity and stability to the cell wall.

Transpeptidases and other related proteins constitute penicillin-binding proteins(PBP) and, are located in the bacterial cell membrane. β-lactam antibiotics are bactericidal. This is because bacterias swell and burst due to deficient cell walls when they divide in the presence of β-lactam antibiotics. Penicillins, cephalosporins, monobactams, and carbapenems are examples of β-lactam antibiotics.

Gram-positive bacteria are more susceptible to β-lactam antibiotics than gram-negative because their cell wall is almost entirely made of peptidoglycan.

Resistance to β-lactam antibiotics develops due to the production of the beta-lactamase enzyme and the development of altered penicillin-binding proteins like in methicillin-resistant Staphylococcus aureus (MRSA). β-lactamases inactivate β-lactam antibiotics by opening the β-lactam ring. This could be overcome by using drugs that inhibit this enzyme. Examples of β-lactamase inhibitors are clavulanic acid, sulbactam, and tazobactam.

Other options:

Option A: Fosfomycin inhibits step 1 in the image. It inhibits the cytoplasmic enzyme enol pyruvate transferase that catalyses the initial step in the bacterial cell wall and hence cell wall synthesis. It is used for the treatment of urinary tract infections.

Option B: Bacitracin inhibits step 2 in the image. It is a cell wall synthesis inhibitor that interferes with dephosphorylation in the cycling of the lipid carrier which transfers peptidoglycan subunits to the growing cell wall. It is only given for topical application because of its severe nephrotoxicity when given systemically.

Option C: Vancomycin inhibits step 3 in the image. It binds to the D-Ala-D-Ala terminus of the newly formed peptidoglycan pentapeptide. This prevents further elongation of the peptidoglycan and its cross-linking. It is used against MRSA and Clostridium difficile infection. Redman syndrome due to histamine release following infusion is an important side effect.

Note: The FDA has approved the use of cefepime-enmetazobactam, a combination of a fourth-generation cephalosporin and beta-lactamase inhibitor for use in complicated UTIs (including pyelonephritis).

Solution to Question 12:

Phospholipase C acts via the Gq type of G protein-coupled receptors.

G protein-coupled receptors (GPCRs) are cell membrane receptors that span across the membrane 7 times. They also serve as receptors for various peptide hormones, neurotransmitters, amino acids, etc.

Subtypes of GPCRs are distinguished by their alpha subunits. The important subtypes of GPCRs are Gs, Gp, Gq, and Go.

GPCRs act via various second messengers. The important ones with their action on the effector are:

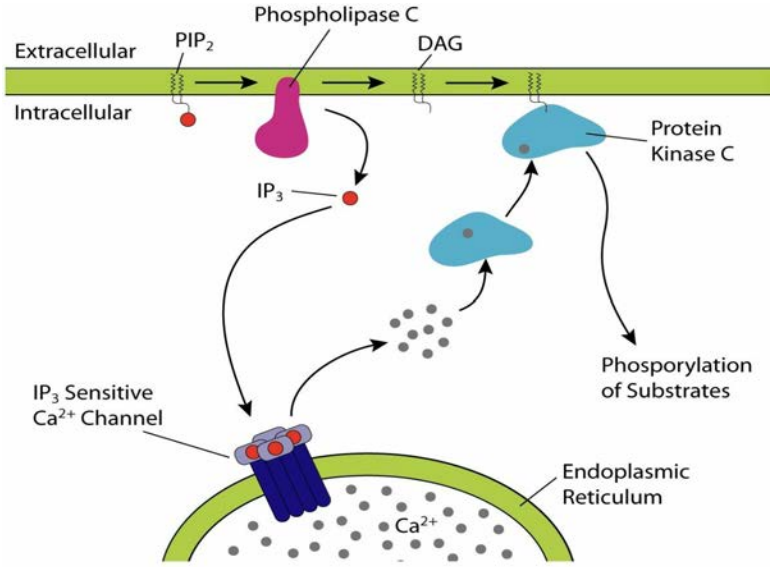
• Gs causes activation of adenylyl cyclase and results in Ca2+ channel opening.

• Gi causes inhibition of adenylyl cyclase and results in K+ channel opening.

• Go causes Ca2+ channel inhibition.

• Gq causes activation of phospholipase C which generates the second messengers inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG). The water-soluble IP3 diffuses to the cytosol and mobilizes Ca2+ from endoplasmic reticular depots.

The given below image shows the effects of phospholipase C after activation by Gq



Solution to Question 13:

Isoniazid is the first-line antitubercular drug that acts by inhibiting the synthesis of mycolic acid.

Isoniazid is a first-line bactericidal drug that is used for the treatment of tuberculosis. This drug enters bacilli by passive diffusion. It then gets activated to its toxic form by the enzyme catalase-peroxidase(the enzyme encoded by the Kat gene).

Normally, InhA and KasA are involved in the synthesis of mycolic acid. Upon activation, the reactive metabolite of isoniazid forms complexes with NAD that inhibit InhA and KasA. Hence, isoniazid inhibits the production of mycolic acid.

The reactive isoniazid metabolite also forms complexes with NADP. This complex inhibits mycobacterial dihydrofolate reductase which results in the interruption of DNA synthesis.

Side effects of isoniazid include:

• Peripheral neuritis due to interference with the production of active coenzyme pyridoxal phosphate from pyridoxine. Therefore, pyridoxine 10mg/day (vitamin B6) is given prophylactically along with isoniazid to prevent neurotoxicity.

• Hepatitis - isoniazid must be stopped at the first sign of hepatotoxicity.

• Rashes

• Anaemia

• Arthralgia

Toxicity of isoniazid results in metabolic acidosis, seizures, and coma.

Other options:

Option B: Rifampin acts by binding to DNA-dependent RNA polymerase to form a stable drug-enzyme complex. This complex suppresses RNA synthesis. Side effects of rifampin are hepatitis, flu-like illness, orange-red colored urine, and body secretions.

Option C: Pyrazinamide is a prodrug, it is converted into an active metabolite pyrazinoic acid which makes the intracellular environment acidic and collapses the transmembrane proton motive force, thereby killing the bacteria. Side effects include hyperuricemia and hepatotoxicity.

Option D: Ethambutol inhibits arabinose transferase III, thereby decreasing arabinogalactan biosynthesis. This results in disruption in mycobacterial cell wall synthesis. Optic neuritis is an important side effect of ethambutol. It results in decreased visual acuity and loss of red-green discrimination.

Solution to Question 14:

Bradycardia is the possible presenting feature which led to the diagnosis of muscarinic poisoning.

Muscarinic poisoning occurs due to the consumption of poisonous mushroom-like Inocybe. Muscarinic symptoms appear within an hour of eating the mushroom. These symptoms (along with nicotinic symptoms) can also be seen in organophosphate poisoning.

There are 5 subtypes of muscarinic receptors they are M1, M2, M3, M4, and M5. The effects exerted by the M receptors are given below:

• M1: Increased seizure activity.

• M2: Tremors, bronchoconstriction, bradycardia, abdominal cramping

• M3: Increased bladder contraction, miosis, increased salivary secretion

• M4: Cataplexy(sudden muscle weakness)

Atropine is used for the management of muscarinic poisoning. It competitively blocks the acetylcholine at the muscarinic receptors.

Solution to Question 15:

Valproate should be avoided for being highly teratogenic to the fetus.

Valproate is an anti-epileptic medication. It is also used as a mood stabilizer in manic episodes as well as in bipolar disorder. The repetitive firing caused by depolarization of cortical or spinal cord neurons is inhibited by valproate. It also prolongs the sodium channel inactivation.

The side effects of valproate (mnemonic: VALPROATE)

• Vomiting

• Alopecia

• Liver toxicity

• Pancreatitis

• Rash

• Obesity

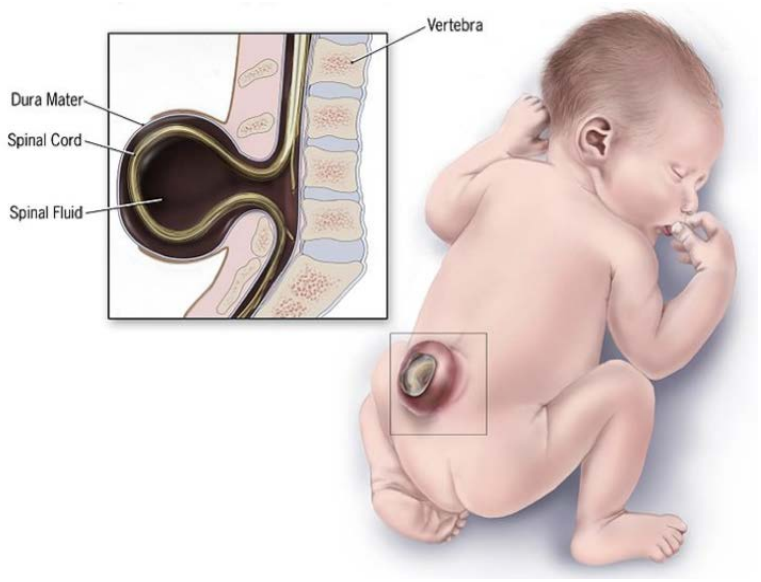
• Anorexia

• Teratogenicity

• Oedema

It causes congenital anomalies like neural tube defects (spina bififda), clefts, and cardiac anomalies. The intelligence quotient score of school-going children who were exposed in utero to valproate is found reduced. It also contributes to poor cognitive development in children. Folate supplementation reduces the chances of neural tube defects.

The images below show a baby and a USG with spinal bifida:



Other options:

Option B: Lithium is used for the treatment of bipolar disorder as well as mania. It was earlier implicated in causing Ebstein anomaly, however, recent studies suggest that lithium has a weak teratogenic effect.

Option C: Oxcarbazepine was earlier associated with teratogenicity and fetal malformations, however, recent studies suggest that oxcarbazepine monotherapy during pregnancy does not carry a significant risk of fetal malformations.

Option D: Olanzapine is an antipsychotic and an antimanic and it is not associated with teratogenicity.

Solution to Question 16:

True statements regarding the administration of 5 alpha-reductase inhibitors are 1,4. They reduce dihydrotestosterone levels and decrease prostate-specific antigen (PSA) levels.

5 alpha-reductase inhibitors are the competitive inhibitors of the enzyme 5 α-reductase which converts testosterone into the more active dihydroxy testosterone (DHT). This enzyme inhibition results in:

• Decreased DHT levels

• Decreased PSA levels

• Reduces prostate volume

However, plasma testosterone levels and LH (luteinizing hormone) levels remain unchanged

Finasteride and dutasteride are the 5 α-reductase drugs currently in use. They are used in benign prostatic hyperplasia (BPH) along with surgery and adrenergic α1 blockers for symptomatic relief. They can also be used in male pattern of baldness and hirsutism.

Side effects of 5 α-reductase drugs are:

- Impotence
- Decreased libido
- Gynecomastia
- Skin rashes

Solution to Question 17:

This type of drug is called a misbranded drug. A drug stating that 500mg of paracetamol is present in each tablet, but contains only 200mg is a misbranded drug, according to the Drugs and Cosmetics Act, 1940 definition of misbranded drugs.

According to the Drugs and Cosmetics act, 1940, a misbranded drug is a drug if its label or container or anything accompanying the drug bears any statement, design, or device which makes any false claim for the drug or which is false or misleading in any particular.

Other options:

Option A: Spurious drugs include drugs manufactured under another drug or manufacturer's name, imitations of other drugs, and drugs with labels from a fictitious company or individual. It also includes drugs substituted partly or wholly by another drug or substance.

Option B: Adulterated drugs include those drugs that contain filthy, or decomposed substances, substances that are injurious to health, or if the drug harmful substances to reduce the quality or strength of the drug. It also includes drugs that were prepared in unsanitary conditions.

Option C: The term unethical drug is not standard terminology in pharmacology. However, the term ethical drug is sometimes used to describe those drugs that are available only by prescription of a medical practitioner.

Solution to Question 18:

Canagliflozin is associated with an increased risk of fractures.

Canagliflozin is a sodium-glucose transporter-2 (SGLT2) inhibitor. SGLT2 is a Na+-glucose cotransporter that is located in the proximal convoluted tubule. They reabsorb glucose and sodium from the tubular lumen back into the blood through the epithelial cells. SGLT2 inhibitors block the transport of glucose in the proximal tubule and promote glycosuria and hence, lowering blood glucose.

The currently available SGLT2 inhibitors are canagliflozin, dapagliflozin, and empagliflozin. Other than decreasing blood glucose they also decrease blood pressure and, cause weight loss of 2–4 kg. Empagliflozin and canagliflozin reduce the risk for major cardiovascular events.

The main side effect of SGLT2 inhibitors is an increase in lower urinary tract infections and genital mycotic infections. This is because of their glycosuric properties. A recent warning from the FDA says that SGLT2 inhibitors may increase the risk of fractures. They also affect circulating levels of parathyroid hormone, and 1,25-hydroxy vitamin D thereby

affecting the mineral balance in bone.

Other options:

Option A: Rosiglitazone is a thiazolidinedione that acts as a peroxisome proliferator-activated receptor γ agonist in the adipose tissue which increases insulin sensitivity and adipose differentiation. Side effects are weight gain, edema, and increased risk of fractures. Compared to rosiglitazone, canagliflozin is commonly used in clinical practice. American diabetes association recommends canagliflozin as the first-line drug along with metformin, in patients with a high risk of cardiovascular disease, renal failure, and heart failure. Even when thiazolidinediones are required, clinicians prefer pioglitazone over rosiglitazone due to the higher risk of cardiovascular-related mortality in rosiglitazone. Therefore, canagliflozin would be a better option compared to rosiglitazone.

Option B: Liraglutide is a long-acting glucagon-like peptide-1 agonist. Nausea, diarrhea, and acute pancreatitis are some frequent side effects.

Option C: Voglibose reduces the intestinal absorption of starch, dextrin, and disaccharides by inhibiting the action of α-glucosidase in the intestinal brush border. The most prominent adverse effects are malabsorption, flatulence, diarrhea, and abdominal bloating.

Solution to Question 19:

The active metabolite of cyclophosphamide is 4 - hydroxy cyclophosphamide.

Cyclophosphamide is an alkylating agent with antitumor and immunosuppressant properties. It is used for many solid tumors. The important side effects are cystitis due to metabolite acrolein and bladder carcinoma.

Cystitis caused by cyclophosphamide is treated by systemic administration of mesna and by irrigating the bladder with acetylcysteine. Both these drugs contain –SH which detoxifies the toxic metabolites. Plenty of fluids and frequent bladder voiding are also helpful.

Solution to Question 20:

Alkalinization of urine will be helpful in the removal of aspirin, which is a weakly acidic drug and is susceptible to ion trapping in the urine.

Aspirin is a weak acid, with a pKa of 3.0. Drugs that are subjected to renal clearance are excreted into the urine by glomerular filtration and active tubular secretion. Nonionized compounds are reabsorbed more rapidly than ionized polar molecules. When the pH of the urine increases, more salicylate is in its ionized form at equilibrium. Hence, salicylic acid diffuses into the tubular lumen of the kidney. Urine alkalinization is recommended as a first-line treatment only for moderately severe salicylate poisoning that does not meet the criteria for hemodialysis.

Alkalinization of the urine is achieved by administration of 100–150 mEq of sodium bicarbonate in 1 L of 5% dextrose in water (D5W). It is infused intravenously at twice the maintenance fluid requirements.

Alkalinization of urine is contraindicated in renal failure or if fluid administration may worsen pulmonary edema or congestive heart failure.

Solution to Question 21:

A hospital conducting a double-blinded study in multiple centers to check the efficacy of statins describes phase 3 of the clinical trial. A phase 2 clinical trial is generally conducted at a few centers (2-4) by physicians.

Phase 3 of a clinical trial is also known as a multisite trial. It is conducted on a large patient population (500–3000) by several physicians at multiple centers. This phase involves patients who have been diagnosed with the disease that the drug claims to treat. Its purpose is to confirm the efficacy of the newly developed drug in a larger population. Phase 3 is randomized, controlled, and may be blinded.

Solution to Question 22:

The given clinical scenario and the image showing a pin-point pupil (miosis) suggest opioid overdose. The true statement among those given is that it is caused by activation of the Edinger-Westphal nucleus.

Edinger-Westphal nucleus is a part of the light reflex pathway and is located in the midbrain. This nucleus is responsible for causing pupillary constriction when the retina is exposed to light.

Opioid overdose symptoms are a triad of coma, respiratory depression, and pinpoint pupils (miosis). Other features are hypotension, bradycardia, shallow breathing, and hypothermia.

Tolerance to miosis does not develop even in addicts who develop a high tolerance to opioids. Miosis is induced by all opioid agonists.

Naloxone is the drug of choice for opioid overdose. It is administered after adequate ventilation is established. Airway protection and ventilatory maintenance are the most important steps in the treatment of opioid overdose; this is because respiratory depression is the major cause of mortality in such cases. Single-dose activated charcoal can be administered if the opioid ingestion occurred within one hour.

Levallorphan is an opioid antagonist, with properties similar to those of naloxone. It can be used for opioid overdose. It reverses severe opioid-induced respiratory depression.

Phenylephrine is an α1-selective agonist that causes mydriasis, but it is not useful in the reversal of opioid-induced miosis.

Solution to Question 23:

The correct answer is option B: A-4, B-1, C-3, D-2

In a patient with head injury, morphine is contraindicated because it increases intracranial tension due to CO■ retention, precipitates respiratory depression, and may cause vomiting, miosis, and altered mental state which interferes with assessment of mental state.

Amiodarone should not be used in patients with prolonged QT interval because it may cause marked prolongation of the QT interval, bradycardia, and torsades de pointes.

Vigabatrin, an inhibitor of GABA-transaminase, an anti-convulsant, is contraindicated in pregnancy due to its potential teratogenic effect.

Estrogen preparations can contribute to the incidence and severity of thromboembolism, particularly if other risk factors are present. The risk of serious cardiovascular side effects is particularly marked in women more than 35 years of age who smoke heavily.

A. Morphine	4. Head Injury
B. Amiodarone	1. QT prolongation
C. Vigabatrin	3. Pregnancy
D. Estrogen preparations	2. Thromboembolism

Solution to Question 24:

1 and 2 are true statements regarding memantine.

Memantine is a non-competitive NMDA receptor antagonist. It inhibits glutamate excitotoxicity. It delays the progression of dementia in Alzheimer's disease. Commonly, it is started in patients with moderate-to-severe disease.

It can be given both as monotherapy or can be given along with cholinesterase inhibitors. It can be started at a dose of 5 mg once daily and then progressively increased up to 10 mg twice daily for a minimum of 6 months.

It can cause dizziness and headache. Since it is excreted in the kidney, careful dose adjustments should be made in patients with renal failure.

Solution to Question 25:

Step 5 in the given life cycle shows the integration of the viral DNA into the host genome. Raltegravir is an integrase inhibitor and is active against both HIV-1 and HIV-2. It can be used in adults and children >1 month old.

It is advised for patients to consume antacids and sucralfate, 6 hours before or 2 hours after raltegravir intake.

It may cause headaches, nausea, weakness and fatigue. Rarely, it can lead to drug reactions with eosinophilia and systemic symptoms (DRESS) syndrome.

The steps involved in the lifecycle of HIV as given in the image are described as follows:

• Step 1: Binding of HIV-1 to the cell membrane of a CD4+ cell

• Step 2: HIV-1 enters the cell via interaction with the membrane glycoproteins

• Step 3: Reverse transcription of the viral genetic material using the virus' reverse transcriptase enzyme

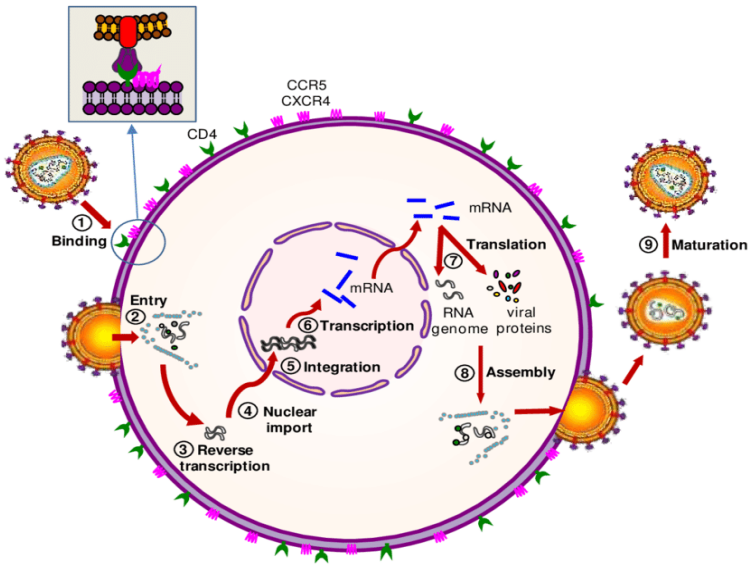
• Step 4: The HIV-1 genome travels into the nucleus

• Step 5: The viral genome integrates into the host's DNA through the integrase enzyme

• Step 6: The HIV-1 proviral genome undergoes transcription with the host DNA

• Step 7: The viral messenger RNA (mRNA) undergoes translation to produce new viral proteins

• Steps 8 and 9: Assembly and maturation of the virion



Other options:

Option B: Enfuvirtide acts at step 2 in the given image. It blocks gp41 of the cell membrane and blocks the entry of the virus into the cell. It prevents the free viral particles from invading new CD4+ cells. It is effective against HIV-1.

Option C: Tenofovir acts at step 3 in the given image. It is a nucleotide reverse transcriptase inhibitor (NRTI) that is effective against HIV-1,2 and hepatitis B infections. It is used in adults and children >2 years old. It can also be used for pre-exposure prophylaxis.

Option D: Zidovudine also acts at step 3 in the given image. It is an NRTI and is effective against HIV-1,2 and Human T-cell Lymphoma Virus (HTLV). It can be used in adults and children. It can also be used to prevent mother-to-child transmission.

Solution to Question 26:

Phase 4 clinical trials are also called post-marketing surveillance is the correct statement.

Other options:

Option A: New drug application is done after phase 3 of clinical trials.

Option C: Phase 3 trials may or may not be blinded.

Option D: Phase 2 trials are the first round of trials in patients. Phase 1 trials are done in healthy volunteers.

Solution to Question 27:

The correctly matched pairs of teratogenic drugs and their effects is 1-d, 2-c, 3-b, 4-a.

Lithium use in early pregnancy causes Ebstein anomaly in the fetus. Fetal lithium exposure is associated with neonatal goiter, CNS depression, hypotonia (floppy baby syndrome), and cardiac murmur.

Gray baby syndrome occurs in neonates, especially premature ones, exposed to high doses of chloramphenicol (100 mg/kg), which are administered prophylactically.

Fetal warfarin syndrome or warfarin embryopathy presents with CNS abnormalities, depressed nasal bridge/ saddle nose at birth, bleeding diathesis, and growth retardation. Hypoplasia of the nose, eye sockets, and long bones with stippling of epiphyses are also seen.

Fetal thalidomide exposure causes phocomelia. This disorder is associated with underdeveloped limbs and absent pelvic bones. Both upper and lower limbs are affected, and a part of the limbs may be missing. Fused fingers and missing thumbs are also seen. Thalidomide was originally used for the treatment of pregnancy-associated morning sickness but was withdrawn due to this adverse effect. It re-entered the market for the treatment of erythema nodosum leprosum. It also has antiangiogenic and immunomodulatory effects.

Solution to Question 28:

The drug used to manage this condition is prazosin as it can counteract the effects of breathlessness most probably caused by pulmonary edema.

The venom is a potent autonomic stimulator that causes the release of massive amounts of catecholamines from the adrenals. It also has a direct effect on the myocardium.

It can present as neurotoxicity with restlessness or seizure-like activity, abnormal oculomotor function, and loss of pharyngeal muscle control that leads to respiratory compromise. Tongue fasciculations and hypersalivation are also common. Cardiovascular toxicity from systemic envenomation includes tachycardia, hypertension, pulmonary edema, and cardiogenic shock.

If the scorpion has hemolytic venom, the reaction is mainly local, with edema, pain, and reddening. This usually lasts for one to two hours.

Treatment:

• Pain - Paracetamol, NSAIDs, or opioids

• Sedation for agitation, oculomotor abnormalities, uncoordinated neuromuscular activity, and muscle spasms - Benzodiazepines

• Hypertension and pulmonary edema - Prazosin counteracts the adrenergic surge that can lead to these effects

• Cardiogenic shock - Antivenom, prazosin, nitroglycerin, dobutamine

• Cholinergic effects - Atropine

• Supportive care, wound care

Solution to Question 29:

Phase 4 in the graph indicates the nicotinic action of acetylcholine at higher doses.

In phases 1 and 2, acetylcholine (Ach) acts on muscarinic receptors (at 2 micrograms and 50 micrograms) bringing down blood pressure. Atropine blocks the muscarinic receptor, so this action of acetylcholine is not seen in phase 3. However, in phase 4, higher doses of Ach (like 5 mg) act via the nicotinic receptor, shooting up the blood pressure. This phenomenon is called the reversal of Ach in blood pressure and was studied by Dale.

Nicotinic receptors are ligand-gated ion channels. It can be divided into two groups: muscle receptors (NM), which are found at the skeletal neuromuscular junction, and neuronal receptors (NN), which are found in the ganglia and CNS. When stimulated at higher doses, Ach acts on NN receptors, leading to the stimulation of sympathetic ganglia and adrenal medulla. This increases the heart rate, blood pressure, and myocardial contractility.

Muscarinic receptors are G-coupled protein receptors involved in the parasympathetic nervous system. M1, M2, M3, M4, and M5 are the receptor subtypes. They act via Gi or Gq subunits. When Ach is administered, it acts on muscarinic receptors, primarily the M3 receptors, which are located on vascular endothelial cells. It stimulates guanylyl cyclase and promotes relaxation via a cyclic GMP–dependent mechanism. At higher doses, it acts on M2 receptors, which have direct effects on the heart. It also inhibits the release of norepinephrine from sympathetic nerve terminals and decreases cyclic AMP levels.

Solution to Question 30:

The most likely drug causing hyperpigmentation of the hands and soles would be emtricitabine.

Emtricitabine is an anti-retroviral drug that acts by inhibiting nucleoside reverse transcriptase (NRTI). It is well-tolerated and has minimal toxic effects. Adverse effects include hyperpigmentation of the skin (especially sun-exposed areas, palms, and soles), headache, vomiting, and nausea.

Other options:

Option A: Nelfinavir is a protease inhibitor that causes diarrhea or loose stools. It usually resolves within a month of starting the drug.

Option C: Abacavir is an NRTI that can cause a life-threatening hypersensitivity syndrome. The syndrome presents with fever, abdominal pain, and maculopapular rash within 6 weeks of initiating abacavir. The drug must be immediately discontinued and must not be administered to the patient thereafter. Rarely, there might be respiratory and musculoskeletal side effects.

Option D: Zidovudine is an NRTI that causes malaise, fatigue, myalgia, anorexia, and insomnia. Chronic use leads to nail hyperpigmentation. It can also cause bone marrow suppression.

Solution to Question 31:

Dorzolamide is a topical ocular carbonic anhydrase inhibitor.

It acts on carbonic anhydrase in the ciliary processes of the eye and mediates the formation of HCO_3^- in aqueous humor. Inhibition of carbonic anhydrase decreases the rate of formation of aqueous humor and consequently reduces intraocular pressure.

The major indication for carbonic anhydrase inhibitors is open-angle glaucoma. Dorzolamide and brinzolamide, which are available only as ophthalmic drops, are used for this purpose.

Dorzolamide may be used for secondary glaucoma and in acute angle-closure glaucoma to lower intraocular pressure before surgery.

Solution to Question 32:

Sildenafil is a phosphodiesterase 5 inhibitor and the action of the drug is mediated through cGMP. Erectile dysfunction is treated by phosphodiesterase-5 (PDE-5) inhibitors like sildenafil, vardenafil, and tadalafil.

The corpus cavernosum produces nitric oxide during arousal that stimulates the formation of cGMP. cGMP causes relaxation of the smooth muscle of the corpus cavernosum and penile arteries, engorgement of the corpus cavernosum, and erection.

The above-mentioned drugs compete for cyclic GMP, binding at the site of cyclic GMP hydrolysis on PDE5, enhancing the accumulation of cGMP and hence used in the management of erectile dysfunction. They are useful in treating pulmonary arterial hypertension.

Adverse effects of the drug are headache, flushing, nasal congestion, nasopharyngitis, and dyspepsia. Sildenafil and Vardenafil also cause retinal PDE-6 inhibition and can result in blurring of vision and blue-green tinting of the vision.

Solution to Question 33:

The correct match is as follows:

Acetazolamide, a carbonic anhydrase inhibitor, acts on the enzyme in epithelial cells of the proximal convoluted tubule. Acetazolamide is mainly used in patients with secondary glaucoma to reduce intra-ocular pressure, provide symptomatic relief in acute mountain sickness, and as

treatment for absence seizures.

Torsemide, a loop diuretic, inhibits the Na+-K+-ATPase symporter in the thick ascending loop of Henle. It is used in acute pulmonary edema, edema associated with congestive cardiac failure, hypertension with renal insufficiency, and hyponatremia.

Chlorthalidone, a thiazide-like diuretic, inhibits the Na+-Cl- symporter in the distal convoluted tubule. It is used in hypertension and in edema associated with congestive cardiac failure, hepatic cirrhosis, nephrotic syndrome, and chronic renal failure.

Vasopressin, also known as anti-diuretic hormone, is secreted by the posterior pituitary and mainly acts on the collecting duct, and increases the reabsorption of water (anti-diuresis). Vasopressin or its agonists (such as desmopressin) are used in cases of diabetes insipidus, type I and type II von Willebrand's disease, primary nocturnal enuresis, and postoperative ileus.

Column A	Column B
A. Acetazolamide	4. Proximal convoluted tubule
B. Torsemide	1. Thick ascending loop of Henle
C. Chlorthalidone	3. Distal convoluted tubule
D. Vasopressin	2. Collecting duct

Solution to Question 34:

Alkalinization of urine will be helpful in the removal of weakly acidic drugs as they are susceptible to ion trapping in the urine.

Drugs that are subjected to renal clearance are excreted into the urine by glomerular filtration and active tubular secretion. Nonionized compounds are reabsorbed more rapidly than ionized polar molecules. When the pH of the urine increases, more salicylate is in its ionized form at equilibrium. Hence, salicylic acid diffuses into the tubular lumen of the kidney. Urine alkalinization is recommended as a first-line treatment only for moderately severe salicylate poisoning that does not meet the criteria for hemodialysis.

Alkalinization of the urine is achieved by administration of 100–150 mEq of sodium bicarbonate in 1 L of 5% dextrose in water (D5W). It is infused intravenously at twice the maintenance fluid requirements.

Alkalinization of urine is contraindicated in renal failure or if fluid administration may worsen pulmonary edema or congestive heart failure.

Solution to Question 35:

Hyponatremia occurs more frequently in the case of oxcarbazepine than carbamazepine.

Both carbamazepine and oxcarbazepine are sodium-channel blockers.

Carbamazepine is most effective in complex partial seizures. It is also used in GTCS and simple partial seizures, trigeminal and related neuralgias, and manic depressive psychosis.

Carbamazepine potentiates the action of antidiuretic hormone (ADH). It can result in water retention with decreased osmolarity and hyponatremia, especially in elderly patients with cardiac disease. Carbamazepine and oxcarbazepine can cause leukopenia, aplastic anemia, hepato-toxicity and hyponatremia in the elderly.

Oxcarbazepine shows lesser hypersensitivity reaction. Hence, rashes are more commonly seen with carbamazepine than with oxcarbazepine.

Studies have shown that carbamazepine elevates enzyme gamma-glutamyl transpeptidases (GGT) more frequently than oxcarbazepine because of enzyme P450 induction.

Mechanism of action of some common antiepileptics:

Mechanism of action	Antiepileptics
Sodium-channel blockers	PhenytoinCarbamazepine, Oxcarbazepine Eslicarbazepine LamotrigineTopiramateFelbamateValproateRufinamideLevetiracetam
Calcium-channel blockers	ValproateLamotrigineEthosuximide
GABAAreceptor modulators	BenzodiazepinesPhenobarbitalFelbamatePrimidoneTopiramateCarbamazepine, OxcarbazepineStiripentolClobazam
GABA uptake inhibitors	TiagabineVigabatrin
NMDA receptor antagonist	Felbamate
AMPA/Kainate receptor antagonist	PhenobarbitalTopiramatePerampanel
HCN channel activity enhancers	Lamotrigine
Inhibitors of brain carbonic anhydrase	AcetazolamideZonisamideTopiramate
Potassium-channel openers	RetigabineTopiramate

Solution to Question 36:

The correct pairs are as follows:

Trastuzumab is a humanized monoclonal antibody against the external domain of HER2/neu. It is indicated as an adjuvant in the management of metastatic HER-2-positive breast cancer.

Infliximab binds with high affinity to TNF-α and prevents the cytokine from binding to its receptors. Infliximab is used for the treatment of rheumatoid arthritis; it is used in combination with methotrexate in patients who do not respond to methotrexate alone. Infliximab is also used for the treatment of the symptoms of moderate-to-severe Crohn's disease.

Sirolimus is an antimetabolic and antiproliferative drug. It acts by forming a complex with an immunophilin called FKBP-12, which in turn inhibits the mammalian target of rapamycin (mTOR). mTOR is a protein kinase that blocks cell cycle progression at the G1 phase to S phase transition. It is used in the prophylaxis of organ transplant rejection.

Imatinib is a first-generation tyrosine kinase inhibitor. Imatinib attacks BCR-ABL translocation and is used in chronic myelocytic leukemia. It also inhibits c-kit and produces extended control of GI stromal tumors.

A. Trastuzumab	4. HER2/neu
B. Infliximab	3. TNF α
C. Sirolimus	2. mTOR
D. Imatinib	1. BCR-ABL tyrosine kinase

Solution to Question 37:

Oxazepam can be used in patients with elevated transaminases. It is short-acting and so, can be used in patients with liver impairment or brain damage.

Oxazepam is an orally available benzodiazepine used to treat anxiety and alcohol withdrawal states. Hepatic oxidation is decreased in persons with liver disease and the elderly. Oxazepam and lorazepam undergo only hepatic glucuronidation.

Other options:

Option A: Midazolam is the benzodiazepine of choice for induction of anesthesia. The onset of anesthesia is within 30 to 60 seconds. It can also be used to control seizures, but there is no difference in the efficacy of intravenous midazolam and intravenous diazepam.

Option B: Diazepam is a long-acting benzodiazepine. It is metabolized in the liver to active metabolites like nordazepam which are long-acting. Diazepam and its long-acting metabolites can accumulate significantly in elderly patients with liver disease and therefore should not be used in such cases.

Option C: Alprazolam is metabolized by hepatic oxidation which is significantly decreased in liver impairment and elderly patients.

Solution to Question 38:

Atorvastatin 80 mg can be used to treat this condition. The first line of therapy in controlling cholesterol in patients with atherosclerotic cardiovascular disease (ASCVD) is starting a high-intensity statin. High-intensity statins include atorvastatin (40-80 mg) and rosuvastatin (20-40 mg).

Statins are competitive inhibitors of HMG-CoA reductase. This leads to a decrease in cholesterol biosynthesis. Statins are also effective in reducing LDL and triglyceride levels.

Other options:

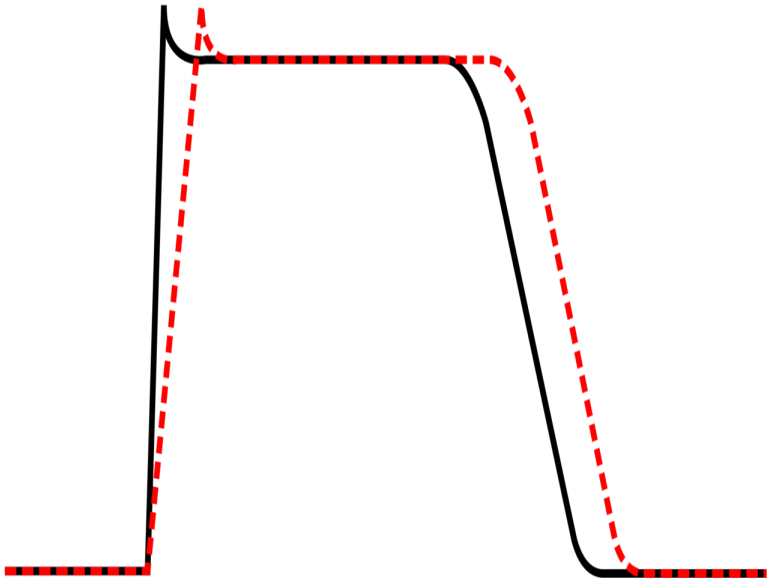
Option A. Fenofibrate reduces lipoprotein levels by interacting with Peroxisome proliferator-activated receptor (PPAR-α) and stimulating lipoprotein lipase. They are used as drugs of choice for treating hyperlipoproteinemia and severe hypertriglyceridemia (>1000 mg/dL).

Option B. Rosuvastatin and fenofibrate combination was previously used to reduce atherosclerotic cardiovascular disease risk. But recent studies have indicated no change in reduction and hence is not recommended anymore.

Option C: Rosuvastatin 10 mg is a low-intensity statin and is mainly used for primary prevention against atherosclerotic cardiovascular disease.

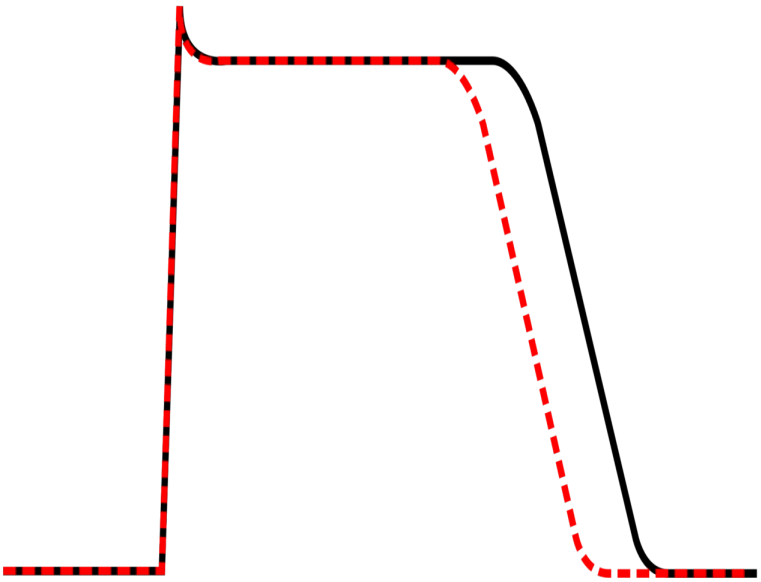
Solution to Question 39:

Quinidine is a class IA anti-arrhythmic agent. Class 1a agents are sodium channel blockers with significant potassium channel blocking properties. This slows conduction and prolongs the QRS duration and action potential duration.



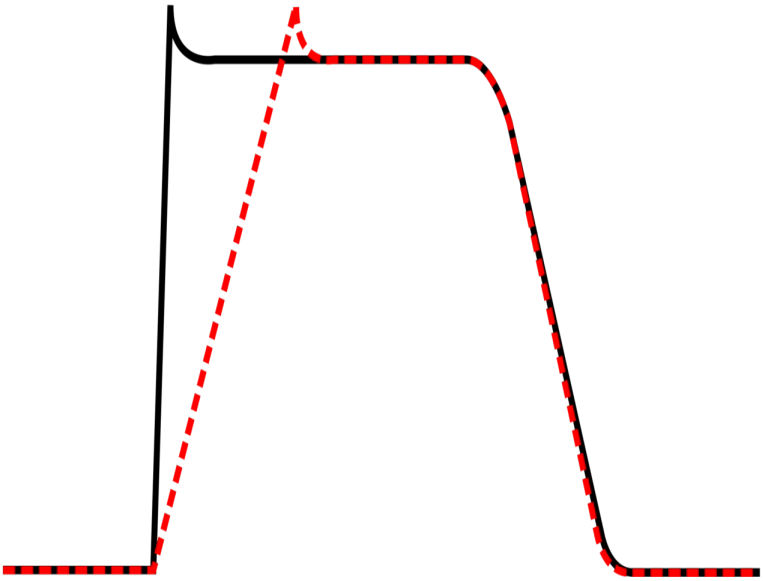
Lignocaine and tocainide (Options D and A) are class 1b anti-arrhythmic drugs. These are sodium channel blockers that inhibit both inactivated and open sodium channels and can open potassium channels. It reduces phase 4 slope and reduces automaticity. It also alters the excitation threshold.

The below image shows the changes in the action potential of a cardiac muscle when a class 1b anti-arrhythmic drug is used.



Class 1c agents like flecainide and propafenone block sodium channels with insignificant potassium channel-blocking properties.

The image below illustrates the action potential changes when a class 1c anti-arrhythmic is used.



Option B: Propranolol is a β-receptor-blocker and a class II antiarrhythmic.

Solution to Question 40:

The false statement regarding statins is that they can be given with verapamil and other enzyme inhibitors.

Statins like atorvastatin and rosuvastatin are metabolized by the cytochrome 3A4 enzymes of the liver. Verapamil is a cytochrome 3A4 inhibitor and may interfere with statin degradation. This leads to an increase in serum statin levels. The most important feature of statin toxicity is myopathy. It can present as myalgia but can sometimes also lead to fatal rhabdomyolysis.

Statins are the most commonly used hypolipidemic drugs. Statins act by inhibiting the rate-limiting HMG-CoA reductase enzyme, which in turn inhibits cholesterol synthesis. They decrease levels of low-density lipoproteins (LDL) and triglycerides and increase the levels of high-density lipoproteins (HDL) in plasma.

Other options:

Option A: Lipoprotein (lp) a is an LDL molecule that has apolipoprotein b and an additional apolipoprotein a. Studies indicate that these molecules are atherogenic and may independently cause cardiovascular disease. Although HMG-CoA reductase inhibitors substantially reduce the risk of cardiovascular events, there is a mild increase in lipoprotein a levels.

Option B: Statins can be continued during surgery. These drugs have proved to decrease overall mortality due to cardiovascular events. Statins also influence inflammatory responses and can be safely used in trauma.

Option D: Chronic administration of high statin doses also leads to an increased incidence of type 2 diabetes mellitus.

Solution to Question 41:

The drugs marked A, B and C are aspirin, eptifibatide, and vorapaxar, respectively.

Aspirin causes inhibition of cyclooxygenase-1 (COX-1), which would inhibit the formation of thromboxane A2. Thromboxane A2 is an inducer of platelet aggregation and is a potent vasoconstrictor. Hence, inhibition of its formation is responsible for antiplatelet action.

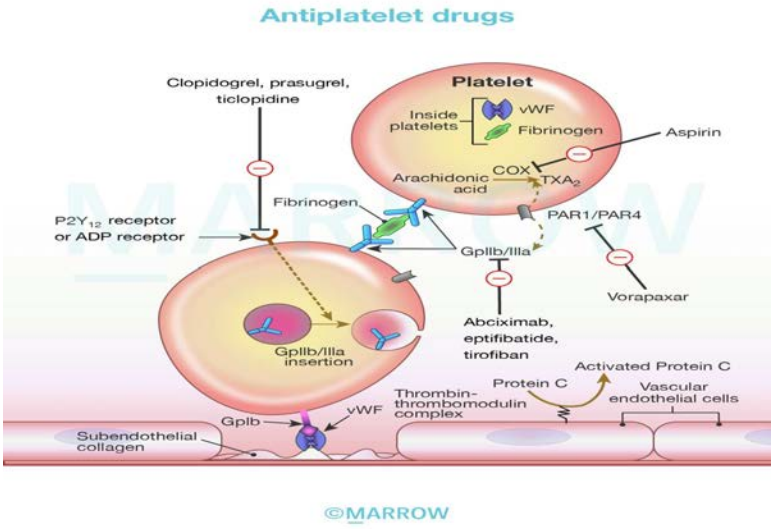
Aspirin is a non-competitive, irreversible inhibitor of the cyclooxygenase (COX) enzyme. It is a nonselective COX inhibitor and inhibits both COX-1 and COX-2.

Abciximab, tirofiban, and eptifibatide act by blocking Gp IIb/IIIa receptors. They are mainly used during percutaneous coronary intervention for acute coronary syndrome. They carry a high risk of bleeding and can cause thrombocytopenia.

Vorapaxar primarily inhibits platelet aggregation caused by thrombin. PAR-1 activation by thrombin contributes to platelet aggregation. Vorapaxar is a competitive antagonist of protease-activated receptor-1 (PAR-1). Vorapaxar is indicated in combination with aspirin and/or clopidogrel to reduce thromboembolic events in patients with MI or peripheral vascular disease.

Prasugrel is an irreversible P2Y12 inhibitor and lasts for the entire lifetime of a platelet.

Prasugrel is a prodrug that is used in patients with acute coronary syndrome who have undergone percutaneous coronary intervention. It reduces the rate of thrombotic cardiovascular events in such patients.



Solution to Question 42:

The wrong statement/s regarding disulfiram is only 3.

Disulfiram is an irreversible inhibitor of both cytosolic and mitochondrial forms of aldehyde dehydrogenase. It is used in behavioral modification for alcohol de-addiction. The principle of action is aversive conditioning (not anti-craving).

Disulfiram can be given only to highly motivated individuals. It should not be administered until the person has abstained from alcohol for at least 12 hours. The disulfiram-alcohol reaction may persist as long as 14 days after the last dose of disulfiram.

Alcohol consumption during disulfiram therapy can lead to increased concentrations of acetaldehyde. This can cause aversive reactions, resulting in flushing, pulsating headache, throbbing pain in the head and neck, nausea, vomiting, rashes, respiratory difficulties, chest pain, and autonomic manifestations.

Disulfiram is usually given in the dose of 250 mg/day (range of 125–500 mg/day).

Solution to Question 43:

G6PD deficiency will manifest with primaquine.

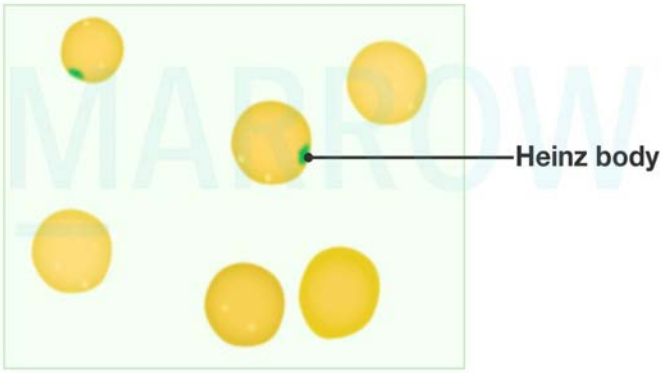
G6PD deficiency is an X-linked recessive (XLR) disorder that causes congenital hemolytic anemia due to enzyme deficiency. Hemolysis occurs in conditions of high oxidative stress that are triggered by infections, fava beans, and certain drugs.

G6PD is an enzyme in the hexose monophosphate pathway (HMP) that maintains the cellular levels of NADPH. NADPH then provides reducing equivalents needed for the conversion of oxidized glutathione to reduced glutathione. Reduced glutathione helps neutralize free radicles, protecting against oxidant injury.

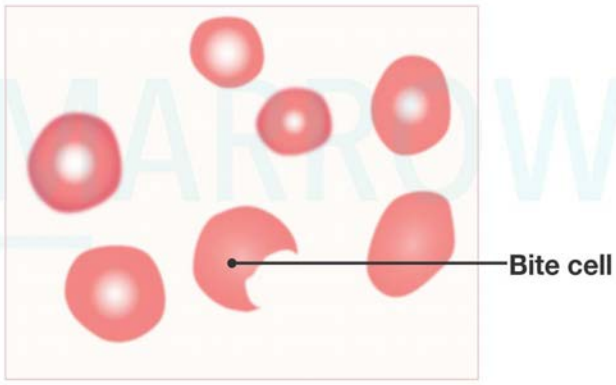
Clinically, most patients are asymptomatic. Some patient develops episodic hemolysis, causing hemolytic anemia, hemoglobinemia, and hemoglobinuria.

Both primaquine and chloroquine cause hemolysis in G6PD-deficient individuals, but hemolysis is rare with chloroquine and it can be used in patients with G6PD deficiency, whereas primaquine is contraindicated in these individuals.

Hematological findings in G6PD deficiency are shown below:



©MARROW



©MARROW

Drugs that carry a risk of clinical hemolysis in persons with G6PD deficiency:

CLASS	DRUGS
Antimalarials	Primaquine >ChloroquineDapsone/chlorproguanil
Sulphonamides/sulphones	SulfamethoxazoleSulfasalazine, Sulfisoxazole

CLASS	DRUGS
Antibacterial/antibiotics	Cotrimoxazole,Ciprofloxacin, Chloramphenicol, Nalidixic a cid, Norfloxacin,Nitrofuranto in
Others	Naphthalene, RasburicaseMe thylene blue

Solution to Question 44:

The correct option regarding the drugs used to treat schizophrenia symptoms is option C.

Drugs used to treat schizophrenia can be classified:

• Typical or 1st generation antipsychotics.

• Atypical or 2nd generation antipsychotics.

All typical antipsychotics markedly improve positive symptoms of schizophrenia, which is attributed to their antagonism at the D2 receptor. Some of the drugs included in this class are chlorpromazine and haloperidol.

Atypical antipsychotics are antagonists or inverse agonists at the 5HT2A receptor. 5HT2A antagonism is responsible for reducing negative symptoms in schizophrenia. Some of the drugs that belong to this class are clozapine, aripiprazole, and brexpiprazole.

Atypical antipsychotics have lower extrapyramidal symptoms as compared to typical antipsychotics as the former has a lesser affinity to the D2 receptor. Muscarinic antagonists can be given to decrease the extrapyramidal symptoms. For example, promethazine or hydroxyzine is given for acute muscular dystonia, which is a form of extrapyramidal symptoms.

5HT1A receptor antagonism, not agonism, has been found to reduce food intake and hence reduce body weight.

Aripiprazole and brexpiprazole are atypical antipsychotics that have partial agonist effects at the 5HT1A receptor. They have been approved for the treatment of schizophrenia and as an adjunctive treatment for depression.

Solution to Question 45:

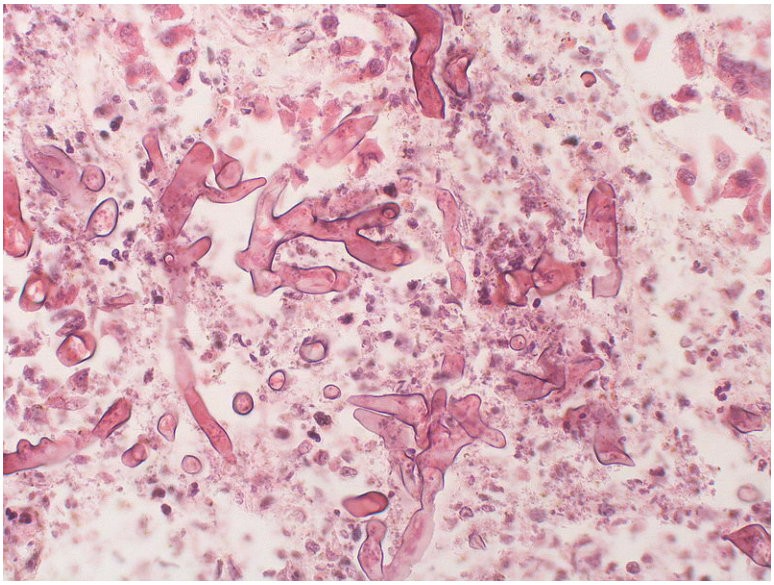
The given clinical scenario is suggestive of mucormycosis. The patient can be given injection amphotericin B for 8 weeks, followed by oral posaconazole.

Mucormycosis is an opportunistic mycosis. It is typically seen in immunocompromised patients and invades blood vessels.

The rhino-orbital-cerebral is the most common form of mucormycosis. Patients present with rhinitis, eye or facial pain, and facial numbness, followed by the onset of conjunctival suffusion and swelling along with blurry vision.

Diagnosis is made by biopsy with histopathologic examination. The biopsy shows characteristic wide, ribbon-like aseptate hyphal elements that branch at right angles.

The image below shows biopsy findings seen in mucormycosis:



Treatment of the infection includes 4 steps:

• Initiation of therapy (amphotericin B) as early as possible. Posaconazole can also be used in the management of this condition.

• Surgical debridement

• Reversal of underlying conditions and risk factors

• Treatment of underlying malignancy if present

Amphotericin B is a broad-spectrum antifungal. It binds to ergosterol in the fungal membrane and forms pores or channels in the fungal cell membrane. This allows the leakage of cytosolic molecules and ions, leading to a loss of membrane integrity.

Other options:

Option A: Itraconazole can be used for the treatment of chronic aspergillosis if there is resistance or failure of voriconazole. Ketoconazole is used for both dermatophytosis and deep mycosis, but it has been replaced by itraconazole.

Option C: Fluconazole is used for the treatment of candidiasis and cryptococcosis.

Option D: Amphotericin B in combination with 5-flucytosine is used as induction treatment for cryptococcal meningitis.

Solution to Question 46:

The antilipidemic drugs likely to cause gallstones are the peroxisome proliferator-activated receptors (PPARs) that act by activating PPAR alpha.

PPARs are a superfamily of nuclear receptors involved in the regulation of energy homeostasis and metabolic function. It has three subtypes:

• PPARα - reduces triglyceride level

• PPARγ - causes insulin sensitization

• PPARδ - enhances fatty acids metabolism

Lipoprotein lipase (LPL) is a key enzyme in the degradation of VLDL. Fibrates bind to PPAR alpha and cause stimulation of lipoprotein lipase enzyme. Increased LPL synthesis enhances the clearance of triglyceride-rich lipoproteins. Additionally, fibrates also stimulate fatty acid oxidation and reduce the expression of apo C-III (inhibitor of lipolysis). All fibrates increase the lithogenicity of bile, thereby increasing the risk of gall stones

Other options:

Class	HMG- CoA reductase inhibitors (statins)	Niacin	Bile acid-binding resins
Examples	Lovastatin, atorvastatin	Niacin	Colestipol,colesevelam
Mechanism of action	Inhibits HMG-CoA reductase	Decreases the production of VLDLs and the catabolism of HDLs	Binds to bile acids in the intestinal lumen and increases excretion.
Major effects on lipoprotein levels	Reduces LDL levels	Reduces triglycerides, LDL, and lipoprotein a levelsSignificantincrease HDLlevels	Reduces LDL levels
Important side effects	MyopathyElevations of serum amino-transferase activityElevation of creatine kinase activity	Cutaneous vasodilationElevations in amino-transferases levels	ConstipationBloating

Solution to Question 47:

In the given image, drug A & drug B are agonists.

Drugs that bind to physiological receptors and mimic the regulatory effects of endogenous signaling compounds' are agonists. Drugs that are only partially as effective as agonists are partial agonists.

The efficacy of a drug indicates the capacity of a drug to activate a receptor and generate a cellular response. A drug with high efficacy is a full agonist, eliciting a full response at some concentration. A drug with a low intrinsic efficacy will be a partial agonist. Drug A & drug B are agonists (Option C) that have the same efficacy (Option A), although, at different concentrations.

Drug C does not produce a full response at any concentration, making it a partial agonist. In the presence of a full agonist, a partial agonist behaves like a competitive antagonist (Option D).

When two drugs produce equivalent responses, the drug whose dose-response curve lies to the left is said to be the more potent since it requires a lower dose to produce the same effect. Drug A

& drug B produce the same action and level of response in the tissue. The curve of drug A on the left indicates that it produces the same response at a lower concentration, making it more potent than drug B (Option B).

Solution to Question 48:

Dipivefrine and dopexamine are β2-adrenergic receptor agonists.

Dipivefrine causes a decrease in aqueous production and increases outflow. It was used in the treatment of open-angle glaucoma and ocular hypertension but has since been replaced.

Dopexamine is a synthetic analogue related to dopamine with activity at D1 and D2 receptors as well as at β2 receptors. It is used in patients with severe congestive heart failure, sepsis, and shock.

Other options:

B. Fenoldopam is a peripheral D1 agonist with moderate affinity for α2-adrenergic receptors. It is a rapidly acting vasodilator that is used in severe hypertension.

D. Mirabegron is a β3-adrenergic receptor agonist which is used for bladder incontinence. Activation of this receptor in the bladder leads to detrusor muscle relaxation and increased bladder capacity. This action prevents voiding and provides relief for those with an overactive bladder and urinary incontinence.

Solution to Question 49:

Sildenafil acts by inhibiting phosphodiesterase-5 (PDE-5) and is used in the treatment of erectile dysfunction.

PDE-5 inhibitors cause the accumulation of cGMP in the corpus cavernosum, which leads to the relaxation of smooth muscles of penile arteries that fill the corpus cavernosum, thereby improving erectile function in patients with erectile dysfunction.

In addition to erectile dysfunction, sildenafil can be used in the treatment of pulmonary arterial hypertension.

Adverse effects include headache, flushing, nasal congestion, blue-green tinting of vision, and erections lasting more than 4 hours.

Sildenafil is contraindicated in patients using nitrate vasodilators, which could result in dangerously low blood pressure.

Solution to Question 50:

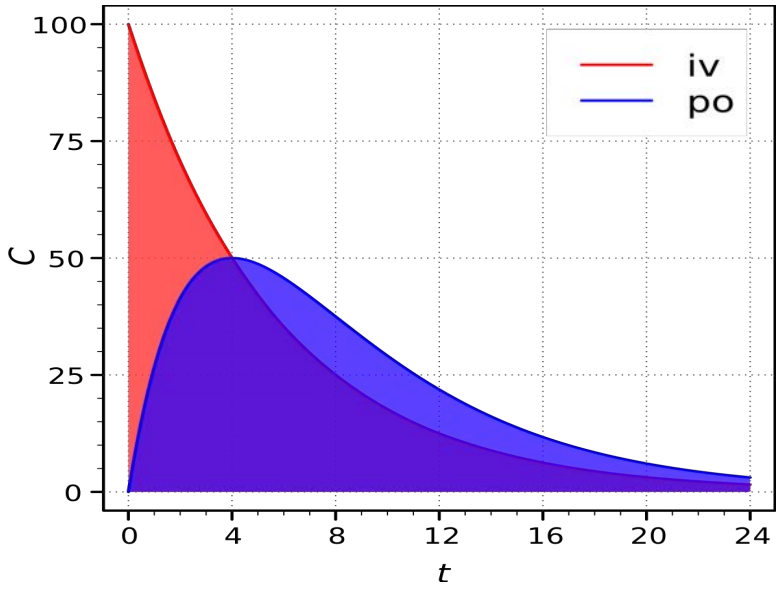
The correct option among the following is A, C, and D.

Bioavailability is defined as the fraction of a drug reaching systemic circulation in an unchanged form after administration by any route. The area under the blood concentration-time curve (AUC) is proportional to the dose and the extent of bioavailability for a drug.

Bioavailability (F) = Quantity of drug reaching systemic circulation/Quantity of drug administered

Bioavailability depends on two factors, absorption and 1st pass metabolism. The bioavailability of the drug injected intravenously is 100%. But it is lower after oral ingestion because of incomplete absorption and first-pass metabolism in the intestinal wall or liver and lies between 5% to <100%. The bioavailability of subcutaneous and intramuscular routes lies between 75% to ≤100%.

The image given below shows the difference between the bioavailability of drugs injected intravenously (IV) and administered per orally (PO). Note the area under the respective curves shaded in red and blue colors which represent the absorption of the drug.



Solution to Question 51:

In this hypertensive patient with hyperkalemia, losartan must be stopped.

Losartan is competitive angiotensin I (AT1) receptor antagonist, which binds to the AT1 receptor with high affinity. Uses of losartan are:

• Antihypertensive

• Renoprotective drug in diabetes mellitus

• Stroke prophylaxis

• Portal hypertension in cirrhosis without compromising renal function

• Anti-aggregant as it is a competitive antagonist of the thromboxane A2 receptor.

Hyperkalemia is an important side effect of ARBs. Losartan appears to be a safe and efficacious agent to lower serum uric acid levels in patients with hyperuricemia.

Option A: Gingival hyperplasia and ankle swelling are side effects of calcium channel blockers like amlodipine. Ankle edema occurs due to increased hydrostatic pressure in the capillaries present in the dependent parts of the body. This is due to reflex constriction of postcapillary vessels. Other common side effects of amlodipine include headache, dizziness, and abdominal pain.

Option B: Metoprolol is a cardioselective beta blocker. Cardioselective beta blockers are less likely to cause hyperkalemia as an adverse effect. The risk of metoprolol-induced hyperkalemia is increased if the patient is also diabetic.

Option D: Furosemide is a loop diuretic. It acts by inhibiting the Na+-K+-2Cl- symporter in the thick ascending limb of the loop of Henle resulting in increased excretion of sodium, potassium, and chloride. Hypokalemia, hyperuricemia, hypocalcemia, and hypomagnesemia are the important side effects.

Solution to Question 52:

Varenicline is the most effective oral drug for smoking cessation.

Nicotine is the principal constituent of tobacco responsible for its addictive behaviour. Varenicline works by blocking the effects of nicotine on the brain. It blocks $\alpha 4$, and $\beta 2$ nicotinic acetylcholine receptor subtypes and inhibits dopaminergic activation produced by smoking through their partial agonism. It decreases the craving and withdrawal syndrome that occurs with cessation attempts. It prevents nicotine stimulation of the mesolimbic dopamine system associated with nicotine addiction, thus helping to occlude the rewarding effect of smoking.

Varenicline is prescribed only to patients 18 years or older. It is taken orally and the dose taken is 0.5 mg once daily on days 1 to 3, increased to 0.5 mg twice daily on days 4 through 7, and 1 mg twice daily after day 8 for 11 weeks. Therapy should start one week before the target quit date. It can be continued for another 12 weeks (1 mg BD) to maintain abstinence.

The adverse effects include nausea, disturbed sleep, sleepwalking, agitation, drowsiness, and constipation, and may also increase the risk of pancreatitis. Varenicline has also been implicated in specific skin syndromes such as Stevens-Johnson syndrome, erythema multiforme, and photosensitivity. Varenicline can cause renal failure and kidney stones, thus renal function must be monitored.

The FDA has issued a warning about mood and behavioural changes associated with its use, and there is some evidence of increased cardiovascular risk.

Cevimeline is a muscarinic agonist with an affinity for both M1 and M3 receptors on the lacrimal and salivary glands. While M1 activation results in increased secretion, M3 activation results in smooth muscle contraction, and expulsion of the secretions. Cevimeline enhances lacrimal secretions in Sjogren's syndrome.

Solution to Question 53:

The correct option is Option C: 1-a, 2-d, 3-b, 4-c

Quinidine is a class IA anti-arrhythmic agent. Class 1a agents are sodium channel blockers with significant potassium channel blocking properties. This slows conduction and prolongs the QRS duration and action potential duration.

Digoxin is a Na+ K+ ATPase inhibitor that works by increasing AV node refractoriness.

Esmolol is a β-receptor-blocker and a class II antiarrhythmic.

Ibutilide is a class III anti-arrhythmic agent. It works by blocking K+ channels.

Solution to Question 54:

The drug that increases trabecular outflow is netarsudil.

Netarsudil is a rho-kinase inhibitor used in the treatment and management of glaucoma and ocular hypertension. It lowers the intra-ocular pressure directly through the relaxation of the trabecular meshwork, leading to an increase in aqueous outflow. It also reduces aqueous humor production.

Netarsudil ophthalmic solution is instilled in one drop into the affected eye once daily in the evening. Adverse effects are conjunctival hyperemia, and corneal verticillata.

Other options:

Option A- Timolol is a non-selective β-blocker that decreases the IOP by reducing the aqueous humor production through the blockade of the β-receptors on the ciliary epithelium. Ocular adverse effects are allergy, decreased corneal sensation, and punctate keratitis.

Option C- Brimonidine is a selective alpha-2 agonist which decreases aqueous synthesis and increases uveoscleral outflow. It can cross the blood-brain barrier and, hence, causes drowsiness and CNS depression. It is contraindicated in infants and children.

Option D- Acetazolamide is a topical carbonic anhydrase inhibitor that decreases IOP by reducing aqueous formation. The main adverse effect is the bitter taste following administration. It is contraindicated in people with allergies to sulfonamide antibiotics.

Solution to Question 55:

Finasteride is used to treat male pattern baldness acts by inhibiting 5-alpha reductase.

Finasteride is a competitive inhibitor of the 5-alpha-reductase enzyme that inhibits the conversion of testosterone into its active form dihydrotestosterone (DHT).

Finasteride inhibits type 2 5-alpha reductase within the hair follicle and reduces the production of DHT. Hence, it is used in the treatment of male pattern hair loss. But, new hair growth will be lost when finasteride is discontinued, similar to minoxidil.

On long-term use (nearly 6 months), it produces an effect by reducing prostatic epithelial cell proliferation, thereby reducing the size of the prostate and improving urine flow.

Adverse effects of finasteride:

• Decreased libido

• Erectile dysfunction

• Ejaculation disorder and decreased ejaculate volume

Finasteride is highly teratogenic and pregnant women should not be exposed to the drug because of the potential for inducing genital abnormalities in male fetuses.

Solution to Question 56:

Rituximab is a monoclonal antibody that acts against CD20 B-cell antigen expressed on the surface of B-lymphocytes, plasma cells, and B-cell lymphomas.

It promotes apoptosis through transmembrane signalling as well as by antibody dependent and complement dependent cytotoxicity. It is used in the treatment of B-cell lymphoma, non-Hodgkin lymphoma, and chronic lymphocytic leukemia. It can be used both as a single agent as well as in combination with cytotoxic chemotherapy.

Adverse effects are infusion reactions like chills, fever, urticarial rashes, pruritus, dyspnea, and hypotension. Pretreatment with antihistaminics and corticosteroids prevents the reactions.

Solution to Question 57:

New drug application is filed after phase 3 of clinical trials.

Other options:

Option A: Phase 4 clinical trials are also called post-marketing surveillance.

Option C: Phase 2 trials are the first round of trials in patients.

Option D: Phase 1 trials are done in healthy volunteers.

Pharmacology NEET 2022

Question 1:

A male patient with chronic obstructive pulmonary disease (COPD) was prescribed theophylline. He noticed that his urine output had increased the following day. This action of the drug is mediated through which of the following receptors?

a) Interleukin-10

b) Histone deacetylase

c) Adenosine A1

d) Beta 2 adrenergic receptors

Question 2:

Which of the following drugs is not likely to cause a pleural pathology?

a) Metformin

b) Methysergide

c) Bleomycin

d) Nitrofurantoin

Question 3:

A patient with deep vein thrombosis was started on a new drug. After 2 days, he presented with the given finding. Which of the following drugs is implicated in causing the above condition?

a) Warfarin

b) Heparin

c) Dabigatran

d) Rivaroxaban

Question 4:

A patient undergoing chemotherapy was given an antiemetic, after which he developed symptoms like acute dystonia, bradykinesia, and tremors. Which of the following drugs would have caused these symptoms?

a) Ondansetron

b) Metoclopramide

c) Meclizine

d) Scopolamine

Question 5:

A young patient started to take a weight loss medication that acts by inhibiting fat absorption from food. After a few weeks, she developed easy bruising and increased menstrual bleeding. Deficiency of which of the following vitamins is responsible for her condition?

a) Vitamin E

b) Vitamin K

c) Vitamin B6

d) Vitamin D

Question 6:

A woman presenting with symptoms of urinary tract infection was prescribed a drug that causes tendon rupture and arthropathy. What is the mechanism of action of the drug?

a) DNA gyrase inhibition

b) Ribosomal inhibition

c) Cell wall synthesis inhibition

d) Inhibition of folic acid synthesis

Question 7:

A patient was brought to the emergency with a history of consumption of 8 tablets of digoxin. On examination, he was unstable and his heart rate was 56 bpm. ECG showed a 3rd-degree heart block. What is the next step in the management of this patient?

a) Antibody against digoxin

b) Lidocaine

c) DC cardioversion

d) Phenytoin

Question 8:

An elderly man, who is a known case of diabetic nephropathy, presented to the emergency with palpitations and chest discomfort. ECG showed tall T-waves. Laboratory investigations showed elevated potassium levels. Which of the following drugs will cause the shift of potassium back into the cell?

a) Epinephrine

b) Glucagon

c) Atropine

d) Lactic acid

Question 9:

A patient with a pituitary tumor that overproduced growth hormone underwent surgical removal of the tumor. The resection was found to be incomplete. What is the first-line treatment for this patient?

a) Leuprolide

b) Goserelin

c) Nafarelin

d) Octreotide

Question 10:

A middle-aged male patient presents with protrusion of the chin, excessive sweating, impaired glucose tolerance, and enlargement of hands and feet. Which of the following is a growth hormone receptor antagonist used to treat this condition?

a) Octreotide

b) Pegvisomant

c) Cabergoline

d) Olcegepant

Question 11:

A diabetic patient presented with rhinitis and facial swelling. An intranasal biopsy revealed the presence of broad-based aseptate hyphae with branching at right angle. Evidence of vascular invasion was present. What will be the drug of choice for this condition?

a) Fluconazole

b) Amphotericin B

c) Ketoconazole

d) Griseofulvin

Question 12:

A tuberculosis patient on anti-tubercular treatment presents with a tingling sensation and paresthesia in the lower limbs. He is not a diabetic and occasionally consumes alcohol. Which of the following vitamins must be supplemented to this patient?

a) Vitamin B6

b) Vitamin B12

c) Vitamin B2

d) Vitamin B3

Question 13:

An elderly woman received a botox injection for the treatment of wrinkles. Which of the following is the mechanism of action of botulinum toxin?

a) Inhibits the release of acetylcholine

b) Release of noradrenaline at synaptic cleft

c) Selectively and irreversibly inhibits nicotinic receptors

d) Stimulates muscarinic and nicotinic receptors

Question 14:

Which of the following is a PCSK9 inhibitor?

a) Evolocumab

b) Ezetimibe

c) Bempedoic acid

d) Clofibrate

Question 15:

An elderly man presents with rigidity and tremors. On examination, he has blank facial expressions. Which of the following drugs can be used to manage this condition?

a) Clozapine

b) Donepezil

c) Selegiline

d) Haloperidol

Answer Key

Question No.	Correct Option

1	c
2	a
3	a
4	b
5	b
6	a
7	a
8	a
9	d
10	b
11	b
12	a
13	a
14	a
15	c

Detailed Explanations

Solution to Question 1:

An increased urine output after administering theophylline is due to the antagonism at adenosine A1 receptors.

The adenosine A1 receptors are present in the afferent arteriole of the glomeruli. When activated, they cause vasoconstriction that reduces the glomerular filtration rate (GFR) and renal blood flow. This reduces urine output. Antagonistic action on these receptors will cause an increased GFR and renal blood flow and hence increased urine output.

Methylxanthines like theophylline and aminophylline are the bronchodilators used mainly in chronic obstructive pulmonary disease (COPD) and bronchial asthma. The pharmacological actions of theophylline are:

• It inhibits phosphodiesterase (PDE) non-selectively, thereby increasing cellular cAMP and cGMP, causing bronchodilation.

• Adenosine causes bronchoconstriction by releasing histamine and leukotrienes. Theophylline antagonizes adenosine A1 receptors and causes bronchodilation.

• It increases IL-10 release, which has anti-inflammatory actions.

• It causes a decrease in gene transcription of pro-inflammatory cytokines.

• It promotes apoptosis of granulocytes and thereby, reduces the inflammatory load in the airways.

Adverse effects of theophylline:

• Headache, nausea, and vomiting (due to inhibition of PDE4)

• Increased acid secretion (due to PDE inhibition)

• Diuresis (due to inhibition of adenosine A1 receptors)

• Cardiac arrhythmias (due to inhibition of cardiac PDE3 and antagonism of cardiac A1 receptors).

• Seizures (due to central A1 receptor antagonism).

Theophylline is mainly metabolized mainly by the enzyme CYP1A2. Therefore, it has various drug interactions, which include:

• Agents that lower its plasma level are smoking, phenytoin, rifampicin, and phenobarbitone.

• Drugs that increase its plasma level are erythromycin, ciprofloxacin, oral contraceptives, and allopurinol.

Solution to Question 2:

Metformin is not associated with pleural pathology.

Metformin belongs to the biguanides class of oral hypoglycemic agents. It acts by activation of AMP-dependent protein kinase (AMPK). This results in reduced hepatic glucose production.

Side effects of metformin are lactic acidosis, gastrointestinal disturbance, and vitamin B12 deficiency.

Contraindications for metformin include :

• GFR <30 ml/min

• Unstable CHF

• Radiographic contrast studies

• Hospitalized patients who cannot take anything orally

• Acidosis

Other options:

Option B: Methysergide is a serotonin(5-HT) receptor antagonist. It was used for the treatment of migraine prophylaxis and carcinoid syndrome. But its use has been discontinued due to side effects like abdominal, pulmonary and endocardial fibrosis.

Option C: Bleomycin is an anticancer antibiotic used for the treatment of squamous cell cancer and Hodgkin lymphoma. It chelates copper or iron and produces superoxide ions that damage DNA. Side effects are mucocutaneous toxicity and pulmonary fibrosis.

Option D: Nitrofurantoin is a urinary antiseptic. They are used for the treatment of lower urinary tract infections (UTIs). It acts by damaging DNA and inhibiting protein synthesis in susceptible bacteria. Important side effects are gastrointestinal disturbances, liver damage and pulmonary fibrosis.

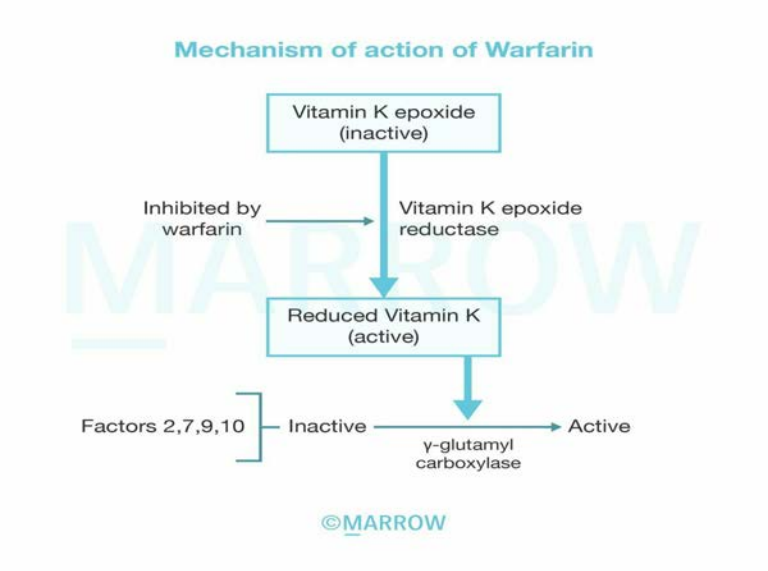
Solution to Question 3:

The clinical scenario of the development of purple toe syndrome, after starting a new drug for the treatment of deep vein thrombosis, is suggestive of the adverse effect of warfarin.

Purple toe syndrome is a rare complication of warfarin therapy. It occurs due to cholesterol microemboli released from atheromatous plaques, which cause arteriolar occlusion. Warfarin must be immediately stopped and replaced with an oral factor Xa inhibitor (e.g. apixaban).

Activation of coagulation factors II, VII, IX, and X and proteins C and S are done by carboxylation of their glutamate residues, with the help of the reduced form of vitamin K as a co-factor. This reduced form of vitamin K needs to be constantly recycled back from its oxidized form for the reaction to continue. This recycling is done by the enzyme vitamin K epoxide reductase, which is competitively inhibited by warfarin. Hence, there will be a reduction in the activation of coagulation factors.

The image below shows warfarin's mechanism of action.



The half-life of proteins C and S are 8 and 24 hours, respectively, which is relatively shorter than the half-lives of other clotting factors, particularly factor II. Therefore, the full antithrombotic effect of warfarin is not achieved for 4 to 5 days. For this reason, warfarin must be bridged with a rapidly acting parenteral anticoagulant, such as heparin, low-molecular-weight heparin (LMWH), or fondaparinux, in patients with thrombosis or at high risk for thrombosis.

Uses of warfarin are acute deep vein thrombosis, pulmonary embolism, and preventing stroke or systemic embolization in patients with a mechanical heart valve.

Adverse effects of warfarin are bleeding, skin necrosis, purple toe syndrome, and fetal warfarin syndrome (hypoplasia of the nose, eye socket, hand bones, and growth retardation).

The therapeutic dose of warfarin is monitored by an INR range of 2-3. Warfarin toxicity can occur when the INR exceeds 4 and can lead to fatal bleeding. Treatment includes withholding warfarin, with vitamin K, and blood transfusions or fresh frozen plasma to replenish clotting factors.

Warfarin, LMWH, and UFH do not accumulate in breast milk and do not have an anticoagulant effect in the newborn. They are compatible with breastfeeding.

Warfarin is mainly metabolized by the CYP2C9 enzyme. Drugs that affect the CYP2C9 enzyme can alter the anticoagulant function of warfarin and these include the following:

Reduced efficacy:

• CYP2C9 activation by drugs: barbiturates, carbamazepine, rifampin

• Oral contraceptives: increase blood levels of clotting factors

Increased efficacy:

• Drugs causing CYP2C9 inhibition:

• Amiodarone

• Azole antifungals

• Cimetidine

• Clopidogrel

• Cotrimoxazole

• Disulfiram

• Isoniazid

• Metronidazole

• Fluoxetine

• Sulfinpyrazone

• Zafirlukast

Other options:

Option B: Heparin acts by activating antithrombin III, thereby inactivating the active form of clotting factors II, IX, X, XI, XII, and XIII. Adverse effects are bleeding and heparin-induced thrombocytopenia (HIT) due to the formation of antibodies against the heparin-platelet complex.

Option C: Dabigatran is a direct thrombin inhibitor. It is used for the prevention of embolism and stroke in patients with atrial fibrillation. Bleeding and dyspepsia are the most important adverse effects.

Option D: Rivaroxaban is a direct inhibitor of factor Xa. It is used for prophylaxis and treatment of deep vein thrombosis. Side effects reported are bleeding, nausea, hypotension, tachycardia, and edema.

Solution to Question 4:

In the above scenario, the patient has developed extrapyramidal adverse effects like acute dystonia, bradykinesia, and tremors. This is likely due to the antagonist action on dopamine receptors by metoclopramide.

Metoclopramide is a prokinetic and antiemetic. It has the following pharmacological actions:

• Dopamine receptor antagonist

• Serotonin (5HT4) receptor agonist

• Serotonin (5HT3) antagonist

• Sensitization of muscarinic receptors on smooth muscle. This results in increased lower esophageal sphincter tone and stimulates gastric antral contractions.

Metoclopramide acts on both the gastrointestinal system and central nervous system. It is used as an upper antiemetic for many types of vomiting, especially migraine, drug-induced, and chemotherapy-induced. It is also used as a prokinetic in gastroparesis to increase gastric emptying.

Adverse effects of metoclopramide are mainly extrapyramidal effects, and these include acute dystonia, Parkinson-like symptoms (tremors, bradykinesia, rigidity), tardive dyskinesia, galactorrhea due to hyperprolactinemia, and methemoglobinemia in neonates.

Extrapyramidal symptoms can be treated by discontinuation of metoclopramide and administration of anticholinergics or antihistaminics.

Other options:

Option A: Ondansetron is a 5-HT3 receptor antagonist. It blocks impulses at the peripheral origin in GIT. It is most commonly indicated for the treatment of postoperative and chemotherapy-induced nausea and vomiting. Headache and dizziness are the common adverse effects.

Option C: Meclizine is a long-acting H1 antihistaminic drug. It is used for seasickness. It is less sedative and less anticholinergic.

Option D: Scopolamine (hyoscine) is a muscarinic antagonist. It blocks neural pathways from the vestibular apparatus in the inner ear to the emetic center in the brainstem. A transdermal patch of scopolamine is used as an antiemetic in motion sickness. Constipation, drowsiness, dry mouth, and blurred vision are the common adverse effects.

Solution to Question 5:

The clinical scenario of easy bruising and increased menstrual bleeding following weight loss medication that inhibits fat absorption from food is suggestive of vitamin K deficiency.

Vitamin K is a fat-soluble vitamin. Hence, drugs that inhibit the absorption of fat (eg; ezetimibe) also inhibit the absorption of fat-soluble vitamin K. The following are the vitamers of vitamin K:

• Phylloquinone (Vitamin K1) is the normal dietary source of Vitamin K that is found in green vegetables.

• Menaquinone (Vitamin K2) is synthesized by intestinal bacteria.

• Menadione (Vitamin K3) is a synthetic compound that is metabolized to phylloquinone.

Vitamin K is required for γ-carboxylation of glutamate residues of clotting factors like prothrombin (factor II), factors VII, IX, and X. Warfarin inhibits γ-carboxylation by preventing the conversion of vitamin K to its active hydroquinone form.

Vitamin K deficiency in adults may be seen in patients with liver disease, obstructive jaundice, malabsorption, and prolonged antimicrobial therapy. Vitamin K deficiency is usually diagnosed

on the basis of an elevated prothrombin time or reduced clotting factors.

Vitamin K deficiency is treated with a parenteral dose of 10 mg followed by 5mg (duration depends on the severity of vitamin K deficiency).

Other options:

Option A: Vitamin E is a fat-soluble vitamin. The levels of vitamin E also will get decreased following taking weight loss medication that inhibits fat absorption from food. But the symptoms of vitamin E deficiency include hemolytic anemia and neuromuscular manifestations.

Option C: Vitamin B6 is a water-soluble vitamin. Drugs that cause vitamin B6 deficiency are isoniazid, hydralazine, cycloserine, penicillamine, and oral contraceptives. Patients usually present with peripheral neuritis, anemia, seborrheic dermatitis, glossitis, lowered seizure threshold, or convulsions (due to fall in brain GABA levels).

Option D: Vitamin D is a fat-soluble vitamin. Vitamin D levels will also decrease following weight loss medication that inhibits fat absorption from food. Patients with vitamin D deficiency will typically develop rickets in children and osteomalacia in adults.

Solution to Question 6:

In the above scenario, the antimicrobial prescribed for urinary tract infection, which has a propensity to cause tendon rupture and arthropathy, is likely to be a fluoroquinolone. The mechanism of action of the drug is DNA gyrase inhibition.

Normally, during replication, to prevent excessive positive supercoiling of the strands, DNA gyrase nicks double-stranded DNA and introduces negative supercoils. Fluoroquinolones, by inhibiting DNA gyrase (in gram-negative bacteria), result in the production of damaged DNA. This is finally digested by exonucleases, resulting in bactericidal action.

Fluoroquinolones inhibit topoisomerase IV in gram-positive bacteria.

Fluoroquinolones are used in the treatment of urinary tract infections, prostatitis, and gastrointestinal, respiratory infections, and as a second-line drug in anti-tubercular therapy. They are avoided in children and pregnant women.

Adverse effects of fluoroquinolones are arthralgia, tendon rupture, Clostridium difficile colitis, dysglycemia, prolonged QT interval, rashes, hallucinations, delirium, and seizures.

Other options:

Option B: Ribosomal inhibition is the mechanism of action of various antimicrobials like tetracyclines, aminoglycosides, chloramphenicol, and macrolides.

Option C: Cell wall synthesis inhibition is done by beta-lactam antibiotics.

Option D: Inhibition of folic acid synthesis is the mechanism of action of sulfonamides and co-trimoxazole.

Solution to Question 7:

Administration of digibind (antibody against digoxin) is the next step in managing this patient. An unstable patient with bradycardia and 3rd-degree heart block following digoxin toxicity should be treated with digibind.

Digibind is a nonimmunogenic antibody used to treat cardiotoxicity due to digoxin. It is nonimmunogenic because it lacks the Fc fragment.

Digoxin is the cardiac glycoside used to treat heart failure and control ventricular rate in atrial fibrillation/flutter.

It inhibits Na+/K+ ATPase, a membrane-bound transporter to increase intracellular sodium. As a result, there is less expulsion of calcium from the cell by the sodium-calcium exchanger (NCX). Increased calcium inside the myocyte leads to an increase in cardiac contractility.

The most common cardiac manifestations of digitalis toxicity are ventricular tachycardia, partial to complete A-V block, severe bradycardia, and atrial fibrillation/flutter.

Factors that increase the risk of digoxin toxicity are:

• Hypokalemia

• Drugs that decrease digoxin elimination (inhibitors of P-glycoprotein) like quinidine

• Renal/hepatic failure

• Thyrotoxicosis

Option B: Lidocaine is commonly used as a local anesthetic. It has anti-arrhythmic properties and is used to suppress ventricular tachycardia caused by digitalis toxicity.

Option C: DC cardioversion is used for tachyarrythmias when pharmacologic treatment fails. It is not used in bradyarrhythmias.

Option D: Phenytoin is an antiepileptic used for the treatment of generalized tonic-clonic seizures and partial seizures. It can also be used for the treatment of polymorphic ventricular tachycardia due to QT prolongation.

Solution to Question 8:

The clinical scenario with ECG showing tall T-waves and elevated serum potassium levels are suggestive of hyperkalemia. Epinephrine will cause the shift of potassium back into the cell.

Epinephrine is an agonist at alpha 1, beta 1, and beta 2 receptors.

The β actions are mediated through cAMP. Epinephrine binds to Gs → ATP and is broken down to cAMP by the enzyme adenylyl cyclase. This results in:

• In the liver and muscle- hyperglycemia and hypokalemia due to potassium uptake in muscle and liver

• In adipose tissue- increased plasma free fatty acids

• In the heart- an increased force of contraction reinforces the positive inotropic action

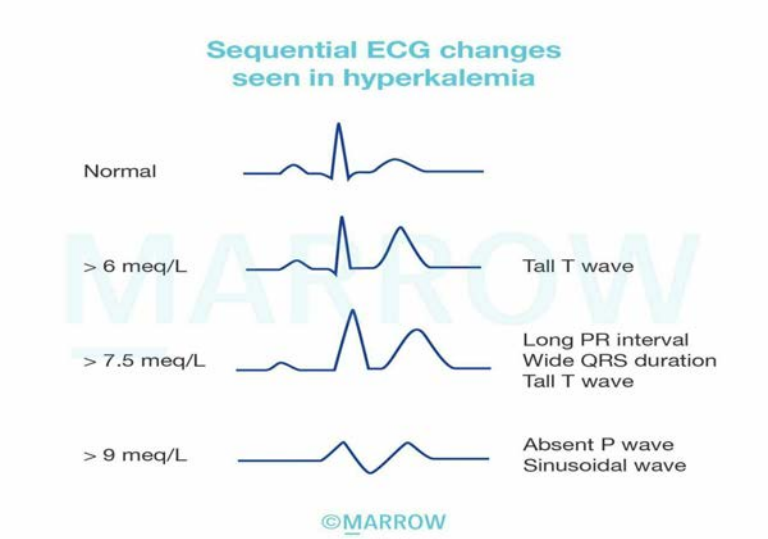
• In pancreatic islets- increases glucagon secretion

Epinephrine is used in anaphylaxis, to prolong the action of local anesthetics, cardiac arrest, and as inhalational epinephrine in the treatment of post-intubation and infectious croup.

Epinephrine is contraindicated in anesthesia with halothane due to the risk of arrhythmias and in patients receiving beta-blockers because a marked rise in BP can occur due to unopposed alpha action.

Hyperkalemia refers to an increase in the levels of serum potassium >5.5mEq/L.

The image given below shows sequential ECG changes seen in hyperkalemia.



Hyperkalemia is a medical emergency and has to be treated when ECG changes are present or severe hyperkalemia (serum K+ >6.5) without ECG changes. Management is as follows:

• Intravenous infusion of 10 ml of 10% calcium gluconate for 2-3 minutes with cardiac monitoring. It helps to antagonize the cardiac effects.

• Intravenous regular insulin 10 units followed by 50mL of 50 % dextrose. This helps in shifting the plasma K+ into the cells.

• Nebulisation with β2 agonists such as albuterol or salbutamol.

• Cation exchange resins, diuretics, and/or dialysis are useful to remove the excess potassium.

Solution to Question 9:

The above scenario with a pituitary tumor producing growth hormone is likely to cause acromegaly in the patient. Octreotide is the first-line treatment for this condition.

Octreotide is a synthetic analog of somatostatin.

Octreotide can be used in the following conditions:

• Acromegaly

• Secretory diarrheas associated with carcinoid, AIDS, cancer chemotherapy, or diabetes- by suppression of hormones that enhance intestinal mucosal secretion.

• Bleeding esophageal varices- reduces hepatic blood flow and helps stop bleeding.

• Dumping syndrome in post gastric surgery patients

Adverse effects of octreotide are:

• Abdominal pain

• Nausea

• Steatorrhea

• Gall stones (due to biliary stasis)

• Hyperglycemia

Other options:

Option A: Leuprolide is a long-acting GnRH agonist. It is used for palliation of carcinoma prostate, uterine fibroids, endometriosis, and precocious puberty. Side effects include hot flashes, decreased bone mineral density, vaginal dryness, and erectile dysfunction.

Option B: Goserelin is also a GnRH agonist used for the treatment of endometriosis, dysfunctional uterine bleeding, and for prostate and breast cancer.

Option C: Nafarelin is a long-acting GnRH agonist. It is used for the treatment of endometriosis, uterine fibroids, and central precocious puberty.

Solution to Question 10:

The clinical features of protrusion of the chin, excessive sweating, impaired glucose tolerance, and enlargement of hands and feet are suggestive of acromegaly. Pegvisomant is a growth hormone receptor antagonist used to treat this condition.

Acromegaly is commonly caused due to growth hormone-secreting somatotroph adenoma. It occurs secondary to mutations of the pituitary-specific gene PIT-1.

Patients present with frontal bossing, increased hand and foot size, mandibular enlargement with prognathism, widened space between the lower incisor teeth, soft tissue swelling resulting in increased heel pad thickness, coarse facial features, and large fleshy nose.

Serum IGF-1 levels (elevated) and GH suppression test with oral glucose are useful in the diagnosis. The levels of GH do not reduce in response to the oral glucose load.

Transsphenoidal surgical resection of the tumor, octreotide, and pegvisomant will be helpful in the management of this condition.

Other options:

Option A: Octreotide is a synthetic analog of somatostatin. It is used for the treatment of acromegaly and secretory diarrhea.

Option C: Cabergoline is a dopamine D2 receptor agonist. It is used as a first-line drug for the treatment of hyperprolactinemia.

Option D: Oglcegepant is a calcitonin gene-related peptide (CGRP) antagonist. It is used for the treatment of migraine.

Solution to Question 11:

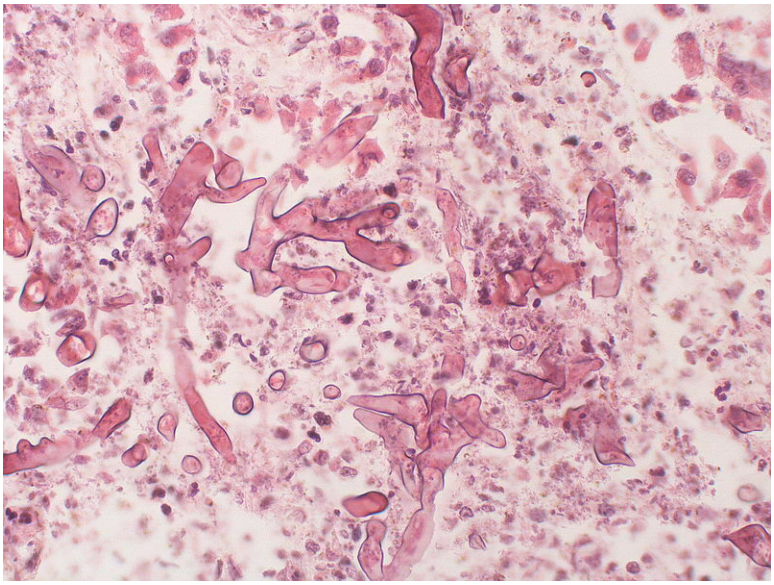
The above scenario and biopsy findings showing broad-based aseptate hyphae with branching at right angles are suggestive of mucormycosis. The drug of choice for mucormycosis is amphotericin B.

Mucormycosis is an opportunistic mycosis. It is typically seen in patients with diabetes mellitus and/or diabetic ketoacidosis and invades blood vessels.

The rhino-orbital-cerebral is the most common form of mucormycosis. Patients present with rhinitis, eye or facial pain, and facial numbness followed by the onset of conjunctival suffusion and swelling along with blurry vision.

Diagnosis is made by biopsy with histopathologic examination. The biopsy shows characteristic wide, ribbon-like aseptate hyphal elements that branch at right angles.

The below image shows biopsy findings seen in mucormycosis.



Treatment of the infection includes 4 steps:

• Initiation of therapy (amphotericin B) as early as possible.

• Surgical debridement.

• Reversal of underlying conditions and risk factors.

• Treatment of underlying malignancy if present.

Amphotericin B binds to ergosterol in the fungal membrane and forms pores or channels in the fungal cell membrane. This allows the leakage of cytosolic molecules and ions, leading to a loss of membrane integrity.

It is a broad-spectrum antifungal that can be used against Candida albicans, Cryptococcus neoformans, Blastomyces dermatitidis, Histoplasma capsulatum, Sporothrix schenckii, Coccidioides immitis, Aspergillus.

Amphotericin B also has antiprotozoal action along with antifungal properties and is effective against Leishmania.

Adverse effects of amphotericin B:

• Infusion-related fever and chills

• Azotemia/nephrotoxicity- all lipid formulations of amphotericin B are less nephrotoxic than conventional amphotericin B

• Renal tubular acidosis

• Renal wasting of potassium and magnesium

• Hypochromic normocytic anemia- due to decreased erythropoietin production from the kidney

Note: Mucormycosis recently emerged as an important superinfection in COVID-19 patients, especially in India. The surge in cases is most likely due to diabetes mellitus and steroid use.

Other options:

Option A: Fluconazole is used for the treatment of candidiasis and cryptococcosis.

Option C: Ketoconazole is used for both dermatophytosis and deep mycosis, but it has been replaced by itraconazole.

Option D: Griseofulvin is used for dermatophytosis. It is effective against the mycotic disease of the skin, hair, and nails due to Microsporum, Trichophyton, and Epidermophyton.

Solution to Question 12:

Vitamin B6 must be supplemented for this patient. The clinical features of tingling sensation and paresthesias in a patient on anti-tubercular treatment are suggestive of the adverse effect of isoniazid.

Isoniazid is the first-line antitubercular drug that inhibits the production of mycolic acid. It is a bactericidal drug against tubercle bacilli.

Adverse effects of isoniazid:

• Peripheral neuritis (paresthesias, numbness, tingling sensation) due to interference with the production of active coenzyme pyridoxal phosphate from pyridoxine. Therefore, pyridoxine 10 mg/day (vitamin B6) is given prophylactically along with isoniazid to prevent neurotoxicity.

• Hepatitis - isoniazid must be stopped at the first sign of hepatotoxicity.

• Rashes

• Anemia

• Arthralgia

Toxicity of isoniazid results in metabolic acidosis and seizures.

Note: Vitamin deficiency in alcoholics includes the following:

• Folate causes megaloblastic anemia. It is treated by supplementation of oral doses of 5-15 mg of folic acid.

• Vitamin B6 results in peripheral neuritis, anemia, and glossitis, and lowers the seizure threshold. It is treated by supplementation of oral doses of 2-5 mg of pyridoxine.

• Thiamine results in Wernicke's encephalopathy. It is treated with 200 mg of intravenous thiamine three times daily, followed by 10 mg/day until complete recovery.

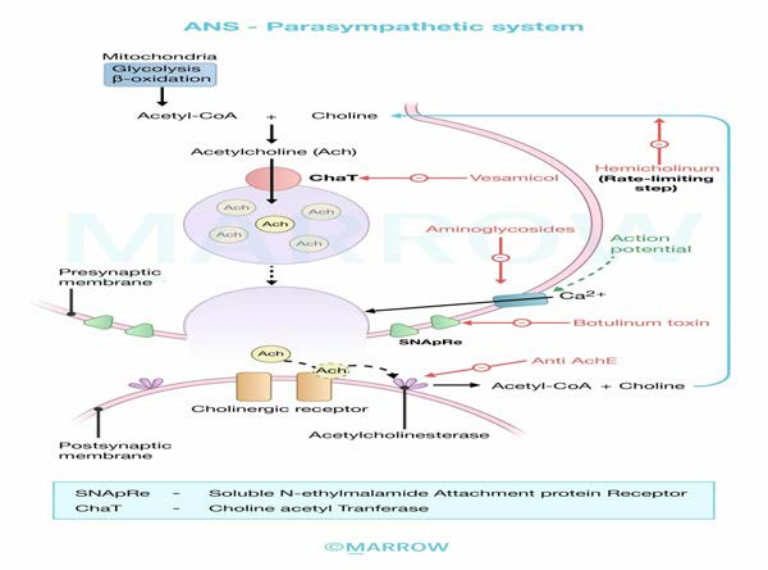
• Vitamin A results in xerophthalmia and night blindness. It is treated with supplementation of oral vitamin A 3000-5000 IU/day.

Solution to Question 13:

The botulinum toxin acts by inhibiting the release of acetylcholine into the synaptic cleft.

Botulinum toxin cleaves SNARE protein, which is involved in the exocytosis of acetylcholine. Thus, it inhibits the release of acetylcholine.

The image given below shows the site of action of botulinum toxin:



This toxin causes a long-lasting loss of cholinergic transmission. Hence, it can be employed for the treatment of several spastic and neurological conditions caused by the overactivity of cholinergic nerves, such as age-related facial wrinkles, blepharospasm, spastic cerebral palsy, spasmodic torticollis, post-stroke spasticity, and axillary hyperhidrosis.

Adverse effects occur due to incorrect injection and overdose; they include ptosis, diplopia, facial swelling, dry mouth, muscle weakness, and respiratory paralysis.

Botulinum toxin is an exotoxin produced by the bacteria Clostridium botulinum. It is responsible for a type of food poisoning called botulism.

Solution to Question 14:

Evolocumab is a PCSK9 inhibitor.

PCSK9 refers to proprotein convertase subtilisin/kexin type 9. They are mainly involved in the downregulation of low-density lipoprotein (LDL) receptors in the liver.

Evolocumab is a monoclonal antibody that inhibits PCSK-9 (proprotein convertase subtilisin/kexin). Inhibition of PCSK-9 prevents the degradation of LDL receptors and thus increases LDL-cholesterol clearance by the liver. They are used in patients with atherosclerotic cardiovascular disease (ASCVD) to decrease LDL levels.

Side effects of PCSK9 inhibitors are injection-site reactions, nasopharyngitis, urinary tract infection, and upper respiratory tract infection and it does not increase the risk of myopathy.

Other options:

Option B: Ezetimibe inhibits cholesterol absorption by enterocytes in the small intestine. It lowers the total and LDL-C levels.

Option C: Bempedoic acid inhibits adenosine triphosphate-citrate lyase (ACL) and results in decreased LDL in patients not responding to statin therapy.

Option D: Clofibrate binds to PPAR-alpha and causes stimulation of fatty acid oxidation and increased LPL synthesis. This results in reduced triglycerides, LDL and increased high-density lipoprotein (HDL) levels. It causes myopathy when combined with statins and is associated with an increased risk of gallstone formation.

Solution to Question 15:

The clinical features of rigidity, tremors, and blank facial expressions are suggestive of Parkinson's disease. Monoamine oxidase-B (MAO-B) inhibitors like selegiline are used for the treatment of Parkinson disease.

Normally, MAO-B oxidizes dopamine. Selegiline is a selective and irreversible MAO-B inhibitor. Therefore, it increases dopamine levels in the brain. It is used as an adjuvant to levodopa in Parkinson's disease. It prolongs and enhances the action of levodopa.

Adverse effects of selegiline are postural hypotension, nausea, confusion, involuntary movements, and psychosis. Selegiline is contraindicated in patients with convulsive disorders.

Other options:

Option A: Clozapine is an atypical antipsychotic that selectively blocks dopamine (D4) receptors in the brain. It is used in the treatment of refractory schizophrenia. Agranulocytosis and metabolic syndrome are the important adverse effects.

Option B: Donepezil is a reversible cholinesterase inhibitor used for the treatment of Alzheimer's disease.

Option D: Haloperidol is a typical antipsychotic used for the treatment of acute schizophrenia, Huntington’s disease, and Gilles de la Tourette syndrome.

Pharmacology NEET 2023

Question 1:

A bronchial asthma patient on inhalational steroids presented with white patchy lesions on the tongue and buccal mucosa. What is the drug that can be used to treat this condition?

a) Clotrimazole

b) Griseofulvin

c) Terbinafine

d) Flucytosine

Question 2:

A pregnant woman with a history of bronchial asthma is in the third stage of labor. Which of the following drugs should be avoided in the management of postpartum hemorrhage in this mother?

a) Carboprost

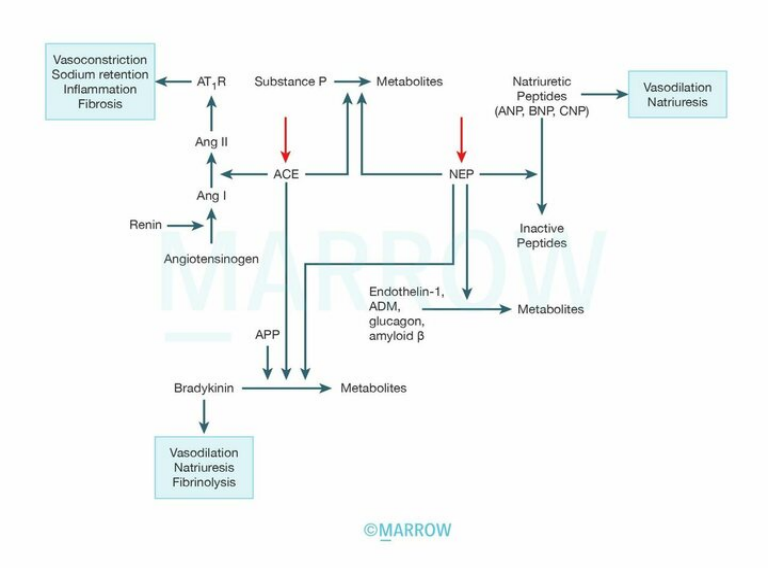
b) Oxytocin

c) Dinoprostone

d) Methyl ergometrine

Question 3:

Name the drug that acts on both the marked areas.



a) Sacubitril

b) Omapatrilat

c) Losartan

d) Nesiritide

Question 4:

A patient with a previous history of myocardial infarction and ventricular arrhythmia is on treatment for a few months. He developed fatigue, dyspnea, and weight gain. He had also developed pulmonary fibrosis. Which of the following drugs is responsible for the above-mentioned side effects?

a) Amiodarone

b) Atenolol

c) Aspirin

d) Spironolactone

Question 5:

A young female comes to the emergency department after consuming 100 tablets of aspirin. What should be the next step in management?

a) N-acetyl cysteine to replenish glutathione stores

b) Pralidoxime

c) Glucagon to control bradycardia and hypoglycemia

d) Give sodium bicarbonate to alkalize urine

Question 6:

A chronic smoker was on nicotine replacement therapy and clonidine tablets for smoking de-addiction. He stopped taking clonidine tablets and now presents with a headache. What is the reason behind this condition?

a) Postural hypotension

b) Receptor upregulation

c) Rebound hypertension

d) Receptor hypersensitivity

Question 7:

A patient with recurrent attacks of gout was started on a therapy that inhibits the synthesis of uric acid. His symptoms were reduced after therapy. Which drug was he started on?

a) Probenecid

b) Colchicine

c) Diclofenac

d) Allopurinol

Question 8:

A patient with a malignancy is undergoing chemotherapy. The platelet counts were reduced after the previous cycle of chemotherapy. Which of the following drugs can be used in the treatment of this patient?

a) Oprelvekin (IL-11)

b) Filgrastim

c) Erythropoietin

d) Amifostine

Question 9:

The true statement among the following is _____

a) The dose of telmisartan should be reduced in renal failure but not in hepatic failure.

b) The dose of irbesartan should be reduced in case of mild-moderate hepatic failure and renal failure.

c) The dose of candesartan should be reduced in mild-moderate liver failure but not in renal failure.

d) Losartan acts as thromboxane A2 antagonist and inhibits platelet aggregation.

Question 10:

A patient given digoxin started having side effects like nausea and vomiting. The serum concentration of digoxin was 4 mg/dL. The plasma therapeutic range is 1 mg/dL. If the half-life of digoxin is 40 hours, how long one should wait before resuming the treatment?

a) 40 hours

b) 80 hours

c) 120 hours

d) 140-180 hours

Question 11:

A patient comes to the casualty with organophosphate poisoning. He was started on atropine infusion and pralidoxime. After 2 hours, the patient had a sudden rise in temperature. What is the likely cause of fever?

a) Atropine toxicity

b) Side effect of pralidoxime

c) Due to organophosphate poisoning

d) Idiopathic

Question 12:

The mechanism of action of tissue plasminogen activator is _____

a) Inhibit extrinsic pathway

b) Inhibits platelet aggregation

c) Enhance fibrin degradation

d) Inhibit clot formation

Answer Key

Question No.	Correct Option
1	a
2	a
3	b
4	a
5	d
6	c
7	d
8	a
9	d
10	b
11	a
12	c

Detailed Explanations

Solution to Question 1:

The given clinical scenario of white patchy lesions on the tongue and buccal mucosa in a patient using inhalational steroids is oral candidiasis. The drug that can be used for the treatment is clotrimazole.

MDI results in the deposition of steroids in the oropharyngeal space, which can cause cough, dysphonia, and oropharyngeal candidiasis.

Clotrimazole is a topical imidazole used in the treatment of tinea infections like ringworm. It is particularly used for the treatment of vaginitis as a once-daily application because of its long-lasting residual effect.

For oral candidiasis, 10 mg troche of clotrimazole is allowed to dissolve in the mouth 3-4 times a day. Alternatively, lotion or gel is applied and swirled in the mouth for as long as possible. Side effects are local irritation and a burning sensation.

Other options:

Option B: Griseofulvin acts by inhibiting microtubule assembly, disrupting the fungal cell division. It is mainly used against dermatophytes and is the drug of choice for tinea capitis in children. It is not effective against Candida.

Option C: Terbinafine acts by inhibiting epoxidation of fungal squalene that reduces ergosterol biosynthesis. It is helpful for treating nail onychomycosis and tinea capitis.

Option D: Flucytosine acts by inhibiting fungal DNA synthesis. It is used exclusively in combination with amphotericin B for cryptococcal meningitis.

Solution to Question 2:

The drug that should be avoided in the management of postpartum hemorrhage in this mother with a history of bronchial asthma is carboprost.

Carboprost is an analog of PGF2α. It is used in obstetrics to induce second-trimester abortions and to control postpartum hemorrhage. Vomiting, diarrhea, and bronchoconstriction can occur.

Contraindications of carboprost:

Absolute	Relative
AsthmaPulmonary hypertensionSuspected amniotic fluid embolism	Pre-eclampsiaRenal diseaseLiver diseaseHeart disease

Other options :

Option B: Oxytocin is the first-line drug to prevent and treat PPH according to WHO guidelines. It is administered by intravenous route and may lead to hypotension and reflex tachycardia.

Option C: Dinoprostone is a prostaglandin E2 analog used for cervical ripening, induction of labor, and in atony treatment. It should be avoided in patients with a history of asthma, glaucoma, or myocardial infarction. One major adverse effect is uterine hyperstimulation.

Option D: Ergot derivatives are used in the control of postpartum uterine bleeding. It is given intramuscularly and is effective within 1–5 minutes. It is given at the time of delivery of the placenta or immediately after if bleeding is significant. Side effects are gastrointestinal disturbances like diarrhea, nausea, and vomiting.

Solution to Question 3:

The drug that acts on both the marked areas is omapatrilat.

Omapatrilat is a dual inhibitor of neutral endopeptidase and Angiotensin-converting enzyme (ACE). It decreases angiotensin II and increases atrial and brain natriuretic peptide, promoting vasodilation, diuresis, and anti-hypertrophic effect.

Other options:

Option A - Sacubitril is a neprilysin inhibitor. It reduces the breakdown of natriuretic peptides such as ANP, BNP, and CNP, thereby increasing their levels. Sacubitril combined with valsartan reduces mortality in heart failure with reduced ejection fraction (HFrEF).

Option C - Losartan is the angiotensin receptor blocker used in the treatment of hypertension. Hyperkalemia is an important side effect of ARBs. It appears to be a safe and efficacious agent to lower serum uric acid levels in patients with hyperuricemia.

Option D - Nesiritide is a recombinant human brain natriuretic peptide (BNP). It causes vasodilatation and natriuresis. It is administered intravenously and used in acute decompensated heart failure.

Solution to Question 4:

The drug that is responsible for the above-mentioned side effects is amiodarone.

Amiodarone is a class III antiarrhythmic drug. The most serious adverse effect during chronic amiodarone therapy is pulmonary fibrosis, which is rapidly progressive and fatal. The side effects of amiodarone include:

• Pulmonary fibrosis

• Hypotension, depressed myocardial function

• Corneal microdeposits

• Hepatotoxicity

• Neuropathies

• Photosensitivity

• Hypo- or hyperthyroidism

Other options:

Option B: Atenolol is a beta-1 selective antagonist. Bradycardia, fatigue, and cold extremities are common adverse effects. It is used in combination with a diuretic, in elderly patients with isolated systolic hypertension. CNS side effects like depression and nightmares are seen.

Option C: Aspirin is a nonsteroidal anti-inflammatory drug (NSAID) that blocks the formation of thromboxane A2 by acetylation of COX1. Through this mechanism, it shows antipyretic, analgesic, and anti-inflammatory actions. Higher doses can result in bleeding.

Option D: Spironolactone is a potasium-sparing diuretic. It is a competitive inhibitor of the mineralocorticoid receptor in the late distal tubule and collecting duct of the kidneys. It promotes sodium diuresis but maintains the body's potassium levels. It is contraindicated in patients with hyperkalemia. Side effects are gynecomastia, impotence, decreased libido, and menstrual irregularities.

Solution to Question 5:

The next step in the management of this patient who consumed 100 tablets of aspirin is to give sodium bicarbonate to alkalize the urine.

Alkalinization of urine will be helpful in the removal of aspirin, which is a weakly acidic drug and is susceptible to ion trapping in the urine. It is done by administration of sodium bicarbonate in 1

L of 5% dextrose in water (D5W). It is infused intravenously at twice the maintenance fluid requirements.

Alkalinization of urine is contraindicated in renal failure or if fluid administration may worsen pulmonary edema or congestive heart failure.

Other options:

Option A: N-acetyl cysteine is used as an antidote for the treatment of paracetamol poisoning which replenishes glutathione stores in the liver.

Option B: Pralidoxime is also used in organophosphate poisoning. It regenerates active acetylcholinesterase and relieves skeletal muscle end-plate block. It is usually used as an adjuvant to atropine.

Option D: Glucagon is used in beta-blocker toxicity.

Solution to Question 6:

The mechanism that causes headache in this patient, who stopped taking clonidine is rebound hypertension.

Clonidine is an alpha-2 receptor agonist and a centrally acting antihypertensive agent. It treats high blood pressure by stimulating presynaptic α2 receptors in the vasomotor center in the brainstem. This binding has a sympatholytic effect, by suppressing the release of norepinephrine and other sympathomimetics.

Abrupt withdrawal after long-term therapy can result in rebound hypertension, restlessness, and sympathetic overactivity. Dry mouth and sedation are the major side effects of clonidine. It can also cause impotency and constipation.

Phentolamine is used for the control of hypertension due to clonidine withdrawal.

Solution to Question 7:

Allopurinol which inhibits uric acid synthesis is the likely drug that was added to the regimen.

It is a purine antimetabolite and a competitive inhibitor of the xanthine oxidase enzyme. It prevents the conversion of hypoxanthine and xanthine to uric acid reducing plasma uric acid levels. The metabolite of allopurinol called oxypurinol is a non-competitive inhibitor of xanthine oxidase.

It is used in the treatment of hyperuricemia in patients with gout and also in patients with hematological malignancies about to undergo chemotherapy.

Other options:

Option A: Probenecid is a uricosuric agent that promotes the excretion of uric acids by inhibiting the organic anion transporter, particularly URAT-1 in the renal tubule. It is used to decrease the body pool of urate in patients with chronic gout. It is used as an adjuvant to allopurinol in chronic gout and hyperuricemia. Plenty of fluids are given to avoid urate

calculi formation.

Option B: Colchicine is an antimitotic drug that is used in the treatment of acute gout. It acts by inhibiting microtubule and spindle formation. Side effects are nausea, vomiting, myelosuppression, aplastic anemia, and rhabdomyolysis.

Option C: Diclofenac is a commonly used NSAID that has analgesic, antipyretic, and anti-inflammatory activities. It acts by inhibiting the cyclooxygenase-2 enzyme. Side effects are rashes, fluid retention, edema, and renal function impairment.

Solution to Question 8:

The most probable diagnosis for this patient is chemotherapy-induced thrombocytopenia. Oprelvekin can be used in the treatment of this patient.

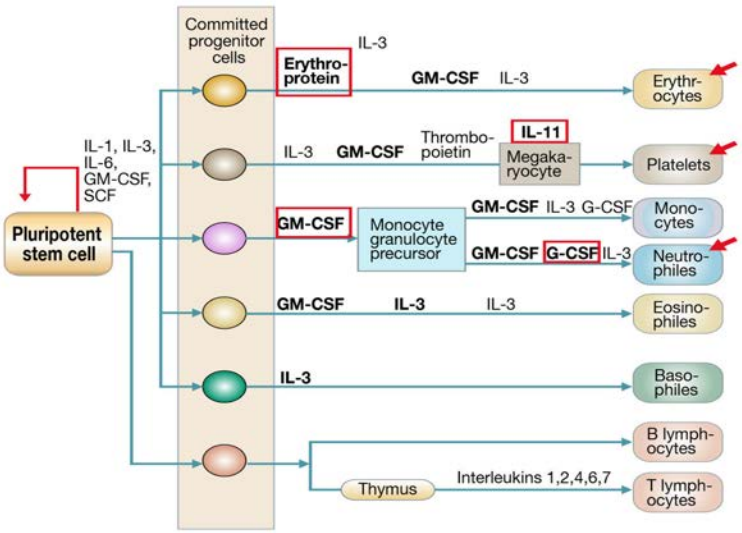
Oprelvekin is an IL-11 analog used in the treatment of chemotherapy-induced thrombocytopenia. It increases thrombopoiesis. It is used in the treatment of thrombocytopenia due to non-myeloid malignancies. Important adverse effects are fluid retention, tachycardia, palpitation, edema, and shortness of breath.

Other options:

Option B: Filgrastim is a granulocyte-colony-stimulating factor (G-CSF) that is used for the treatment of severe neutropenia after high-dose cancer chemotherapy.

Option C: Epoetin alfa and darbepoetin alfa are recombinant human erythropoietin. They are used in the treatment of anemias associated with surgery, AIDS, cancer chemotherapy, and certain chronic inflammatory conditions.

Option D: Amifostine is used in the reduction of nephrotoxicity associated with cisplatin.



Solution to Question 9:

The true statement is losartan acts as a thromboxane A2 antagonist and inhibits platelet aggregation.

Losartan is a competitive angiotensin receptor antagonist. It binds to the AT1 receptor with high affinity. It is also a competitive antagonist of the thromboxane A2 receptor and attenuates platelet aggregation.

Losartan is the angiotensin receptor blocker used in the treatment of hypertension. Hyperkalemia is an important side effect of ARBs. It appears to be a safe and efficacious agent to lower serum uric acid levels in patients with hyperuricemia.

Other options:

Option A: The clearance of telmisartan is mainly by biliary secretion. The clearance is affected by hepatic insufficiency. The dose of telmisartan should be reduced in hepatic failure but not in renal failure.

Option B: Irbesartan is metabolized to glucuronide conjugate, and is cleared mainly by biliary excretion. The plasma clearance is unaffected by either renal or mild-to-moderate hepatic insufficiency. Hence, the dose need not be reduced in either of the cases.

Option C: The plasma clearance of candesartan is by biliary excretion and renal elimination. The clearance is affected by renal insufficiency. Hence, the dose should be reduced in case of renal failure and not in mild-moderate liver failure.

Solution to Question 10:

The treatment can be resumed after 80 hours.

The half-life (T1/2) is the time it takes for the plasma concentration of the drug to be reduced by 50%. In the given scenario, the half-life of digoxin is given as 40 hours. The serum concentration of digoxin is given as 4 mg/dL.

After 40 hours, the serum concentration of digoxin becomes 2 mg/dL (half of the initial concentration), and after 80 hours, it will be reduced to 1 mg/dL. So, to reach a serum concentration of 1 mg/dL (therapeutic range), it will take 80 hours.

Solution to Question 11:

The most likely cause of fever in this patient is atropine toxicity.

The clinical scenario is suggestive of organophosphate consumption and atropine is used for its management. Atropine is a muscarinic receptor antagonist, and it competitively blocks the acetylcholine at muscarinic receptors.

Organophosphates are powerful acetylcholinesterase inhibitors. It is absorbed by inhalation or through the skin. Mucous membranes and the gastrointestinal tract are also the sites for absorption.

The predominant initial signs are of muscarinic excess which includes: (DUMBBELSS)

• Diarrhoea

• Urination

• Miosis

• Bronchospasm

• Bradycardia

• Emesis

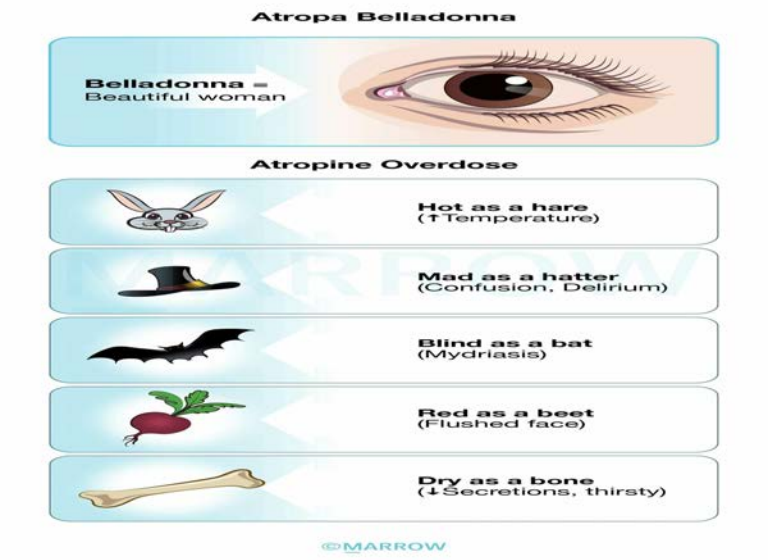
• Lacrimation

• Salivation

• Sweating

Nicotinic manifestations include twitching of eyelids, tongue, and facial muscles which then leads to paralysis. CNS stimulation results in headache, tremors, ataxia, coma, and death.

Atropine in larger doses can lead to atropine toxicity. The features are depicted in the following image:



Solution to Question 12:

The mechanism of action of the tissue plasminogen activator is to enhance fibrin degradation.

Tissue plasminogen activators activate plasminogen bound to fibrin, and catalyze the conversion of plasminogen to plasmin, resulting in increased formation of plasmin. This results in fibrinolysis of formed thrombus (thrombolysis).

It is indicated in pulmonary embolism with hemodynamic instability, acute ischemic stroke, and acute myocardial infarction. Recombinant variants of t-PA like reteplase and tenecteplase have a longer half-life.

All thrombolytics can cause bleeding, which may be counteracted by the administration of antifibrinolytics, such as aminocaproic acid and tranexamic acid.

Pharmacology INI-CET 2023

Question 1:

A patient underwent a hysterectomy and was given morphine in the post-operative period and in the ward for pain. She now presents with respiratory depression and pin point pupils. What is the drug used to treat this condition?

a) Naloxone

b) Pethidine

c) Atropine

d) Buprenorphine

Question 2:

Drug used for trastuzumab-resistant her 2 positive breast cancer is:

a) Vismodegib

b) Lapatinib

c) Vemurafenib

d) Erlotinib

Question 3:

Nomogram used for vancomycin dosing is?

a) Salazar

b) Halsted

c) Rummack-mathew

d) Matzke

Question 4:

Which of the following is true statement regarding lithium?

a) It is not absorbed from the stomach

b) It can cause fine tremors in the therapeutic range

c) Approved for the treatment of absent seizures

d) It is not teratogenic

Question 5:

Match the following

a) A-2, B-3, C-4, D-1

b) A-3, B-4, C-1, D-2

c) A-4, B-2, C-3, D-1

d) A-1, B-2, C-3, D-4

Question 6:

True about therapeutic index of a drug is:

a) Denotes safety and efficacy after experiments on humans

b) Denotes safety and efficacy in the population

c) Denotes safety and efficacy in an individual

d) Ratio of median lethal dose in 50% of population to median effective dose in 50% of population

Question 7:

Osimertinib is used in NSCLC with which of the following mutation?

a) T790M mutation

b) L858R mutation

c) T890M mutation

d) M790T mutation

Question 8:

A patient was started on a drug for mood disorder and he developed priapism. The causative drug is:

a) Trazodone

b) Venlafaxine

c) Bupropion

d) Mirtazapine

Question 9:

Cyclosporine-induced cholestasis is due to which receptor?

a) MDR 1

b) BRCA

c) MRP 1

d) OAT1B1

Question 10:

A diabetic patient was started on a drug that decreased her HbA1C from 7.6 to 6.7. She started complaining of itching around vulvovaginal area . What was the most likely drug she was started on?

a) Acarbose

b) Canagliflozin

c) Linagliptin

d) Liraglutide

Question 11:

An anti-diabetic drug causes a decrease in HbA1C by causing an increase in GIP and GLP-1 levels and a decrease in glucagon levels. It is an oral drug causing a reduction in both pre and post-prandial glucose. The drug is:

a) Pramlinitide

b) Alogliptin

c) Liraglutide

d) Metformin

Question 12:

What is true about keynote 189 trial?

a) Pembrolizumab plus chemotherapy used in NSCLC

b) Pembrolizumab used in NSCLC

c) Nivolumab plus chemotherapy used in NSCLC

d) Nivolumab is used in NSCLC

Question 13:

Which of the following is not a mechanism for thalidomide teratogenicity?

a) Release of reactive oxygen species and free radicles

b) Supression of angiogenesis

c) Cereblon binding

d) Inhibition of IL2, IL4, IL5

Question 14:

Which is a rare but very severe side effect of clozapine that requires regular monitoring?

a) Suicidal tendency

b) Agranulocytosis

c) Myocarditis

d) Cerebral bleeding

Question 15:

Which of the following newly approved anti-diabetic drugs can be given for heart failure with reduced ejection fraction and impaired renal function?

a) Empaglifozin

b) Degludec

c) Linagliptin

d) Rosiglitazone

Question 16:

A patient diagnosed with ulcerative colitis presents with 2-3 episodes of bloody stools per day. What should be given to manage this patient ?

a) Budesonide

b) Azathioprine

c) 6-mercaptopurine

d) 5-aminosalicylic acid

Question 17:

A 25 year old male patient presents with several purpuric skin lesions and is diagnosed with idiopathic thrombocytopenic purpura. Which of the following tyrosine kinase inhibitors can be used in his condition?

a) Eltrombopag

b) Romiplostim

c) Bosutinib

d) Fostamatinib

Question 18:

A 40-year-old woman with multidrug-resistant tuberculosis presents with fatigue, constipation, weight gain, and neck swelling. Which of the following drugs is implicated in this case?

a) Pyrazinamide

b) Ethionamide

c) Cycloserine

d) Streptomycin

Question 19:

A patient on amitriptyline was found in an unconscious state. Which of the following does not suggest amitriptyline toxicity?

a) Arrhythmias

b) Confusion

c) Hypothermia

d) Mydriasis

Question 20:

Which of the following is beneficial in reducing the painful crisis of sickle cell anemia?

a) Hydroxyurea

b) Methotrexate + leukovorin

c) Methionine

d) Eltrombopag

Question 21:

What is the most useful drug to treat doxorubicin induced cardiotoxicity?

a) Dexrazoxane

b) Dexamethasone

c) Aprepitant

d) Amifostine

Question 22:

An elderly patient with dementia is not compliant with oral medications. Which of the following will be beneficial in this case?

a) Donepezil

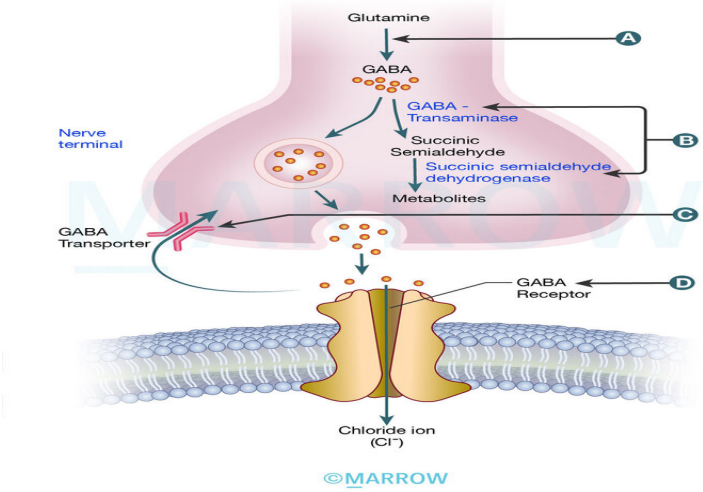
b) Rivastigmine

c) Galantamine

d) Memantine

Question 23:

Sodium valproate has an inhibitory action at which of the following sites?



a) A

b) B

c) C

d) D

Question 24:

Which of the following drugs acts via the ATP-binding cassette transporter?

a) Verapamil

b) Diltiazem

c) Nifedipine

d) Amlodipine

Question 25:

A 12 year old boy presents with complaints of profuse watery stools and an elevated WBC count of 16000 cells/mm3. He has been on treatment with amoxicillin for the past 1 week. What is the treatment of choice for his condition?

a) Fidaxomycin

b) Clindamycin

c) Zanamivir

d) Cilastatin

Question 26:

Which of the following mood stabilisers causes hepatotoxicity and hyperammonemia?

a) Lithium

b) Valproate

c) Carbamazepine

d) Topiramate

Question 27:

Which of the following pathogens is correctly matched with its intrinsic drug resistance?

a) Aspergillus niger - Voriconazole

b) Candida krusei - Fluconazole

c) Candida Glabrata - Amphotericin B

d) Sporothrix - Itraconazole

Question 28:

A child was receiving a blood transfusion. At what serum iron level will desferrioxamine be administered to him?

a) 350 mcg/dL

b) 400 mcg/dL

c) 450 mcg/dL

d) 500 mcg/dL

Question 29:

A patient on fluoxetine was started on a pain control drug for neuropathic pain. He developed an episode of syncope after 2 weeks. ECG reveals QT interval of 477 ms. Which of the following is the causative drug?

a) Methadone

b) Morphine

c) Meperidine

d) Propoxyphene

Question 30:

All of the following side effects are more commonly seen with carbamazepine than oxcarbazepine except

a) Rashes

b) Hyponatremia

c) Blood dyscrasia

d) Hepatitis

Question 31:

A patient with hemophilia on antiretroviral therapy is brought in altered mental status following complaints of nausea, vomiting and headache. Which of the following medications was he taking?

a) Lopinavir

b) Tipranavir

c) Darunavir

d) Ritonavir

Question 32:

A 60-year-old patient with chronic kidney disease suddenly develops chest pain and palpitations. He had previously complained about feeling weak for the past week. Serum potassium was found to be 6.5mEq/L. Which of the following is likely to be found in this patients ECG?

a) Tall peaked T waves

b) Flat T waves

c) Tall QRS complexes

d) Prolonged PR intervals

Question 33:

Which of the following drugs can be used in diabetic neuropathy, post herpetic neuralgia and spinal cord injury?

a) Amitriptyline

b) Phenytoin

c) Carbamazepine

d) Pregabalin

Question 34:

Which of the following antibiotics acts by inhibiting the 50s ribosome?

a) Aztreonam

b) Daptomycin

c) Linezolid

d) Rifampicin

Detailed Explanations

Solution to Question 1:

The drug of choice for the reversal of respiratory depression is naloxone. Naloxone is a competitive antagonist at μ-opioid receptors and rapidly reverses the effects of opioid toxicity when administered.

Opioid overdose symptoms:

• Triad of coma, respiratory depression, and pinpoint pupils (miosis).

• Hypotension, bradycardia

• Shallow breathing

• Hypothermia

Naloxone is a pure opioid antagonist which reverses all effects, except sedation. Naloxone is also used for reversing neonatal asphyxia due to opioid usage in labor.

Other options

Option B - Meperidine (pethidine) is a mu-opioid receptor (MOR) agonist. It has a strong analgesic effect on the central nervous system. It is mainly used as an analgesic but can also be

used in post-anesthetic shivering. It has a greater ability to enter the CNS and produce analgesia at lower systemic concentrations compared to morphine. Therefore, constipation, urinary retention, and nausea are less frequent compared to morphine.

Meperidine can cross the placenta and cause significant respiratory depression in the fetus. In patients or addicts who are tolerant to the depressant effects of meperidine, large doses repeated at short intervals may produce an excitatory syndrome that includes hallucinations, tremors, muscle twitches, etc.

Option C -Atropine is an anticholinergic drug. It acts through reversible, competitive inhibition of the postsynaptic muscarinic acetylcholine receptors. It is indicated in the treatment of organophosphate/muscarinic poisoning, in bradycardia, and to reduce salivary secretions.

The adverse effects of atropine are due to the antimuscarinic effects, including xerostomia, blurring of vision, photophobia, tachycardia, flushing, warm, dry skin, constipation, urinary retention, anhidrosis, delirium, and coma. Intoxication with atropine results in all the above symptoms along with convulsions, and circulatory collapse due to respiratory failure. Death may occur secondary to respiratory paralysis.

Option D - Buprenorphine is a partial μ agonist and an antagonist at δ and κ receptors. It is used as an analgesic and in the management of opioid dependence.

Solution to Question 2:

Lapatinib is used for trastuzumab-resistant HER-2 neu-positive breast carcinoma.

Lapatinib is an orally bioavailable, small-molecule inhibitor of the EGFR and HER2 tyrosine kinases. Lapatinib is metabolized by CYP3A4.

Lapatinib in combination with capecitabine is approved for the treatment of patients with metastatic HER2-positive trastuzumab-refractory breast cancer. Lapatinib is also used in combination with the aromatase inhibitor letrozole to treat postmenopausal women with hormone receptor-positive, metastatic breast cancer that overexpresses HER2.

Frequent adverse effects include acneiform rash, diarrhea, cramping, and exacerbation of gastroesophageal reflux. Cardiac toxicity appears less pronounced than with trastuzumab, although lapatinib should be used with caution in combination with cardiotoxic drugs. A dose-dependent prolongation of the QT interval has been reported; thus, careful monitoring of patients with heart disease is recommended. Hepatotoxicity that may be severe has been observed.

Trastuzumab is a monoclonal antibody that inhibits the HER2 receptor. It is used in the treatment of HER2-positive breast cancer.

Other options:

Option A: Vismodegib is a hedgehog pathway inhibitor used to treat metastatic and locally advanced BCCs.

Option C: Vemurafenib is a BRAF inhibitors used in metastatic melanoma and thyroid cancers with BRAF V600E mutation.

Option D: Erlotinib is a protein kinase antagonists which is the first line treatment of non-small cell lung carcinoma with EGFR deletion of exon 19 or L858R mutation

Solution to Question 3:

The nomogram used for vancomycin dosing is the Matzke nomogram.

The Matzke nomogram includes dosing intervals ranging from 0.5 to 12 days on a continuum of CLcr(Creatinine clearance) values from 0 to 120 mL/min. It is designed to guide the determination of the initial empiric dose and interval of intravenous (IV) vancomycin in hospitalized adults who are not receiving hemodialysis. The nomogram does not apply to patients who exhibit highly variable vancomycin pharmacokinetics. These patients include the critically ill, those with burn injuries affecting more than 20 percent of their body surface, patients with rapidly changing renal function, pregnant women, those with liver failure/ascites, individuals at the extremes of weight, patients who are acutely post-transplant, and those with cystic fibrosis

The Rumack-Matthew nomogram uses the serum acetaminophen concentration, in relation to the time after ingestion, to assess potential hepatotoxicity after a single, acute ingestion of acetaminophen.

Solution to Question 4:

The true statement about lithium is it can cause fine tremors in the therapeutic range.

Lithium has a very narrow therapeutic index of 0.8-1.2 mEq/L. The severity of lithium toxicity is often divided into the following three grades:

A fine tremor is common in patients taking lithium at therapeutic doses. Therapeutic lithium tremor is generally symmetric, limited to the arms, and nonprogressive. The tremor from lithium toxicity is coarser and more disabling, may also affect the legs, and occurs with other symptoms of toxicity. Other adverse effects include mental confusion, hypothyroidism, nephrogenic diabetes insipidus, and edema. Lithium use in early pregnancy causes Ebstein anomaly in the fetus(Option D). Fetal lithium exposure is associated with neonatal goiter, CNS depression, hypotonia (floppy baby syndrome), and cardiac murmur.

As lithium is readily dialyzed, lithium overdose or toxicity is treated with hemodialysis.

Lithium is a mood stabilizer with a very narrow therapeutic index. Lithium is administered orally. Lithium is almost completely absorbed from the GI tract(Option A). It is the first line of management in bipolar disorder.

Lithium is also used in the management of mania and has anti-suicidal properties. (Option C) It has a narrow therapeutic index, and blood levels in excess of this may cause symptoms of toxicity. Therapeutic drug monitoring is done by measuring lithium levels 12 hours after the last dose.

Grade	Sr. lithium concentration(in mEq/L)	Symptoms
Mild symptoms	1.5-2.5	Nausea, vomiting,tremor, and fatigue
Moderate intoxication	2.5-3.5	Confusion, agitation, deliriu m, tachycardia, and hyperton ia
Severe intoxication	>3.5	Coma,seizures, hyperthermia, and hypotension

Solution to Question 5:

Mirabegron is a β3-adrenergic receptor agonist which is used for bladder incontinence. Activation of this receptor in the bladder leads to detrusor muscle relaxation and increased bladder capacity. This action prevents voiding and provides relief for those with an overactive bladder and urinary incontinence.

Indacaterol is a very long acting beta 2 agonists (V-LABA) and can be used once daily in COPD maintenance.

Betaxolol is a β1 selective third-generation β-blocker with additional calcium entry blockade activity and a slight membrane-stabilizing property. It does not have agonist activity.

Isoproterenol is a non-selective beta agonist (β1=β2) with no α action. The direct action on cardiac β1 receptors causes an increased risk of tachycardia and arrhythmias. The decrease in peripheral vascular resistance is due to β2 action causing a fall in diastolic blood pressure. Isoproterenol currently may be used as a cardiac stimulant in patients with bradycardia or heart block, particularly in anticipation of inserting an artificial cardiac pacemaker.

A. Mirabegron	3. Beta 3
B. Indacaterol	4. Beta 2
C. Betaxolol	1. Beta 1
D. Isoproterenol	2. Beta

Solution to Question 6:

The therapeutic index of a drug denotes the safety and efficacy of the drug in the population (option B), not the individual (option C).

The therapeutic index is calculated with the following equations:

LD50/ED50 or TD50/ED50

where LD50 is the median lethal dose, TD50 is the mean toxic dose, and ED50 is the median effective dose

The therapeutic index (TI) describes a relationship between the doses of a drug that causes lethal or toxic effects with the dose that causes therapeutic effects. It is also called the therapeutic ratio. The therapeutic index is used to assess the safety of the drug administered.

Median lethal dose (LD50) and median toxic dose (TD50)

• LD50 is the dose of the drug at which 50% of the experimental animals die

• In human trials, TD50 can be considered. It is the dose of the drug that causes adverse effects in 50% of the population (Option D)

• The larger the LD50 or TD50, the safer the drug

Median effective dose (ED50) is the quantity of a drug that can produce the desired therapeutic effects in 50% of the population.

Therapeutic window refers to a range of concentrations at which the likelihood of efficacy is high and the probability of adverse effects is low.

Note: Option D is incorrect as it does not make the necessary distinction that the therapeutic index is the ratio of the median lethal dose in 50% of animals (as the human population cannot be used for lethal studies) to the median effective dose in 50% of the population. LD50 is measured in animals, not in humans. Option B is a better choice.

Solution to Question 7:

The T790M mutation in the EGFR gene is known to cause resistance to first and second-generation EGFR inhibitors. Osimertinib, as a third-generation EGFR inhibitor, is effective against this resistance, hence it is often used for patients with the T790M mutation after they've progressed on first or second-generation EGFR inhibitors.

The question seems to be asking specifically for the mutation that osimertinib is particularly known for being used against, and that would be the T790M mutation.

Osimertinib is a kinase inhibitor that is approved for

• Patients with metastatic non small cell lung carcinoma(NSCLC) that has progressed after prior EGFR TKI treatment and is positive for the EGFR T790M mutation.

• First-line treatment of patients with metastatic NSCLC and adjuvant therapy after resection of NSCLC with EGFR exon 19 deletions or exon 21 L858R mutations

So, osimertinib is used both for the L858R mutation and T790M mutation in different settings. But T790M mutation is often highlighted because of its association with resistance to first and second-generation EGFR inhibitors, and because osimertinib can overcome this resistance.

Osimertinib is administered orally and is a substrate of CYP3A. The drug is primarily eliminated in the feces and to a lesser extent in the urine. Concurrent administration of inducers of CYP3A4 may necessitate an increase in the dose.

The adverse effects after osimertinib treatment are leukopenia, diarrhea, skin rash, interstitial lung disease, QTc prolongation, and left ventricular dysfunction.

Solution to Question 8:

Trazodone causes priapism.

Trazodone is an atypical antidepressant drug. It is a serotonin receptor antagonist. Other drugs which belong to this include nefazodone, mirtazapine, and mianserin. Low doses of trazodone (50–200 mg) have been used widely, both alone and concurrently with SSRIs or SNRIs, to treat insomnia. Trazodone use is associated with priapism in rare instances. Intracavernous injection of phenylephrine can be used to treat priapism.

Other options:

Option B: Venlafaxine is a second-line drug used in generalized anxiety disorder. It belongs to the class of serotonin-norepinephrine reuptake inhibitors (SNRIs). Venlafaxine can induce sustained diastolic hypertension (diastolic blood pressure >90 mmHg at consecutive weekly visits). Venlafaxine also is associated with an increased risk of perinatal complications.

Option C: Bupropion is a first-line drug used for nicotine cessation and has the added benefit of causing weight loss. Weight gain is commonly seen after stopping nicotine use. Hence this drug can be used in this patient as it treats both of these.

Option D: Mirtazapine is used in major depressive disorder. It increases appetite and causes significant weight gain.

Solution to Question 9:

Cyclosporine induced cholestasis is due to MDR1 transporter.

ABC transporters such as MRP2, MDR1, BCRP, BSEP, and MDR3 in the bile canalicular membrane of hepatocytes mediate the efflux (excretion) of drugs and their metabolites, bile salts, and phospholipids against a steep concentration gradient from liver to bile. This primary active transport is driven by ATP hydrolysis.

Cyclosporine, an MDR1 substrate can cause cholestatic liver injury through the following mechanisms:

• Competitive inhibition of ATP dependent transporters.

• Inhibition of intrahepatic vesicle transport and targeting of ATP dependent transporters to the canalicular membrane.

• Impairment of bile secretion partly by increasing canalicular membrane fluidity without affecting the expression of canalicular transporters.

Cyclosporine is an immunomodulatory drug that inhibits calcineurin activity by forming a complex with cyclophilin, a cytoplasmic-receptor protein present in target cells, to form a cyclosporine-cyclophilin complex.Calcineurin is a calcium/calmodulin-dependent phosphatase required for the induction of T cell lymphokine production and proliferation.

This drug-receptor complex specifically and competitively binds to and inhibits calcineurin, a calcium and calmodulin-dependent phosphatase. This, in turn, inhibits the translocation of a family of transcription factors (NF-AT), leading to reduced transcriptional activation of cytokine genes for interleukin (IL)-2, tumor necrosis factor (TNF)-alpha, IL-3, IL-4, CD40L, granulocyte-macrophage colony-stimulating factor, and interferon-gamma. Ultimately, the proliferation of T lymphocytes is reduced, resulting in immunomodulation.

Its uses are as follows:

• In solid organ transplantation, to prevent organ rejection in kidney, liver, and heart allogeneic transplants

• In patients with rheumatoid arthritis, when the disease has not adequately responded to methotrexate

• Cyclosporine reportedly is effective in Behc■et's disease, acute ocular syndrome, endogenous uveitis, atopic dermatitis, inflammatory bowel disease, and nephrotic syndrome.

Adverse effects of cyclosporine include a decrease in glomerular filtration rate (GFR) and metabolic disturbances like hypomagnesemia, hyperkalemia, dyslipidemia, gynecomastia, hypertrichosis; neurotoxicity in the form of convulsions. There is an increased risk of developing skin and lymphoproliferative malignancies in cyclosporine-treated psoriasis patients.

Solution to Question 10:

In the above clinical scenario, the most likely cause of itching around the vulvovaginal area is canagliflozin. The side effects associated with canagliflozin are urinary tract infections, genital mycotic infections due to the high glucose content of the urine, increased risk of fractures, and lower extremity amputations.

Canagliflozin is a sodium-glucose transporter 2 (SGLT-2) inhibitor. Other SGLT-2 inhibitors include dapagliflozin and empagliflozin. They act by inhibiting the SGLT-2 transporter which is present on the proximal segment of the renal tubule. It is responsible for the reabsorption of 80-90% of filtered glucose. It inhibits glucose reabsorption resulting in glycosuria and a change in the renal threshold.

SGLT2 inhibitors can cause mild weight loss and reduction in blood pressure. Drugs like empagliflozin and canagliflozin are found to reduce major cardiovascular events.

The common side effects include urinary tract infections and genital mycotic infections due to the high glucose content of the urine. There is a risk of the development of diabetic ketoacidosis. It increases the risk of fractures and lower limb amputations due to the creation of an imbalance with the minerals and circulating parathormone and vitamin D. Since SGLT2 inhibitors depend on the rate of glucose filtration to be effective, potency decreases if given in stage 3 kidney disease (GFR 60–30 mL/min).

Other options:

Option A: Acarbose is an alpha-glucosidase inhibitor. It reduces the intestinal absorption of glucose by inhibiting the intestinal brush border enzyme, alpha-glucosidase. These drugs also increase GLP-1 levels in circulation. They reduce post-prandial glucose levels.

Option C: Linagliptin is a dipeptidyl-peptidase-4 (DPP-4) inhibitor. It is used in type 2 diabetes as monotherapy or in combination therapy when metformin is not tolerated or contraindicated. It binds extensively to plasma proteins and is cleared primarily by the hepatobiliary system. Hence, no dosage adjustment is needed in renal failure. Dipeptidyl peptidase-4 inhibitors enhance the release of insulin postprandially, decrease glucagon, and thereby lower mealtime as well as fasting glucose. They are weight neutral.

Option D: Liraglutide is also a GLP-1 receptor agonist and is given only in the subcutaneous injectable form. It was recently approved in the treatment of obesity.

Solution to Question 11:

Alogliptin is a dipeptidyl peptidase-4 (DPP) inhibitor. Glucagon-like peptide (GLP) and glucose-dependent insulinotropic polypeptide (GIP) are both incretins that promote the exocytosis of insulin into circulation. Both these incretins are rapidly inactivated by dipeptidyl peptidase. So, inhibition of dipeptidyl peptidase enhances the action of incretins and facilitates insulin release. Dipeptidyl peptidase-4 inhibitors enhance the release of insulin postprandially, decrease glucagon, and thereby lower mealtime as well as fasting glucose.

Other DPP-4 inhibitors include saxagliptin, linagliptin, alogliptin, and vildagliptin. They are weight neutral.

DPP-4 inhibitors are associated with severe joint pain which reduces on discontinuation of the drug. Linagliptin is cleared primarily by hepatobiliary system, with little renal clearance. Only saxagliptin is metabolized by the liver and must be used in lower doses if used along with a cytochrome p450 enzyme inhibitor drug. Other drugs are renally excreted and hence must be used with caution in renal insufficiency.

Other options:

Option A - Pramlintide is an amylin agonist. It reduces postprandial glycemia and leads to weight loss.

Option C - Liraglutide is also a GLP-1 receptor agonist and is given only in the subcutaneous injectable form. It was recently approved for the treatment of obesity.

Option D - Metformin belongs to the biguanides class of oral hypoglycemic agents. It acts by activation of AMP-dependent protein kinase (AMPK). This results in reduced hepatic glucose production. Side effects of metformin are lactic acidosis, gastrointestinal disturbance, and vitamin B12 deficiency.

Solution to Question 12:

Keynote 189 trial is a efficacy and safety study of pembrolizumab and chemotherapy in metastatic non-small cell carcinoma of lung.

Keynote 189 trial is an efficacy and safety study of pembrolizumab (MK-3475) combined with pemetrexed/platinum chemotherapy versus pemetrexed/platinum chemotherapy alone in participants with advanced or metastatic nonsquamous non-small cell lung cancer (NSCLC) who

have not previously received systemic therapy for advanced disease. Participants will be randomly assigned to receive pembrolizumab combined with pemetrexed/platinum.

Methods

In this double-blind, phase 3 trial, patients were randomly assigned (in a 2:1 ratio). 616 patients with metastatic nonsquamous NSCLC without sensitizing EGFR or ALK mutations who had received no previous treatment for metastatic disease to receive pemetrexed and a platinum-based drug plus either 200 mg of pembrolizumab or placebo every 3 weeks for 4 cycles, followed by pembrolizumab or placebo for up to a total of 35 cycles plus pemetrexed maintenance therapy. Crossover to pembrolizumab monotherapy was permitted among the patients in the placebo-combination group who had verified disease progression. The primary endpoints were overall survival and progression-free survival, as assessed by a blinded, independent central radiologic review.

Conclusions

In patients with previously untreated metastatic nonsquamous NSCLC
without EGFR or ALK mutations, the addition of pembrolizumab to standard chemotherapy of pemetrexed and a platinum-based drug resulted in significantly longer overall survival and progression-free survival than chemotherapy alone.

Solution to Question 13:

Thalidomide does not cause teratogenicity by inhibition of IL2, IL4, and IL5.

The mechanism of thalidomide teratogenicity include oxidative stress, anti-angiogenesis, and thalidomide-binding protein, cereblon which has a role in the development of cerebral tissues and because its expression in the hippocampus among other areas is associated with memory and learning processes (CRBN). Fetal thalidomide exposure causes phocomelia. This disorder is associated with underdeveloped limbs and absent pelvic bones. Both upper and lower limbs are affected, and a part of the limbs may be missing. Fused fingers and missing thumbs are also seen. Thalidomide was originally used for the treatment of pregnancy-associated morning sickness but was withdrawn due to this adverse effect. It is now used for the treatment of erythema nodosum leprosum.

Thalidomide is an immunomodulator. Thalidomide absorption from the GI tract is slow and highly variable. It distributes throughout most tissues and organs, without significant binding to plasma proteins. Thalidomide and its metabolites are excreted in the urine, while the nonabsorbed portion of the drug is excreted unchanged in feces.

Common adverse effects of thalidomide include sedation and constipation. However, one of the most serious adverse effects is peripheral sensory neuropathy, characterized by asymmetrical, painful, peripheral paresthesia with sensory loss. Symptoms often present as numbness of the toes and feet, muscle cramps, weakness, signs of pyramidal tract involvement, and carpal tunnel syndrome.

Solution to Question 14:

Agranulocytosis is a rare but very severe side effect of clozapine that requires regular monitoring.

A patient who is on clozapine should undergo regular hematological monitoring due to the risk of agranulocytosis. Avoid combining clozapine with other agranulocytosis-causing drugs like carbamazepine, phenytoin, propylthiouracil, and sulfonamides.

Adverse effects of clozapine are:

• Sedation and weight gain- H1 antagonism

• Syncope, tachycardia, hypotension- α1 antagonism

• Hypersalivation/sialorrhea- M4 agonism

• Seizures- dose-dependant

• Agranulocytosis- dose-independent

Clozapine reduces the seizure threshold thus increasing the risk of seizures. Clozapine, an atypical antipsychotic, is an antagonist of 5HT2A, D1, D3, D4, and α-receptors. Clozapine is used in treatment-resistant schizophrenia, suicidal patients with schizophrenia, severe psychotic depression, and Huntington's disease.

Solution to Question 15:

Empaglifozin, which is a sodium-glucose transporter-2 (SGLT-2) inhibitor has been recently approved for use in patients with Heart Failure with Reduced Ejection Fraction, and can be initiated in patients with impaired renal function with estimated glomerular filtration rate > 20 mL/min/1.73 m2.

Empagliflozin works by inhibiting the sodium-glucose co-transporter-2 (SGLT-2) in the proximal renal tubules resulting in reduced reabsorption and increased urinary excretion of glucose. The glucose-lowering effect is independent of insulin. Empagliflozin acts as a diuretic and natriuretic by reducing sodium and volume load, causing intravascular contraction. Empagliflozin is also associated with weight loss, with reductions in blood pressure without increasing heart rate. Empagliflozin has been found to decrease the risk of mortality from cardiovascular causes in diabetic patients.

SGLT-2 inhibitors have a cardioprotective effect resulting from improved cardiac cell metabolism, improvement of ventricular loading mechanism, reduction of cardiac cell necrosis and fibrosis. It also has a renoprotective property.

Except for empaglifozin which can be used in chronic kidney disease, use of other SGLT-2 inhibitors might lead to acute kidney injury and should be avoided in patients with renal failure. Side effects of empaglifozin includes dehydration, euglycemic diabetic ketoacidosis, urinary tract infections, genital mycotic infections, hypoglycemia and necrotizing fasciitis.

Side effects of SGLT-2 inhibitors include dehydration, hyperkalemia, worsening of diabetic ketoacidosis, increased risk of fractures, leg and foot amputation with canagliflozin, and a possible increased risk of bladder cancer with dapagliflozin. Dapagliflozin has also been recently approved by the FDA for treatment of Heart failure with Reduced Ejection Fraction in both diabetic and non-diabetic patients, it has been associated with increased risk of bladder cancer and breast cancer.

Other options :

Option B : Degludec is a form of long acting insulin, and is not indicated for the treatment of heart failure.

Option C : Linagliptin is a dipeptidyl peptidase-4 (DPP-4) inhibitor, which enhances the action of incretins that promote the release of insulin into circulation. Dipeptidyl peptidase-4 inhibitors enhance the release of insulin postprandially, decrease glucagon, and thereby lower mealtime as well as fasting glucose. Linagliptin is safe to use in chronic kidney disease as it is cleared primarily by hepatobiliary system, but is not approved for heart failure.

Option D : Rosiglitazone is a thiazolidinedione, which activates PPAR-γ receptors in adipose tissue and skeletal muscles. These are insulin sensitizers and increase insulin-mediated glucose uptake in patients with type 2 diabetes. Rosiglitazone is currently banned in India as it has shown an increased risk of developing myocardial infarction, stroke, congestive heart failure, and death.

Solution to Question 16:

5-aminosalicylic acid is is effective in inducing and maintaining remission and is considered to be the first line agents for mild to moderate ulcerative colitis, seen in this patient with 2-3 bloody stools per day.

Treatment of ulcerative colitis differs based on the severity of the disease and involves medical and surgical management. Patients with mild to moderate disease are treated with topical or systemic 5-aminosalicylate drugs such as Salazopyrine/Sulfasalazine and Mesalamine (5 ASA) which are first-line therapy. Glucocorticoids (option A), immunosuppressants, and biologics are effective in patients with moderate to severe disease.

Azathioprine and cyclosporin are used as steroid-sparing agents. Anti-TNF alpha inhibitors (infliximab, adalimumab) can be used as anti-inflammatories.

Surgery is recommended for patients who do not improve after medical treatment or with toxic megacolon, and perforation. Indications for elective surgery include failure of medical therapy, growth retardation, extraintestinal disease, and malignant change.

Ulcerative colitis is an inflammatory bowel disease resulting in superficial erosions confined to the mucosa and submucosa of the colon. It starts from the rectum and extends proximally in a continuous manner. The clinical features include abdominal pain, diarrhea, rectal bleeding, tenesmus, and passage of mucus. Other symptoms include anorexia, nausea, vomiting, fever, and weight loss.

Ulcerative colitis is graded based on the frequency of bowel movements and systemic involvement.

- Mild disease - ≤4 stools per day with/without rectal bleeding;

- Moderate disease - ≥4 stools per day with few systemic signs of illness;

- Severe disease - ≥6 blood stools per day with fever, tachycardia (≥90 beats/min), anemia (hemoglobin <10.5 g/dL), and elevated levels of inflammatory markers (ESR ≥30 mm/h)

- Fulminant disease - >10 stools per day with severe anemia requiring blood transfusion and progressive colonic dilation (toxic megacolon)

Investigations show elevated C-reactive protein, platelet count, erythrocyte sedimentation rate, fecal calprotectin, and fecal lactoferrin. A colonoscopy reveals loss of typical vascular pattern, erythema, friability, regenerative mucosal nodules, pseudopolyps, and ulcerations.

Extraintestinal manifestations associated with IBD include ocular features (episcleritis, and uveitis), dermatological manifestations (erythema nodosum, pyoderma gangrenosum), rheumatological (arthropathies, sacroiliitis, ankylosing spondylitis) and primary sclerosing cholangitis. Complications include toxic megacolon, hemorrhage, strictures, and perforations. These patients are also at increased risk of colon cancer.

Other options

Option B & C : Azathioprine and 6-mercaptopurine are not first line agents for ulcerative colitis.

Solution to Question 17:

Fostamatinib is a tyrosine kinase inhibitor used in the treatment of chronic immune thrombocytopenia (idiopathic thrombocytopenic purpura).

Fostamatinib has activity against spleen tyrosine kinase (SYK). The major metabolite of fostamatinib, R406, inhibits signal transduction of Fc-activating receptors and B-cell receptors. The fostamatinib metabolite R406 reduces antibody-mediated destruction of platelets.

Idiopathic thrombocytopenic purpura (ITP) is an acquired disorder characterized by the immune-mediated destruction of platelets and possibly inhibition of platelet release from the megakaryocyte. It is an autoimmune disorder caused by antibodies directed against platelet membrane glycoproteins IIb-IIIa or Ib-IX. Secondary causes of ITP include systemic lupus erythematosus (SLE), HIV-AIDS, and Hepatitis C.

ITP usually presents with mucocutaneous bleeding, very low platelet count, and normal peripheral blood cells. Patients typically exhibit ecchymoses and petechiae or they may incidentally discover thrombocytopenia during a routine complete blood count. Rarely, life-threatening bleeding may occur. The presence of wet purpura (blood blisters in the mouth) and retinal hemorrhages can serve as warning signs of potentially life-threatening bleeding.

The treatment of ITP is as follows:

Other options :

Option A and B: Eltrombopag and Romiplostim are thrombopoietin (TPO) receptor agonists used in the treatment of immune thrombocytopenia which have failed to respond to conventional treatments. Both drugs act via the Mpl receptor to increase platelet counts and not via tyrosine kinase inhibition.

Option C: Bosutinib is a BCR-ABL tyrosine kinase inhibitor indicated in CML.

	Clinical features	Management
1.	Minor bleeding manifestations (and/or)Platelet count > 5000/ μL	Prednisone (OR)Anti-D immunoglobulin therapy - effective only in Rh-positive patients (OR)Intravenous immunoglobulin (IVIG)
2.	Severe ITP (any of the following):- Significant GI / intracranial bleeding- Platelet count < 5000/μL- Signs of impending bleeding (retinal or large oral mucosal bleeds)	Platelet transfusion (AND)High-dose glucocorticoids (AND)IVIG / Anti-D immunoglobulins + Rituximab
3.	Relapse after first-line therapy	Splenectomy
4.	Unresponsive to all other therapy or relapse after splenectomy	Thrombopoietin receptor agonists - romiplostim (subcutaneous), eltrombopag (oral)

Solution to Question 18:

The given clinical features are suggestive of hypothyroidism with goiter, which is a known adverse effect of ethionamide.

Mutidrug-resistant tuberculosis (MDR-TB) is treated with 2nd line agents that include ethionamide (ETH). ETH is not a first-line agent due to its gastrointestinal side effects. Ethionamide inhibits activity of the InhA gene product, resulting in inhibition of mycolic acid synthesis. It is structurally related to thionamides (propylthiouracil and methimazole) and therefore causes hypothyroidism by preventing organification of iodine in thyroid hormone synthesis. Another antitubercular drug that can cause hypothyroidism is Para-amino salicylic acid (PAS).

ETH/PAS-induced hypothyroidism should be treated with thyroxine replacement therapy, instead of changing the regimen. Thyroid function usually optimizes within 2 months after completing MDR therapy.

Ethionamide also causes hepatotoxicity and neurological adverse effects and may require pyridoxine supplementation.

MDR-TB is when there is resistance to atleast isoniazid and rifampicin which are the most potent first-line drugs. The treatment of MDR-TB is curated with drugs grouped into different classes by the world health organization (WHO).

Group A: Levofloxacin, bedaquiline, linezolid

Group B: Clofazimine, cycloserine

Group C: Ethambutol, pyrazinamide, delamanid, ethionamide

In patients treated previously or with additional drug resistance, a longer MDR-TB regimen of 18-20 months is recommended. Drugs belonging to group A are preferred along with one drug from group B whenever possible. A shorter regimen of 6 months including bedaquiline with other

drugs can be used in patients not treated before and without extensive disease. In pregnant women with MRD-TB, drugs such as bedaquiline and delamanid should be avoided.

Other options :

Option A : Pyrazinamide inhibits fatty acid synthase-I leading to inhibition of cell membrane synthesis. Pyrazinamide causes hyperuricemia and hepatotoxicity.

Option C : Adverse effects of cycloserine are mainly neurological. Half of the patients on cycloserine (1g/day) experience neuropsychiatric symptoms. It ranges from headaches to psychosis, seizures, and suicidal ideas.

Option D : Streptomycin is an aminoglycoside which binds to the 30S ribosomal subunit and interferes with the initiation of protein synthesis. It is a second-line agent for the treatment of active tuberculosis. Streptomycin produces ototoxicity, vestibulotoxicity, optic nerve dysfunction, including scotomas, and peripheral neuritis.

Solution to Question 19:

Hypothermia is not associated with amitriptyline use or tricyclic antidepressant toxicity.

Tricyclic antidepressants (TCAs) such as amitriptyline are used in the treatment of psychotic depression, insomnia, and several pain conditions. Their mechanism of action is inhibition of norepinephrine and serotonin reuptake. They have a quinidine-like sodium channel blockade effect on cardiac conduction. Hence, they cause QT prolongation. Other cardiotoxic effects include atrioventricular (AV) block and hypotension. Rightward-axis deviation is also an associated finding.

TCA toxicity can result in ventricular tachyarrhythmias (Option A), status epilepticus, hyperthermia, and coma. It can also result in anticholinergic syndrome due to muscarinic receptor antagonism. Symptoms include dilated pupils (Option D), high temperature, confusion (option B), dry mouth, urinary retention, tachycardia, and myoclonic movements. It is managed with intravenous sodium bicarbonate bolus (50-100 mEq). This helps in the reversal of sodium channel blockade. Gastric lavage and administration of activated charcoal can be carried out in cases of recent ingestion.

Other side effects of TCAs include postural hypotension from anti-alpha 1 adrenergic action and sedation from anti-histaminic action. ECG changes such as T wave inversion or suppression are also common.

In some cases, it can result in polymorphic ventricular tachycardias with QT prolongation known as torsades de pointes. Recurrent episodes can be treated with intravenous magnesium sulfate.

Solution to Question 20:

Hydroxyurea is beneficial in reducing the painful vasoocclusive crisis of sickle cell anemia.

Hydroxyurea is a myelosuppressive agent that is effective in reducing the frequency of painful episodes like dactylitis and acute chest syndrome, decreasing the rate of hospitalization, and requirement for blood transfusion. It is safe and well-tolerated in children and infants.

Hydroxyurea is approved for long-term maintenance of sickle cell disease, and is recommended for patients of all ages regardless of symptoms.

Hydroxyurea increases fetal hemoglobin levels by an unknown mechanism and interferes with the polymerization of abnormal HbS.

Newer drugs for management of acute painful crisis of sickle cell anemia include L-glutamine and crizanlizumab. For individuals >5 years of age with sickle cell disease who have pain despite hydroxyurea (or who cannot tolerate hydroxyurea), L-glutamine is recommended, regardless of whether they are receiving hydroxyurea. The mechanism of action of this drug, is that it reduces oxidative stress in sickle erythrocytes. Crizanlizumab is a P-selectin-blocking monoclonal antibody which is given intravenously every month to reduce acute painful episodes.

Sickle cell anemia is an autosomal recessive disorder that occurs due to the point mutation in the β-globin gene which results in the replacement of glutamate residue with valine. This causes the production of sickle-shaped red blood cells due to the polymerization of deoxygenated hemoglobin (HbS). Factors that predispose to sickling are infection, dehydration, and acidosis. Sickle cell disease causes hemolytic anemia due to increased erythrocyte destruction. The anemia is generally well compensated. Complications occur due to abnormal erythrocyte configurations that increase hemoglobin polymerization leading to a painful vaso-occlusive state.

Clinical features of sickle cell anemia :

- Moderately severe hemolytic anemia with jaundice.

- Painful bone crisis : hand-foot syndrome or dactylitis of the bones of hands and feet.

- Acute chest syndrome typically presents with fever, cough, chest pain, and pulmonary infiltrates.

- Hyposthenuria : inability to concentrate urine.

- Aplastic crisis stems from the infection of red cell progenitors by parvovirus B19, which causes a transient cessation of erythropoiesis and a sudden worsening of the anemia.

- Spleen : In children, splenic sequestration crises occur which results in splenomegaly due to red pulp congestion. In adolescence or early adulthood, autosplenectomy occurs due to splenic infarction, fibrosis, and progressive shrinkage.

- Increased susceptibility to infection with encapsulated organisms like pneumococcal, meningococcal, and Haemophilus influenza septicemia, but can be reduced by vaccination and prophylactic antibiotics.

- Other clinical features include priapism, leg ulcers, stroke, retinopathy, pigment gallstones, and growth retardation.

Other options :

Option B : Methotrexate interferes with folate metabolism by acting as a competitive inhibitor of the enzyme dihydrofolate reductase. This starves cells for tetrahydrofolate and makes them unable to synthesize purines and thymidine monophosphate. It does not treat painful crisis of sickle cell anemia.

Option C : Methionine is an essential amino acid involved in the synthesis of folate and vitamin B12. It is not used in the management of sickle cell anemia.

Option D : Eltrombopag is a thrombopoetin analog used to treat immune thrombocytopenia. It is not used in the treatment of painful sickle cell crisis.

Solution to Question 21:

Dexrazoxane is the drug of choice to treat doxorubicin induced cardiomyopathy.

Doxorubicin is an anthracycline group of anticancer antibiotics that acts by inhibiting topoisomerase II, and is known to cause cardiotoxicity. Dexrazoxane is a cardioprotective iron-chelating agent that is indicated for use along with high dose doxorubicin to avoid cardiotoxicity.

Dexrazoxane is currently approved to prevent or reduce anthracycline-induced cardiotoxicity in women with metastatic breast cancer who have received a total cumulative dose of doxorubicin of 300 mg/m2 .

Doxorubicin-induced cardiomyopathy takes two forms:

- Acute: pericarditis-myocarditis syndrome, arrhythmias, ST and T wave changes in ECG. Occurs within the first 2–3 days, is transient and in most cases asymptomatic.

- Chronic: Dose dependendent dilated cardiomyopathy associated with heart failure.

Doxorubicin, daunorubicin and epirubicin share similar cardiotoxicity profile. Idarubicin has least cardiotoxicity when compared to other anthracyclines.

Endomyocardial biopsy showing vacuolar degeneration and myofibrillar loss is seen in cardiotoxicity due to anthracyclines.

Difference between cardiotoxicity due to anthracyclins and trastuzumab:

Anthracyclines like doxorubicin can result in a radiation recall reaction, where erythema and desquamation of skin are observed at sites of previous radiation injury. The risk of cardiotoxicity also increases with previous irradiation. Therefore, careful monitoring and dosage adjustments are required for doxorubicin.

Other options :

Option B, C and D : Dexamethasone, aprepitant and amifostine are not used in the management of anthracycline induced cardiotoxicity.

Anthracyclins	Trastuzumab
Irreversible	Reversible
Dose-dependent	Not dose-dependent
Biopsy shows myocyte destruction	Biopsy does not show myocyte destruction

Solution to Question 22:

Rivastigmine transdermal patch can be prescribed to patients with dementia who are non compliant on oral medications.

Rivastigmine is a cholinesterase inhibitor that is available as a transdermal patch for use in alzheimer's disease and dementia. It can be applied for over 24 hours. Transdermal delivery reduces the fluctuation and avoids direct gastric irritation effects associated with oral formulations.

Alzheimer's disease is the most common cause of dementia in the elderly. The characteristic feature of Alzheimer's is the degeneration of cholinergic neurons leading to reduced levels of acetylcholine.

Treatment includes cholinesterase inhibitors like Donepezil, Rivastigmine and Galantamine and NMDA receptor antagonist like memantine. The cholinesterase inhibitors cause significant side effects such as nausea, vomiting, diarrhea and peripheral cholinergic effects, which can be avoided by using a transdermal formulation.

Anticholinesterase drugs

Other options :

Options A, C and D: Donepezil, galantamine and memantine are currently available in the oral form and transdermal formulations are under development and yet to be available in the market.

Reversible inhibitors	
Carbamates	Non-Carbamates
Physostigmine, Neostigmine, Pyridostigmine, Rivastigmine	Edrophonium, Tacrine, Donepezil, Galantamine
Irreversible inhibitors	
Carbamates	Organophosphates
Carbaryl, Propoxur	Dyflos, Echthiophate, Malathion, Diazinon, Tabun, Sarin, Soman

Solution to Question 23:

Sodium valproate has an inhibitory action on the metabolism and degradation of GABA, and also increases its synthesis.

Valproate is an anti-epileptic medication and also used as a mood stabilizer in bipolar disorder. Valproate acts via multiple mechanisms. It blocks both sodium and calcium channels. It prolongs sodium channel inactivation and attenuates calcium-mediated 'T' current. It inhibits metabolism and degradation of the inhibitory neurotransmitter GABA and increases its synthesis from glutamic acid (Option A). It also inhibits excitatory NMDA glutamate receptors. The repetitive firing caused by the depolarization of cortical or spinal cord neurons is inhibited by valproate.

Valproate is a broad spectrum antiseizure drug used in partial seizures, generalised tonic-clonic seziures (GTCS), absence seizures, myoclonic seziures and atonic seziures. It can be used in absence seizures, but it is preferred when the child also suffers from GTCS. It is the drug of choice for juvenile myoclonic epilepsy.

The side effects of valproate (mnemonic: VALPROATE)

Vomiting

Alopecia

Liver toxicity

Pancreatitis

Rash

Obesity

Anorexia

Teratogenicity

Edema

It causes congenital anomalies like neural tube defects (Spina Bifida), clefts, and cardiac anomalies. The intelligence quotient score of school-going children who were exposed in utero to valproate is found reduced. It also contributes to poor cognitive development in children. Folate supplementation reduces the chances of neural tube defects.

Other options :

Option C : Drugs such as vigabatrine and tiagabine inhibit GABA reuptake by inhibiting the GABA reuptake transporter. Vigabatrine is the drug of choice for infantile spasms (West syndrome) seen in tuberous sclerosis.

Option D : Flumazenil acts as an antagonist at the GABA receptor and is used as an antidote for benzodiazepine overdose. Benzodiazepines act by promoting GABA inhibition by binding to the GABA receptor itself and inhibiting nerve transmission.

Solution to Question 24:

Verapamil is a potent inhibitor of P-glycoprotein drug transporter which belongs to the family of ATP-binding cassette (ABC) transporters.

A group of primary active transporters, the ATP-binding cassette (ABC) family, hydrolyze ATP to export substrates across membranes. P-glycoprotein (P-gp) is an ATP-binding cassette (ABC) transporter, which acts as an efflux membrane transporter. It is responsible for limiting cellular uptake and the distribution of xenobiotics and toxic substances. P-glycoprotein is also called ABCB1 or MDR1, and it exports bulky neutral or cationic compounds from cells. MDR1 exports many drugs as well. It is associated with multidrug resistance (MDR) to cancer chemotherapeutics through the multidrug resistance protein 1 or MDR1.

Verapamil can cause interactions with drugs whose disposition is dependent upon P-glycoprotein. Drugs that inhibit P-glycoprotein are -

• Clarithromycin

• Erythromycin

• Amiodarone

• Quinidine

• Verapamil

• Diltiazem

• Cyclosporine

• Itraconazole

• Propafenone

• Flecainide.

P-glycoprotein pumps play a major role in the elimination of certain drugs such as digoxin. Drugs that inhibit P-glycoprotein can thereby decrease their elimination and lead to toxicity. For eg, digoxin is metabolized by P-glycoprotein, and drugs that inhibit it increase the plasma levels of digoxin and may result in toxicity.

Increased P-gp expression: Reduces the absorption of drugs that are substrates for P-gp.

Decreased P-gp expression: Leads to supratherapeutic plasma concentrations and drug toxicity.

Other options :

Option B, C, and D: Although diltiazem, nifedipine, and amlodipine have been reported in the literature to act as p-glycoprotein inhibitors, verapamil is more potent and commonly used for p-glycoprotein inhibition in trials, and would be the best answer.

Solution to Question 25:

Oral Fidaxomicin is the antibiotic indicated for this patient's condition which is suggestive of Clostridium difficile infection, characterized by profuse watery diarrhea and leukocytosis following long term antibiotic use such as ampicillin.

C difficle infection is most commonly associated with prolonged antimicrobial use which interferes with the commensal colonic microflora. The most commonly implicated antibiotics are cephalosporins, ampicillin, clindamycin, and fluoroquinolones. Spores of toxigenic C. difficile when ingested, survive gastric acidity and colonize the lower intestinal tract. Here they produce two toxins: toxin A (an enterotoxin) and toxin B (a cytotoxin). These toxins initiate processes that disrupt the epithelial-cell barrier function, diarrhea, and pseudomembrane formation. The patient presents with non bloody diarrhea, fever, abdominal pain, and leukocytosis.

Clinical features can range from asymptomatic carriage to fulminant colitis.

• Nonsevere disease - Watery diarrhea (≥3 loose stools in 24 hours) is the cardinal symptom. Other manifestations include lower abdominal pain and cramping, low-grade fever, nausea, anorexia, mucus, or occult blood in the stool. Physical examination may demonstrate lower abdominal tenderness. Unexplained leukocytosis in hospitalized patients (even in the absence of diarrhea) may reflect underlying CDI

• Severe colitis - Clinical manifestations of severe colitis include diarrhea, lower quadrant or diffuse abdominal pain, abdominal distention, fever, hypovolemia, lactic acidosis, hypoalbuminemia, elevated creatinine, and marked leukocytosis.

• Fulminant colitis - Characterized by hypotension or shock, ileus, or megacolon.

• Recurrent disease - resolution of CDI followed by recurrence of symptoms within two to eight weeks after treatment has been stopped

Nucleic acid amplification tests including polymerase chain reaction (PCR) assays, for C. difficile toxin A or B gene in stool, are widely used diagnostically. Glutamate dehydrogenase is an enzyme immunoassay to detect C. difficile in stool. Confirmation of the presence of toxin in the stool in addition to PCR or glutamate dehydrogenase positivity is recommended.

Oral vancomycin, fidaxomicin, and metronidazole are used in the management of this condition. Fidaxomicin acts by inhibiting protein synthesis through the blockade of RNA polymerase.

Management of nonsevere to severe initial disease:

Management of recurrent disease:

Management of fulminant disease -

Other options:

Option B : Clindamycin is implicated as a risk factor for development of clostridium difficile colitis and is not used to treat it.

Option C : Zanamavir is a neuraminidase inhibitor used against influenza A and B virus.

Option D : Cilastatin is a reversible dehydropeptidase inhibitor and used adjunctively with imipenem to prolong its action as it rapidly hydrolysed by renal dehydropeptidase. It is not used in the treatment of clostridium difficile colitis.

Nonsevere diseaseSupportive clinical data: White blood cell count ≤15,000 cells/mL and serum creatinine <1.5 mg/dL	Vancomycin 125 mg orally 4 times daily for 10 days,ORFidaxomicin200 mg orally twice daily for 10 daysIf above agents are unavailable: Metronidazole 500 mg orally 3 times daily for 10 days
Severe diseaseSupportive clinical data: White blood cell count >15,000 cells/mL and/or serum creatinine ≥1.5 mg/dL	Vancomycin 125 mg orally 4 times daily for 10 days,ORFidaxomicin200 mg orally twice daily for 10 days

First recurrence	If vancomycin was used for t he initial episode: Vancomyci n pulsed-tapered regimen:12 5 mg orally 4 times daily for 10 to 14 days, then125 mg or ally twice daily for 7 days, the n125 mg orally once daily for 7 days, then125 mg orally eve ry 2 or 3 days for 2 to 8 week s,ORFidaxomicin 200 mg ora lly twice daily for 10 daysIf fi daxomicin or metronidazole was used for the initial episo de: Vancomycin 125 mg orall y 4 times daily for 10 days
Second or subsequent recurr ence	Vancomycin pulsed-tapered r egimen (outlined above),ORF idaxomicin200 mg orally twi ce daily for 10 days,ORVanco mycin followed by rifaximin: Vancomycin 125 mg orally 4 t imes per day for 10 days, the nRifaximin 400 mg 3 times d aily for 20 days,ORFMT

Initial episode	Enteric vancomycin plus pare nteral metronidazole:Vancom ycin 500 mg orally or via nas ogastric tube 4 times daily,A NDMetronidazole 500 mg int ravenously every 8 hoursIf ile us is present, additional cons iderations include:FMT (adm inistered rectally)Rectal vanc omycin (administered as a re tention enema 500 mg in 10 0 mL normal saline per rectu m; retained for as long as pos sible and readministered ever y 6 hours)
Recurrent episo de	Antibiotics as for initial fulmi nant episode aboveSome favo r FMT in the context of a firs t or second recurrence that p resents as a fulminant episod e

Solution to Question 26:

Valproate is a mood stabilizer with the side effect of hepatotoxicity and hyperammonemia.

Valproate is an anti-epileptic medication and also used as a mood stabilizer in manic episodes as well as in bipolar disorder. The repetitive firing caused by the depolarization of cortical or spinal cord neurons is inhibited by valproate. It also prolongs the sodium channel inactivation. Valproate can cause an idiosyncratic hepatic toxicity and interfere with conversion of ammonia to urea leading to hyperammonemia. Valproate is contraindicated in patients with genetic defects in urea metabolism.

Valproate therapy reduces carnitine levels in tissues, potentially impacting mitochondrial function and leading to hyperammonemia and microvesicular steatosis. Genetic factors also play a role, as individuals who are heterozygous for mutations in the gamma polymerase gene, which is primarily present in mitochondria, are more susceptible to valproate-induced liver damage. Intravenous administration of carnitine can be used to manage this condition.

The side effects of valproate (mnemonic: VALPROATE)

Vomiting

Alopecia

Liver toxicity

Pancreatitis

Rash

Obesity

Anorexia

Teratogenicity

Edema

It causes congenital anomalies like neural tube defects (Spina Bifida), clefts, and cardiac anomalies. The intelligence quotient score of school-going children who were exposed in utero to valproate is found reduced. It also contributes to poor cognitive development in children. Folate supplementation reduces the chances of neural tube defects.

Other options :

Option A : Lithium is a mood stabilizer with a very narrow therapeutic index and is the first line of management in bipolar disorder. Its adverse effects can be acute such as tremors, ataxia, weakness, polyuria, polydipsia or chronic such as nephrogenic diabetes insipidus, thyroid dysfunction, and hyperparathyroidism. It is not associated with hepatotoxicity or hyperammonemia.

Option C : Carbamazepine is a sodium channel blocker used in the management of complex partial seizures, GTCS, simple partial seizures and trigeminal neuralgia. It is known to be hepatotoxic but is not associated with hyperammonemia. Other adverse effects include hypersensitivity reactions, eosinophilia, agranulocytosis, aplastic anemia, hyponatremia and stevens-johnson syndrome.

Option D : Topiramate is an anti epileptic and non-opioid pain medication which is associated with significant weight loss of up to 7% as a side effect.

Solution to Question 27:

Among the given options, Candida krusei shows an intrinsic resistance to fluconazole.

The primary or intrinsic resistance of C. krusei to azoles (fluconazole and itraconazole) is mediated through reduced susceptibility of the target enzyme (lanosterol 14α-demethylase) to inhibition by these drugs. However, improved susceptibility is seen with newer generation azoles such as voriconazole.

Life-threatening systemic infections caused by Candida and Aspergillus species are usually seen in severely ill and immunocompromised patients such as HIV, chemotherapy-induced neutropenia, and transplant recipients on immunosuppressants. C. albicans and C. dubliniensis are most susceptible to currently available azoles, C. glabrata is less susceptible, whereas C. krusei is intrinsically resistant to fluconazole. Resistance occurs due to overexpression or point mutation in the gene encoding the target enzyme lanosterol 14α-demethylase. Voriconazole is the preferred therapy for multi-drug resistant infection with C. krusei.

C. albicans and C. glabrata (Option C) showing resistance to Amphotericin B has been increasingly reported over the past several years. But this is a secondary resistance due to alteration or a decrease in the amount of ergosterol in the cell membrane. Amphotericin B is indicated to treat C. glabrata that has developed resistance to azoles.

Aspergillus fumigatus, the most common species to cause Aspergillus infection worldwide, also shows an intrinsic resistance to fluconazole. It is susceptible to echinocandins like micafungin, which acts by inhibiting beta-(1,3)-D-glucan synthase, an enzyme necessary for the synthesis of the cell wall.

Other options

Option A : Aspergillus niger is a common cause of otomycosis and is susceptible to azoles like voriconazole, amphotericin B, and echinocandins.

Option D : The drug of choice for treatment of sporotrichosis is itraconazole.

Solution to Question 28:

IV desferrioxamine (also known as deferoxamine) is indicated when serum iron levels are greater than 500 mcg/dL in cases of iron toxicity.

Desferrioxamine is selectively used as a chelating agent to manage cases of acute iron poisoning, hemochromatosis, and patients with iron overload from repetitive blood transfusions. Desferrioxamine can be administered intramuscularly, intravenously, or subcutaneously but not orally.

Deferiprone and deferasirox are both oral drugs and can be given in transfusion related siderosis but are less effective than desferrioxamine. Although, they can be preferred because of the ease of administration through oral route and multiple transfusions required for beta thalassemia patients.

Iron exhibits toxic effects by hydration of the ferric (F3+) ion which generates H+. Non transferrin bound iron catalyses free radical formation which causes mitochondrial injury, lipid peroxidation, increased capillary permeability, vasodilation, and organ toxicity.

Clinical features of iron toxicity include initial nausea, vomiting, abdominal pain and diarrhea. In severe cases there is high anion gap metabolic acidosis, cardiovascular and CNS depression, hepatitis, coagulopathy, and seizures.

In the case of toxic iron ingestion, radiopaque iron tablets may be seen on abdominal x-ray.

Management of iron toxicity includes the following :

• Whole-bowel irrigation for large ingestions, endoscopy and gastrostomy if clinical toxicity and large number of tablets are still visible on x-ray.

• IV hydration.

• Sodium bicarbonate for acidemia.

• IV desferrioxamine for systemic toxicity, iron level >90 μmol/L (500 μg/dL).

Solution to Question 29:

Methadone is the causative drug for this patient's presentation of syncope and prolonged QT interval after coadministration other QT prolonging drugs such as fluoxetine.

Unlike other opioids, QT prolongation is primarily a side effect of methadone, which is additive with other agents known to cause QT prolongation such as fluoxetine. Serious cardiac arrhythmias including torsades de pointes have been noted with methadone use. Normal QTc is about 440 ms. Values of more than 440 ms in males and 460 ms in females are considered to be prolonged. QT prolongation can present as syncope or cardiac arrest.

Methadone is a synthetic opioid that is chemically different but has similar pharmacological action to that of morphine (Option B). It is a long-acting mu-opioid receptor agonist. Although an effective analgesic, the primary use of methadone hydrochloride is detoxification and maintenance therapy treatment for opioid use disorder. Methadone is also used for the management of chronic pain.

Side effects of methadone are similar to that of morphine such as lethargy, constipation, respiratory depression, and hypotension. Like other opioids, methadone will produce tolerance and dependence. Development of physical dependence during the long-term administration of methadone can be demonstrated following abrupt drug withdrawal or administration of an opioid antagonist.

Other options :

Option B : Morphine is not associated with QT prolongation.

Option C : Meperidine, also known as pethidine, though chemically unrelated to morphine interacts with μ opioid receptors and its actions are blocked by naloxone. Apart from usual opioid side effects, pethidine produces some atropinic effects like dry mouth, blurred vision, tachycardia. Pethidine injected in patients receiving a selective serotonin reuptake inhibitor (SSRI) may produce serotonin syndrome. It is occasionally used to control shivering during recovery from anaesthesia.

Option D : Propoxyphene is a methadone analogue that was used to treat mild-tomoderate pain. Due to reports of cardiotoxicity, it was withdrawn in UK, Europe, and USA and it was banned in India in 2013.

Solution to Question 30:

Hyponatremia occurs more frequently in the case of oxcarbazepine than carbamazepine.

Both carbamazepine and oxcarbazepine are sodium-channel blockers that stabilize neuronal membranes. Oxcarbazepine is the 10-keto analog of carbamazepine and and cannot form an epoxide metabolite. Carbamazepine potentiates the action of antidiuretic hormone (ADH). It can result in water retention with decreased osmolarity and hyponatremia, especially in elderly patients with cardiac disease. Although hyponatremia may occur more commonly with oxcarbazepine than with carbamazepine, most adverse effects of oxcarbazepine are similar to those of carbamazepine.

Carbamazepine and oxcarbazepine can cause leukopenia, aplastic anemia, hepato-toxicity in the elderly.

Oxcarbazepine shows lesser hypersensitivity reaction. Hence, rashes (option A) are more commonly seen with carbamazepine than with oxcarbazepine.

Studies have shown that carbamazepine elevates enzyme gamma-glutamyl transpeptidases (GGT) more frequently than oxcarbazepine because of enzyme P450 induction. Hepatotoxicity from oxcarbazepine occurs less commonly compared to carbamazepine (Option D).

Side effects of carbamazepine therapy include: mnemonic: HEADS

Hypersensitivity reactions

Eosinophilia

Agranulocytosis: report symptoms like sore throat/fever

Aplastic anemia

Ataxia

Dilutional hyponatremia

Diplopia, blurred vision

Splenomegaly

Stevens-Johnson syndrome

Carbamazepine is most effective in complex partial seizures. It is also used in GTCS and simple partial seizures, trigeminal and related neuralgias, and manic depressive psychosis. Oxcarbazepine has been used to treat intractable trigeminal neuralgia refractory to other anticonvulsants.

Mechanism of action of some common antiepileptics:

Mechanism of action	Antiepileptics
Sodium-channel blockers	PhenytoinCarbamazepine, OxcarbamazepineEslicarbazepineLamotrigineTopiramateFelbamateValproateRufinamideLevetiracetam

Mechanism of action	Antiepileptics
Calcium-channel blockers	ValproateLamotrigineEthosuximide
GABA A receptor modulators	BenzodiazepinesPhenobarbitalFelbamatePrimidoneTopiramateCarbamazepine, OxcarbamazepineStiripentolClobazam
GABA uptake inhibitors	TiagabineVigabatrin
NMDA receptor antagonist	Felbamate
AMPA/Kainate receptor antagonist	PhenobarbitalTopiramatePerampanel
HCN channel activity enhancers	Lamotrigine
Inhibitors of brain carbonic anhydrase	AcetazolamideZonisamideTopiramate
Potassium-channel openers	RetigabineTopiramate

Solution to Question 31:

This patient was most likely taking tipranavir, as it is known to be associated with an increased risk of intracranial hemorrhage and hepatotoxicity which is the likely cause of altered mental status in this patient with hemophilia following complaints of nausea, vomiting and headache.

Tipranavir is a protease inhibitor (PI) used in patients who are resistant to other PIs. It is often combined with ritonavir, to achieve better therapeutic outcomes. It should be avoided in patients with head trauma or bleeding diathesis, such as hemophilia as it is associated with an increased risk of intracranial hemorrhage. Other common adverse effects of tipranavir include nausea, vomiting, diarrhea, abdominal pain, urticarial or maculopapular rash, and liver toxicity.

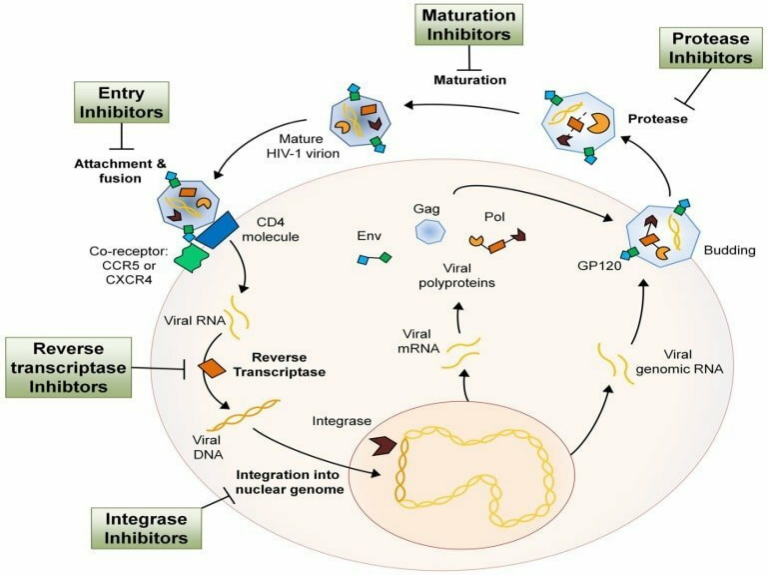
Other Options :

Option A, C and D : Lopinavir, Darunavir and Ritonavir are protease inhibitors that can cause nausea and vomiting, although they are not contraindicated in patients with bleeding diathesis and not associated with an increased risk of intracranial hemorrhage.

The illustration below shows the mechanism of action of various antiretroviral drugs.

Antiretroviral drug	Mechanism of action
Nucleotide/ nucleoside reverse transcriptase inhibitors	Inhibits reverse transcriptase
Non-nucleoside reverse transcriptase inhibitors	Inhibits reverse transcriptase by binding to an allosteric site of the enzyme

Antiretroviral drug	Mechanism of action
Protease inhibitors	Inhibits the viral protease en zyme necessary to produce m ature virions upon budding fr om the host membrane.
Entry inhibitors	Interferes with binding, fusio n, and entry of HIV -1 into th e cell by blocking a target.Ma raviroc works by targetting C CR5, a coreceptor located on human helper T-cells
Integrase inhibitors	Inhibits the viral enzyme inte grase, which is responsible fo r the integration of viral DNA into the DNA of the infected cell.

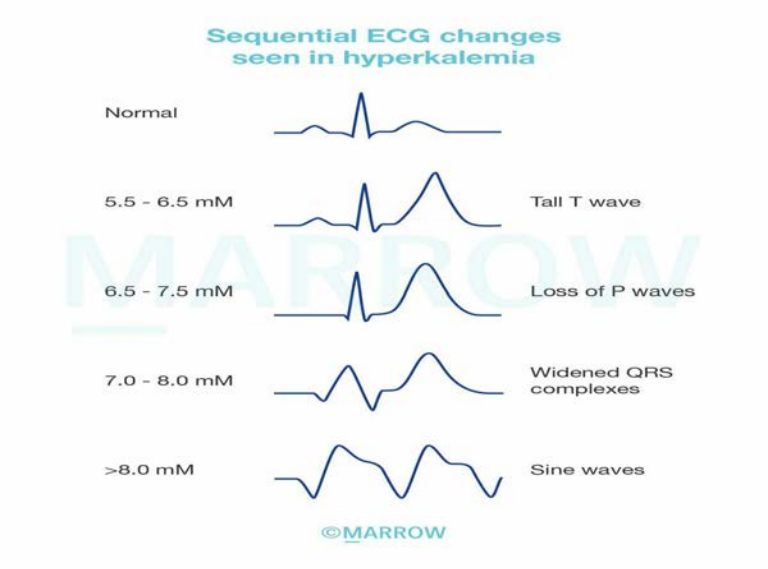


Solution to Question 32:

A chronic kidney disease (CKD) patient with chest pain, palpitations, muscle weakness, and serum potassium of 6.4mEq/L indicates hyperkalemia.

Hyperkalemia can be defined as potassium levels >5.5 mM. In normal patients, hyperkalemia is prevented by aldosterone-dependent secretion and potassium excretion via the gastrointestinal tract. But in patients with CKD, certain situations overcome these preventive mechanisms and cause hyperkalemia. These include high potassium intake, hemolysis, red blood cell transfusion, metabolic acidosis, and drugs that inhibit potassium excretion. The most common drugs that can precipitate hyperkalemia in CKD patients are renin-angiotensin system (RAS) inhibitors, spironolactone, and other potassium-sparing diuretics like triamterene, eplerenone, and amiloride.

ECG shows tall and peaked T waves, widening of QRS complexes, loss of P waves, and sine wave pattern.



Management of hyperkalemia involves an immediate reversal of cardiac effects by administration of 10mL of 10% calcium gluconate intravenously. This leads to the reversal of the depolarization blockade due to hyperkalemia. Redistributing the excess potassium by administering 10U of intravenous insulin followed by 50mL of 50% dextrose can also be given, as insulin facilitates the intracellular shift of potassium. Beta-2-agonists can also be used in the management of hyperkalemia. But patients with end-stage renal disease are resistant to beta-2-agonists and hence must be used with caution. Removal of potassium can be done using cation exchange resins like patiromer and sodium polystyrene sulfonate, diuretics, and dialysis.

Solution to Question 33:

Pregabalin can be used for diabetic neuropathy, post herpetic neuralgia and spinal cord injury. Although amitriptyline can also be used for these conditions, pregabalin is found to be recommended over amitriptyline considering safety and efficacy and hence is the best option.

Pregabalin is an anti-epileptic drug. Its analgesic effect is mediated by binding to α2δ, a protein that is a subunit of voltage-gated calcium channels and causes a decrease in glutamate release at excitatory synapses. Decreased neurotransmitter release is associated with reduced neuronal hyperexcitability. It is used in the management of neuropathic pain associated with diabetic peripheral neuropathy, spinal cord injury or postherpetic neuralgia.

Currently, only duloxetine and pregabalin are approved by the U.S. Food and Drug Administration and the European Medicines Agency to treat painful diabetic neuropathy. Diabetic Neuropathy is the most common cause of peripheral neuropathy in developed countries. Risk factors include long-standing, poorly controlled DM and the presence of retinopathy and nephropathy.

Side effects of pregabalin include sedation and peripheral edema.

Other options :

Option A : Tricyclic antidepressants (TCAs) such as amitriptyline are used in the treatment of several pain conditions such as diabetic neuropathy, post herpetic neuralgia and following spinal cord injury. Their mechanism of action is inhibition of norepinephrine and serotonin reuptake. Although both pregabalin and amitriptyline are among the first line drugs for neuropathic pain, amitriptyline would be the next best option in this question, owing to its side effect profile and good yet controversial efficacy in pain control. It is a non FDA approved drug for diabetic neuropathy (off label indication). Side effects associated with amitriptyline include anticholinergic side effects (dry mouth, tachycardia, hyperthermia), cardiac effects (arrhythmias) and sedation.

Option B : Phenytoin is an antiepileptic drug that is not used in the treatment of pain.

Option C : Carbamazepine is an iminostilbine derivative. It blocks voltage-activated sodium channels, slowing their rate of recovery and limiting the repetitive firing of action potentials. It is used in the treatment of generalized, focal-to-bilateral and idiopathic tonic-clonic seizures, focal seizures, neuropathic pain associated with trigeminal and glossopharyngeal neuralgias.

Solution to Question 34:

Linezolid is a protein synthesis inhibitor that acts by inhibiting the 50s ribosomal subunit.

Linezolid binds to the P site of the 50s ribosomal subunit and inhibits bacterial protein synthesis. It is an oxazolidinone that is active against various resistant organisms including MRSA. It has excellent oral bioavailability. Linezolid is used to treat infections caused by gram-positive bacteria, particularly vancomycin-resistant enterococcus and methicillin-resistant Staphylococcus aureus. Linezolid is also approved for the treatment of community-acquired pneumonia due to S. pneumoniae and nosocomial pneumonia due to S. aureus.

The intrinsic resistance of gram-negative bacteria to linezolid is mediated by endogenous efflux pumps.

Linezolid is associated with the side effect of myelosuppression (anemia, leukopenia, pancytopenia, and thrombocytopenia). Thrombocytopenia is the most common side effect. Linezolid has MAOI (monoamine oxidase inhibitors) activity and therefore can precipitate serotonin syndrome with concomitant use of SSRI (paroxetine) or with other serotonergic medications.

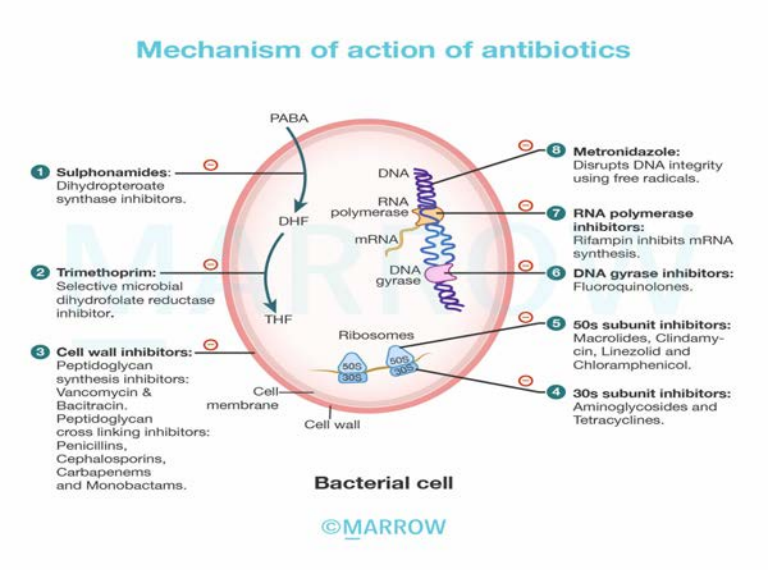
Other adverse effects include peripheral neuropathy, optic neuropathy, lactic acidosis.

Other options :

Option A : Aztreonam is a monobactam, and acts similar to penicillin by inhibiting peptiglycan crosslinking and inhibiting bacterial cell wall synthesis.

Option B : Daptomycin is a cyclic lipopeptide antibiotic. It acts by depolarising bacterial membranes resulting in loss of membrane potential and cell death.

Option D : Rifampicin is an anti tubercular antibiotic that acts by inhibiting bacterial DNA-dependent RNA polymerase.



Mechanism of action of antibiotics
PABA
DHF
THF
DNA
RNA polymerase
mRNA
DNA gyrase
Ribosomes
50S
30S
Cell membrane
Cell wall
1 Sulphonamides: Dihydropteroate synthase inhibitors.
2 Trimethoprim: Selective microbial dihydrofolate reductase inhibitor.
3 Cell wall inhibitors: Peptidoglycan synthesis inhibitors: Vancomycin & Bacitracin. Peptidoglycan cross linking inhibitors: Penicillins, Cephalosporins, Carbapenems and Monobactams.
8 Metronidazole: Disrupts DNA integrity using free radicals.
7 RNA polymerase inhibitors: Rifampin inhibits mRNA synthesis.
6 DNA gyrase inhibitors: Fluoroquinolones.
5 50s subunit inhibitors: Macrolides, Clindamycin, Linezolid and Chloramphenicol.
4 30s subunit inhibitors: Aminoglycosides and Tetracyclines.
Bacterial cell

Pharmacology INI-CET 2024

Question 1:

Which of the following drugs used in the treatment of diabetes is known to cause urinary tract infections?

a) Dapagliflozin

b) Sitagliptin

c) Pioglitazone

d) Glimeperide

Question 2:

Which of the following medications used in treating leprosy causes skin pigmentation?

a) Oflaxacin

b) Dapsone

c) Clofazamine

d) Rifampicin

Question 3:

A patient is set to receive intermittent treatment with teriparatide. Which of the following complications does this drug predispose him to?

a) Osteonecrosis of the jaw bone

b) Subtrochanteric fractures

c) Net loss of bone mass

d) Osteosarcoma

Question 4:

Which of the following monoclonal antibodies is not a HER - 1 inhibitor?

a) Pertuzumab

b) Cetuximab

c) Panitumumab

d) Necitumumab

Question 5:

A G2P1 delivered a preterm baby at 36 weeks. The baby was admitted in the NICU for a week and was given expressed breast milk. Unfortunately the baby did not survive. Which of the following drugs can be used to reduce the engorgement and pain of the lactating breasts?

a) Cabergoline

b) Sumatriptan

c) Chlorpromazine

d) Pramipexole

Question 6:

Coagulation profile monitoring is required for which of the following drugs?

a) Lepirudin

b) Enoxaparin

c) Fondaparinux

d) Dabigatran

Question 7:

A patient known case of diabetes, shows microalbuminuria on urine analysis, done twice at an interval of 6 months. Renal function tests are normal. Which of the following drugs is not useful in preventing the progression of renal damage?

a) Finerenone

b) Hydrochlorothiazide

c) Angiotensin receptor blockers

d) SGLT2 inhibitor

Question 8:

Which of the following causes a decrease in serum parathyroid hormone?

a) Calcitriol

b) Risedronate

c) Furosemide

d) Lithium

Question 9:

Which of the following acts by suicide inhibition?

a) 1,2

b) 3,4

c) 1,2,4

d) 1,3,4

Question 10:

Which of the following diuretics is matched correctly with its location of action?

a) 1,2,3

b) 3,4

c) 2, 4

d) 1,2

Question 11:

Which of the following drugs acts as an inhibitor of PCSK-9?

a) Bempedoic acid

b) Lomitapide

c) Ezetemibe

d) Evolocumab

Question 12:

Inhaled nitric oxide (iNO) is used for?

a) Persistent pulmonary hypertension of newborn

b) Unstable angina

c) Obstructive sleep apnea

d) Erectile dysfunction

Question 13:

A patient presents with complaints of a cough producing tenacious white sputum. Which of the following statements is true about the drug that could be prescribed for this condition?

a) Codeine as it is a potent drug and quickly relieves symptoms.

b) Bromhexine and Dextromethorphan syrup as they liquify sputum and reduce cough due to antitussive effect

c) Dextromethorphan alone as it does not have addictive potential like codeine

d) Bromhexine as it liquifies sputum

Question 14:

Which of the following antidiabetic drugs is known to cause unexplained diarrhea?

a) Sitagliptin

b) Metformin

c) Glimepiride

d) Pioglitazone

Question 15:

A young female weighing 46 kg is on digoxin with vd-6 L/kg and clearance 4.6 L/h. Calculate the half-life of digoxin.

a) 4h

b) 68h

c) 42h

d) 0.9h

Question 16:

Choose the correct option regarding phenytoin.

a) Acute oral overdose results primarily in cerebellar and vestibular symptoms and high doses have been associated with marked cerebellar atrophy

b) High dose causes cardiotoxicity in old and nephrotoxicity in young patients

c) These complications can be minimized by administering fosphenytoin at a rate of less than 250 mg of phenytoin sodium equivalents per minute

d) Given in all patients with seizures regardless of cardiac arrhythmias, hypotension and/or CNS depression

Question 17:

True statement about Iron Isomaltoside 1000 is

a) Iron requirement can be fulfilled in single dose

b) More immunogenic than iron dextran

c) Given intravenously and gets deposited in adipose tissue therefore less toxic

d) Cannot be given with erythropoietin

Question 18:

The drug that binds to CD4 and has action on both CCR5 and CXCR4 in tropic HIV infections is

a) Maraviroc

b) Ibalizumab

c) Elvitregravir

d) Fosamprenavir

Question 19:

Inhibitors of Poly ADP ribose polymerase (PARP) are approved for BRCA-positive breast cancers. Which among the following drugs is used?

a) Pablociclib

b) Rucaparib

c) Regorafenib

d) Vandetinib

Question 20:

A 60-year-old patient who is a known case of hypertension and diabetes underwent PCI stent placement for NSTEMI last year. He is currently on aspirin, metoprolol and atorvastatin. He comes for a follow-up, and his lipid profile is as follows- Total cholesterol 252mg/dl LDL: 156mg/dl, triglyceride 158mg/dl and HDL- 40 mg/dl. Which drugs can be added based on his lipid profile?

a) 1, 2 and 4

b) Only 1 and 2

c) 1,3 and 4

d) Only 1 and 3

Question 21:

Which of the following is a true statement regarding Pretomanid?

a) Given in XDR TB with Bedaquiline and Linezolid

b) Contraindicated in patients on enzyme inducer drugs

c) Acts by reactive oxygen species

d) For resistant cases of malaria

Question 22:

Which of the following drugs act on sodium channels and potentiate slow sodium inactivation?

a) Phenytoin

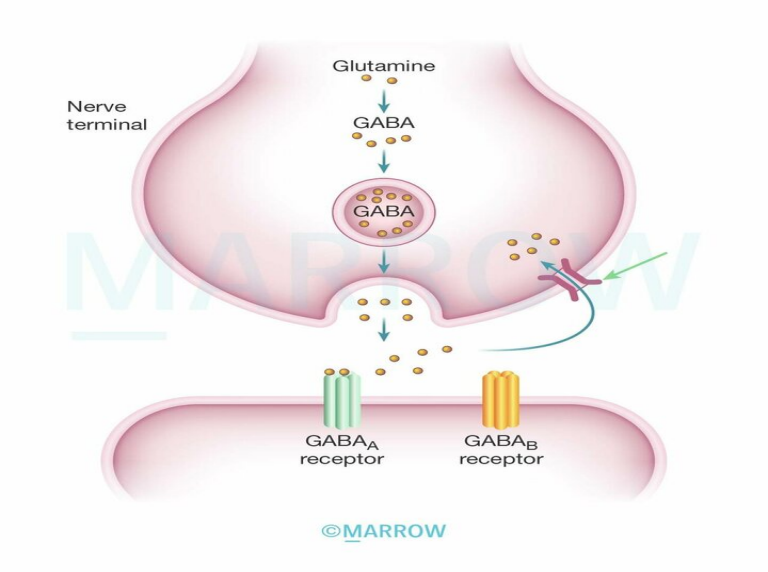
b) Lamotrigine

c) Lacosamide

d) Topiramate

Question 23:

Which drug acts on the marked receptor?



a) Tiagabine

b) Ganaxolone

c) Felbamate

d) Stiripentol

Question 24:

Match the treatment with its respective condition.

a) a-i, b-ii, c-iii, d-iv

b) a-ii, b-iii, c-i, d-iv

c) a-iii, b-i, c-iv, d-ii

d) a-iv, b-ii, c-iii, d-i

Answer Key

Detailed Explanations

Solution to Question 1:

Dapagliflozin is known to cause urinary tract infections.

Dapagliflozin is a sodium-glucose transporter 2 (SGLT-2) inhibitor. It acts by inhibiting the SGLT-2 transporter which is present on the proximal segment of the renal tubule and is responsible for the reabsorption of 80-90% of filtered glucose. This results in glycosuria. Other SGLT-2 inhibitors include canagliflozin and empagliflozin.

Apart from their effect on lowering blood glucose levels, SGLT2 inhibitors can cause mild weight loss and reduction in blood pressure. They have also been shown to reduce the risk of hospitalization in patients with heart failure.

The common side effects include urinary tract infections and genital mycotic infections due to the high glucose content of the urine. There is a risk of the development of diabetic ketoacidosis.

Other options :

Option B - Sitagliptin is a dipeptidyl peptidase-4 inhibitor. Its use is associated with an increased risk of heart failure.

Option C - Pioglitazone is an activator of the peroxisome proliferator-activated receptor γ (PPARγ), which is involved in the regulation of genes related to glucose and lipid metabolism. Its adverse effects include increased incidence of heart failure, peripheral edema, weight gain, macular edema, and osteoporosis.

Option D - Glimepiride belongs to the class of sulfonylureas. It stimulates insulin release by inhibiting the activity of the β cell KATP channel complex. Its side effects include hypoglycemia and weight gain.

Solution to Question 2:

Clofazimine is a dye with leprostatic and antiinflammatory properties.The mechanism of antimicrobial activity of clofazimine against mycobacteria appears to be multifactorial and includes membrane disruption, inhibition of mycobacterial phospholipase A2, inhibition of microbial K+ transport, generation of hydrogen peroxide, interference with the bacterial electron transport chain, and efflux pump inhibition.

Clofazimine is orally active. It accumulates in macrophages and gets deposited as needle-shaped crystals in many tissues including subcutaneous fat.

Clofazimine is used as a component of multidrug therapy (MDT) for leprosy. Because of its anti-inflammatory properties, it is valuable in lepra reactions. Occasionally, it is used as a component of a combination regimen for extensive drug resistant TB (XDR-TB).

Adverse effects -

• Skin - The major disadvantage is reddish-black discoloration of skin, especially on exposed parts. Discoloration of hair and body secretions may also occur. Dryness of the skin, itching and scaling are often troublesome. Acneform eruptions and phototoxicity have been noted. Conjunctival pigmentation may create cosmetic problems.

• GI symptoms - Nausea, anorexia, abdominal pain, weight loss and enteritis with intermittent loose stools can occur, particularly when higher doses are used to control lepra reaction. Deposition of clofazimine crystals in the intestinal submucosa may produce gastrointestinal symptoms.

Clofazimine is to be avoided during early pregnancy and in patients with liver or kidney damage.

Other options :

Option A- Ofloxacin is a fluroquinolone. As a component of MDT, it has been found to hasten the bacteriological and clinical response, where it is cidal to M.leprae. Its side effects include nausea, vomiting, and abdominal discomfort. CNS side effects like dizziness, anxiety and insomnia are also seen. Tendinitis is another adverse effect seen with the use of fluoroquinolones.

Option B- Dapsone exerts its antimicrobial effect by the inhibition of PABA incorporation into folic acid by folate synthase. Apart from being used in leprosy, dapsone is also used for the prophylaxis of T. gondii. The anti-inflammatory effects are the basis for therapy of dermatitis herpetiformis, linear immunoglobulin A bullous disease, and relapsing chondritis. Mild hemolytic anemia is common, especially in those with G-6-PD deficiency. Isolated instances of reversible peripheral neuropathy, drug fever, hematuria, pruritus, psychosis, and a variety of skin rashes have been reported.

Option D - Rifampicin interrupts RNA synthesis by binding to a subunit of mycobacterial DNA-dependent RNA polymerase. Apart from being used to treat leprosy, it is used in the management of tuberculosis, brucellosis, and prophylaxis of Meningococcal meningitis. Hepatitis is a major adverse effect. Other side effects include pruritus with rash, redness and watering of eyes,

flu-like symptoms and abdominal cramps. Urine and secretions may become orange-red.

Solution to Question 3:

The use of teriparatide predisposes an individual to the development of osteosarcoma.

Teriparatide is a parathormone analog, which is given as subcutaneous injections. Pharmacokinetics and systemic actions of teriparatide on mineral metabolism are the same as for PTH. Its main target of action are the osteoblasts.

Teriparatide is administered by once-daily subcutaneous injection of 20 μg into the thigh or abdomen. The site of administration should be rotated, but the time at which the injection is made should be the same each day.

Teriparatide and abaloparatide (PTHrP analog) are the only anabolic agents currently available that increase new bone formation (option C). Candidates for treatment include women who have a history of osteoporotic fracture, who have multiple risk factors for fracture, or who failed or are intolerant of previous osteoporosis therapy. Men with primary or hypogonadal osteoporosis are also candidates for treatment with these agents.

Adverse effects include hypercalcemia, exacerbation of nephrolithiasis, and elevation of serum uric acid levels. The development of osteosarcoma has been a serious concern in patients treated with teriparatide. It comes with a black-box warning, and use should be limited to no more than 2 years and avoided in patients who are at increased baseline risk for osteosarcoma (including those with Paget disease of bone, unexplained elevations of alkaline phosphatase, open epiphyses, or prior radiation therapy involving the skeleton).

Other options :

Options A and B - Osteonecrosis of the jaw bone and subtrochanteric fractures are the adverse effects of bisphosphonates.

Solution to Question 4:

Pertuzumab is a humanized IgG1 monoclonal antibody directed against HER2.

Pertuzumab is approved for the treatment of patients with HER2-positive, locally advanced, inflammatory, or early-stage breast cancer in combination with trastuzumab and docetaxel. Its adverse effect includes cardiotoxicity.

The other three antibodies act against epidermal growth factor receptor (EGFR)/ HER-1.

Option B - Cetuximab is used to treat patients with metastatic colon cancers and head and neck squamous cell carcinoma (HNSCC).

Option C - Panitumumab is approved for the treatment of EGFR-expressing metastatic colorectal cancer.

Option D - Necitumumab is approved for first-line treatment of patients with metastatic, squamous non-small cell lung cancer in combination with gemcitabine and cisplatin.

Solution to Question 5:

In the given scenario, the woman requires suppression of lactation, for which cabergoline is indicated.

In the postpartum period, prolactin promotes lactation. Dopamine(DA) is the primary regulator of prolactin secretion from the pituitary gland. DA released from the hypothalamus into the hypophyseal portal blood supply acts on lactotroph D2 receptors to decrease prolactin secretion. The DA agonists like bromocriptine and cabergoline are used in conditions requiring suppression of prolactin.

Cabergoline is an ergot derivative with a longer t1/2 (~65 h), higher affinity, and greater selectivity for the DA D2 receptor compared to bromocriptine. Cabergoline is the preferred drug for the treatment of hyperprolactinemia because of greater efficacy and lower adverse effects. Therapy is initiated at a dose of 0.25 mg twice a week or 0.5 mg once a week. Cabergoline induces remission in a significant number of patients with prolactinomas. At higher doses, cabergoline is used in some patients with acromegaly alone or in conjunction with somatostatin analogs.

Adverse Effects -

Compared to bromocriptine, cabergoline has a much lower tendency to induce nausea, although it still may cause hypotension and dizziness. Cabergoline has been linked to valvular heart disease, an effect proposed to reflect agonist activity at the serotonin 5HT2B receptor. However, this effect is seen primarily at the high doses used in patients being treated for Parkinson's disease and is not seen in the conventionally used doses (≤2 mg/week) for patients with prolactinomas.

Other options:

Option B - Sumatriptan is a 5HT1B/1D receptor agonist used in the treatment of acute attacks of migraine.

Option C - Chlorpromazine is a typical antipsychotic, which has D2 antagonistic activity. It is used in the treatment of schizophrenia, acute mania, and refractory nausea and vomiting. Hyperprolactinemia is an adverse effect associated with its use.

Option D - Pramipexole is a non-ergot alkaloid with a broader DA receptor agonist activity, with the highest affinity to D3 receptors. It is used in the treatment of Parkinson's disease and restless leg syndrome. It is not indicated for the treatment of breast engorgement.

Solution to Question 6:

Coagulation profile monitoring is required while using lepirudin.

Lepirudin is a parenteral direct thrombin inhibitor, which is a recombinant form of hirudin extracted from the saliva of leech. Its action is independent of anti-thrombin, which means it can reach and inactivate fibrin-bound thrombin in thrombi. It is excreted by the kidney and should be used with great caution in patients with renal insufficiency as no antidote exists.

Like heparin, lepirudin must be administered parenterally and is monitored by aPTT. Lepirudin was approved for use in patients with thrombosis related to heparin-induced thrombocytopenia (HIT). Its production was discontinued by the manufacturer in 2012.

Other options :

Option B - Enoxaparin is a low molecular weight heparin (LMWH) that inhibits activated factor X with less effect on thrombin. Hence, it has a smaller effect on the coagulation profile and does not need monitoring.

Option C - Fondaparinux avidly binds antithrombin, resulting in efficient inactivation of factor Xa. It is effective in the prevention and treatment of venous thromboembolism and does not appear to cross-react with pathologic HIT antibodies in most individuals. Like LMWH, it does not require monitoring of the coagulation profile.

Option D - Dabigatran is an oral direct thrombin inhibitor approved for the reduction in risk of stroke and systemic embolism with nonvalvular atrial fibrillation, treatment of venous thromboembolism (VTE) and VTE prophylaxis following hip or knee replacement surgery. It does not require monitoring of coagulation profile.

Solution to Question 7:

The given clinical scenario suggests chronic kidney disease secondary to diabetes, and hydrochlorothiazide is not useful in preventing the progression of renal damage.

Chronic kidney disease (CKD) is defined as abnormalities of kidney structure or function, present for a minimum of 3 months, with implications for health. CKD is classified based on cause, glomerular filtration rate (GFR) category (G1–G5), and albuminuria category (A1–A3). Some of the leading causes of CKD are diabetes, hypertension, glomerulonephritis and polycystic kidney disease.

In patients with diabetes mellitus, often there exists a state of glomerular hyperfiltration due to decreased vascular resistance of afferent arterioles and increased vascular resistance of efferent arterioles resulting in increased glomerular hydrostatic pressure. This contributes to the progression of the CKD.

The following drugs have been approved in the management of CKD :

• Angiotensin-converting enzyme inhibitors / Angiotensin receptor blockers - These medications appear to slow the rate of decline of kidney function in a manner that extends beyond the reduction of systemic arterial pressure and that involves a reduction in the intraglomerular hyperfiltration and hypertension.

• Finerenone - It is a non steroidal mineralocorticoid receptor antagonist which decreases proteinuria. It has been approved to reduce the risk of end-stage kidney disease, cardiovascular death, and heart failure in diabetic patients with CKD.

• SGLT-2 inhibitors - These drugs inhibit sodium-glucose cotransporter type 2 in the proximal convoluted tubule. By increasing NaCl delivery to the thick ascending limb, gliflozins trigger tubuloglomerular feedback and thereby increase preglomerular vascular resistance and decrease glomerular hypertension. This contributes to the effectiveness of gliflozins to prevent diabetic kidney disease.

Solution to Question 8:

The active form of vitamin D, 1,25-dihydroxyvitamin D (calcitriol), directly suppresses PTH gene expression

Calcitriol is the active form of vitamin D. It increases calcium absorption from the intestines and helps maintain adequate serum calcium levels. When calcium levels rise, this triggers a negative feedback mechanism on the parathyroid glands, leading to decreased secretion of parathyroid hormone (PTH). PTH's primary role is to raise blood calcium levels, so when calcium is sufficient, the need for PTH decreases, resulting in lower PTH levels.

Vitamin D and its derivatives are the primary treatment for hypoparathyroidism. Dihydrotachysterol (DHT), a reduced form of vitamin D2, has a quicker onset, shorter duration, and stronger impact on bone mobilization than traditional vitamin D, making it a preferred option. While most hypoparathyroid patients respond well to any form of vitamin D, calcitriol may be preferred for temporary treatment of hypocalcemia while waiting for the effects of a slower-acting vitamin D form. Calcium is used to address calcium deficiency and as a dietary supplement. Vitamin D is the primary treatment for hypoparathyroidism.

Severe hypermagnesemia or hypomagnesemia can also inhibit PTH secretion.

Other options:

Option B: Risedronate is a bisphosphonate that inhibits bone resorption, but it doesn't directly affect PTH secretion.

Option C: Furosemide is a diuretic that can increase calcium excretion, potentially raising PTH as the body tries to conserve calcium.

Option D: Lithium can actually increase PTH secretion by affecting calcium-sensing receptors in the parathyroid glands.

Solution to Question 9:

Ritonavir and benzbromarone are both suicide inhibitors.

Suicide inhibition is when an inhibitor binds to an enzyme and then undergoes a reaction to form an irreversible complex with the enzyme, inactivating it permanently. Ritonavir is a protease inhibitor used in HIV treatment and benzbromarone is a uricosuric agent used to treat gout by increasing uric acid excretion. It also inhibits CYP2C9 via mechanism-based (suicide) inhibition.

Other options:

Ethinyl estradiol is a synthetic estrogen used in oral contraceptives and hormone replacement therapy. It acts through receptor-mediated mechanisms, not through suicide inhibition.

Spironolactone is a potassium-sparing diuretic and aldosterone antagonist. It works by competitively inhibiting aldosterone receptors in the distal tubules of the kidney, not through suicide inhibition.

Solution to Question 10:

The osmotic diuretics act at the proximal convoluted tubule and the potassium-sparing diuretics act on the collecting tubule. Hence C and D are the right statements.

A - Osmotic diuretics, like mannitol, retain water isoosmotically in the proximal convoluted tubule (PCT) and descending loop of Henle which are freely permeable to water. Luminal fluid is diluted and opposes NaCl reabsorption. They are indicated in raised intracranial tension and in dialysis disequilibrium.

B - Thiazides act on the distal convoluted tubule (DCT). They block the Na+/Cl- co-transporter in the DCT. This results in the loss of sodium, chloride, and water contributing to the diuretic effect. Some of the examples are hydrochlorothiazide, chlorthalidone and metolazone. Their indications include hypertension, edema, diabetes insipidus and hypercalciuria.

C - Carbonic anhydrase inhibitors act on the proximal convoluted tubule (PCT). By inhibiting carbonic anhydrase, HCO_3^- reabsorption is blocked and diuresis occurs. Examples are acetazolamide, methazolamide, dichlorphenamide, and dorzolamide. They are used in the treatment of glaucoma, urinary alkalinization in cystinuria, management of metabolic alkalosis, and acute mountain sickness.

D - Potassium-sparing diuretics include aldosterone antagonists (spironolactone, eplerenone) and inhibitors of renal epithelial Na+ channel (triamterene, amiloride). They act on the late distal tubule and the collecting duct. Aldosterone antagonists are used in the treatment of edema, hypertension, heart failure and Conn's syndrome. Amiloride has a role in lithium-induced diabetes insipidus.

Solution to Question 11:

Evolocumab is a monoclonal antibody that acts by inhibiting PCSK9.

PCSK9 (proprotein convertase subtilisin/kexin type) is a serine protease that causes lysosomal degradation of the low-density lipoprotein (LDL) receptors present on hepatocytes. Monoclonal antibodies against PCSK9 such as alirocumab and evolocumab counter this and cause persistence of LDL receptors on hepatocytes. This leads to more LDL uptake from the circulation, bringing down the LDL-cholesterol levels.

Evolocumab is administered as a 140-mg injection every 2 weeks or as a 420-mg injection once a month. PCKS9 inhibitors should not be used in pregnancy because transmission across the placenta is expected.

PCSK9 inhibitors are indicated only as adjunctive therapy in patients with familial hypercholesterolemia(FH) or established atherosclerotic cardiovascular disease(ASCVD) who have elevated LDL-cholesterol levels despite being on maximum statin therapy.

Other options :

Option A - Bempedoic acid acts by inhibiting de novo hepatocyte cholesterol biosynthesis, by blocking the enzyme adenosine triphosphate citrate lyase. The drug is approved as an adjunct to diet and maximally tolerated statin therapy to further lower LDL-C in patients with FH or established ASCVD.

Option B - Lomitapide acts by inhibiting microsomal triglyceride transfer protein (MTP), which is essential for the intracellular transfer of triglycerides into triglyceride-rich lipoproteins, thus inhibiting the formation of VLDLs in hepatocytes and chylomicrons in intestinal epithelial cells. It is approved as an adjunct to diet for lowering LDL-C levels, total cholesterol, apo B, and non–HDL lipoproteins in patients with FH.

Option C - Ezetimibe inhibits luminal cholesterol uptake by jejunal enterocytes, by inhibiting Niemann-Pick C1–like 1 transport protein. The role of ezetimibe as monotherapy for patients with elevated LDL-C levels is generally limited to a small group of statin-intolerant patients.

Solution to Question 12:

Inhaled nitric oxide(iNO) is used for persistent pulmonary hypertension in newborns. (Option A)

Inhaled NO selectively dilates the pulmonary vasculature, hence used in diseases associated with increased pulmonary vascular resistance. Inhaled NO is an FDA-approved drug for persistent pulmonary hypertension in the newborn.

Inhaled NO can also be used during cardiac catheterization to evaluate the pulmonary vasodilating capacity of patients with heart failure and infants with congenital heart disease. Another use of inhaled NO is to determine the diffusion capacity (DL) across the alveolar-capillary membrane. It is more effective than CO_2 because of its greater affinity for hemoglobin and its higher water solubility at body temperature.

NO is produced from the nasal passages and the lungs of normal human subjects and can be detected in exhaled gas. The measurement of fractional exhaled NO is a noninvasive marker for airway inflammation in the assessment of respiratory tract diseases, including asthma, respiratory tract infection, and chronic lung disease.

Inhaled NO is administered at low concentrations (0.1–50 ppm) since high concentrations of 50 to 100 ppm can cause significant methemoglobinemia that can cause death.

Other options:

Option B: Unstable angina is treated by anti-platelet drugs such as aspirin and clopidogrel, and anticoagulants such as heparin.

Option C: Obstructive sleep apnoea is mainly treated by using a BiPAP machine during sleep and CNS stimulants such as armodafinil for daytime sleepiness associated with the condition.

Option D: Erectile dysfunction is treated by PDE5 inhibitors such as sildenafil, tadalafil, etc.

Solution to Question 13:

Bromhexine should be prescribed for a patient with a productive cough, as it liquifies the sputum.

Bromhexine belongs to a class of drugs called mucolytics, capable of inducing thin copious bronchial secretion. It depolymerizes mucopolysaccharides directly as well as by liberating lysosomal enzymes- the network of fibers in tenacious sputum is broken. It is particularly useful if mucus plugs are present.

Other examples of mucolytics are ambroxol, carbocisteine, and N-acetyl cysteine.

Other options :

Codeine and dextromethorphan belong to the class of drugs called antitussives. These are drugs that act in the CNS to raise the threshold of the cough center or act peripherally in the respiratory tract to reduce tussal impulses, or both these actions. Because they aim to control rather than eliminate cough, antitussive drugs should be used only for dry nonproductive cough or if it is unduly tiring, disturbs sleep, or is hazardous (hernia, piles, cardiac disease, ocular surgery).

Cough is a defensive reflex and its suppression may be inappropriate in bacterial lung infection. Hence, before treatment with antitussives, it is important to identify underlying causal mechanisms that may require therapy.

Solution to Question 14:

Metformin is known to cause unexplained diarrhoea as its adverse effect.

Metformin is a member of the biguanide class of oral hypoglycemic drugs. It acts by primarily by inhibiting hepatic gluconeogenesis. It activates AMP-dependent protein kinase, leading to stimulation of hepatic fatty acid oxidation, glucose uptake, and nonoxidative glucose metabolism and reduction of lipogenesis and gluconeogenesis. It also appears to act in the gut.

Metformin is accepted as the first-line treatment of type 2 diabetes and is the most commonly used oral agent for this condition. It has been used as a treatment of infertility in women with polycystic ovarian syndrome.

The most common side effects of metformin are gastrointestinal: nausea, indigestion, abdominal cramps, bloating, and diarrhea. The use of metformin is also associated with lower blood levels of vitamin B12.

Most adverse GI effects of metformin abate over time and can be minimized by starting at a low dose and gradually titrating to a target dose over several weeks, as well as by having patients take the drug with meals. Extended-release metformin has decreased GI side effects and can be substituted for immediate-release metformin. Lactic acidosis has been linked with the use of metformin.

Other options:

Option A - Sitagliptin is a dipeptidyl peptidase-4 inhibitor. Its use is associated with an increased risk of heart failure.

Option C - Glimepiride belongs to the class of sulfonylureas. It stimulates insulin release by inhibiting the activity of the β cell KATP channel complex. Its side effects include hypoglycemia, and weight gain.

Option D - Pioglitazone is an activator of the peroxisome proliferator-activated receptor γ (PPARγ), which is involved in the regulation of genes related to glucose and lipid metabolism. Its adverse effects include increased incidence of heart failure, peripheral edema, weight gain, macular edema, and osteoporosis.

Solution to Question 15:

The half-life of Digoxin is 42 hours.

In first-order kinetics:

$$\text{Plasma half-life (t1/2)} = 0.693 \times \frac{\text{Volume of distribution } (V_d)}{\text{Clearance (CL)}}$$

Therefore,

t1/2 ~ 0.7 x 46x6/4.6 = 0.7 x 60

t1/2 ~ 42 hours

Where,

t1/2 - Plasma half-life

Vd - Volume of distribution

CL - Clearance

Solution to Question 16:

Acute oral overdose results primarily in cerebellar and vestibular symptoms and high doses have been associated with marked cerebellar atrophy.

Dose-related toxicity of phenytoin causes ataxia, vertigo, diplopia, and nystagmus.

Other options:

Option B: High dose causes cardiotoxicity in both old and young, healthy patients. However, cardiotoxicity is more pronounced and frequent in older patients and those with known cardiac diseases.

Option C: These complications can be minimised by administering fosphenytoin at a rate of less than 150 mg of phenytoin sodium equivalents per minute, not 250 mg.

Option D: Phenytoin is not effective in generalised absent seizures.

Solution to Question 17:

Iron requirement can be fulfilled in a single dose is true regarding Isomaltoside 1000.

Iron isomaltose 1000 is a new IV iron formulation that can supply a complete replacement dose in a short, single visit. It is used in adult patients with an intolerance to oral iron or for patients with CKD not requiring hemodialysis.

Other options:

Option B: Isomaltoside 1000 is not more immunogenic than iron dextran.

Option C: The strength of iron binding causes a controlled slow release of bioavailable iron, decreasing the risk of toxicity from labile-free iron. Its decreased toxicity cannot be attributed to deposition in adipose tissue.

Option D: Isomaltoside 1000 can be given with erythropoietin.

Solution to Question 18:

The drug that binds to CD4 and has an action on both CCR5 and CXCR4 in tropic HIV infections is Ibalizumab.

Ibalizumab is an anti-CD4 monoclonal antibody approved for use in the treatment of multidrug-resistant HIV-1. It has action on both CCR5 and CXCR4 in tropic HIV infections and is administered intravenously.

It acts as an entry inhibitor. It blocks HIV-1 from infecting CD4+ T cells by binding to domain 2 of CD4 cells. It also interferes with post-attachment steps required for the entry of HIV-1 virus particles into host cells and thus prevents the viral transmission that occurs via cell-cell fusion.

Other options:

Option A: Maraviroc binds to the host cell CCR5 receptor to block the binding of viral gp120. It prevents the entry of the viral particles. It does not bind to CD4.

Option C: Elvitegravir is an integrase inhibitor that inhibits HIV 1 viral integrase enzyme and prevents proviral DNA integration into host cells.

Option D: Fosamprenavir is a protease inhibitor that blocks the viral protease enzyme necessary to produce mature virions upon budding from the host membrane.

Solution to Question 19:

Rucaparib is an inhibitor of Poly ADP ribose polymerase (PARP) used for BRCA-positive breast cancers.

Rucaparib is a poly ADP-ribose polymerase/ PARP inhibitor approved for the treatment of breast and advanced ovarian cancer.

PARP is a nuclear protein that transfers ADP-ribose from NAD+ to target proteins and this plays an important role in the DNA damage response. Rucaparib and olaparib are PARP inhibitors.

Inhibitors of PARP (Poly ADP Ribosyl Polymerase) approved for breast cancer:

• Olaparib

• Rucaparib

• Talazoparib

Other options:

Option A: Palbociclib is a selective inhibitor of the cyclin-dependent kinases CDK4 and CDK6. It is used in the treatment of metastatic breast cancer.

Option C: Regorafenib is an angiogenesis inhibitor that is indicated as a second-line treatment for unresectable hepatocellular carcinoma. (The first line is Sorafenib).

Option D: Vandetanib is an oral tyrosine kinase inhibitor recently FDA-approved for unresectable locally advanced or metastatic medullary thyroid carcinoma.

Solution to Question 20:

1,2 and 4 can be added based on his lipid profile.

A patient with hypertension and diabetes who underwent PCI stent placement for NSTEMI has atherosclerotic cardiovascular disease (ASCVD). The treatment goal in patients with ASCVD is to decrease LDL levels.

Ezetemibe, Evolocumab, Bemepedoic acid decrease LDL. Gemfibrozil mainly decreases triglycerides and not LDL.

1. Evolocumab is a monoclonal antibody that inhibits PCSK-9 (proprotein convertase subtilisin/kexin). Inhibition of PCSK-9 prevents the degradation of LDL receptors and thus increases LDL-cholesterol clearance by the liver. They are used in patients with atherosclerotic cardiovascular disease (ASCVD) to decrease LDL levels.

2. Ezetimibe inhibits cholesterol absorption by enterocytes in the small intestine. It lowers the total and LDL-C levels.

3. Gemfibrozil belongs to the fibrate group of drugs that binds to peroxisome proliferator-activated receptors (PPARα), which stimulate fatty acid oxidation and thereby reduce triglyceride levels mainly.

4. Bempedoic acid inhibits adenosine triphosphate-citrate lyase (ACL) and results in decreased LDL in patients not responding to statin therapy.

Note - Ezetimibe, colestipol, bempedoic acid and PCSK-9 inhibitors like alirocumab have been proven to reduce atherosclerosis risk when added to statins, whereas the fibrate group of drugs and niacin show no significant effect in addition to statins.

Solution to Question 21:

Contraindicated in patients on enzyme inducer drugs is the true statement regarding Pretomanid.

Pretomanid is metabolized in part by CYP3A. So co-administration with strong or moderate CYP3A inducers should be avoided. Hence, it is contraindicated in patients on enzyme-inducer drugs.

Pretomanid is a bicyclic nitroimidazole that acts by inhibiting mycolic acid (a component of the mycobacterial cell wall) and protein synthesis in the mycobacteria.

Pretomanid in combination with Bedaquiline and Linezolid, was approved by the FDA in 2019 for the treatment of adult patients with Pre (XDR) TB (resistant to rifampicin and any fluoroquinolones) and for patients who are treatment-intolerant or nonresponsive to multidrug-resistant pulmonary (MDR) TB treatment.

Other options:

Option A: Pretomanid is given for Pre -XDR TB (not XDR TB) in combination with Bedaquiline and Linezolid (BPaL regimen). Pre-XDR TB is resistant to rifampicin and any fluoroquinolone, and therefore, BPaL is given to such patients.

Option C: Pretomanid acts by reactive nitrogen species like NO and not by reactive oxygen species.

Option D: Pretomanid is not used for resistant cases of malaria.

*Note: For people with MDR/RR-TB, the regimen comprises bedaquiline (B), pretomanid (Pa), linezolid (L) and moxifloxacin (M), and is referred to as BPaLM. For people who have pre-XDR-TB, the regimen can be used without moxifloxacin (BPaL).

Solution to Question 22:

Lacosamide is a drug acting on sodium channel and potentiating slow sodium inactivation.

Lacosamide acts by blocking the voltage-gated sodium channels. It is used as adjunctive therapy for focal-onset seizures in patients older than 17 years.

It is the first anti-seizure medication that limits persistent repetitive firing, the neuronal firing pattern typical of focal seizures, and prolongs the gradual inactivation of voltage-gated Na+

channels. Additionally, lacosamide binds to the phosphoprotein collapsing response mediator protein-2 (CRMP-2), which is mostly expressed in the nervous system and has a role in controlling axonal outgrowth and neuronal differentiation.

The role of CRMP-2 binding in seizure control is unknown.

Therapeutic Uses:

• It is used for both monotherapy and add-on therapy for focal-onset seizures in patients 17 years and older.

• It is mostly beneficial in hospitalized patients because it is available in an intravenous formulation, has minimal hepatic metabolism, and has no adverse respiratory effects.

Antiepileptic Drugs	Mechanism of Action
Phenytoin (Option A)CarbamazepineLamotrigine (Option B)	Inhibit Na channels
PhenobarbitalVigabatrinTiagabine	Enhance GABA inhibitionVigabatrin – block GABA aminotransferase irreversiblyTiagabine – block GABA reuptake
EthosuximideZonisamideGabapentinPregabalin	Block Ca channelsEthosuximide, Zonisamide –block T-type Ca channelsGabapentin, Pregabalin –block voltage sensitive Ca channels
Levetiracetam	Binds synaptic vesicle protein 2A
Valproate	Multiple MOA:GABA related actionNMDA receptor antagonistHistone deacetylase inhibitor
Topiramate (Option D)	Multiple MOA:GABAergic actionAMPA receptor antagonistActs on Na, Ca and K channels
Drugs acting on glutamate receptors	NMDA-type glutamate receptors:Valproate, FelbamateAMPA-type glutamate receptors: Topiramate, Perampanel
Newer drugs:RufinamideLacosamideEzogabinePerampanel	Prolongs inactivation of voltage-gated Na channels Enhances inactivation of voltage-gated Na channels Inhibits collapsin response mediator protein 2Potassium channel openerAMPA-type glutamate receptor antagonist

Solution to Question 23:

The marked receptor is GABA Transporter 1 Receptor (GAT-1), and Tiagabine acts on this receptor.

Tiagabine inhibits the neuronal uptake of GABA and prolongs its time in the synaptic cleft, where the GABA molecules can activate GABA receptors.

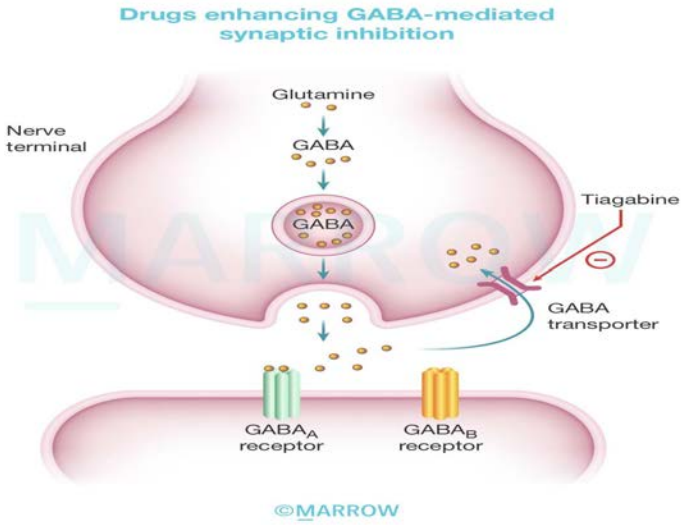
Other drugs which act on the GABAergic pathway are:

• Activation of GABA A receptors - Barbiturates, Phenobarbitone

• Activation of GABA B receptors - Baclofen

• Prevents the uptake of GABA - Tiagabine

• Prevents the degradation of GABA (inhibits GABA transaminase) - Vigabatrin



Other options:

Option B: Ganaxolone is a recently approved drug for the treatment of seizures associated with CDKL5 deficiency. The exact mechanism of action of Ganaxolone is unknown, but its anticonvulsant effects are thought to result from positive allosteric modulation of the GABA-A receptor in the CNS. It can be used in adults as well as children older than 2 years of age. The most common adverse reactions associated with the drug are somnolence, pyrexia, salivary hypersecretion and seasonal allergy.

Option C: Felbamate is the NMDA receptor antagonist prescribed to this patient. It also potentiates GABA action. It is indicated in refractory primary or secondary generalised seizures and Lennox-Gastaut syndrome. Felbamate is associated with aplastic anemia and liver failure.

Option D: Stiripentol is a GABA A receptor modulator with GABA-enhancing activity. It is clinically used in conjunction with valproate and clobazam for refractory generalized tonic-clonic seizures with severe myoclonic epilepsy in infants (Dravet syndrome).

Solution to Question 24:

The correct set of matching is a-ii, b-iii, c-i, d-iv.

Naloxone is an opioid antagonist used to reverse the effects of opioid overdose, such as respiratory depression.

Oxazepam is a benzodiazepine used for the management of delirium tremens, a severe alcohol withdrawal syndrome.

Varenicline is a partial agonist at the nicotinic acetylcholine receptors, used for smoking cessation by reducing withdrawal symptoms and cravings.

Acamprosate is a modulator of glutamate and GABA neurotransmission, used for the treatment of alcoholism by reducing cravings and the risk of relapse in alcohol abstinence.

a. Naloxone	ii. Opioid overdose
b. Oxazepam	iii. Delirium tremens
c. Vareniclin e	i. Smoking cessation
d. Acampros ate	iv. Treatment of alcoholism

Pharmacology NEET 2024

Question 1:

A man presents with mixed infection of Plasmodium vivax and Plasmodium falciparum in a health centre in Rajasthan. What is the dosage of the treatment given on the second day?

a) 4 tablets of Artesunate 50mg + 6 tablets of Primaquine 2.5mg

b) 4 tablets of Artesunate 50mg + 6 tablets of Primaquine 7.5mg

c) 4 tablets of Artesunate 50mg + Sulphadoxine 1500mg + 6 tablets of Primaquine 2.5mg

d) 4 tablets of Artesunate 45mg + Sulphadoxine 1500mg + 6 tablets of Primaquine 7.5mg

Question 2:

Which drug is used to treat multiple myeloma that is known to cause reactivation of Herpes Zoster?

a) Bortezomib

b) Lenalidomide

c) Daratumumab

d) Elotuzumab

Question 3:

A patient presented with breathing difficulty and nasal polyposis when he took aspirin for fever. He faced this issue previously too when he took aspirin. Which among the following is not true about this?

a) There is no allergic sensitization to aspirin and its metabolites

b) Responds to Monteleukast

c) Occur on exposure to only aspirin

d) Occurs with exposure to other NSAIDs too that block COX 1

Question 4:

A 75-year-old female presented with urinary incontinence. She also has cognition decline and dementia. Which of the following drugs is useful for treating urinary incontinence?

a) Tiotropium

b) Ipratropium

c) Tolterodine

d) Telenzipine

Question 5:

A 7-year-old boy presents with a two-week history of persistent fever, fatigue, and pallor. His parents also report easy bruising and gum bleeding. On examination, he is pale with petechiae on his legs, hepatosplenomegaly, and generalized lymphadenopathy. Blood tests show severe anemia, thrombocytopenia, and elevated white blood cell count with blast cells. What is the most appropriate initial treatment regimen for this patient?

a) IVIG

b) Doxorubicin + Idarubicin

c) Prednisolone + vincristine

d) Radiotherapy of lymph nodes

Question 6:

Lignocaine is used in a loading dose for the treatment of arrhythmias. The loading dose of this drug depends upon which of the following factors?

a) Clearance

b) Volume of distribution

c) Plasma half life

d) Bioavailability

Question 7:

A hypertensive patient with chronic kidney disease was having frequent attacks of renal colic. Which of the following diuretics is used?

a) Furosemide

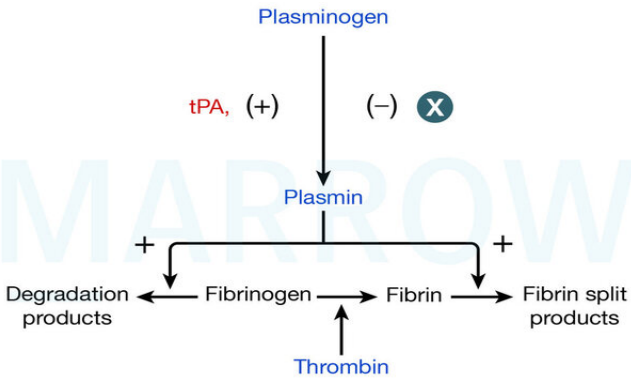
b) Mannitol

c) Hydrochlorothiazide

d) Spironolactone

Question 8:

Identify the drug marked as 'X' in the image.



a) Clopidogrel

b) Amino caproic acid

c) Tenecteplase

d) Heparin

Question 9:

Which of the following beta-adrenergic blockers are beneficial for patients with reduced ejection fraction and can reduce mortality in chronic heart failure without causing exacerbations over a few years?

a) Propanolol

b) Pindolol

c) Esmolol

d) Bisoprolol

Question 10:

Which drug is used for maintenance therapy in opium addiction?

a) Buprenorphine

b) Naloxone

c) Butarphanol

d) Clonidine

Question 11:

A patient who recently underwent surgery has complaints of nausea and vomiting. He was prescribed a drug called aprepitant. What is its mechanism of action?

a) NK-3 antagonist

b) NK-2 agonist

c) NK-1 antagonist

d) NK-1 agonist

Question 12:

An HIV patient developed a fever and dry cough. He was diagnosed with TB. He is currently on Lamivudine, Zidovudine and Nevirapine. Which Anti -TB drug should be changed in this patient?

a) Isoniazid

b) Rifampicin

c) Streptomycin

d) Ethambutol

Question 13:

A 32-year-old woman diagnosed with diarrhoea-predominant irritable bowel syndrome presented to the casualty with severe abdominal pain. She was prescribed a drug that exerts a direct spasmolytic effect on the smooth muscles of the gastrointestinal tract. Which drug could it be?

a) Dicyclomine

b) Scopolamine

c) Galantamine

d) Rivastigmine

Question 14:

A patient is started on a 3 HP TPT regimen. Which of the following is true regarding the regimen?

a) There is more compliance in 3HP than 9H and 6H

b) No significant difference in 3HP, 6H, 9H

c) Chance of abortion in 3 HP is same as 6H

d) 3HP regimen is less effective than 6H and 9H in preventing active TB

Question 15:

A female suffered a head injury from a road traffic accident. On examination, there is elevated intracranial pressure. Which diuretic among the following can be used in her condition?

a) Mannitol

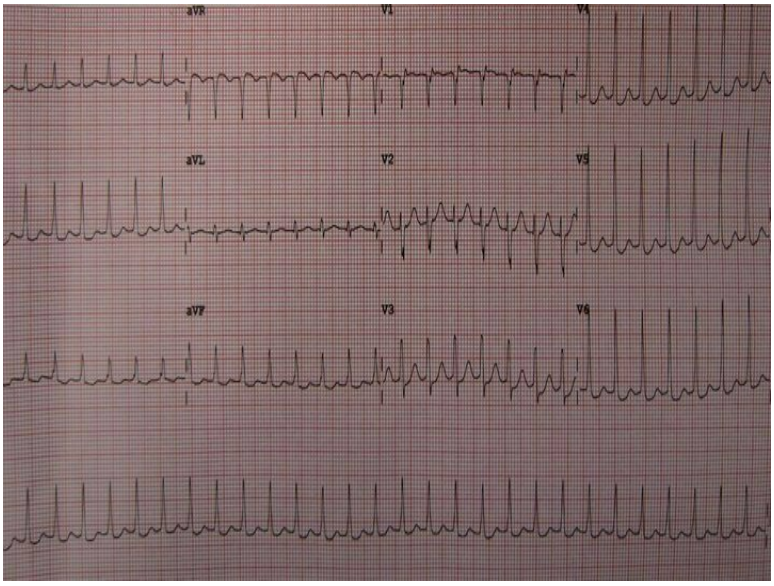
b) Hydrochlorothiazide

c) Spironolactone

d) Acetazolamide

Question 16:

A 2-year-old child presents to the emergency department with lethargy, difficulty feeding, and dehydration. His vitals are stable and his ECG is shown below. What is the next step in his management?



a) Synchronized cardioversion with 2J of current

b) Adenosine 0.1 mg/kg

c) Adenosine 0.2 mg/kg

d) Synchronized cardioversion with 1J of current

Question 17:

Which of the following drugs when added with erythromycin can lead to torsades de pointes?

a) Doxylamine

b) Loratidine

c) Promethazine

d) Astemizole

Question 18:

A child was started on ciclesonide inhalational therapy for bronchial asthma. Which of the following statements is incorrect regarding his treatment?

a) It has fewer side effects compared to other inhalational steroids

b) It is a prodrug metabolised by bronchial esterase

c) The occurence of oral candidiasis is more compared to other inhaled steroids

d) Oral bioavailability is negligible

Question 19:

A patient diagnosed with hypertriglyceridemia was started on a medication, following which, he developed flushing, hyperglycemia, and elevated liver enzymes. Identify the drug consumed by the patient.

a) Nicotinamide

b) Rosuvastatin

c) Ezetemibe

d) Fenofibrate

Question 20:

Which of the following reasons best explains the combination of Atropine (0.025 mg) and Diphenoxylate (2.5 mg) for treating secretory diarrhoea?

a) Atropine potentiates the action of smooth muscle relaxation

b) It prevents overdose and abuse of Diphenoxylate

c) It antagonizes the side effect of Diphenoxylate

d) Atropine increases the antimotility action of diphenoxylate

Question 21:

A hypertensive patient is started on a drug to control his BP. He had complaints of dry mouth, drowsiness, and confusion after taking this drug, but he still continued to take the drug for 1 year. He had to travel abroad for work, and he forgot to take his medications. He now presents with a blood pressure of 200/120mmHg. Identify the drug he was on?

a) Amlodipine

b) Atenolol

c) Clonidine

d) Enalapril

Question 22:

In which phase of clinical trials is drug dosing done?

a) Phase I

b) Phase II

c) Phase III

d) Phase IV

Question 23:

A patient with a gynecological malignancy is started on Methotrexate. Later she develops oral and gastric ulcers. Which nucleotide synthesis is affected in her?

a) UDP

b) CTP

c) TMP

d) GMP

Question 24:

The drug 'X' is a GHRH analogue that is FDA-approved for the treatment of HIV-associated lipodystrophy and not used for Growth hormone deficiency. Identify the drug 'X'.

a) Octreotide

b) Somatropin

c) Tesamorelin

d) Mecasermin

Detailed Explanations

Solution to Question 1:

The dosage of the treatment given on the second day for mixed infection with Plasmodium vivax and Plasmodium falciparum is 4 tablets of Artesunate 50mg + 6 tablets of Primaquine 2.5mg.

For treating mixed infections of Plasmodium vivax and Plasmodium falciparum, the following treatment regimen is recommended. This approach ensures comprehensive treatment by addressing both the blood stages of Plasmodium falciparum with ACT and the liver stages of Plasmodium vivax with Primaquine.

Dosage chart for treatment of mixed (vivax and falciparum) malaria with ACT-SP

Age	Day 1			Day 2		Day 3		Day 4-14
	AS tablet (50 mg)	SP tablet	PQ (2.5 mg)	AS tablet (50 mg)	PQ (2.5 mg)	AS tablet (50 mg)	PQ (2.5 mg)	PQ (2.5 mg)
Less than 1 year	½	½	0	½	0	½	0	0

©MARROW

Solution to Question 2:

The drug used to treat multiple myeloma and that has the potential to cause reactivation of Herpes Zoster is bortezomib.

Bortezomib is an inhibitor of proteasome-mediated protein degradation. It is central to the treatment of multiple myeloma, both untreated and relapsed. Bortezomib is given intravenously or subcutaneously and dosage depends upon the disease, route of administration, and the patient's history. It is known to predispose patients to the reactivation of herpesvirus, including Herpes Zoster.

Adverse effects include thrombocytopenia, fatigue, peripheral neuropathy, neutropenia, anaemia, anorexia, nausea, limb pain, dizziness, etc. Other adverse events like cardiac tamponade, disseminated intravascular coagulation, toxic epidermal necrolysis, etc. have been reported.

Other options:

Option B: Lenalidomide is the drug of choice in patients with myelodysplastic syndrome (MDS) associated with 5q deletion, and is an immunomodulatory analogue of thalidomide. It suppresses bone marrow and is often associated with significant leukopenia.

Option C: Daratumumab is a monoclonal antibody against CD-38.

Option D: Elotuzumab is a monoclonal antibody against SLAMF7, a glycoprotein expressed in multiple myeloma cells and natural killer cells. It is used in combination with lenalidomide and dexamethasone for the treatment of multiple myeloma.

Solution to Question 3:

The diagnosis for this patient with breathing difficulty and nasal polyposis, triggered by aspirin, a COX-1 inhibitor is aspirin-induced asthma, also known as Samter's triad. The statement that is

not true is that "it occurs on exposure to only aspirin", as this condition can also be triggered by other NSAIDs that inhibit COX-1, and is not restricted to just aspirin alone.

Samter's triad is also known as aspirin-induced asthma or aspirin-sensitive asthma. It consists of:

• Nasal polyposis

• Bronchial asthma

• Aspirin intolerance

A patient with Samter's triad experiences severe asthma and nasal polyposis triggered by aspirin or other COX-1 inhibitors. This condition involves nasal congestion, rhinorrhea, anosmia, and recurrent chronic rhinosinusitis, with acute asthma attacks often occurring a few hours after ingestion of these medications.

These patients overproduce leukotrienes due to COX-1 inhibition and decreased prostaglandin E2 (PGE2) levels. Therefore, they should avoid COX-1 inhibitors like aspirin and most NSAIDs but can generally tolerate COX-2 inhibitors and acetaminophen.

Treatment typically includes leukotriene modifiers, and in some cases, aspirin desensitization may be used to manage symptoms and allow the use of aspirin or NSAIDs if necessary for other conditions. Recent advances in treatment include biologics such as Dupilumab and IL-5 inhibitors, which are increasingly effective in managing aspirin-induced asthma and may replace aspirin desensitization except when ongoing aspirin or NSAID therapy is required.

Other options:

Option A: The reaction in aspirin-induced asthma is not due to an allergic sensitization but rather due to the inhibition of COX-1 and subsequent overproduction of leukotrienes.

Option B: Montelukast, a leukotriene receptor antagonist, is effective in managing symptoms of aspirin-induced asthma by counteracting the elevated levels of leukotrienes that contribute to inflammation and respiratory issues.

Option D: It occurs with exposure to other NSAIDs too, that block COX-1. Patients with aspirin-induced asthma can react to other NSAIDs that inhibit COX-1, not just aspirin.

Solution to Question 4:

For managing urinary incontinence in a 75-year-old female with cognitive decline and dementia, tolterodine is useful.

Tolterodine is a muscarinic receptor antagonist specifically effective for treating urinary incontinence. It exhibits selectivity for the urinary bladder, which helps to minimize side effects compared to other antimuscarinic agents. This selectivity is beneficial for patients with cognitive decline or dementia, as it reduces the risk of adverse effects. Tolterodine is metabolized by CYP2D6, so its dosage may need adjustment based on individual CYP2D6 activity, making it a suitable option for managing urinary incontinence while minimizing potential side effects.

Other muscarinic antagonists for urinary incontinence include oxybutynin, trospium chloride, darifenacin, solifenacin, and fesoterodine. Oxybutynin, though effective, often causes antimuscarinic side effects such as xerostomia. Trospium chloride, being a quaternary amine, is better tolerated and excreted primarily via the kidneys, requiring dosage adjustments in renal

impairment. Darifenacin and solifenacin have selectivity for M3 receptors, which helps balance efficacy and side effects, while fesoterodine, a prodrug, provides a stable pharmacokinetic profile due to its conversion to tolterodine's active metabolite.

Other Options:

Option A: Tiotropium and Option C: Ipratropium are muscarinic antagonists used primarily for respiratory conditions such as chronic obstructive pulmonary disease (COPD) and asthma, rather than urinary incontinence. Tiotropium is a long-acting agent with selectivity for M1 and M3 receptors, while Ipratropium is used more frequently for its short-acting effects.

Option D: Telenzepine, an analogue of Pirenzepine, displays higher potency and selectivity for M1 receptors compared to pirenzepine and is used in treating acid-peptic disease, not urinary incontinence.

Solution to Question 5:

The given clinical scenario suggests a diagnosis of Acute Lymphoblastic Leukemia (ALL), and standard initial treatment in children includes a chemotherapy regimen with drugs like prednisolone and vincristine during the induction phase.

Patients diagnosed with ALL present with symptoms of impaired marrow function like anaemia, infections secondary to neutropenia, and bleeding due to thrombocytopenia. Other symptoms include bone pain, generalized lymphadenopathy, splenomegaly, hepatomegaly, testicular enlargement, headache, vomiting, and nerve palsies.

Treatment of ALL

Induction: L-Asparaginase, vincristine, prednisolone, and anthracycline

CNS prophylaxis with intrathecal methotrexate

Consolidation: Methotrexate, cytarabine

Maintenance: 6-Mercaptopurine, methotrexate plus intrathecal therapy

Other Options:

Option A: IVIG: Intravenous immunoglobulin (IVIG) is not used for treating ALL.

option B: Both doxorubicin and idarubicin are anthracyclines used in chemotherapy. While doxorubicin can be part of certain ALL treatment protocols, idarubicin is more commonly used in Acute Myeloid Leukemia (AML) rather than ALL. This combination is not typically used in the induction phase for ALL children.

Option D: Radiotherapy is not a standard initial treatment for ALL. It may be considered in specific cases, such as central nervous system involvement or certain high-risk cases, but the primary treatment for ALL is systemic chemotherapy, not localized radiotherapy.

Solution to Question 6:

The volume of distribution of the drug determines the loading dose of the drug.

Loading Dose = Volume of distribution x Desired steady-state plasma concentration.

When the time to reach a steady-state is long, as it is for drugs with long half-lives, it may be desirable to administer a loading dose that promptly raises the concentration of the drug in plasma to the target concentration.

Other options:

Option A: Clearance is used to determine the maintenance dose.

Maintenance dose = clearance x desired steady-state plasma concentration.

Options C and D: Plasma half-life primarily determines the frequency of dosing, while bioavailability determines the route of administration. Though bioavailability may affect the dose necessary, it will not be the primary factor considered during the calculation of the loading dose.

Solution to Question 7:

For a hypertensive patient with chronic kidney disease experiencing frequent attacks of renal colic, hydrochlorothiazide, a thiazide diuretic, is often used.

Thiazide diuretics are particularly effective in cases of calcium oxalate kidney stones because they reduce urinary calcium excretion. They work by acting on the distal convoluted tubule (DCT) of the nephron, where they inhibit the Na+/Cl- co-transporter. This inhibition decreases the intracellular sodium concentration, which, through compensatory mechanisms, leads to increased calcium reabsorption into the bloodstream.

While this mechanism helps in decreasing urinary calcium and managing calcium oxalate stones, thiazide diuretics can also cause adverse effects such as hypokalemia, hyperuricemia, and hypercalcemia. The increased reabsorption of uric acid due to the diuretic effect can exacerbate conditions like gout and should be monitored carefully.

In addition to their use in treating calcium oxalate kidney stones, thiazide diuretics are commonly prescribed for managing uncomplicated hypertension and treating edema associated with heart, liver, and kidney diseases. They are also used for conditions like osteoporosis and nephrogenic diabetes insipidus.

Other options:

Option A: Furosemide is a diuretic that can increase calcium excretion, potentially raising PTH as the body tries to conserve calcium.

Option B: Osmotic diuretics, like mannitol, retain water isoosmotically in the proximal convoluted tubule (PCT) and descending loop of Henle which are freely permeable to water. Luminal fluid is diluted and opposes NaCl reabsorption and promotes calcium excretion. They are indicated in raised intracranial tension and in dialysis disequilibrium.

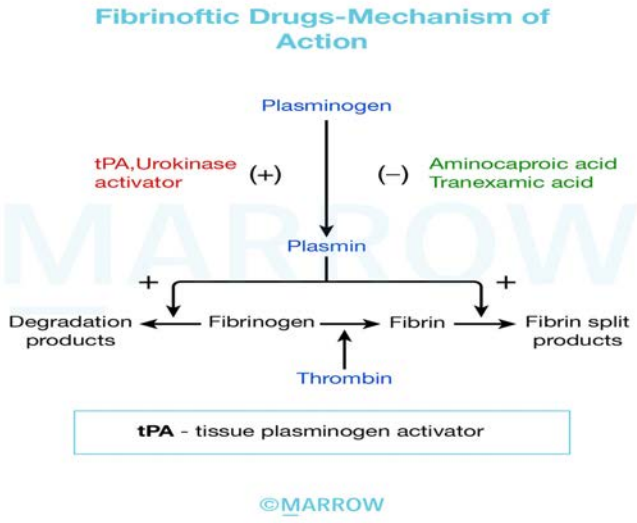
Option D: Spironolactone is a potassium-sparing diuretic and aldosterone antagonist. It works by competitively inhibiting aldosterone receptors in the distal tubules of the kidney.

Solution to Question 8:

The drug marked as 'X' in the image is aminocaproic acid.

ε-Aminocaproic acid, a lysine analogue that competes with plasminogen for binding sites on fibrin. By blocking this interaction, ε-Aminocaproic acid prevents the conversion of plasminogen into plasmin, thereby inhibiting fibrinolysis. This action makes it a useful agent for reversing the effects of fibrinolytic therapy.

However, ε-Aminocaproic acid should be administered with caution as it can suppress intrinsic fibrinolytic activity, potentially leading to complications such as disseminated intravascular coagulation (DIC). To address this, fresh frozen plasma and cryoprecipitate may be used to restore fibrin and clotting factors.



Solution to Question 9:

The beta-adrenergic blocker that is useful in patients with reduced ejection fraction and can reduce mortality in chronic heart failure without causing exacerbations over a few years is bisoprolol.

Bisoprolol is preferred for use in patients having heart failure with reduced ejection fraction (HFrEF).

The exacerbation mentioned in the context of beta-blockers for heart failure refers to the potential worsening of heart failure symptoms in some patients, despite the overall benefits of these medications. They can sometimes lead to a decline in left ventricular function, particularly in individuals with limited cardiac reserve who rely heavily on adrenergic stimulation. This deterioration can manifest as increased heart failure symptoms or a decrease in cardiac function. The only beta-blockers that have been proven to improve the survival of patients with HFrEF or chronic HF are -

• Bisoprolol

• Metoprolol

• Carvedilol

HFrEF is a complex clinical syndrome where the ventricle fails to adequately fill with or eject blood, typically defined by an ejection fraction (EF) less than or equal to 40%. Key etiologies include coronary artery disease, valvular heart disease, congenital heart diseases, and autoimmune diseases like giant cell myocarditis. Patients with HFrEF commonly experience symptoms like dyspnea on exertion, orthopnea, and paroxysmal nocturnal dyspnea, and may present with pedal edema, elevated jugular venous pressure (JVP), ascites, and hepatomegaly on examination.

The pharmacological management of HFrEF involves drugs with both symptomatic and mortality benefits, including Angiotensin receptor–neprilysin inhibitors (ARNIs) such as sacubitril/valsartan, angiotensin-converting enzyme (ACE) inhibitors like ramipril and enalapril, β-blockers such as metoprolol and carvedilol, mineralocorticoid receptor antagonists like spironolactone and eplerenone, sodium-glucose cotransporter 2 (SGLT2) inhibitors like dapagliflozin, and hydralazine plus isosorbide dinitrate (noting a mortality benefit specifically in African-American patients). Drugs used primarily for symptomatic relief, such as loop diuretics (e.g., furosemide), and digoxin, are reserved for specific indications or during decompensation. Non-pharmacological therapies for HFrEF include implantable cardioverter-defibrillators (ICD) and cardiac resynchronization therapy.

Solution to Question 10:

The drug used among the following options for maintenance therapy in opium addiction is buprenorphine.

Buprenorphine is a partial μ-opioid agonist and an antagonist at δ and κ receptors. It is widely used both as an analgesic for chronic pain conditions, such as cancer pain, and as a treatment for opioid dependence, serving as an alternative to methadone.

It effectively controls cravings and blocks the effects of higher-efficacy opioids. It is often administered in combination with naloxone to prevent misuse, although it may be given alone to pregnant women or individuals with naloxone allergies. Initial dosing typically starts at 2-4 mg daily, with adjustments made to stabilize the dose at approximately 12 to 16 mg/day.

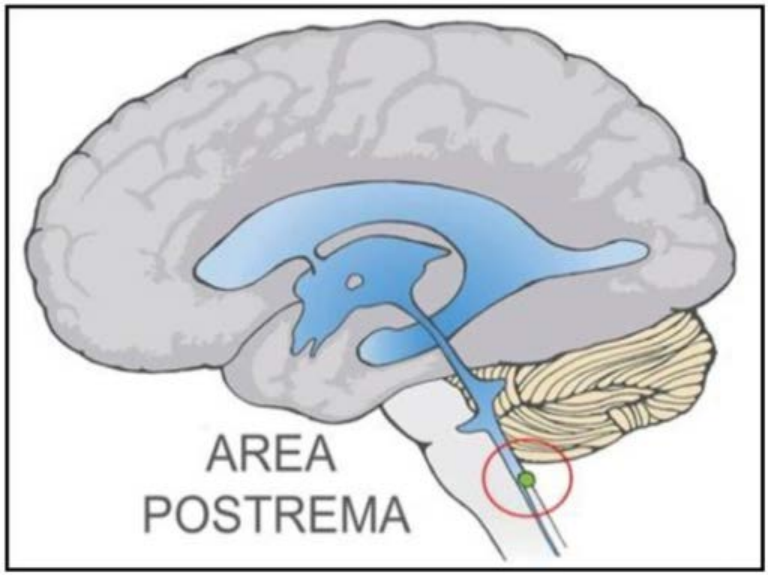
For opioid use disorder, effective management includes both withdrawal and long-term treatment strategies. Withdrawal and detoxification generally start with managing physical dependence using medications like methadone or buprenorphine. Methadone, a full agonist, is used to stabilize and reduce withdrawal symptoms, while buprenorphine helps with cravings and has a lower risk of overdose.

Clonidine and lofexidine, alpha-2 agonists, are used to ameliorate withdrawal symptoms. Lofexidine, approved by the FDA, is the first non-opioid treatment specifically for opioid withdrawal in adults. Naltrexone, a long-acting opioid antagonist, is used as an adjunct in patients who are already opioid-free; however, it will precipitate acute withdrawal symptoms if administered to those still dependent on opioids.

Solution to Question 11:

The class of drugs most preferred in patients suffering from postoperative nausea and vomiting (PONV), following surgery are the NK1 antagonists like aprepitant.

Substance P is a neuropeptide that interacts with neurokinin-1 (NK-1) receptors. NK1 antagonists inhibit substance P at central and peripheral receptors. Aprepitant, fosaprepitant are examples of NK1 antagonists. It also acts on the chemotrigger zone whose location is shown below.



PONV Physiology: Afferents from the chemoreceptor trigger zone (CTZ), vagal neurons in the gastrointestinal system, neurons from the vestibular system and midbrain afferents relay within the vomiting centre in the reticular formation of the brainstem which then project into the nucleus tractus solitarius.

Risk factors for PONV are divided into:

• Patient factors

• Female>male

• Age<50 years

• Prior history of motion sickness

• Non-smokers > smokers (CTZ is desensitized)

• Preoperative factors

• (Fasting and anxiety, while possibly contributing to PONV, have yet to be demonstrated)

• Intraoperative factors

• Surgical - Cholecystectomy, gynaecological and laparoscopic procedures have higher incidences

• Drugs - Nitrous oxide, Opioids, Cyclopropane,

• General anaesthesia has a times more risk of developing PONV than regional anaesthesia.

• Postoperative factors

• Pain and early ambulation contribute to a higher risk of PONV.

Scoring systems used to grade PONV are the Apfel score and the Koivuranta score.

Drugs used in the prophylaxis and treatment of PONV:

• 5-HT 3 antagonists - ondansetron, palonosetron

• Butyrophenones- droperidol

• Dexamethasone

• Transdermal scopolamine

• Aprepitant

Note: Double-blind studies have found no difference in the efficacy between aprepitant(NK1 antagonists) and ondansetron (5HT3 antagonist) in the first 24 hours following surgery. But after 24 hours aprepitant has proven to be more productive than ondansetron in the management of PONV.

Solution to Question 12:

Rifampicin should be avoided as it is a potent inducer of CYP enzymes including CYPs 1A2, 3A4, 2C9, and 2C19, which in turn can induce the metabolism of nevirapine and results in therapeutic failure of ART.

Rifabutin causes the least induction of cytochrome enzymes and is therefore preferred in HIV patients who are on protease inhibitors/NNRTIs.

Cytochrome enzyme-inducing potency of rifamycins is rifampicin > rifapentine > rifabutin.

Note:

Cytochrome p-450 inducers	Cytochrome p-450 inhibitors
BarbituratesCarbamazepineRifampinPhenytoinAminoglutethimideCigarette smokingChronic alcoholism	Macrolide antibioticsAzole antifungalsChloramphenicolOmeprazoleSelective serotonin reuptake inhibitors (SSRIs)HIV protease inhibitorsCimetidineCiprofloxacinMetronidazole

Solution to Question 13:

Dicyclomine is a weak muscarinic receptor antagonist with non-specific direct spasmolytic effects on the smooth muscle of the gastrointestinal tract.

Other options:

Option B: Scopolamine exerts spasmolytic activity indirectly through its antimuscarinic action. It is not preferred due to its adverse effects like drowsiness, dryness, and blurred vision.

Option C and D: Galantamine and rivastigmine are central cholinesterase inhibitors and do not possess spasmolytic activity.

Solution to Question 14:

The 3HP regimen, which involves once-weekly doses of Isoniazid and Rifapentine for 12 weeks, has been found to have higher patient compliance than the 9-month regimen of Isoniazid (9H) and the 6-month regimen (6H).

The shorter duration and reduced number of doses in the 3HP regimen make it more convenient and thus lead to better adherence. Studies have shown that patients are more likely to complete the 3HP regimen due to the shorter treatment duration and lower pill burden.

TPT stands for Tuberculosis Preventive Therapy. It is a treatment given to individuals who are at high risk of developing active tuberculosis (TB) to prevent the progression from latent TB infection (where the person is infected with the TB bacteria but does not have symptoms) to active TB disease.

There are different regimens for TPT, including:

• 3HP: A regimen consisting of once-weekly doses of Isoniazid (H) and Rifapentine (P) for 12 weeks.

• 6H: A regimen consisting of daily Isoniazid for 6 months.

• 9H: A regimen consisting of daily Isoniazid for 9 months.

TPT is particularly important for individuals with latent TB who have a higher risk of developing active TB, such as those with HIV, close contacts of TB patients, or those with certain medical conditions that weaken the immune system.

Other options:

Option B: Research has demonstrated that the 3HP regimen offers better compliance and similar effectiveness compared to the traditional 6H and 9H regimens. The shorter duration of 3HP (once weekly for 12 weeks) makes it more convenient and tolerable for patients, which leads to higher adherence rates. Thus, there is a significant difference in patient compliance between these regimens, with 3HP showing clear advantages.

Option C: Although 3HP is generally considered safe, data suggests that the risk profile for adverse effects, including potential reproductive impacts like abortion, differs between regimens. Specifically, 6H may have a different side effect profile due to the prolonged exposure to the drug over six months, compared to the shorter and intermittent dosing of 3HP.

Option D: Studies have confirmed that the 3HP regimen is as effective as 6H and 9H in preventing active tuberculosis (TB). Both regimens aim to prevent latent TB from progressing to active disease, and 3HP has been shown to achieve similar outcomes with fewer doses, enhancing patient compliance.

Solution to Question 15:

In this patient with raised intracranial pressure after a road traffic accident, mannitol is the diuretic of choice in her management to reduce intracranial pressure.

Mannitol is an osmotic diuretic that draws fluid out of the brain tissue and into the bloodstream as it forms a hypertonic solution when it reaches the bloodstream, thereby reducing intracranial pressure (ICP). It is commonly used in cases of traumatic brain injury or other conditions that cause elevated ICP. This effect helps to relieve pressure on the brain, preventing further damage.

Other options:

The other diuretics listed Hydrochlorothiazide, Spironolactone, and Acetazolamide are not typically used for managing elevated ICP. They are not hypertonic solutes and thus do not lead to a rapid reduction of the ICP as mannitol does.

Solution to Question 16:

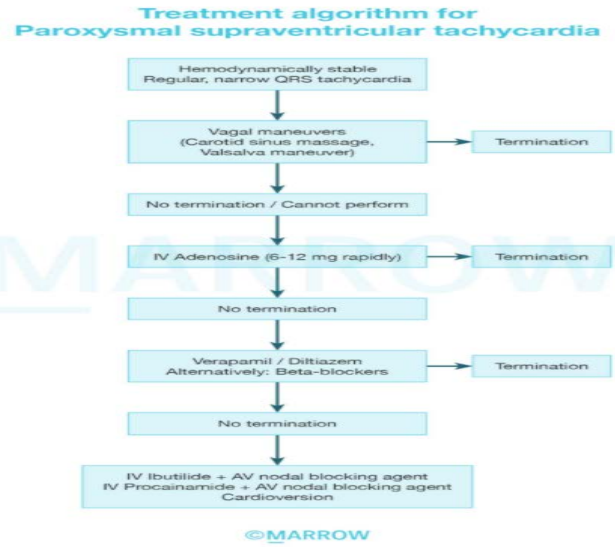
This clinical history along the EKG showing narrow QRS complexes without P waves and pseudo R waves in aVR lead suggests paroxysmal supraventricular tachycardia (PSVT) and the next step in his management would be an initial dose of adenosine at 0.1 mg/kg.

PSVT is a regular, narrow QRS complex tachycardia, most often caused due to an atrioventricular nodal re-entrant circuit. Patients may present with sudden onset palpitations, dizziness, and diaphoresis.

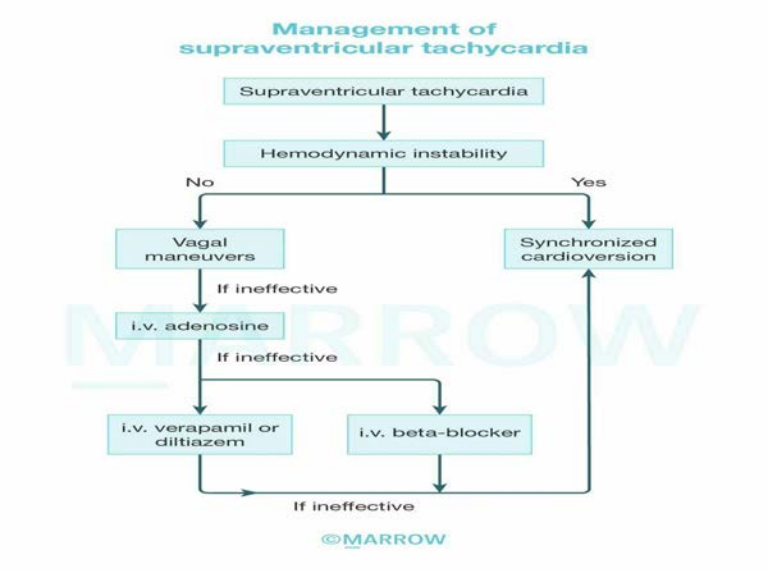
Management involves slowing AV node conduction and vagal maneuvers (e.g., Valsalva maneuver, splashing cold water on the face) are the first step. If this does not work, intravenous (IV) adenosine is the drug of choice used to terminate the majority of PSVT episodes.

Adenosine is a very short-acting endogenous purine signal molecule. It is administered as a 6 mg IV bolus over 2-3 seconds followed by a rapid flush with 20 mL NS. It can be followed up with a 12 mg IV bolus dose if required. It causes membrane hyperpolarization of cardiac muscle cells to terminate the re-entrant circuit through the AV node.

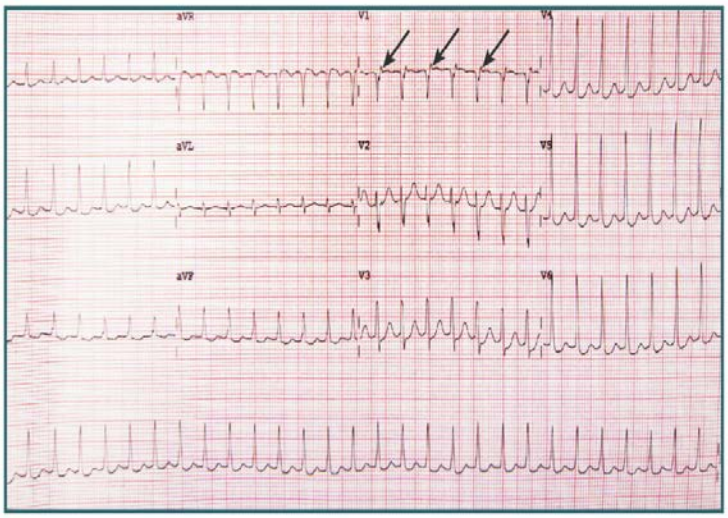
Since the action of the drug lasts for less than a minute, adverse effects are short-lived. These include transient shortness of breath, chest pain, hypotension, and cutaneous flushing due to vasodilation. It can however precipitate bronchospasm in asthmatics and verapamil is preferred in such patients.



When the patient is hemodynamically unstable, i.e., hypotension with unconsciousness or respiratory distress, QRS-synchronous direct current cardioversion is done.



The given ECG shows pseudo R' waves:



Solution to Question 17:

Among the given drugs, astemizole increases the risk of Torsades de pointes when used concomitantly with erythromycin.

Drugs that block potassium channels and prolong QT increase arrhythmogenic potential. Astemizole is a second-generation antihistamine that blocks delayed potassium channels and prolongs the QT interval.

Other options:

Option A: Doxylamine is an antihistamine commonly used as a short-term treatment for insomnia. It is combined with pyridoxine (vitamin B6) to treat nausea and vomiting during pregnancy (morning sickness). It does not prolong the QT interval.

Option B: Loratadine is a second-generation antihistamine used to treat allergic rhinitis (hay fever) and urticaria (hives). It is known for being non-sedating due to its minimal penetration into the central nervous system. It does not prolong the QT interval.

Option C: Promethazine is a first-generation antihistamine with multiple uses, including the treatment of allergies, motion sickness, nausea and vomiting, and as a sedative or sleep aid. It also has antiemetic properties and is sometimes used in the management of postoperative nausea and vomiting.

Solution to Question 18:

The incorrect statement is option C as ciclesonide has a lower risk of oral candidiasis as compared to other inhaled steroids.

Ciclesonide is an inhaled corticosteroid that is unique because it is a prodrug. It is metabolised by bronchial esterases in the lungs to its active form, which allows for targeted action within the airways. This feature reduces systemic side effects and the risk of local side effects, such as oral candidiasis (thrush), compared to other inhaled steroids.

Other options:

Option A: Ciclesonide's activation in the lungs minimises systemic absorption, leading to fewer side effects.

Option B: Ciclesonide is inactive until it is converted to its active form in the lungs.

Option D: Due to its prodrug nature and metabolism in the lungs, ciclesonide has low oral bioavailability, reducing systemic exposure.

Solution to Question 19:

The drug most likely responsible for causing flushing, hyperglycemia, and elevated liver enzymes in a patient being treated for hypertriglyceridemia is Nicotinamide (Niacin).

Niacin (nicotinic acid), is commonly used to treat hypertriglyceridemia and hypercholesterolemia. However, it is associated with side effects such as flushing, which is due to prostaglandin-mediated vasodilation. Niacin can also lead to hyperglycemia by impairing insulin sensitivity and may cause elevated liver enzymes, indicating potential hepatotoxicity.

Other options:

Option B: Rosuvastatin is a statin, primarily used to lower LDL cholesterol, and while it may elevate liver enzymes, it is less commonly associated with flushing and hyperglycemia. It can cause myopathy in patients.

Option C: Ezetimibe inhibits cholesterol absorption in the intestines and is not typically associated with these side effects.

Option D: Fenofibrate is used to lower triglycerides can elevate liver enzymes and can increase the risk of developing myopathy if used concomitantly with statins, but it does not commonly cause flushing or hyperglycemia.

Solution to Question 20:

Atropine is included in combination with diphenoxylate to prevent abuse and overdose of diphenoxylate.

Diphenoxylate is structurally similar to opioids and has the potential for misuse at higher doses. Additionally, it crosses the blood-brain barrier, making it more likely to cause dependence. The anticholinergic effects of atropine (e.g., dry mouth, tachycardia, blurred vision) become prominent at higher doses, discouraging overdose.

Diphenoxylate is an opioid agonist primarily used as an antidiarrheal agent. It works by slowing down intestinal motility, allowing more time for water and electrolytes to be absorbed from the intestines, which helps reduce diarrhea. However, because of its structural similarity to opioids, diphenoxylate has the potential for abuse and dependence if taken in large doses.

Solution to Question 21:

The adverse effects seen in this patient and the presentation of rebound hypertension on sudden drug withdrawal indicate that the drug is clonidine.

Clonidine is an alpha-2 receptor agonist and a centrally-acting antihypertensive agent. It treats high blood pressure by stimulating presynaptic $\alpha 2$ receptors in the vasomotor center in the brainstem. This binding has a sympatholytic effect, by suppressing the release of norepinephrine and other sympathomimetics.

Abrupt withdrawal after long-term therapy can result in rebound hypertension, restlessness, and sympathetic overactivity. Dry mouth and sedation are the major side effects of clonidine. It can also cause impotency and constipation. Rebound hypertension is a potentially serious complication and occurs if the drug is missed for 1–2 days. This is associated with an alarming rise in blood pressure which may be more than the pretreatment level.

Phentolamine is used for the control of hypertension due to clonidine withdrawal.

Solution to Question 22:

The dosing of a new drug is tested in phase I of a clinical trial.

Phase I trials are usually performed on healthy volunteers to check the safety and pharmacokinetic properties of a drug. The participants in this phase do not gain any direct health benefits from taking part. They are generally paid a fee for their time, with the payments being

regulated and not related to the risk involved.

In clinical trials, drug dosing typically occurs in Phase I, where researchers establish the optimal dose to achieve desired effects while minimizing side effects. In these phases, they focus on safety, tolerability, and pharmacokinetics.

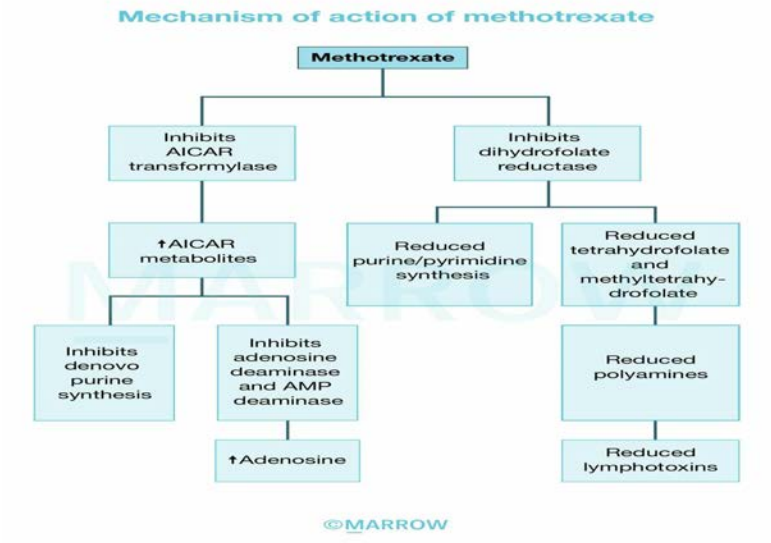
Dose-ranging, primarily conducted in Phase II trials, involves testing multiple doses to identify the most effective and safe dose range. This phase helps determine the minimum effective dose and maximum tolerated dose, providing critical data for subsequent studies in Phase 3, where the chosen dose is tested for efficacy and safety in a larger population.

Solution to Question 23:

TMP synthesis is affected due to methotrexate.

Methotrexate inhibits dihydrofolate reductase (DHFR), which is required to synthesize tetrahydrofolate. Tetrahydrofolate is essential for converting dUMP to dTMP (thymidine monophosphate) in the nucleotide synthesis pathway. Therefore, the nucleotide synthesis affected in this patient is TMP (thymidine monophosphate).

By inhibiting DHFR, methotrexate reduces the availability of THF, thereby disrupting the production of thymidylate (TMP), which is necessary for DNA replication and repair. This disruption leads to impaired DNA synthesis in rapidly dividing cells, such as cancer cells. However, it also affects other rapidly dividing cells, including those in the gastrointestinal tract and oral mucosa, leading to side effects like oral and gastric ulcers.



Solution to Question 24:

Tesamorelin is approved for use in HIV-associated lipodystrophy but not for GH deficiency. It is a synthetic N-terminal modified form of human GHRH. It does not get degraded by dipeptidyl peptidase 4 and therefore has a longer duration of action.

It increases the levels of growth hormone (GH) and insulin-like growth factor (IGF-1) but reduces visceral fat accumulation.

Tesamorelin is approved for use in HIV-associated lipodystrophy but not for GH deficiency.

Other options:

Option A: Octreotide is a somatostatin analogue that decreases growth hormone levels. It is used in the treatment of acromegaly, variceal bleeding, diarrhoea due to adenomas secreting VIP (vasoactive intestinal peptide), and sulfonylurea toxicity. One of its adverse effects is gallstone formation.

Option B: Somatropin is a growth hormone analogue. It is used in growth hormone deficiency and other short-stature conditions like Turner's syndrome, Noonan syndrome, and Prader-Willi syndrome. Their use is contraindicated in acute critical illness, active malignancy, and proliferative retinopathy.

Option D: Mecasermin is a recombinant human IGF-1. It is used in IGF-1 deficiency, growth hormone receptor defects, and antibodies against growth hormone receptors. Adverse effects include hypoglycemia and lipohypertrophy. Another recombinant human IGF-1 with its IGFBP-3, mecasermin rinfabate has been FDA-approved for HIV-associated adipose redistribution syndrome.

Microbiology AIIMS 2017

Question 1:

A 28 year old male admitted with history of altered sensorium and hydrophobia. A suspicion of rabies was made and you want to diagnose the condition. You have taken corneal scrapings from the patient and which of the following tests will you do to confirm your diagnosis

a) Indirect immunofluorescence

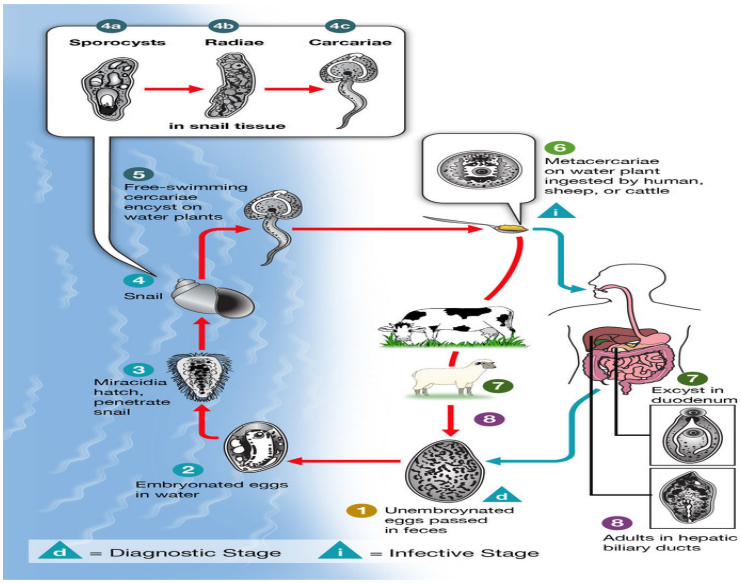
b) Seller stain for negri bodies

c) Viral culture

d) Real time PCR

Question 2:

Identify the parasite from the given life cycle.



a) Fasciola hepatica

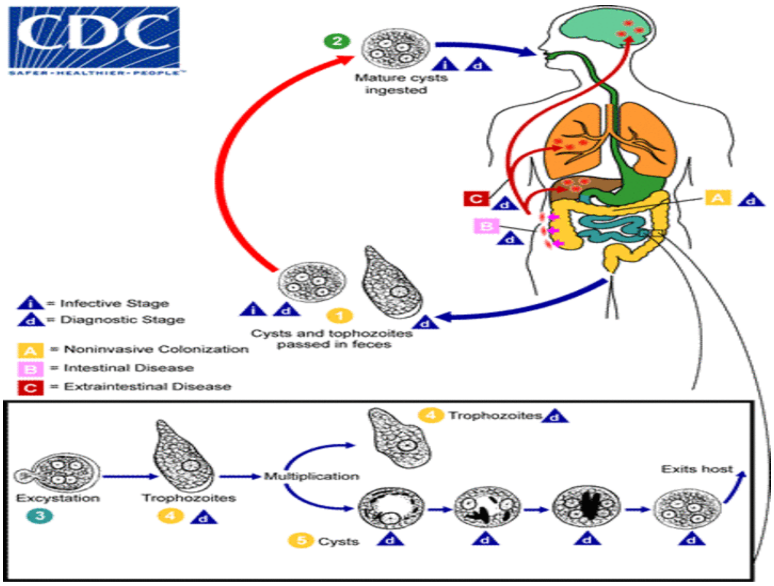
b) Fasciolopsis buski

c) Pargaonimus westermani

d) Clonorchis sinensus

Question 3:

The life cycle given below is of which of the following:



a) Entamoeba vermicularis

b) Ancylostoma duodenal

c) Balantidium coli

d) Entamoeba histolytica

Question 4:

A 25 year old male with history of fever and enlarged lymph nodes and sore throat was suspected to have infectious mono-nucleosis and was ordered a Paul Bunnel test. Which of the following is the principle of the test?

a) Complement mediated cell damage

b) Agglutination reaction

c) Heterophile antibody test

d) Neutralisation reaction

Question 5:

A blood spill in the operation theatre must be cleaned with _____.

a) Chlorine compound

b) Phenolic compound

c) Quarternary ammonium compounds

d) Alcoholic compounds

Question 6:

Urine LAM is used for the diagnosis of _____

a) M. tuberculosis

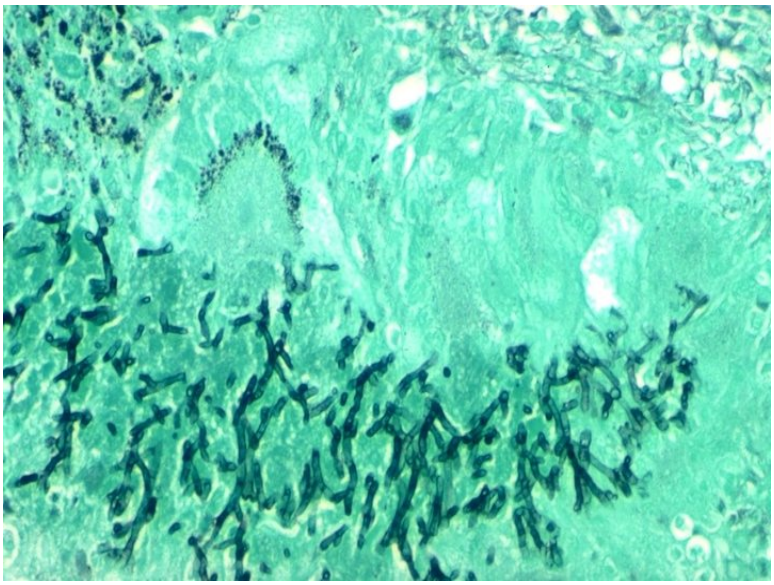
b) M. leprae

c) Mycoplasma

d) Listeria monocyogenes

Question 7:

Identify the organism in the given slide stained with Gomori methenamine silver stain.



a) Obtuse angled mucor

b) Acute angled penicillium

c) Acute angled branching aspergillus

d) Obtuse angled rhizopus

Question 8:

A confirmed case of which of the following viral haemorrhagic fevers was found in India?

a) Ebola hemorrhagic fever

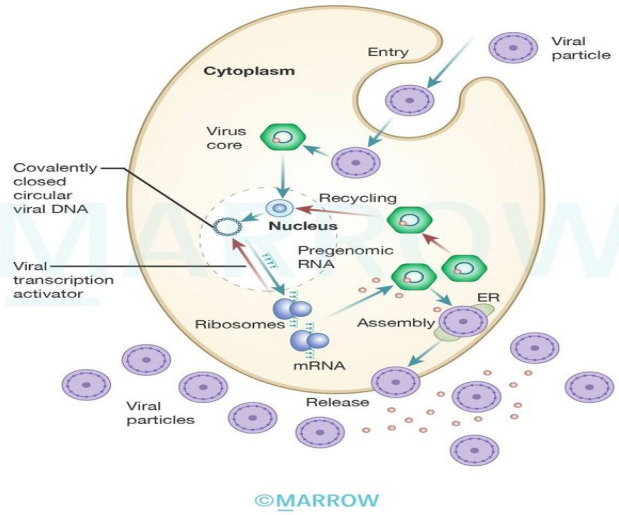
b) Yellow fever

c) Crimean congo hemorrhagic fever

d) Marburg hemorrhagic fever

Question 9:

The given life cycle is suggestive of which of the following viruses?



a) HIV

b) Hepatitis B

c) Influenza

d) Herpes simplex

Question 10:

1,3 beta D- glucan is helpful for identification of?

a) Invasive candidiasis

b) Rhizopus

c) Cryptococcus

d) Mucormycosis

Question 11:

Relapse is seen in ?

a) Plasmodium vivax and falciparum

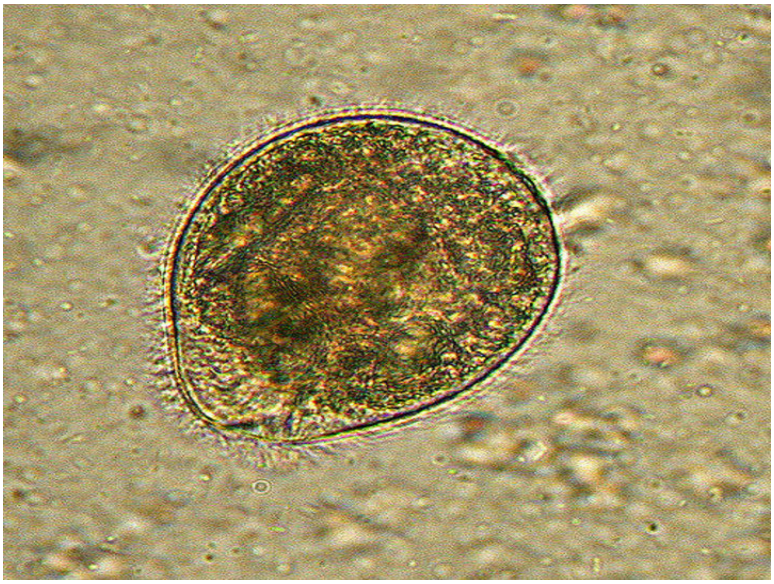
b) Plasmodium ovale and falciparum

c) Plasmodium vivax and ovale

d) Plasmodium vivax and malariae

Question 12:

Identify the organism.



a) Balantidium coli

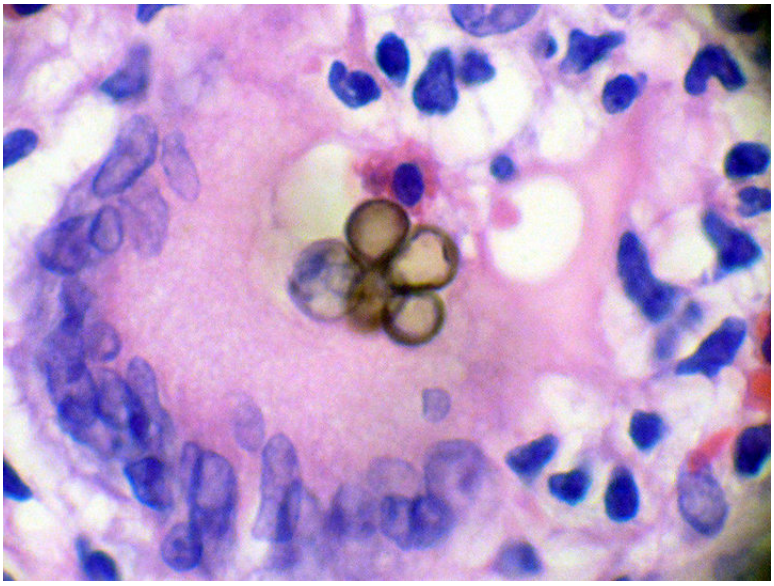
b) Entamoeba dispar

c) Cryptosporidium

d) Giardia

Question 13:

A female from Himachal Pradesh presented with H/O thorn prick, a year back has a verrucous lesion in the skin with the following microscopic findings. Identify the agent?



a) Blastomycosis

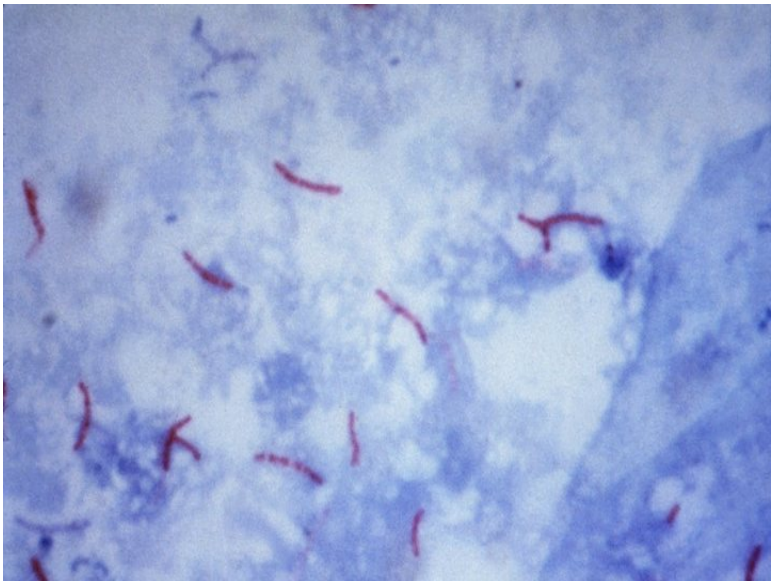
b) Pheohyphomycosis

c) Chromoblastomycosis

d) Sporotrichosis

Question 14:

The following slide is given as a spotter in your microbiology practical examination. Identify the following organism.



a) Mycobacteria

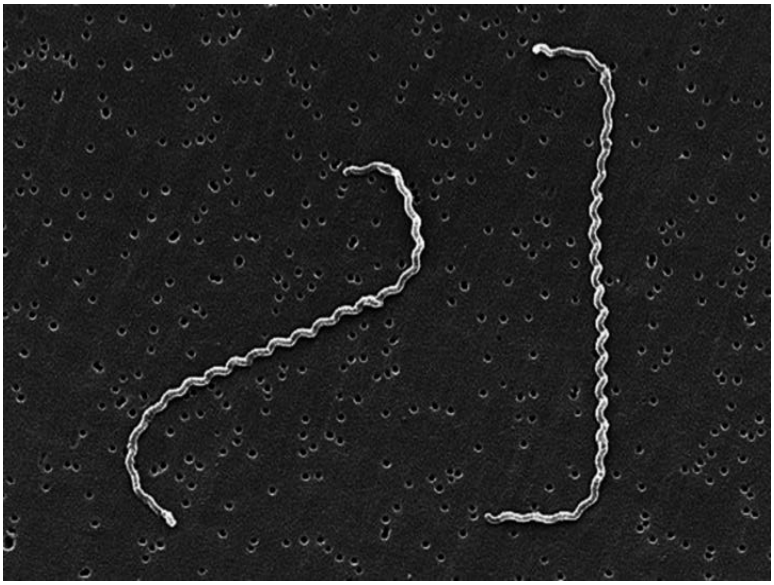
b) Nocardia

c) Actinomyces

d) Corynebacterium

Question 15:

Identify the organism from the given image?



a) Vibrio

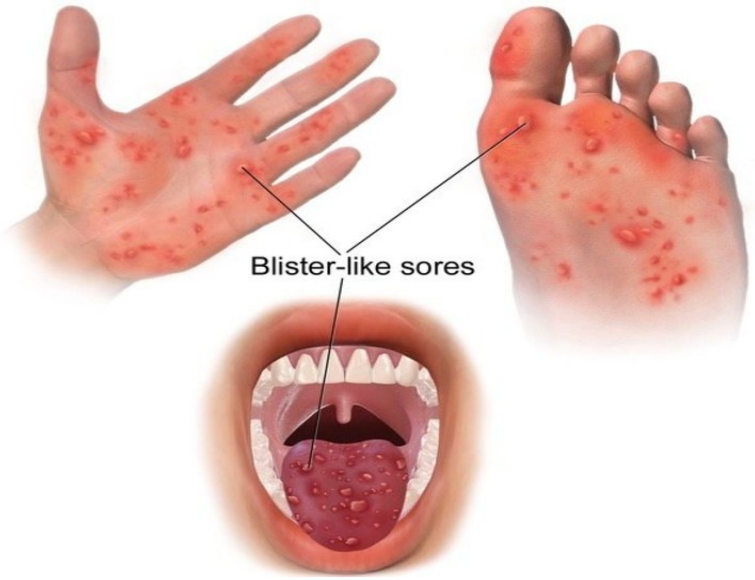
b) Leptospira

c) Helicobacter

d) Salmonella

Question 16:

Which of the following organisms causes the following disease?



a) Coxsackievirus

b) Human herpes virus 7

c) Pox virus

d) Molluscum contagiosum

Question 17:

Which of the following is not a dimorphic fungus?

a) Blastomyces dermatidis

b) Histoplasma capsulatum

c) Pneumocystis jirovecii

d) Penicillium marneffi

Question 18:

There are 3 to 5% healthy hepatitis B carriers in India who are asymptomatic. They are at the risk of developing hepatocellular carcinoma in the future because _____

a) They are unable to mount inflammation against the virus

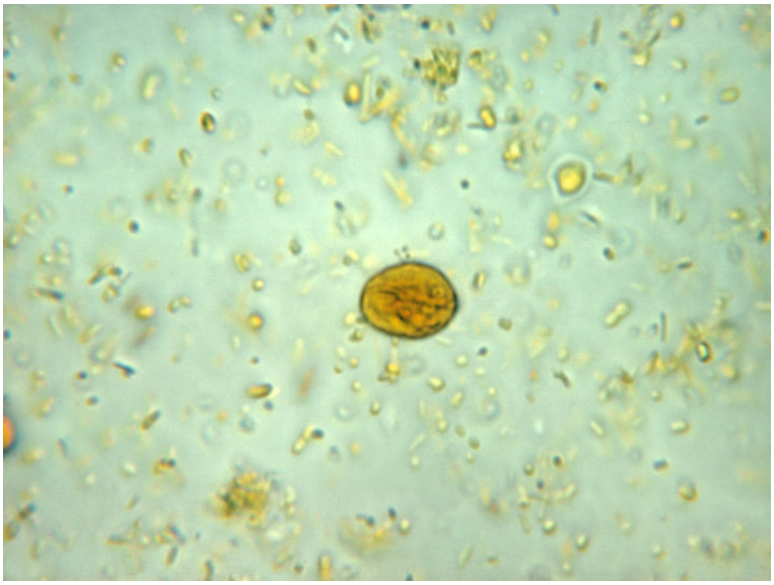
b) Virus can integrate with host DNA and form complementary DNA

c) There is a risk of elevation of transaminases

d) Liver parenchymal cells are in a state of high proliferation

Question 19:

Identify the following?



a) Entamoeba dispar

b) Giardia lamblia

c) Balantidium coli

d) Entamoeba histolytica

Question 20:

Best method of diagnosis for Clostridium difficile?

a) Pure strain isolation from culture

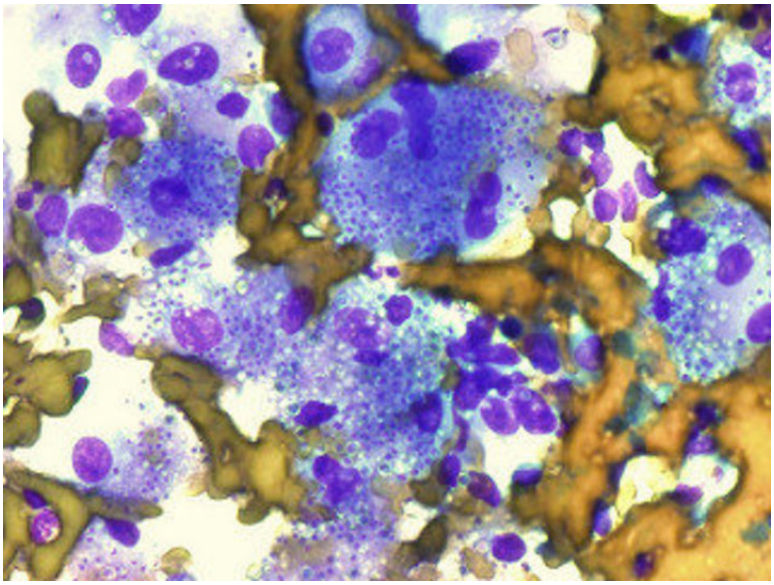
b) Immunoflourescence

c) Toxin gene detection by PCR

d) Toxin Detection by ELISA

Question 21:

A patient with HIV develops diarrhoea and faecal examination shows Isospora belli. He was treated with cotrimoxazole. Diarrhoea subsided but fever persisted. Bone marrow examination of this patient is shown in the given image. Which of the following statement is false?



a) It cannot be grown in sabouraud dextrose agar

b) Spores are infective form

c) It is intracellular budding yeast

d) It can cause systemic disease

Question 22:

Bio-film confer resistance to antibiotics by all except _____

a) Mechanical barrier

b) Increased excretion of antibiotics

c) Slow metabolism

d) Adherence

Question 23:

Identify the egg in the picture given below:

a) A. lumbricoides

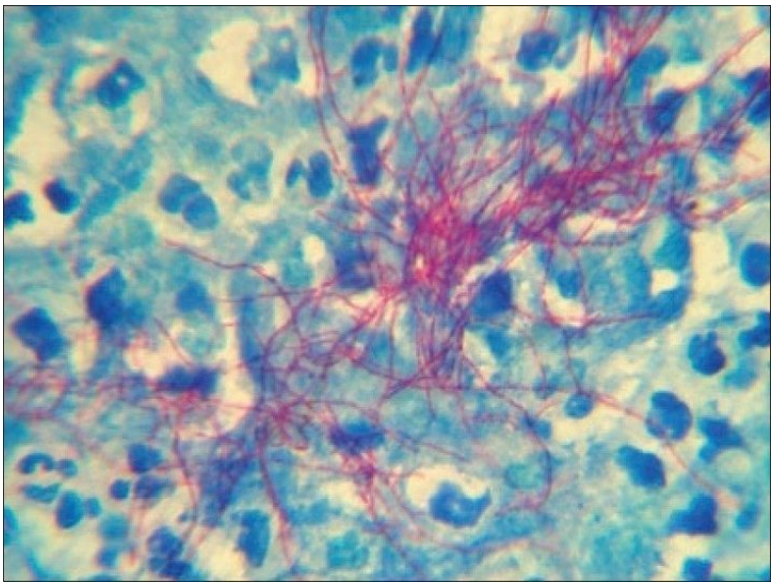
b) Strongyloides stercoralis

c) E. vermicularis

d) Ancylostoma duodenale

Question 24:

Identify the organism from the given staining technique.



a) Mycobacterium leprae

b) Mycobacterium tuberculosis

c) Actinomyces israelli

d) Nocardia asteroids

Question 25:

Which of the following staphylococcal infections is not toxin mediated?

a) Food poisoning

b) Toxic shock syndrome

c) Septicemia

d) Staphylococcal scalded skin syndrome

Question 26:

All are features of Zika Fever except

a) Petechial rash

b) Guillan barre syndrome

c) Fever with arthritis

d) Conjunctivitis

Question 27:

(1–3)-β-D glucan assay can not be used in

a) Invasive cryptococcosis

b) Invasive aspergillosis

c) Pneumocystis jiroveci pneumonia

d) Invasive candidiasis and candidemia

Question 28:

A patient was sputum negative for tuberculosis, but chest X-ray was suggestive of tuberculosis. Which is the next step according to RNTCP ?

a) Line probe assay

b) CB - NAAT

c) Liquid culture

d) None of the above

Answer Key

Detailed Explanations

Solution to Question 1:

Viral culture from corneal scrapings is used to confirm diagnosis.

Multiple tests in succession/simultaneously are the best. Usually Direct Fluorescent Antibody test followed by virus isolation/culture is useful.

Virus isolation through culture: Best specimens are brain and saliva. CSF, corneal smears and centrifuged urine can also be used.

Option A: Serological tests like indirect immunofluorescence are insensitive.

Option B: Negri bodies can only be demonstrated in brain (pyramidal cells of Ammon's horn, and the Purkinje cells of the cerebellum are the most common site).

Option D: Real time-PCR Amplification Detection of rabies virus RNA is highly sensitive and specific. This technique can detect virus in freshsaliva samples, skin, CSF, and brain tissues. However it is not confirmatory test.

Solution to Question 2:

The given life cycle belongs to Fasciola hepatica.

Fasciola hepatica (sheep liver fluke) causes disease primarily in sheep and other domestic animals. Humans are infected by eating watercress (or other aquatic plants) contaminated by larvae (metacercariae) that excyst in the duodenum, penetrate the gut wall, and reach the liver, where they mature into adults.

The adult flukes in the bile ducts produce eggs, which are excreted in the feces. The eggs hatch in freshwater and miracidia enter the snails. Miracidia develop into cercariae, which then encyst on aquatic vegetation. Sheep and humans eat the plants, thus completing the life cycle. Most infections are asymptomatic. Halzoun is a painful pharyngitis caused by the presence of adult flukes on the posterior pharyngeal wall after eating raw sheep liver. Obstructive jaundice can occur months or years later.

Diagnosis is made by identification of the eggs in the feces.

Solution to Question 3:

The given life cycle is of Entamoeba histolytica.

Its life cycle includes 2 stages - the motile trophozoite and the non-motile cyst, both of which are seen in the image shown above. The transmission is primarily by the fecal-oral route. There is no animal reservoir. The most frequent site of systemic disease is the liver.

The ingested cysts differentiate into trophozoites in the ileum which invade the colonic epithelium. The trophozoites penetrate the submucosal layer and form abscesses which break down to form flask-shaped ulcers.

The trophozoites multiply by binary fission and produce cysts, and both stages are passed in the feces. Trophozoites are rapidly destroyed outside the body. Cysts survive in the external environment and are responsible for transmission.

Note: The genus Entamoeba has four morphologically identical species - E. histolytica, E. dispar, E. bangladeshi, and E. moshkovskii. E. moshkovskii which was initially thought to be non-pathogenic has recently been shown to be a causative agent of non-invasive diarrhea.

Solution to Question 4:

Paul Bunnell test is a heterophile antibody reaction test and is used in glandular fever like Infectious Mononucleosis.

Heterophile antibodies have the ability to agglutinate RBCs of different animal species.

Paul Bunnell test uses sheep erythrocytes for agglutination and Monospot test uses horse erythrocytes for agglutination.

In Infectious Mononucleosis, IgM heterophile antibodies are detectable for the first 3 months of infection and they can agglutinate sheep erythrocytes.

Type of test	Name of the test	Test used for
Tube agglutination	Widal	Typhoid
	Standard agglutination test	Brucellosis
	Microscopic agglutination tes t	Leptospirosis
	Paul-Bunnell test	Infectious mononucleosis
	Weil-felix test	Rickettsial infection
	Streptococcal MG agglutinati on test	Primary atypical pneumonia
Antiglobulin test	Direct coomb's test	Detecting fetal RH Antibody
	Indirect Coomb's test	Detecting maternal Rh antib ody
Passive agglutination test	Hemagglutination	Rose Waaler test
	Latex agglutination test	Detection of ASO, CRP, RA f actor, HCG
	Coagglutination test	Diagnosis of legionellosis, Go norrhea

Solution to Question 5:

Sodium hypochlorite, a compound of chlorine, is the best disinfectant for surface blood spills. It is used with a concentration of 0.5-5%.

If the spill contains large amounts of blood or body fluids, clean the visible matter with disposable absorbent material and discard the contaminated materials in appropriate, labelled containment.

A 1:10–1:100 dilution of 5.25%–6.15% sodium hypochlorite (i.e., household bleach) or an EPA-registered tuberculocidal disinfectant has been recommended for decontaminating blood spills.

Solution to Question 6:

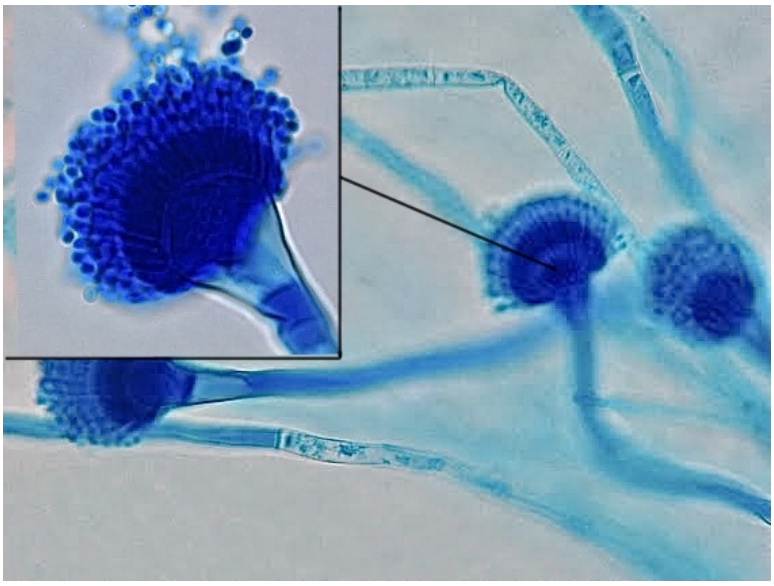
Urine lipoarabinomannan (LAM) assay is used for the diagnosis of tuberculosis.

Lipoarabinomannan (LAM) antigen is a lipopolysaccharide present in mycobacterial cell wall. It is released from metabolically active cells or degenerating cells of patients having tuberculosis. Urine LAM testing is especially useful in diagnosing TB in patients with HIV and low CD 4 counts.

Solution to Question 7:

The given slide stained with GMS shows acute-angled (45o) uniform, branching septate hyphae which is suggestive of Aspergillus species.

Aspergillus species grow rapidly, producing aerial hyphae that bear conidia in chains. Long aseptate conidiophores (specialised conidia-bearing hyphae) are seen with terminal vesicles. Phialides (vase-shaped cells producing conidia) with conidia are arranged in basipetal chains on the terminal vesicle. The following image shows the lactophenol cotton blue solution (LPCB) mount of Aspergillus fumigatus showing the long conidiophores with terminal vesicles.



Option A: Mucor produces nonseptate, broad hyphae with aerial sporangiophores which end in a sporangium.

Option B: Penicillium produces septate hyphae with branched, septate and brush-like conidiophores.

Option D: Rhizopus appears similar to Mucor but it has rhizoids with sporangiophores arising in groups directly above the rhizoids.

Solution to Question 8:

Crimean Congo hemorrhagic fever has been found in India.

Four cases were first described in India in 2011 in the state of Gujarat. It is a severe form of viral hemorrhagic fever caused by negative sense ssRNA Nairovirus species. It is zoonotic in origin with Ixodes ticks as vectors with livestock as primary reservoirs. The outbreak was caused due to person-to-person transmission in a tertiary care hospital where the index patient (first identified case) was admitted.

Solution to Question 9:

The given life cycle is of the hepatitis B virus.

Steps:

• The infectious virion attaches to cells and uncoating occurs.

• Cell enzymes in the hepatocytes convert dsDNA to covalently closed circular double-stranded DNA (cccDNA)

• HBV mRNA and pre-genome RNA is synthesized using cccDNA as a template.

• pre-genome RNA is encapsidated by packaging signal into new core particles.

• These new core particles are templates for HBV reverse transcriptase.

• Negative-strand DNA is synthesized by viral polymerase by reverse transcription.

• The cores bud from the pre-Golgi membranes, acquiring HBsAg-containing envelopes.

• Once viral particles are assembled, they either exit the cell or cause reinfection of the same cell.

Solution to Question 10:

1,3 beta D- glucan is helpful for the identification of Invasive candidiasis (invasive fungal infections).

1-3 beta D-glucan assay test detects the presence of (1-3)-β-d-glucan (BDG) which is an abundant cell wall polysaccharide found in most fungi except

• Cryptococci

• Zygomycetes

• Blastomyces dermatitidis

Solution to Question 11:

Relapse is seen in cases of Plasmodium vivax and ovale.

Malaria relapse :

In case of Plasmodium vivax and ovale two kinds of sporozoites are seen, some of which multiply inside hepatic cells to form schizonts and others persist and remain dormant as hypnozoites.

True relapse is caused due to hypnozoites (resting forms). Some get activated to become schizonts and release merozoites, which go on infecting RBCs producing clinical relapse.

In case of Plasmodium falciparum and malariae, the initial tissue phase disappears completely and no hypnozoites are found, hence relapse is not seen.

Solution to Question 12:

The given image is the trophozoite form of the Balantidium coli.

Balantidium coli occurs in two stages

• Trophozoites are oval in shape and contain two nuclei. There is the presence of cilia over the entire surface and are larger around the mouth. Its anterior end is narrow and the posterior end is broad. At the anterior end, there is a groove leading to the mouth (cytostome). Posteriorly, there is a small anal pore (cytopyge).

• Cysts are smaller, round with a micronucleus, a macronucleus and many contractile vacuoles.

Living trophozoites/cysts are yellowish or greenish in color on wet mount.

Solution to Question 13:

The given clinical history and histopathological image are suggestive of Chromoblastomycosis

Chromoblastomycosis (chromomycosis) is a subcutaneous mycotic infection that is usually caused by traumatic inoculation.

Over months to years, the primary lesion becomes verrucous and wart-like with extension along the draining lymphatics.

Histologically, the lesions are granulomatous and the dark sclerotic bodies may be seen within leukocytes or giant cells (medlar/copper penny bodies)

The following are the various dematiaceous species of fungi

• Phialophora verrucosa

• Fonsecaea pedrosoi

• Fonsecaea compacta

• Rhinocladiella aquaspersa

• Cladophialophora carrionii

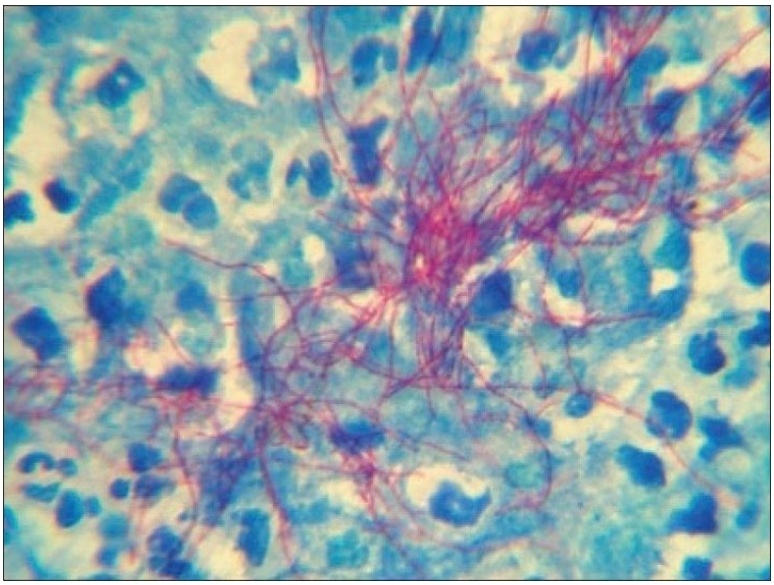
Treatment: Surgical excision with wide margins is the treatment of choice for small lesions. Chemotherapy with flucytosine or itraconazole may be efficacious for larger lesions. The application of local heat is also beneficial.

Solution to Question 14:

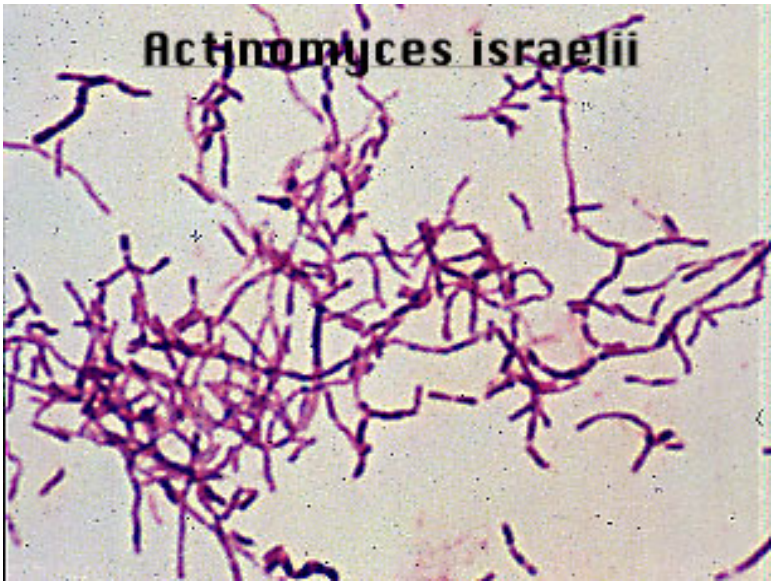
The image shows pink non-branching acid-fast bacilli on a blue background. These findings are consistent with the staining characteristics of mycobacteria. The stain used is the Ziehl-Neelsen stain.

Other options:

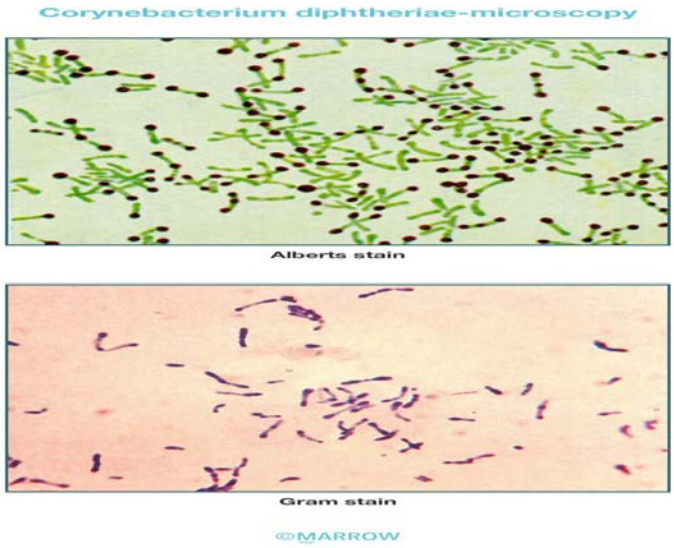
Option B: The image below shows Nocardia stained using an acid-fast staining technique. Nocardia is partially acid-fast and appears as branching filaments.



Option C: The image given below is of a gram-stained specimen of Actinomyces israelii. A. israelii is non acid-fast



Option D: The images below show the staining characteristics of Corynebacterium diphtheriae. It is stained with Albert's stain which shows the needle appearance.



Solution to Question 15:

The organisms in the image are leptospira.

In spirochetes, the presence of two axial filaments (periplasmic flagella) with polar insertions are located in periplasmic space called as endoflagella.

Endoflagella are seen in :

• Treponema

• Borrelia

• Leptospira

Solution to Question 16:

The image shows vesicles on the palms, soles, and oral mucosa, consistent with hand-foot-and-mouth disease. It is caused by coxsackievirus.

Hand-foot-and-mouth disease (HFMD) is an exanthematous fever affecting mainly young children, characterized by oral and pharyngeal ulcerations and a vesicular rash of the palms and soles that may spread to the arms and legs. Vesicles heal without crusting, which clinically differentiates them from the vesicles of herpesviruses and poxviruses. It is usually a benign illness resolving in 1-2 weeks.

Coxsackie A16, A9, and B 1-3 are common causative agents.

Other diseases caused by Coxsackie A virus:

• Aseptic meningitis is associated with a maculopapular rash.

• Herpangina

• Minor respiratory infections

Note: Conditions associated with the rash on palms and soles: Secondary syphilis, Hand foot, and mouth disease, Rickettsial feature caused by Rickettsia rickettsiae

Solution to Question 17:

Pneumocystis jiroveci is not a dimorphic fungi, it is a yeast like organism.

Dimorphic fungi :

• Blastomyces dermatitidis

• Histoplasma capsulatum

• Paracoccidioides brasiliensis

• Penicillium marneffei

• Sporothrix schenckii

• Coccidioides immitis

• Coccidioides posadasii

Solution to Question 18:

In most tumors, HBV DNA is integrated into the cell genome, and in most cases, the virus DNA has undergone rearrangements, including deletions. After integration, it promotes the overexpression of cell genes that can also contribute to oncogenesis.

The only viral gene product that is consistently present in the tumor cells is the X protein.

Solution to Question 19:

The above image shows giardia lamblia.

Cysts are resistant forms and are responsible for transmission of giardiasis. Both cysts and trophozoites can be found in the feces (diagnostic stages). The cysts are hardy and can survive several months in cold water.

Infection occurs by the ingestion of cysts in contaminated water, food, or by the fecal-oral route (hands or fomites).

In the small intestine, excystation releases trophozoites (each cyst produces two trophozoites).

Trophozoites multiply by longitudinal binary fission, remaining in the lumen of the proximal small bowel where they can be free or attached to the mucosa by a ventral sucking disk.

Encystation occurs as the parasites transit toward the colon. The cyst is the stage found most commonly in nondiarrheal feces. Because the cysts are infectious when passed in the stool or shortly afterward, person-to-person transmission is possible.

Giardia lamblia exists in :

• Infective form – Quadrinucleate cyst

• Tennis racket shaped trophozoite is actively motile with central axostyle with pair of nuclei

• Oval shaped cyst denoted with cyst wall

Solution to Question 20:

Nucleic acid amplification tests, including PCR assays, for C. difficile toxin A or B gene in stool have been approved for diagnostic purposes of Clostridium difficile infection due to high sensitivity, specificity and rapid turnaround time.

The diagnosis of CDI is based on a combination of clinical criteria:

(1) diarrhea (≥3 unformed stools per 24 h for ≥2 days) with no other recognized cause plus

(2) toxin A or B detected in the stool, toxin- producing C. difficile detected in the stool by PCR or culture, or pseudomembranes seen in the colon.

Other diagnostic methods include :

• Stool Culture in selective media

• Demonstrating Toxin by Hep-2 cell cultures

• Toxin gene identification by Enzyme immunoassay

• Colonscopy or sigmoidoscopy

Despite the array of tests available for C. difficile and its toxins, no single traditional test has high sensitivity, high specificity, and rapid turnaround.

Most laboratory tests for toxins, including enzyme immunoassays, lack sensitivity.

Nucleic acid amplification tests, including PCR assays, for C. difficile toxin A or B gene in stool have now been approved for diagnostic purposes and appear to be both rapid and sensitive while retaining high specificity.

Solution to Question 21:

The given clinical findings and bone marrow examination is suggestive of Histoplasma capsulatum.

It can be grown in sabouraud dextrose agar and blood agar.

In SDA – white cottony mycelia growth can be seen.

Mode of infection – Inhalation of spores

Yeast cells occur within budding yeasts as intracellular fungi

Disseminated infection can occur in immunocompromised patients with reticuloendothelial system being affected the most.

Solution to Question 22:

Adherence is a mechanism of bacteria to attach to host cell for penetration. It is not a mechanism of resistance.

Mechanisms of biofilm-mediated resistance to antibiotics:

• Mechanical barrier: The lipopolysaccharide biofilms prevent entry of water-soluble drugs.

• Efflux pumps: These pumps on the biofilms actively excrete drug out.

• Slow metabolism: Decreased oxygen and nutrients passage through the biofilms slows down the metabolism of bacteria.

• Anaerobic pathway: Because of the above reason bacteria follow anaerobic metabolism.

• Persisters: Some bacteria undergo phenotypic modification into dormant, spore-like structure and survive antibiotic insult. These are called as persisters which are activated later.

• Enzymatic inactivation of drugs by biofilms

• Genetic adaptation to antibiotic insults

• Quorum sensing: It is cell to cell signaling among the bacteria to coordinate among themselves for contribution in biofilm synthesis.

Solution to Question 23:

The egg in the given picture is that of a hookworm. Eggs of both Ancylostoma Duodenale (old world hookworm) and Necator Americanus (new world hookworm) are identical.

The eggs of hookworm are :

• Oval or elliptical

• Colorless

• Not bile stained

• With a thin transparent hyaline shell membrane

• Thin shell

• Segmented ovum - 4 to 8 blastomeres

• There is clear space between segmented ovum and egg shell.

• Eggs float in saturated salt solution.

Humans are infected when filariform larvae in moist soil penetrate the skin.

Solution to Question 24:

The organism shown above is the Nocardia species. The above image shows acid-fast staining, where the organisms are shown appear as acid-fast (stained with fuschia) and branching rods or filaments. They are aerobes found particularly in the soil and are found to produce lung infections in the immunocompromised.

Options A, B: Mycobacteria species are acid-fast but do not have branching filaments.

Option C: Actinomyces species is gram-positive but not acid-fast.

Solution to Question 25:

Staphylococcal septicemia is not toxin mediated.

Septicemia occurs due to the invasion of bacterial organisms into the bloodstream. This causes an inflammatory response to bacterial products, leading to various manifestations seen in sepsis - fever, hypotension, alkalosis.

Toxin mediated staphylococcal infections include food poisoning caused by enterotoxin, toxic shock syndrome caused by toxic shock syndrome toxin and staphylococcal scalded skin syndrome caused by exfoliative/epidermolytic toxin.

Solution to Question 26:

Petechial rash is not a feature of Zika Virus. Though petechiae may rarely appear in Zika virus disease it is however not included in the CDC case definition of Zika virus disease. Petechial rash points towards a diagnosis of Dengue fever while a maculopapular rash suggests a Zika virus

disease.

Zika virus infection is characterised by influenza-like clinical signs including fever, headache and malaise. A maculopapular rash, conjunctivitis, myalgia and arthralgia usually accompany or follow those manifestations.

The complications of Zika virus are:

• Gullian Barre Syndrome

• Fetal microcephaly in pregnant women.

Solution to Question 27:

(1-3) - β - D glucan assay is used for diagnosis of candida infections, invasive aspergillosis and Pneumocystis jirovecii pneumonia.

It is not useful in case of invasive cryptococcosis.

Solution to Question 28:

• CB-NAAT and Line probe assay are rapid molecular diagnostic techniques used for diagnosis of tuberculosis and also to assess resistance to isoniazid and rifampicin.

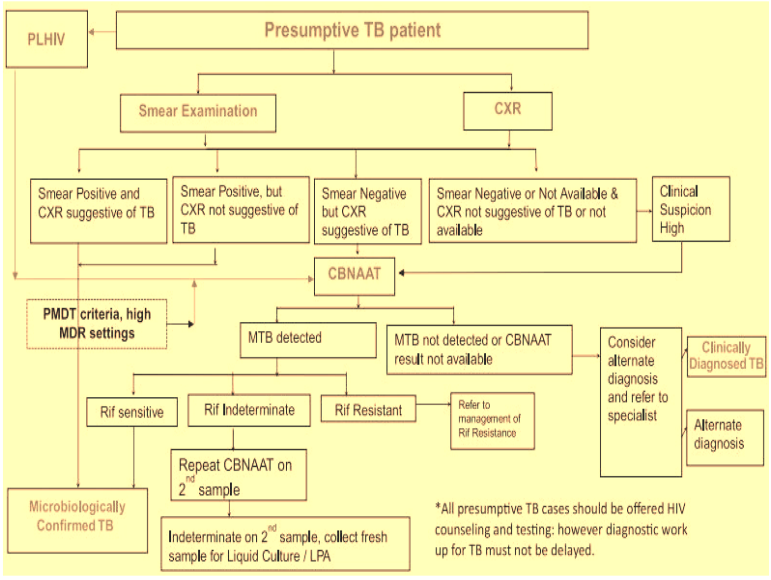
• CB NAAT (Cartridge Based Nucleic Acid Amplification Test) provides rapid and accurate diagnosis of TB by detecting Mycobacterium tuberculosis and mutations responsible for rifampicin resistance.

• It can be used for sputum samples as well as samples from extrapulmonary sites.

• It is mainly used for diagnosis of DR-TB in presumptive DR-TB patients and TB in key populations such as pediatric population, PLHIV and extrapulmonary TB.

• It is done when smear is negative for TB but chest X-ray is suggestive of tuberculosis and also in cases smear is negative and chest X-ray is not suggestive of TB but there is high index of clinical suspicion.

Diagnostic algorithm for pulmonary TB:

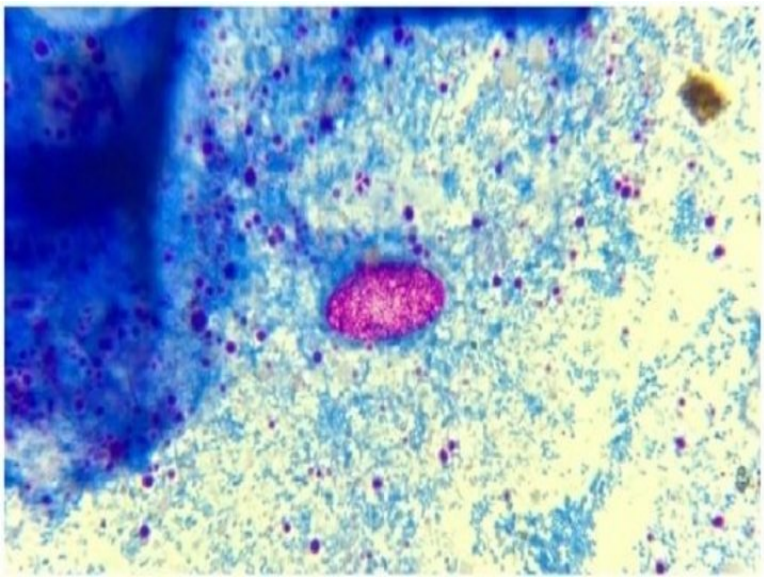


PLHIV
Presumptive TB patient
Smear Examination
CXR
Smear Positive and CXR suggestive of TB
Smear Positive, but CXR not suggestive of TB
Smear Negative but CXR suggestive of TB
Smear Negative or Not Available & CXR not suggestive of TB or not available
Clinical Suspicion High
CBNAAT
PMDT criteria, high MDR settings
MTB detected
MTB not detected or CBNAAT result not available
Consider alternate diagnosis and refer to specialist
Clinically Diagnosed TB
Alternate diagnosis
Rif sensitive
Rif Indeterminate
Rif Resistant
Refer to management of Rif Resistance
Repeat CBNAAT on 2nd sample
Microbiologically Confirmed TB
Indeterminate on 2nd sample, collect fresh sample for Liquid Culture / LPA
*All presumptive TB cases should be offered HIV counseling and testing: however diagnostic work up for TB must not be delayed.

Microbiology AIIMS 2018

Question 1:

A kinyoun positive oocyst (25 µm) was isolated from an HIV patient with diarrhea. Identify the organism.



a) Cystoisospora

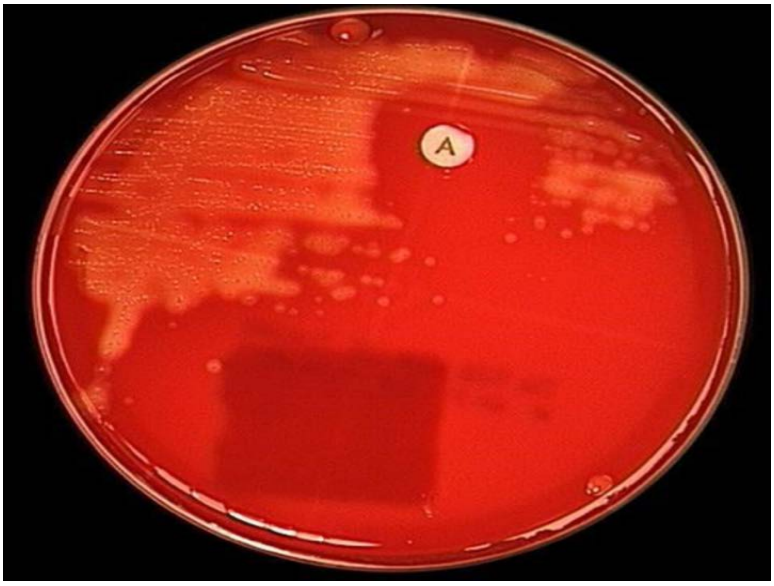
b) Cyclospora

c) Cryptosporidium

d) Microspora

Question 2:

The test shown below, which uses a bacitracin disk, is useful in identifying _____.



a) Staphylococcus aureus

b) Streptococcus pyogenes

c) Clostridium botulinum

d) Bacillus

Question 3:

What is the incubation period of lymphogranuloma venereum?

a) 1-5 days

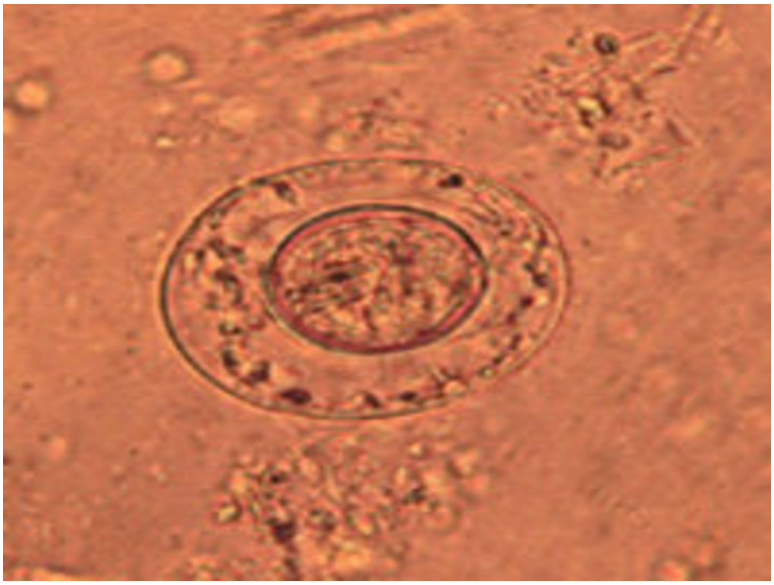
b) 7-10 days

c) 10-30 days

d) 30-60 days

Question 4:

Which is the agent used to treat the infection caused by the cestode egg in the image?



a) Praziquantel

b) Ivermectin

c) Albendazole

d) Diethylcarbamazine

Question 5:

Human herpesvirus 8 is associated with all except _____.

a) Kaposi sarcoma

b) Castleman's disease

c) Adult T-cell leukemia

d) Primary effusion lymphoma

Question 6:

Identify the condenser in the following image.

a) Above the stage

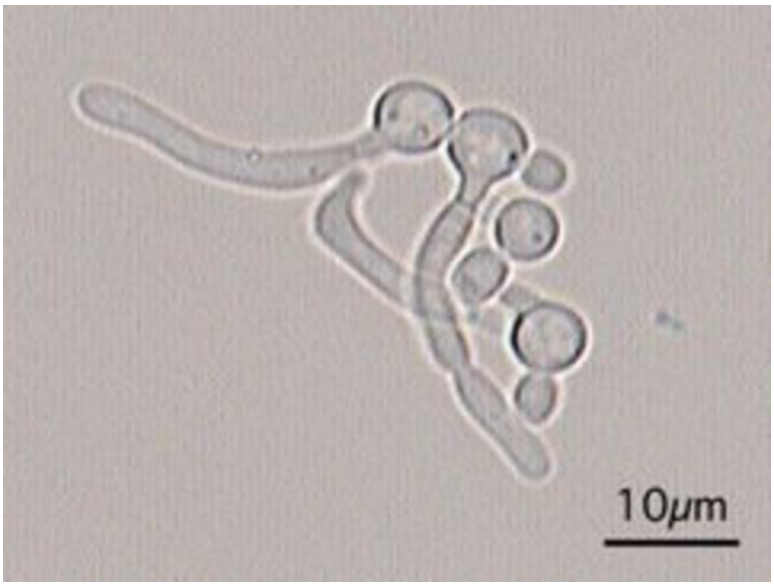
b) Below the stage

c) Near the eyepiece

d) Above the objective lenses

Question 7:

The following test is positive for identification of _____



a) Candida albicans

b) Candida glabrata

c) Candida parapsilosis

d) Candida tropicalis

Question 8:

Choose the correct statement regarding CMV.

a) Ganciclovir resistance is due to mutation in UL97 phosphotransferase gene

b) CMV can be cultured in vitro in any mammalian cell

c) Commonest manifestation of CMV associated disease is watery diarrhea

d) UL54 mutated CMV strains do not show cross resistance to foscarnet

Question 9:

Solvent/Detergent (SD) plasma destroys lipid-enveloped viruses. So, on SD plasma transfusion, which of the following infection is likely to occur?

a) Human Immunodeficiency Virus (HIV)

b) Hepatitis A Virus (HAV)

c) Hepatitis B Virus (HBV)

d) Hepatitis C Virus (HCV)

Question 10:

Plasma sterilization makes use of _____.

a) Hydrogen peroxide

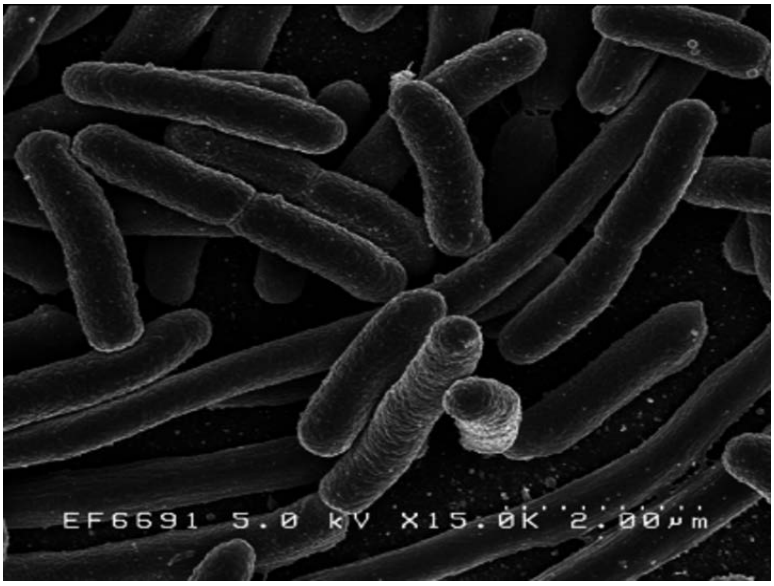
b) Ethylene oxide

c) Gamma rays

d) UV rays

Question 11:

Identify the organism below that causes effacement and attachment of intestinal cells.



a) ETEC

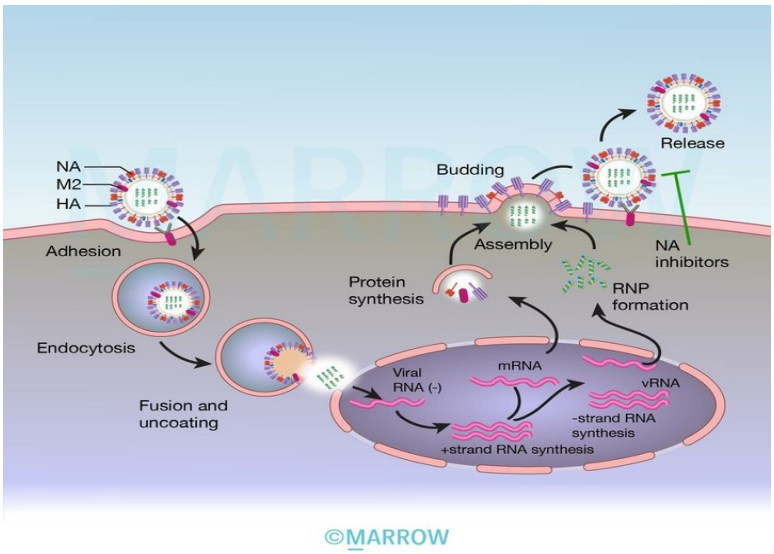
b) EIEC

c) EPEC

d) EAEC

Question 12:

Which of the following organisms is represented by the given form of replication?



a) Hepatitis virus

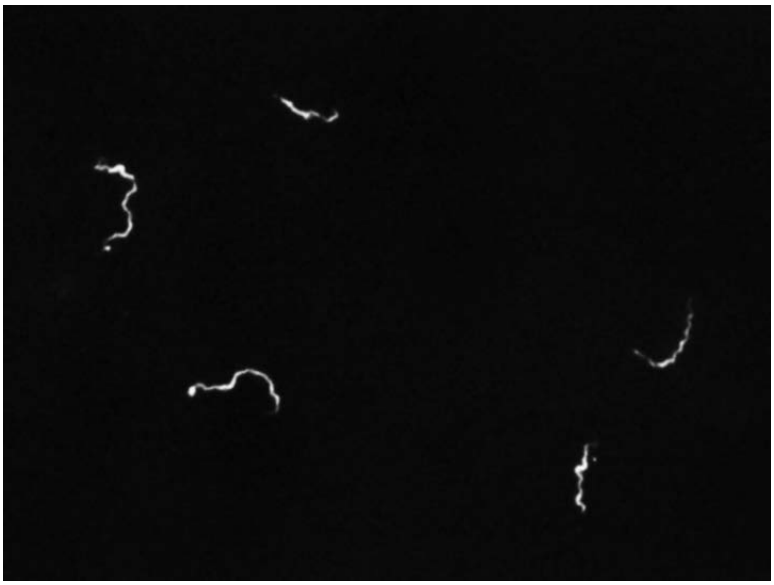
b) Influenza virus

c) HIV

d) Herpes virus

Question 13:

Which method of diagnosis is shown in the image?



a) Darkfield microscopy

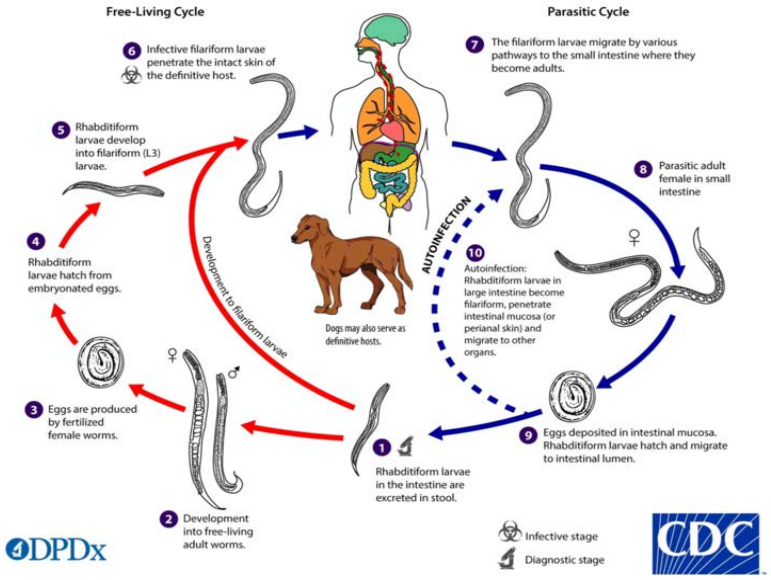
b) Phase contrast microscopy

c) Fluorescent microscopy

d) Electron microscopy

Question 14:

Identify the helminth from the life cycle given below.



a) Ancylostoma duodenale

b) Strongyloides stercoralis

c) Ascaris lumbricoides

d) Enterobius vermicularis

Question 15:

Northern blotting is used for detection of which of the following?

a) DNA

b) RNA

c) Proteins

d) None

Question 16:

A cook prepares sandwiches for 10 people going for picnic. Eight out of them develop severe gastroenteritis within 4-6 hrs of consumption of the sandwiches. It is likely that on investigations the cook is found to be the carrier of:

a) Salmonella typhi

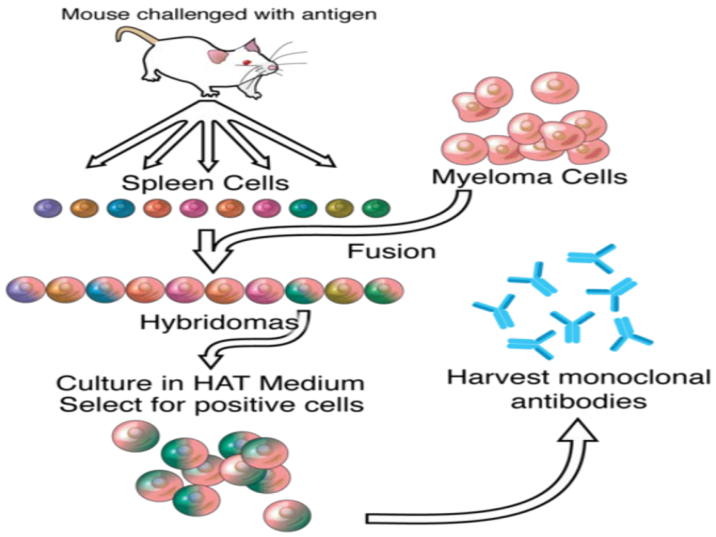
b) Vibrio cholera

c) Entamoeba histolytica

d) Staphylococcus aureus

Question 17:

The following image depicts:



a) Production of monoclonal antibodies

b) Cell lines for viral culture

c) Vaccine synthesis

d) Process of genetic engineering

Question 18:

A patient has complains of fever with chills. A throat examination reveals swollen glands and a thick, whitish membrane over his tonsils. Albert staining is to be done. What are the constituents of Albert's stain?

a) Carbol fuschin and methylene blue

b) Carbol fuschin and malachite green

c) Toluidine and malachite green

d) Toluidine and methylene blue

Question 19:

Which of the following infection presents with mucus in stools and abdominal pain?

a) Giardia

b) Entamoeba

c) Campylobacter

d) Staphylococcus aureus

Question 20:

A patient's plasma has high levels of interferon beta. He most likely has an infection due to _____

a) Virus

b) Bacteria

c) Fungi

d) Mycoplasma

Question 21:

Which of the following is the most potent stimulator of naive T-cells?

a) Mature dendritic cells

b) Follicular dendritic cells

c) B lymphocytes

d) NK cells

Question 22:

Which of the following is an immunologically privileged site?

a) Seminiferous tubule

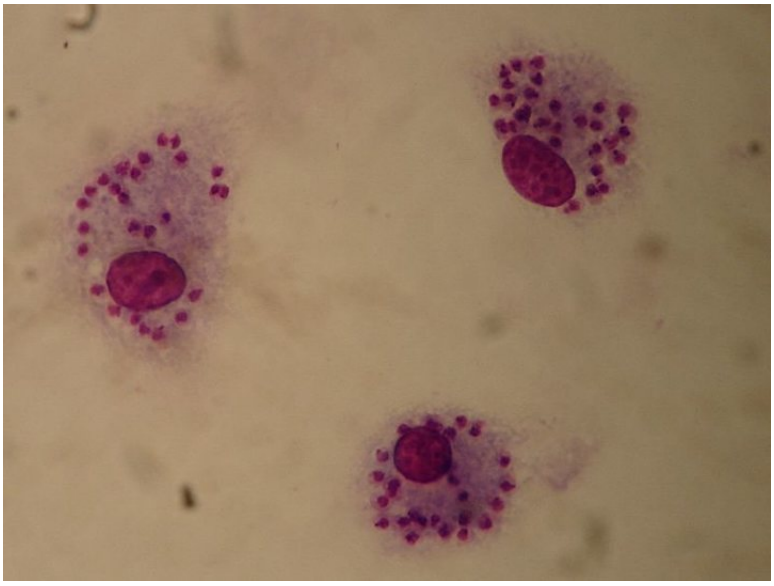
b) Area postrema

c) Optic nerve

d) Loop of Henle

Question 23:

Bone marrow aspirate of a patient shows the following features. Which of the following is true?



a) Buffy coat is used to diagnose the parasite

b) It is an obligate extracellular parasite

c) It is transmitted from sheep

d) Stibogluconate is the first line of treatment in India.

Question 24:

Which of the following drugs is not used for typhoid fever in adults?

a) Azithromycin

b) Ciprofloxacin

c) Ceftriaxone

d) Amikacin

Answer Key

Detailed Explanations

Solution to Question 1:

Diarrhea in an HIV patient is suggestive of a coccidean parasitic infestation. Kinyoun stain positive oocysts in the image are identified as Cystoisospora.

Points in favor:

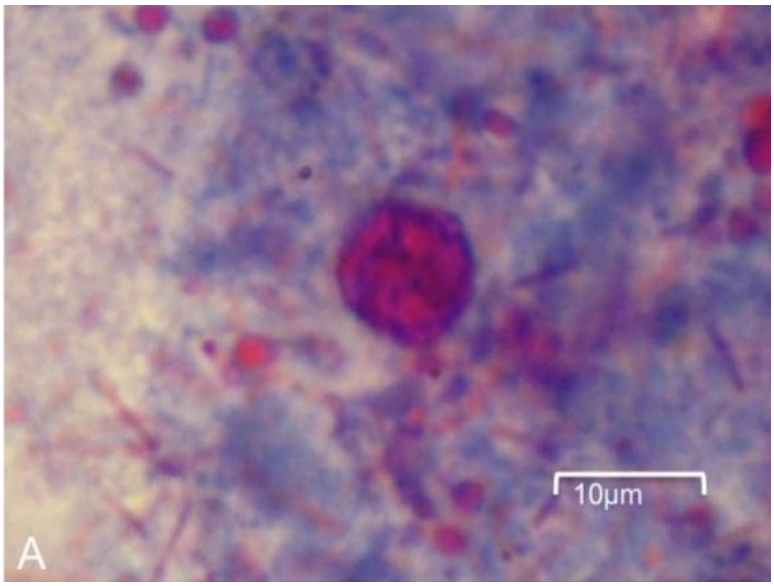
• HIV patient with diarrhea

• Oocysts are long and oval-shaped, which stain pink to red with Kinyoun staining.

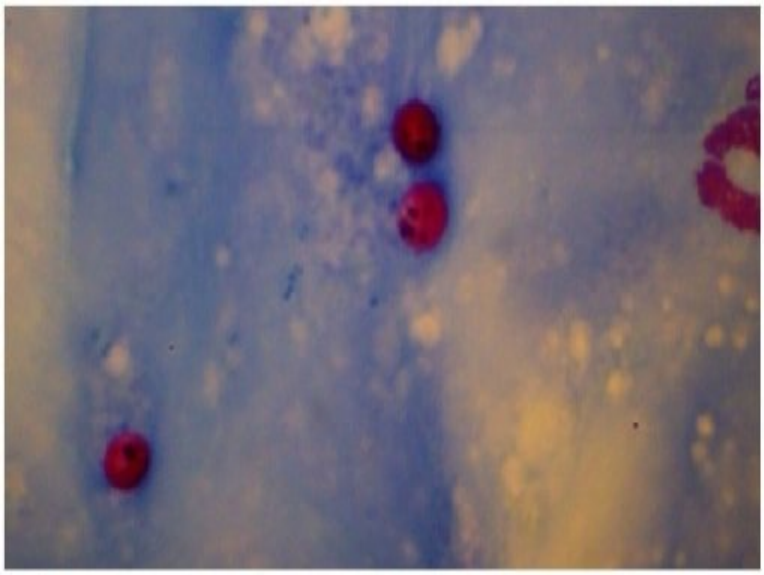
Comparison of coccidian parasites causing diarrhea in an immunocompromised host:

Property	Cryptosporidium	Cyclospora	Cystoisospora
Sporulated oocyst	4-6 µm, round, contains f our sporozoites	8-12 µm, round, contains 2 sporocyst each having t wo sporozoites	23-36 µm, oval, contain t wo sporocysts, each havin g four sporozoites.
Acid-fast detection	Uniformly acid-fast	Variable acid-fast	Uniformly acid-fast
Sporulation of the ooc yst	Occurs inside the host cell	Occurs in soil	Occurs in soil

Property	Cryptosporidium	Cyclospora	Cystoisospora
Diagnostic form	Sporulated cyst	Unsporulated cyst	Unsporulated oocyst



Modified acid-fast staining (like Kinyoun stain) showing oocysts of Cyclospora cayetanensis.



Modified acid-fast staining (like Kinyoun stain) showing oocysts of Cryptosporidium species.

In immunocompromised patients, the infection causes severe diarrhea similar to cholera and require hospitalization.

The diagnosis is made with stool microscopy. The cyst wall and sporoblasts are dyed red with the Ziehl–Neelsen (warm) or Kinyoun (cold) staining methods. Both methods have good specificity and therefore are useful as confirmatory tests.

The treatment is fluid replacement and cotrimoxazole.

Solution to Question 2:

The given image shows blood agar culture with bacitracin disk with a zone of inhibition around the disk, which means that the organism is sensitive to bacitracin.

Among the options given, Streptococcus pyogenes is susceptible to bacitracin.

Streptococci belonging to group A are identified (presumptively) by inhibition of growth by bacitracin.

Solution to Question 3:

The incubation period of Lymphogranuloma venereum ranges from 10-30 days.

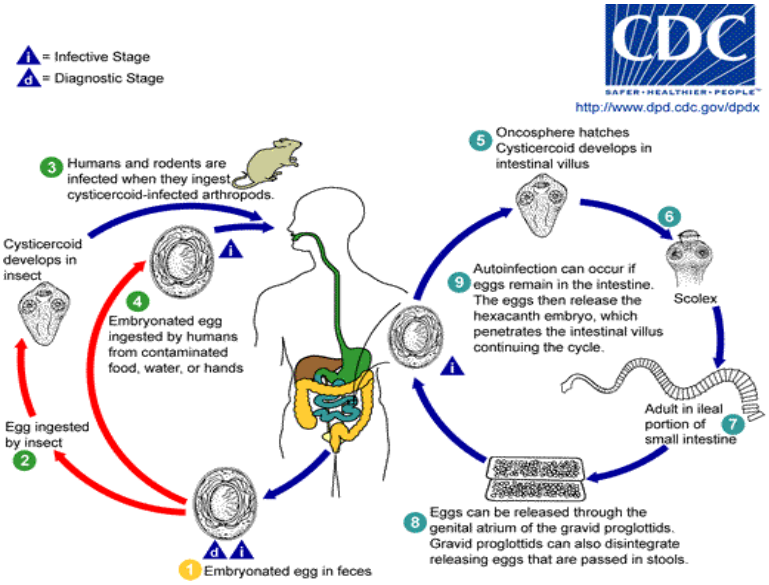
Chlamydia trachomatis serovars L1, L2, and L3 cause lymphogranuloma venereum (LGV). The most common presentation is the inguinal syndrome, which is characterized by painful inguinal lymphadenopathy.

Solution to Question 4:

The egg in the image is of Hymenolepis nana (dwarf tapeworm) and it is treated by praziquantel (5–10 mg/kg once).

The egg is oval, colorless, non-bile stained, and has a single shell with two distinct membranes. Inner membrane has two small knobs or poles from which 4 to 8 polar filaments arise and spread out between the two membranes. It is embryonated and the oncosphere has six hooks (three pairs of hooklets).

Life cycle of Hymenolepis nana:



Hymenolepiasis is the most common of all the cestode infections and is usually asymptomatic.

Solution to Question 5:

Adult T-cell leukemia is caused by HTLV-1 (and not HHV8).

Human Herpesvirus 8 (HHV8), also known as Kaposi sarcoma-associated herpesvirus (KSHV), is lymphotropic virus and is closely related to Ebstein–Barr virus (EBV).

Diseases caused by HHV:

• Kaposi sarcomas

• Vascular tumors of mixed cellular composition

• Body cavity-based lymphomas occurring in AIDS patients (Primary effusion lymphoma)

• Multicentric Castleman disease

Solution to Question 6:

This is a modern compound microscope, and the condenser is located below the stage.

The purpose of the condenser lens is to focus the light from the illuminator onto the specimen. Microscopes with a stage condenser lens render a sharper image than those with no condenser lens.

The simple microscope was invented first by Antonie van Leeuwenhoek, the father of microscopy and microbiology. It uses 1 lens for magnification. The compound microscope, introduced by Hans and Zacharias Janssen uses 2 lenses, an objective lens and an eyepiece, to provide better magnification power than the simple microscope.

Solution to Question 7:

The image shows the germ tube test used for identifying Candida albicans.

Candida species, when cultured, grow as oval, budding yeast cells with pseudohyphae. Unlike other species of candida, Candida albicans can also produce true hyphae or germ tubes. This can be demonstrated after incubation in serum maintained at 37°C for about 90 minutes. This is known as the Reynolds-Braude phenomenon. This test is positive for Candia dubliniensis as well. Another distinguishing feature of C. albicans is that it produces large, spherical chlamydospores on nutritionally deficient media.

Solution to Question 8:

Resistance to ganciclovir most commonly occurs due to mutations in the UL97 phosphotransferase gene.

Cytomegalovirus (CMV) is a beta-herpes virus. It is the most common congenital infection. In adults, its disease is mostly subclinical (option C). An apparent CMV infection resembles infectious mononucleosis (fever, sore throat, enlarged lymph nodes and splenomegaly). It is the most common infection in the donor organ seen 1-4 months after solid organ transplantation. In immunosuppressed hosts, it causes pneumonia and colitis.

Diagnosis is by PCR assays. Human CMV replicates in vitro only in human fibroblasts (option B) and can thus be cultured in them, although the virus is often isolated from epithelial cells of the host. The cultured fibroblasts show owl-eye inclusion bodies after 2-3 weeks.

UL54 (DNA polymerase) gene mutations can confer CMV resistance to ganciclovir, cidofovir and foscarnet (option D).

Solution to Question 9:

Solvent detergent plasma is a form of blood plasma made from plasma collected from many people which is then processed with solvents to try to get rid of viruses. HAV is a non-enveloped virus, and hence it’s not affected by solvent/detergent (SD) plasma.

Only the viruses with an envelope are susceptible to SD plasma destruction.

Hepatitis B, C, and HIV are enveloped.

Solution to Question 10:

A variety of hydrogen peroxide gas–based processes that use plasma as part of the sterilization process are known as "plasma sterilization."

The mechanisms of antimicrobial action in these processes are primarily due to hydrogen peroxide gas (or condensed gas) and not plasma, although the plasma generation phase of these processes is known to assist in the breakdown of residual peroxide in the chamber load.

Solution to Question 11:

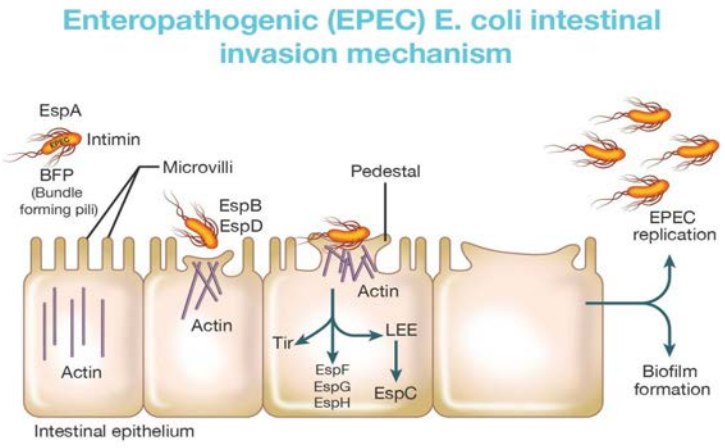
Attachment and effacement lesions on intestinal cells are caused by enteropathogenic Escherichia coli (EPEC).

E. coli is the second most common cause of diarrhea in the pediatric age group. Rotavirus is the most common cause. EPEC causes watery diarrhea which is self-limiting.

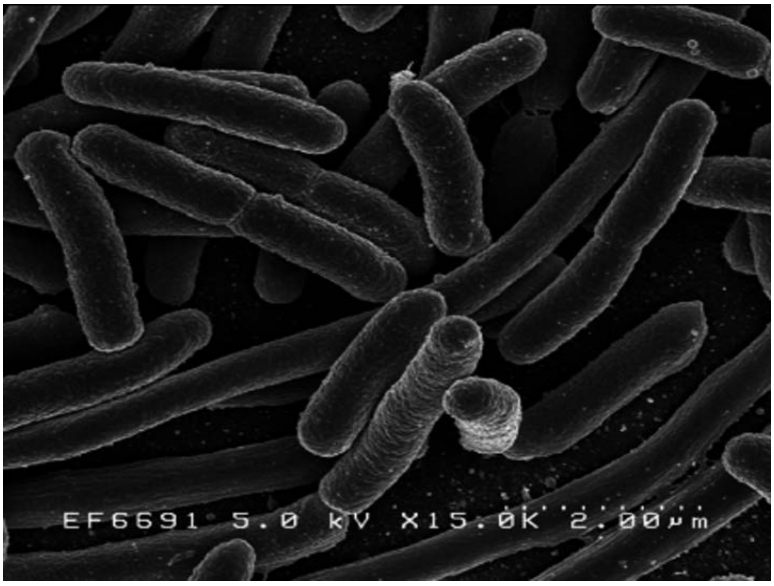
EPEC adheres to the mucosal cells of the small bowel and causes loss of microvilli (effacement). This leads to the formation of filamentous actin pedestals or cuplike structures and occasionally may cause entry of the EPEC into the mucosal cells.

Pathogenicity requires the presence of two important factors:

- Bundle-forming pilus encoded by plasmid containing EPEC adherence factor (EAF).
- Chromosomal locus of enterocyte effacement (LEE) pathogenicity island.



The image below shows an electron microscopy image of E Coli.



Solution to Question 12:

The given image shows generation of mRNA from negative sense RNA within the nucleus. This occurs during the replication of influenza virus.

Orthomyxoviruses (influenza virus) contain segmented (8 segments) negative sense ssRNA that is replicated in the nucleus. Stages of viral replication include the following:

• Attachment, penetration, uncoating: The virus attaches to cell-surface sialic acid via hemagglutinin. It is then internalized by receptor-mediated endocytosis. There is fusion of the viral envelope and cell membrane, resulting in uncoating or release of nucleocapsid into the host cell cytoplasm.

• Transcription and translation: mRNAs are produced from nucleocapsids via a virus-encoded polymerase. This process occurs in the nucleus. The mRNAs thus produced are translated into viral proteins in the cytoplasm.

• Viral RNA replication: The viral genome is replicated by the same virus-encoded polymerase involved in transcription. The negative sense RNA is converted to its positive sense form. The positive sense copies serve as templates for replication of the viral genome.

• Maturation: The virus matures by budding from the surface of the cell.

Solution to Question 13:

The given image is of darkfield microscopy as it has a dark background with a refractile organism.

The dark ground microscope has an optical system that enhances the contrast of unstained bodies.

Dark ground microscopy is the most specific and sensitive technique to diagnose syphilis when an active chancre or condyloma lata is present to visualize Treponema pallidum.

Solution to Question 14:

The image shows the life cycle of Strongyloides stercoralis.

Strongyloides stercoralis is the smallest nematode known to cause human infection. It has both a free-living and a parasitic life cycle. Its natural host is man. The infective form to man is the filariform larva. Infection occurs through penetration of the skin by larvae in the soil. Then, the larvae migrate to the small intestine. They molt twice and become adult female worms in the small intestine. The eggs laid in the mucosa of the intestine hatch immediately releasing the rhabditiform larva (L1 stage). Thus, it is ovoviviparous. These rhabditiform larvae in the bowel can develop directly into filariform larvae that penetrate the colonic wall or perianal skin and enter the circulation to repeat the migration. This establishes ongoing internal reinfection.

The rhabditiform larva can also be passed in the stool. It may directly metamorphose to the infective filariform larva in the soil, or develop into adult worms. The free-living adult worms then pass eggs, which hatch and mature to form infective filariform larvae.

In Ancylostoma duodenale infestation, eggs containing segmented ova (not rhabditiform larvae) are passed in the stool. The rhabditiform larva hatches 2 days after the eggs are passed in the soil.

Note: Based on the method of reproduction, nematodes are classified as follows:

• Oviparous - They lay eggs:

• Unsegmented eggs: Ascaris lumbricoides, Trichuris trichuria

• Segmented eggs: Ancylostoma duodenale, Necator americanus

• Eggs containing larva: Enterobius vermicularis

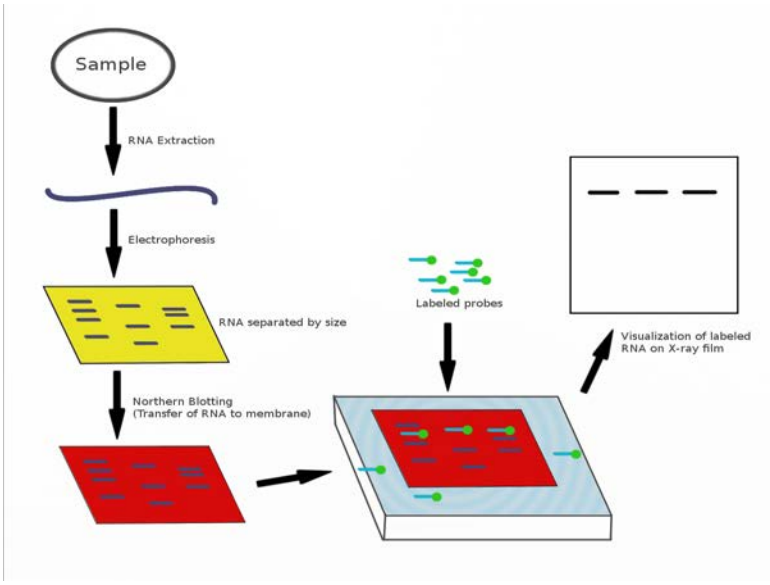
• Viviparous - They produce larvae. e.g., Trichinella spiralis, Wuchereria bancrofti, Brugia malayi

• Ovoviviparous – They lay eggs containing fully formed larvae that hatch immediately. e.g., Strongyloides stercoralis

Solution to Question 15:

Northern blotting is used for the detection of RNA.

Southern blotting is used for the detection of DNA and Western blotting is used for the detection of protein.



Solution to Question 16:

The cook is most likely to be carrier of Staph. aureus.

The onset of food poisioning with in 4-6 hrs of food is mainly due to:

• Staphylococcus aureus

• Bacillius cereus (has no carriers)

Solution to Question 17:

The image depicts the production of monoclonal antibodies by hybridoma technology.

The following are the steps involved in hybridoma technology:

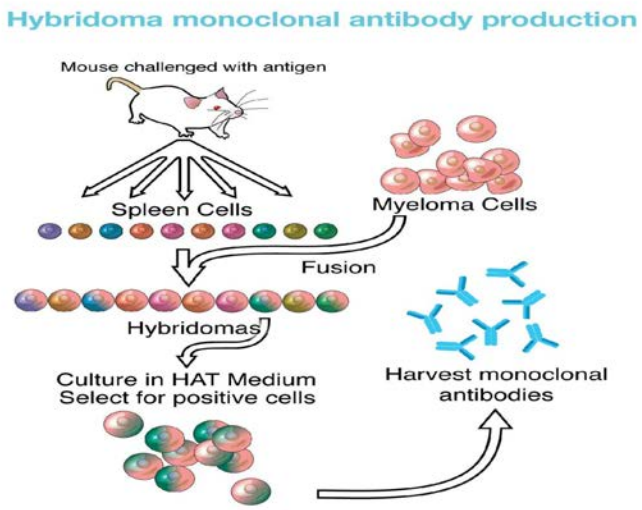
• Mice are immunized with an antigen. After several weeks of immunization, blood samples are obtained from mice for measurement of serum antibodies.

• When the antibody titer is high enough, mice are commonly boosted by injecting antigen, without adjuvant, intraperitoneally or intravenously. Then the mice are euthanized and their spleens removed for in vitro hybridoma cell production.

• Fusing antibody-producing spleen cells, which have a limited life span, with myeloma cells (derived from an immortal tumor of lymphocytes) results in a hybridoma that is capable of unlimited growth.

• The cells are cultured in a medium containing hypoxanthine, aminopterin, and thymidine (HAT medium) which allows only the fused cells to survive in culture.

• Monoclonal antibodies are then harvested.

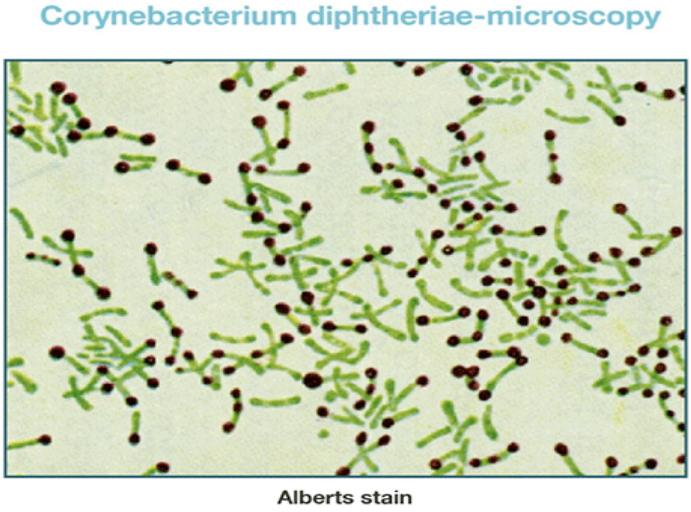


Solution to Question 18:

The given scenario is suggestive of diphtheria caused by Corynebacterium diphtheria. This organism is stained using Albert's stain which contains toluidine blue 'O' and malachite green. Both these dyes have an affinity for acidic cytoplasm as they are basic dyes.

Albert's, Neisser's, and Ponder's stain are used to demonstrate the metachromatic granules(Volutin / Babes Ernst granules) of Corynebacterium diphtheria.

Corynebacterium diphtheria appears as green-coloured bacilli with purple-blue-coloured metachromatic granules in cuneiform arrangement.



Solution to Question 19:

Stools with mucus and abdominal pain are seen in infection due to Entamoeba.

Clinical features of intestinal amebiasis:

• Acute intestinal amebiasis presents as dysentery accompanied by lower abdominal discomfort and flatulence. Stools usually have blood and mucus.

• Chronic amebiasis presents with low-grade symptoms such as occasional diarrhea, weight loss, and fatigue.

• A granulomatous lesion called an ameboma may form in the cecal or rectosigmoid areas of the colon which can resemble an adenocarcinoma of the colon.

Other options:

Option a - Giardia is often asymptomatic, but in some cases can lead to fat malabsorption, dull epigastric pain, and flatulence.

Option c - Campylobacter presents with fever, pain and bloody or watery diarrhea. Stool contains leucocytes and blood.

Option d - Staphylococcal food poisoning is toxin-mediated and presents with nausea, vomiting, and diarrhea.

Solution to Question 20:

Interferon-beta is secreted during infection due to viruses.

Interferons are classified as cytokines. Interferons are non-toxic, non-antigenic and species-specific molecules. They are inactivated by proteases. They are stable at pH over 2-10, except INF-γ (labile at pH 2) and are non-dialysable and non-sedimentable.

There are three types of interferons - α, β and γ. IFN-α or leukocyte interferon is produced by leucocytes. It has antiviral activity, is immunoregulaotry and antiproliferative. IFN-β or fibroblast interferon is produced by fibroblasts and epithelial cells. It has antiviral activity and is thus increased in viral infections. It enhances MHC class 1 and NK cell activity. IFN-γ or immune interferon is produced by T-lymphocytes, NK cells . It activates macrophages, increases neutrophil function, enhances both MHC class 1 and class II expression and has anti-proliferative (anti-tumour) functions.

Solution to Question 21:

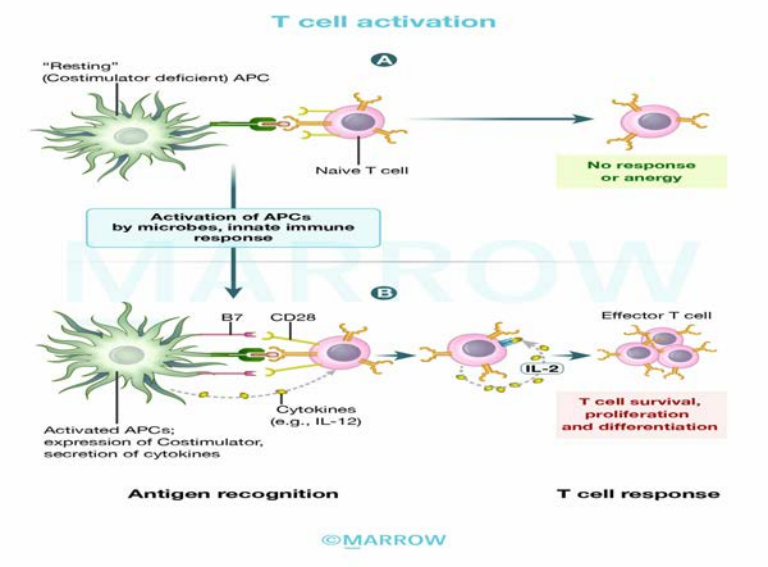
Mature dendritic cells are the most potent stimulator of naive T cells.

Naive CD4+ T cells are activated when they come in contact with two ligands - MHC class II and a costimulary membrane protein (eg: CD28). Both of these are present in antigen-presenting cells, the most potent of which is the mature dendritic cell. Other professional antigen-presenting cells include macrophages and B lymphocytes (option C).

Other options:

Option B: Follicular dendritic cells are functionally different from dendritic cells. They are not antigen-presenting-cells and do not activate naive T cells.

Option D: NK cells do not stimulate naive T cells.



Solution to Question 22:

The seminiferous tubules are an immunologically privileged site.

Immunologically privileged sites can tolerate the introduction of antigens without eliciting an immune response. This allows a higher likelihood of graft survival, even without perfect HLA matching. As a result, an allograft can be placed in these sites without endangering a rejection reaction.

The unique immune tolerance in these regions is primarily due to the lack of effective lymphatic drainage, which prevents antigen presentation to the immune system, and the presence of blood-tissue barriers that restrict immune cell infiltration. Low vascularity contributes to immune privilege by minimising antigen exposure and immune cell recruitment.

Examples of immune-privileged sites are the anterior chamber of the eye, cornea, testes, and brain.

Note: Although part of the brain, the blood-brain barrier is absent at the area postrema, therefore it is not an immune-privileged site.

Solution to Question 23:

The given image shows the amastigote form of leishmaniasis located intracellularly in macrophages. Buffy coat is used to diagnose the parasite.

Visceral leishmaniasis (kala-azar) is a slowly progressing indigenous disease caused by a protozoan parasite of genus Leishmania. Leishmaniasis is a parasitic disorder transmitted by the

bite of an infected female Phlebotomus sandfly in developing countries. The disease is transmitted by sand flies, which inoculate the flagellated promastigotes into the skin of the host.

In human beings, the disease presents in four different forms with a broad range of clinical manifestation:

• Visceral leishmaniasis, or kala-azar,

• Cutaneous leishmaniasis,

• Mucocutaneous leishmaniasis, and

• Diffuse cutaneous leishmaniasis.

The life cycle of Leishmania involves two forms,

• The promastigote which develops and lives extracellularly in the sandfly vector and

• The amastigote which multiplies intracellularly in the reticuloendothelial cells of the host.

It lowers immunity, causes persistent fever, anemia, liver and spleen enlargement, and if left untreated, death may occur due to opportunistic infection.

Diagnosis:

• Rapid diagnostic test: rK39 Rapid diagnostic test and Kala azar dipstick test strip.

• Parasitological diagnosis: Demonstration of LD bodies in buffy coat smear - confirmatory.

• Aldehyde test of Napier: Widely used for surveillance.

• Serological tests for diagnosis: Rapid dipstick test, Direct agglutination test, ELISA, Indirect Fluorescent Antibody Test

• Leishmanin (Montenegro) test: Induration of 5mm or more is considered positive, usually positive 4-6 weeks after onset in cutaneous leishmaniasis, valuable for distinguishing immune from nonimmune subjects and endemicity.

Drugs used in the treatment of visceral leishmaniasis are sodium stibogluconate, miltefosine, and amphotericin. Liposomal amphotericin single dose 10mg/Kg IV is the first line of treatment in India.

Solution to Question 24:

Amikacin is not used in the treatment of typhoid fever.

Amikacin is an aminoglycoside. Despite showing efficient in vitro killing of Salmonella, first- and second-generation cephalosporins and aminoglycosides have proven to be ineffective in actual clinical cases.

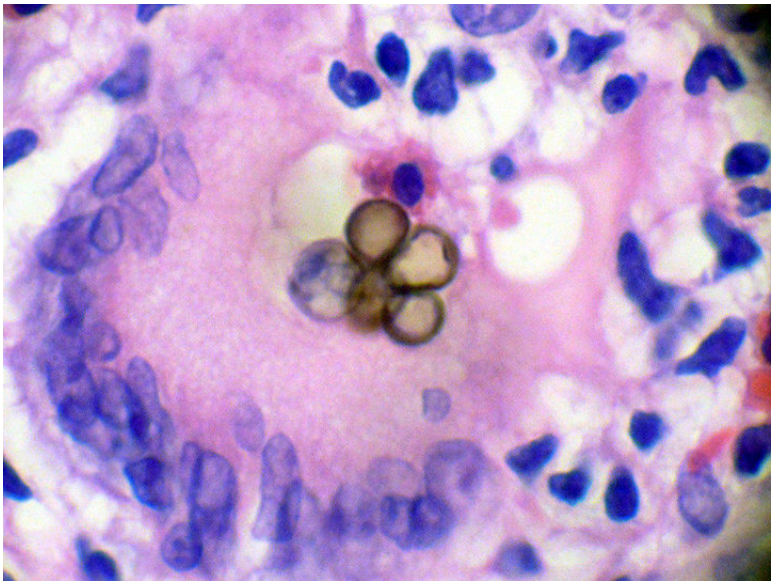
Antibiotic therapy for enteric fever in adults			
Indication	Agent	Dosage (Route)	Duration, Days
Empirical Treatment			

Antibiotic therapy for enteric fever in adults			
	Ceftriaxone	2 g/d (IV)	10-14
Azithromycin	1 g/d (PO)	5	
Fully Susceptible			
Optimal treatment	Ciprofloxacin	500 mg bid (PO) or 400 mg q12 h (IV)	5-7
Azithromycin	1 g/d (PO)	5	
Alternative treatment	Amoxicillin	1 g tid (PO) or 2 g q6h (IV)	14
Chloramphenicol	25 mg/kg tid (PO or IV)	14-21	
Trimethoprim-sulfamethoxazole	160/800 mg bid (PO)	7-14	
Multidrug-resistant, fluroquinolone-susceptible			
Optimal treatment	Ceftriaxone	2 g/d (IV)	10-14
Azithromycin	1 g/d (PO)	5	
Alternative treatment	Ciprofloxacin	500 mg bid (PO) or 400 mg q12h (IV)	5-14
Quinolone-resistant			
Optimal treatment	Ceftriaxone	2 g/d (IV)	10-14
Azithromycin	1 g/d (PO)	5	
Alternative treatment	High dose ciprofloxacin	750 mg bid (PO) or 400 mg q 12h (IV)	10-14
Ceftriaxone-resistant			
Optimal treatment	Meropenem	1 g q8h (IV)	10-14
Azithromycin	1 g/d (PO)	5	

Microbiology AIIMS 2019 (May & Nov)

Question 1:

A farmer from the sub-Himalayan belt had a thorn prick injury a year back and developed a warty, verrucous growth at the site of prick. A skin biopsy sample was taken and sent for histopathological examination. The characteristic microscopic body as shown in the image was seen. Which of the following could be the most likely diagnosis?



a) Blastomycosis

b) Pheohyphomycosis

c) Chromoblastomycosis

d) Sporotrichosis

Question 2:

Choose the wrong statement about Plasmodium species:

a) Drug resistant falciparum is seen in India

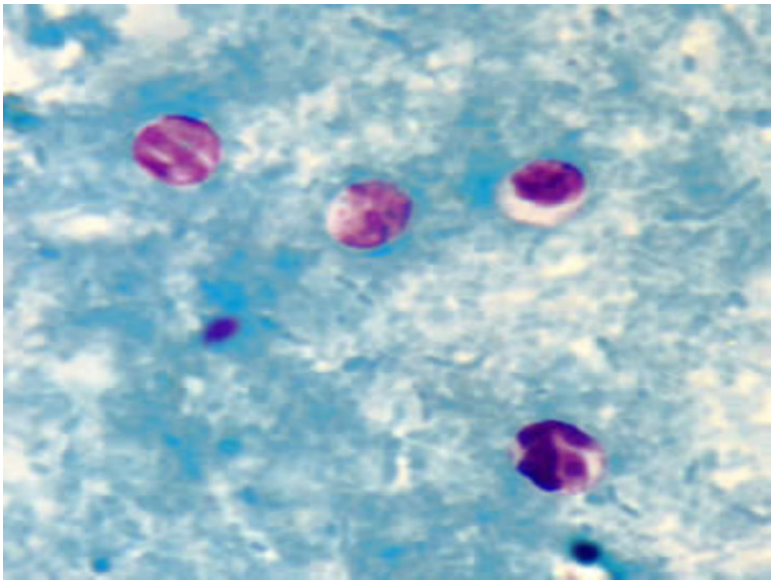
b) Presence of duffy blood group antigen is protective against vivax

c) Severe malaria with shock is called algid malaria

d) Relapse is seen in P. ovale

Question 3:

A HIV patient with fever, chronic diarrhea presented to OPD. His stool was examined which showed the following oocysts. Identify the components used for staining the stool.



a) Crystal violet, iodine, acid alcohol, carbol fuchsin

b) Methanol, Kinyoun's carbol fuchsin, acid alcohol, methylene blue

c) Methanol, dilute carbol fuchsin, acid alcohol, crystal violet

d) Methylene blue, iodine, acid alcohol, carbol fuchsin

Question 4:

Which immunoglobulin is elevated in a case of chronic allergy?

a) IgA

b) IgM

c) IgE

d) IgG

Question 5:

A patient is diagnosed with Hepatitis B infection. Which of the following markers will always be present in his serum, even during recurrences, or if he develops chronic hepatitis?

a) HBc Ag

b) Anti HBs Ab

c) Anti HBc Ab

d) HBe Ag

Question 6:

Which among the following occupation is a risk factor for this presenting illness?

a) Kennel Worker

b) Lifeguard in a swimming pool

c) Veterenarian

d) Poultry worker

Question 7:

Transmission assessment survey is carried out for:

a) P. vivax

b) P. falciparum

c) Filariasis

d) Leishmania

Question 8:

Which among the following is a subcutaneous fungal agent?

a) Cryptococcus neoformans

b) Histoplasma capsulatum

c) Sporothrix schenckii

d) Talaromyces marneffei

Question 9:

A hospital has reported an outbreak of MRSA infection. On investigation, it was found out that a staff nurse had nasal carriage of MRSA. Which of the following drugs helps in the removal of colonization of bacteria?

a) Oral vancomycin

b) Inj cephalosporin

c) Topical mupirocin

d) Inhaled colistin

Question 10:

Mw vaccine is extracted from which bacteria, mentioned below:

a) M. indicus pranii

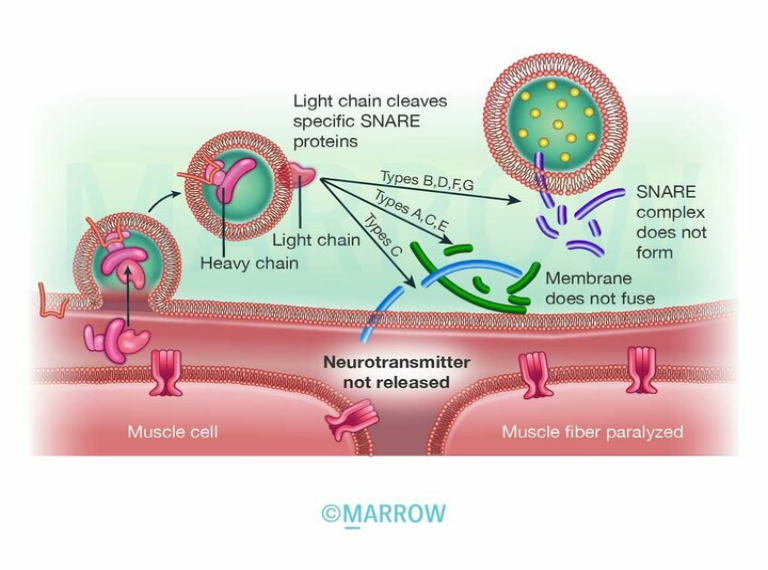
b) M. welchii

c) M. leprae

d) M. bovis

Question 11:

Which toxin acts via the mechanism depicted in the image below?



a) Botulinum

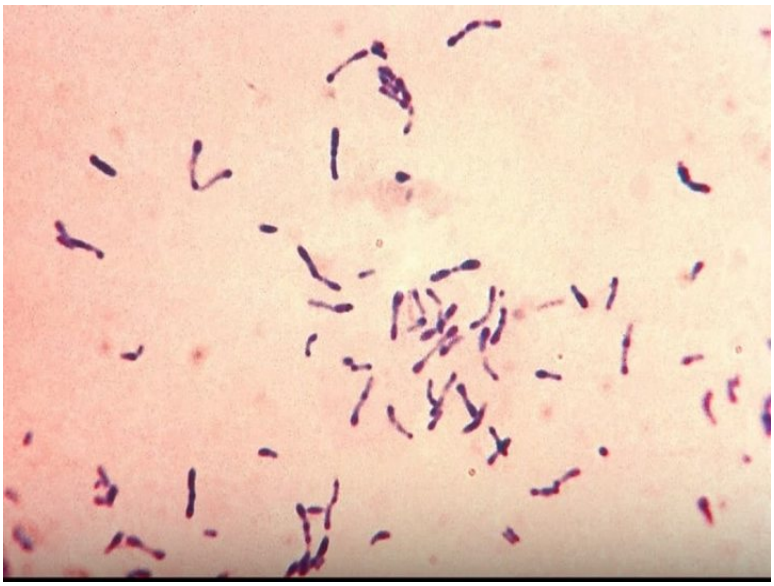
b) Tetanus

c) Diphtheria

d) Pertussis

Question 12:

The toxin produced by the organisms shown below acts via?



a) Increase in cAMP

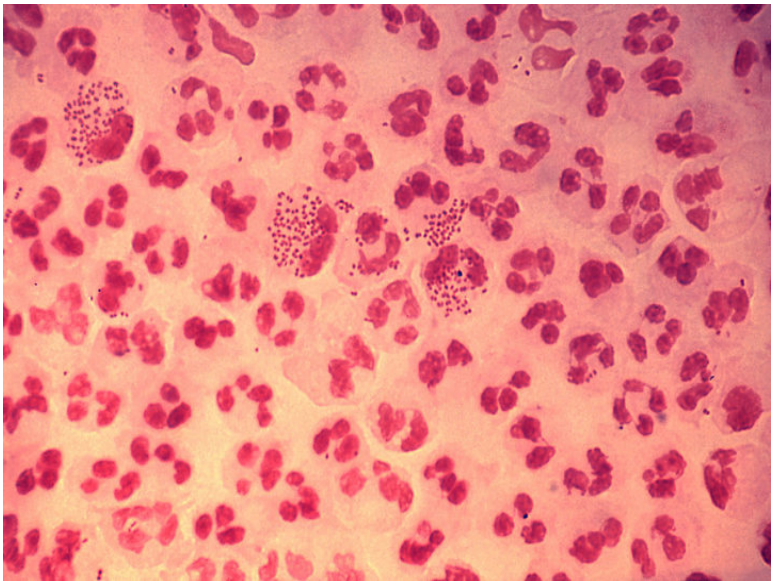
b) Increase in cGMP

c) ADP ribosylation of EF2

d) RNA glycosidase

Question 13:

A 25-year old man presents with a history of urethral discharge for the last three days. A gram stain smear of the discharge is shown below. All of the following are true regarding the likely etiology except?



a) Catalase and oxidase positive

b) Pili is a virulence factor

c) Obligate intracellular organism

d) Shows twitching motility

Question 14:

The CLED medium is preferred over MacConkey agar for the culture of organisms in case of UTI because:

a) It inhibits proteus swarming

b) It promotes the growth of candida, streptococcus and staphylococcus

c) It differentiates between lactose-fermenting and non-lactose fermenting bacteria

d) It promotes the growth of pseudomonas

Question 15:

Which of the following organisms cause multiple alveolar-like lesions in the liver?

a) Echinococcus multilocularis

b) Echinococcus granulosus

c) Entamoeba histolytica

d) Cysticercus cellulosae

Question 16:

All of the following can be seen intracellularly in hepatocytes except:

a) Toxoplasma

b) Plasmodium

c) Babesia

d) Leishmania

Question 17:

A Giemsa stain of a thin peripheral smear is prepared. Which of the following cannot be diagnosed?

a) Coxiella burnetii

b) Toxoplasma gondii

c) Bartonella henselae

d) Ehrlichia chaffeensis

Question 18:

Which of the following is false about influenza?

a) Virus shedding is present before symptoms begins

b) 5-12 years is a high risk group

c) Aquatic birds act as reservoir

d) Secondary attack rate is 5-15%

Question 19:

β 1-3 glucan assay is used to diagnose all except?

a) Candidiasis

b) Aspergillosis

c) Pneumocystis pneumonia

d) Mucormycosis

Question 20:

Which of the following is a xenodiagnostic method?

a) Rabbit ileal loop assay for ETEC

b) Injecting Aedes thorax with blood of a patient with suspected dengue

c) Injecting a hamster with splenic biopsy for diagnosis of leishmaniasis

d) Intradermal test on guinea pigs for toxigenicity of Corynebacterium diphtheria

Answer Key

Question No.	Correct Option

17	a
18	b
19	d
20	b

Detailed Explanations

Solution to Question 1:

The history of a slowly spreading warty, verrucous lesion following a thorn prick injury and the histopathological image showing medlar bodies is suggestive of chromoblastomycosis.

Chromoblastomycosis (chromomycosis) is a subcutaneous mycotic infection that is usually caused by traumatic inoculation. Over months to years, the primary lesion becomes verrucous and wart-like with extension along the draining lymphatics.

Histologically, the lesions are granulomatous and the dark sclerotic bodies may be seen within leukocytes or giant cells called medlar/copper penny bodies.

Subcutaneous mycoses	Causative agent/s
Sporotrichosis	Sporothrix schenckii
Chromoblastomycosis	Phialophora verrucosaFonsecaea pedrosoiFonsecaea compactRhinocladiella aquaspersa Cladophialophora carrionii
Phaeohyphomycosis	Exophiala jeanselmeiPhialophora richardsiaeBipolaris spiciferaWangiella dermatitidis
Mycetoma	Pseudallescheria boydii (Anamorph Scedosporium apiospermum).Madurella mycetomatisMadurella griseaE jeanselmeiAcremonium falciforme

Solution to Question 2:

The absence, not the presence, of the Duffy blood group antigen, is protective against P. vivax because the Duffy antigen normally serves as the receptor for Plasmodium vivax.

Drug Efflux pumps are the primary mode of resistance for Chloroquine. It is mediated by an ABC transporter encoded by P. falciparum multidrug resistance gene 1 (Pfmdr1). The resistance of P. falciparum to chloroquine increased over time and is present across all regions of the country.

Algid malaria is a rare complication of severe malaria characterized by hemodynamic collapse manifesting as shock with pronounced metabolic changes and hypothermia.

Relapse is seen in cases of Plasmodium vivax and Plasmodium ovale.

Malaria relapse :

True relapse is caused due to Hypnozoites.

These are resting forms.

In the case of Plasmodium vivax and ovale two kinds of sporozoites are seen, some of which :

• multiply inside hepatic cells to form - Schizonts

• others persist and remain dormant as - hypnozoites

From time to time some are activated to become schizonts and release merozoites, which go on infecting RBCs producing clinical relapse.

In the case of Plasmodium falciparum and Plasmodium malariae, the initial tissue phase disappears completely and no hypnozoites are found, hence technically relapse is not seen.

Solution to Question 3:

Diarrhea in an HIV patient is suggestive of a coccidian parasitic infestation. The image shows a blue background and red-stained oocysts, suggestive of modified acid-fast stain positive Cryptosporidium parvum.

The modified Ziehl-Neelsen (ZN) method is used for staining cryptosporidium and isospora species. Unlike the ZN-stain, the modified ZN stain does not require heating of the reagents.

The reagents used in modified ZN stain include:

• Absolute methanol for fixation

• Kinyoun's Carbol fuchsin - Primary stain

• Acid alcohol - Decolourising agent

• Methylene blue or Malachite green - Counterstain

Solution to Question 4:

IgE is elevated in cases of chronic allergy.

Solution to Question 5:

A patient who has had exposure to HBV will have anti-HBc antibody even when he has moved into the chronic or recurrent stages. IgM anti-HBc reappears during acute recurrences while IgG anti-HBc is found in chronic states.

The HBsAg antigen is present in chronic hepatitis B, while the antibody anti-HBs is not.

Solution to Question 6:

The above image shows cutaneous larva migrans. Being a kennel worker is a risk factor for this job as exposure to animal feces is high.

As Larvae are found on sandy beaches, and under dwellings, swimming in natural water bodies would be a risk and not artificial ones like swimming pools.

CLM is caused by various animal hookworm species (e.g., Ancylostoma brazilienses), and the parasite is acquired from direct skin contact with soil contaminated by dog or cat feces. The parasitic infection usually begins with an inflamed papule, often located between the toes, where the hookworm species (e.g., Ancylostoma brazilienses) larvae enter the skin.

Serpentine or linear single-track lines later mark the course of the larvae as they migrate through the epidermis of the trunk and lower extremities.

Ivermectin is the first-line drug for the treatment of cutaneous larva migrans, taken as a single 200 μg/kg oral dose.

Solution to Question 7:

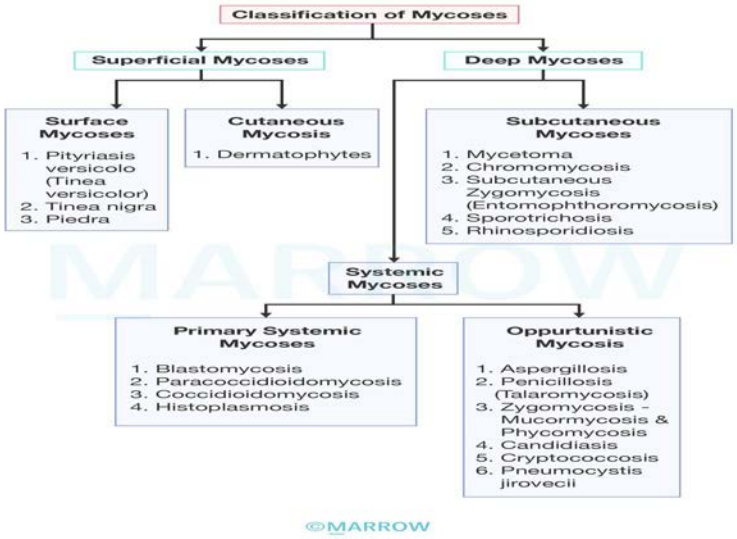
Transmission assessment survey is carried out for filariasis.

Mass Drug Administration is used to reduce infection in the community to levels below a threshold at which mosquitoes are unable to continue spreading the parasites from person to person and thus new infections are prevented.

The transmission assessment survey (TAS) is used to determine when infections have been reduced below target thresholds and Mass Drug Administration can stop. Once MDA has stopped, TAS is used as a surveillance tool to determine that infection levels are sustained below target thresholds.

Solution to Question 8:

Sporothrix schenckii is a subcutaneous fungal agent. The other three mentioned are systemic mycoses.



Solution to Question 9:

Topical mupirocin is the preferred agent for the elimination of nasal carriers of MRSA.

As Mupirocin has no structural similarities with existing systemic antibiotics that might lead to the development of cross-resistance and has minimal toxicity in its topical form, it is approved for the prevention of MRSA outbreaks

Mixed therapy with systemic agents is not preferred as it would cause unnecessary antibiotic exposure potentially paving way for drug resistance.

Solution to Question 10:

Mw vaccine is extracted from M. indicus pranii

MIP immunotherapy is used as an adjunct to chemotherapy for category II tuberculosis.

Here, indicus stands for India, where the M. indius pranii was isolated; and pranii stands for the person who discovered the species (Prof. Pran Talwar) and National Institute of Immunology (nii), where trials were conducted (pran + nii).

Administration: 0.1 ml intradermal. It is divided into two equal doses and given on both arms. Booster doses are injected only on one arm.

Solution to Question 11:

The image given above depicts the mechanism of action of botulinum toxin.

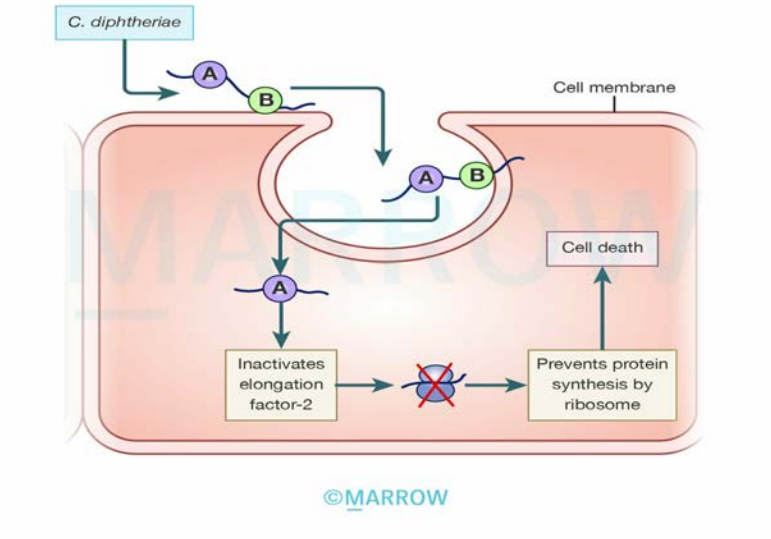
It causes proteolysis of snare proteins. Snare proteins have three components- synaptobrevin, SNAP25 and syntaxin. The snare protein is required for the excocytosis of acetylcholine vesicles. Thus it leads to presynaptic inhibition of neuronal transmission.

There are 7 different strains of clostridium botulinum and each strain acts by a different mechanism. Toxins of C. Botulinum A, C and E cleave SNAP25. Type C also cleaves syntaxin. Type B, D, F and G cleave synaptobrevin.

Solution to Question 12:

The given image shows gram-positive rods with club-shaped ends, beaded appearance, and a Chinese-letter pattern of arrangement indicative of Corynebacterium diphtheriae.

The toxin produced by the bacteria - diphtheria toxin - inhibits polypeptide chain elongation and protein synthesis by inactivating the elongation factor-2 (EF-2) by ADP ribosylation. It has two fragments - fragment B helps in binding of the toxin to host cells and fragment A inactivates EF-2.



Solution to Question 13:

The given slide shows gram-negative diplococci within the polymorphs, characteristic of Neisseria gonorrhoeae infection. Neisseria is not an obligate intracellular organism, it can also occur extracellularly i.e, it is a facultative intracellular organism. The other neisseria that are found as normal inhabitants of the human respiratory tract occur extracellularly.

Neisseria gonorrhoeae is a gram-negative, non-sporulating, non-motile diplococcus that is aerobic but may grow anaerobically also. It is oxidase and catalase-positive.

Although Neisseria are non-motile organisms, they show twitching motility. This is a flagella-independent form of bacterial translocation over moist surfaces that occurs by the extension and retraction of polar type IV pili. These pili act as virulence factors by promoting attachment to host cells and inhibiting phagocytosis.

Virulence factors for gonococci:

• Outer Membrane Proteins (OMPs)

• IgA proteases

• Pili

• Lipo-oligosaccharide (LOS)

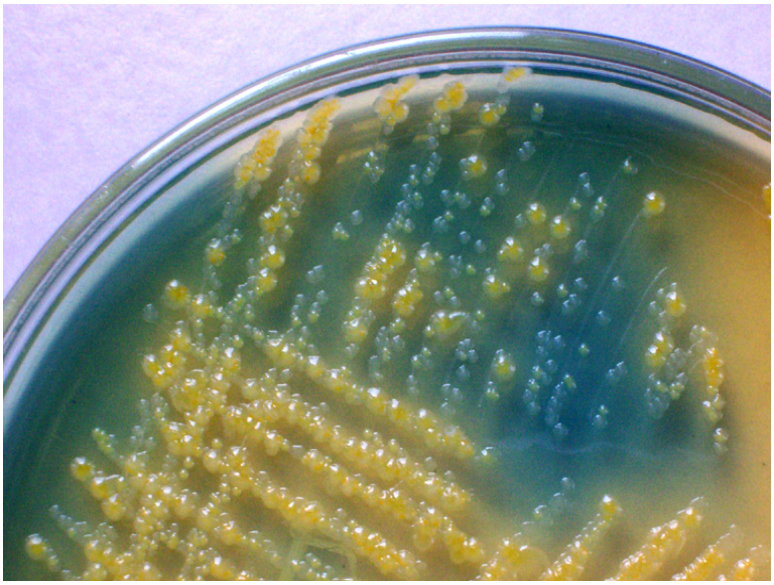
• Transferrin

• Lactoferrin-binding protein

Solution to Question 14:

CLED (Cysteine lactose electrolyte-deficient) medium is preferred over MacConkey agar for the culture of organisms involved in urinary tract infections because it is less inhibitory and promotes the growth of gram-positive bacteria (except β hemolytic streptococcus) and candida.

A combination of blood agar and MacConkey agar is used for the processing of urine specimens. CLED medium is used as an alternative for this combination. It can also prevent swarming of Proteus, and is thus different from blood agar. Like MacConkey agar, it differentiates between lactose fermenters and non-fermenters. Lactose fermenters change the colour of the medium from green to yellow. However, these two facts are not the reason it is better than MacConkey agar for evaluation of UTI.

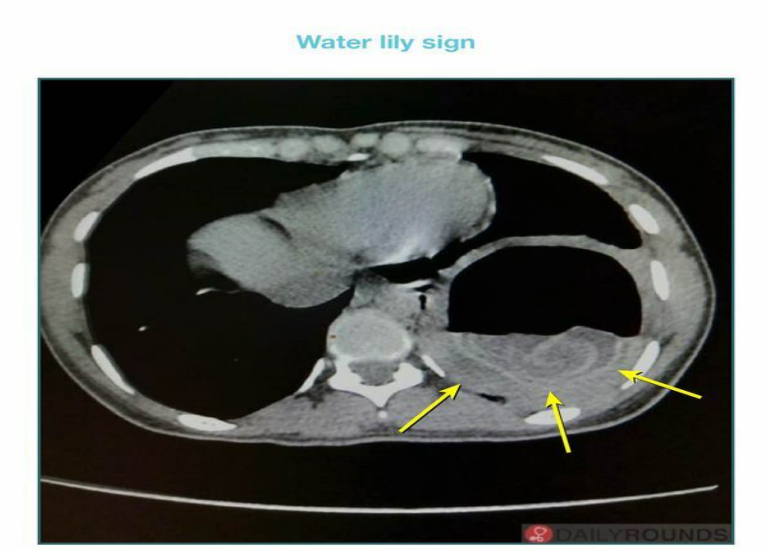


Solution to Question 15:

Echinococcus multilocularis causes multiple alveolar-like lesions in the liver.

E. multilocularis leads to the formation of a multilocular hydatid cyst, most commonly affecting the liver. It presents as multiple small cysts in the liver.

Echinococcus granulosus causes a hollow fluid-filled unilocular cyst in the liver. The CT below shows water lily sign, which is seen in the hydatid disease of the lung. It is caused by Echinococcus granulosus. (Option B)



The water-lily sign occurs due to the detachment of the endocyst membrane from the cyst wall, giving the appearance of floating membranes within the pericyst. This mimics the appearance of a water lily. It is classically visualised on plain radiographs (mainly chest X-ray) when the collapsed membranes are calcified but may be seen on ultrasound, CT, or MRI.

Solution to Question 16:

Babesia is an intracellular parasite of RBCs, not of the hepatocytes.

Its trophozoites invade the RBCs.

The liver is usually not affected as babesia lack an exoerythrocytic phase.

Solution to Question 17:

The diagnosis of Coxiella burnetii cannot be done using a Giemsa stain of a thin peripheral smear.

It is done mainly by serology, which shows a rise in the titer of specific antibodies to C. burnetii.

Microorganisms such as Histoplasma, Leishmania, Toxoplasma, and Pneumocystis can also be detected with Giemsa, and in gastric tissues, Helicobacter pylori (H. pylori) appear thin and distinctly blue. Giemsa's stain is frequently used for diagnostic purposes in haematology to differentiate the nuclear and cytoplasmic morphology of platelets, RBCs, WBCs, and parasites.

Solution to Question 18:

Children <5-years, especially those <2-years of age are at the highest risk of serious complications related to influenza infection.

Other high-risk groups for influenza include adults ≥60 years of age, persons with chronic diseases, persons who are immunocompromised.

Option A: The virus is shed in respiratory secretions a day before the onset of illness and for 3-4 days thereafter.

Option C: Birds, especially aquatic birds act as reservoirs of influenza viruses.

Option D: Secondary attack rate is 5- 15%.

Solution to Question 19:

The β-1-3 glucan assay cannot be used to diagnose mucormycosis. This condition is usually diagnosed based on clinical features and culture.

The β-1-3 glucan assay detects the presence of (1-3)-β-d-glucan (BDG), an abundant cell wall polysaccharide found in most fungi. It is a chromogenic, quantitative enzyme immunoassay (EIA) designed to detect beta-D-glucan by using purified, lysed horseshoe crab (Limulus polyphemus) amebocytes. 1,3 Beta D Glucan level of ≥80 pg/mL is considered a positive result.

Fungi that do not contain BDG in their cell walls include Cryptococcus neoformans, zygomycetes like rhizopus and mucor and Blastomyces dermatitidis. Mucormycosis is an opportunistic mycosis caused by zygomycetes, which do not contain (1-3)-β-d-glucan, and hence, the β 1-3 glucan assay cannot be used for its diagnosis.

Solution to Question 20:

Injecting Aedes thorax with blood of a patient with suspected dengue is the xenodiagnostic method among the given options.

Xenodiagnosis (xenos- foreign) is an indirect method of identifying the infectious disease agents (i.e. the pathogen). In xenodiagnosis, the vector of a pathogenic agent is infected and the pathogen is allowed to multiply in the vector. The vector acts as the “foreign” host. Later, the vector is examined for the presence of the pathogen.

This method was first used by Brumpt for the diagnosis of Chagas disease. Laboratory bred Reduviid bugs (vector/ foreign host) are allowed to feed on the suspected patients (original host). After 4-5 weeks, the feces of the bugs are microscopically examined for amastigote forms of Trypanosoma cruzi (pathogen).

Another method of xenodiagnosis is the intrathoracic inoculation of the mosquitoes (vector) with viruses (pathogen). The virus multiplies in different organs of the mosquito and can be easily demonstrated. Aedes aegypti, Aedes albopictus, and Toxorhynchites mosquitoes are used for the identification of the dengue virus.

In Trichinella spiralis infection, muscle biopsy bits from suspected patients are fed to laboratory rats (vector for T. spiralis). The larvae of T. spiralis can be demonstrated in the muscles of the

infected lab rats.

Advantage of xenodiagnosis: It is useful in cases where a direct microscopic diagnosis is difficult due to the low count of pathogens in the blood of the host/patient.

Other options:

Option A: Rabbit ileal loop assay for ETEC is a method of detection of toxigenicity/ virulence testing.

Option C: Injecting a hamster with splenic biopsy for diagnosis of leishmaniasis is a method of animal inoculation.

Option D: Intradermal test on guinea pigs for toxigenicity of Corynebacterium diphtheria is a method of virulence testing.

Microbiology AIIMS 2020 (May and Nov INI-CET)

Question 1:

A resident had a needle stick injury while dealing with a Hepatitis B positive patient. Serology was done and HBsAg was negative and the Anti-HBs was >105 mIU/ml. What is the next step of management?

a) Booster dose of vaccine

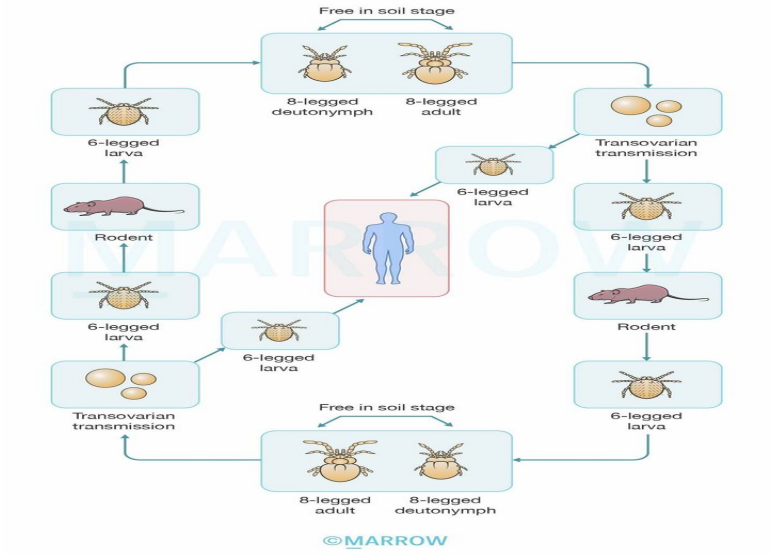
b) Immunoglobulin with full vaccination

c) Repeat full course of vaccine

d) No treatment required as he already has Hep B antibody titres from vaccination

Question 2:

The life cycle of an organism is given below. Identify the vector involved.



a) Hard tick

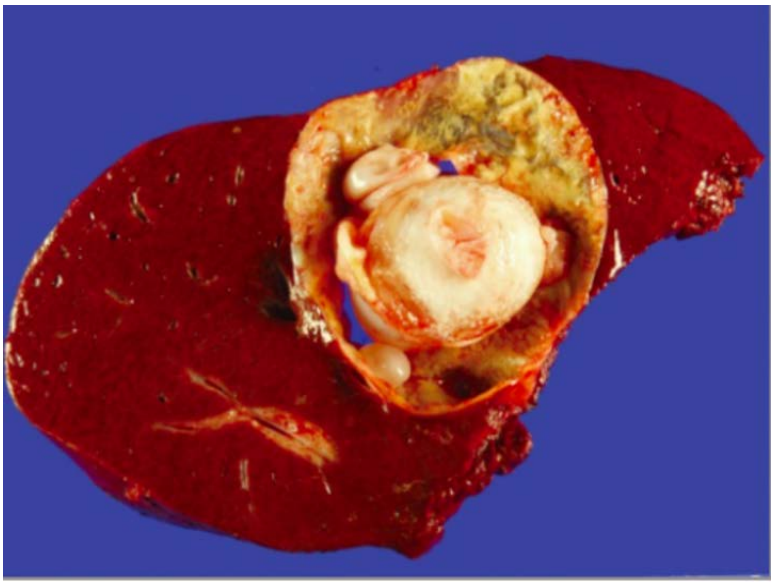
b) Soft tick

c) Trombiculid mite

d) Louse

Question 3:

What is the causative organism for the condition shown in the image below?



a) Echinococcus granulosus

b) Schistoma japonicum

c) Trypanosoma cruzi

d) Schistosoma mansoni

Question 4:

The presence of antibodies against SARS CoV 2 in the blood likely indicates

a) Previous infection even if patient has been asymptomatic

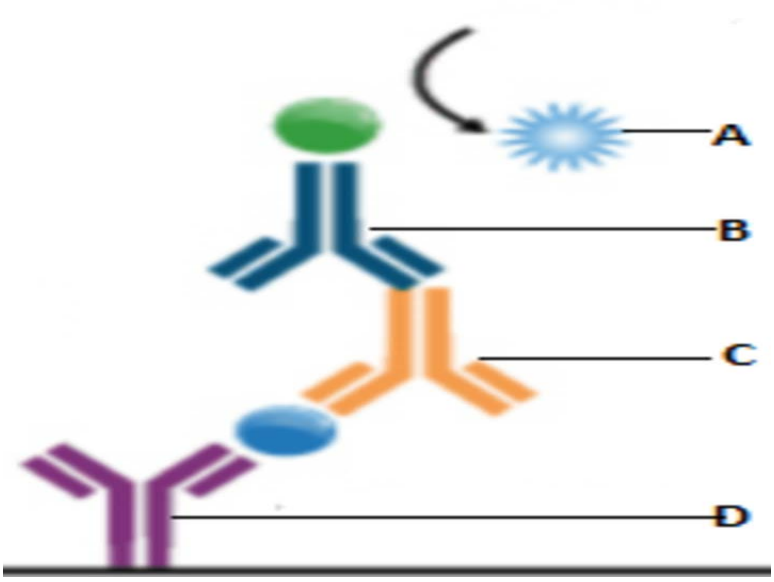
b) Presence of acute viral load

c) A high risk of reinfection

d) That the patient is in window period

Question 5:

Which of the following is the enzyme conjugate in the given ELISA technique?



a) A

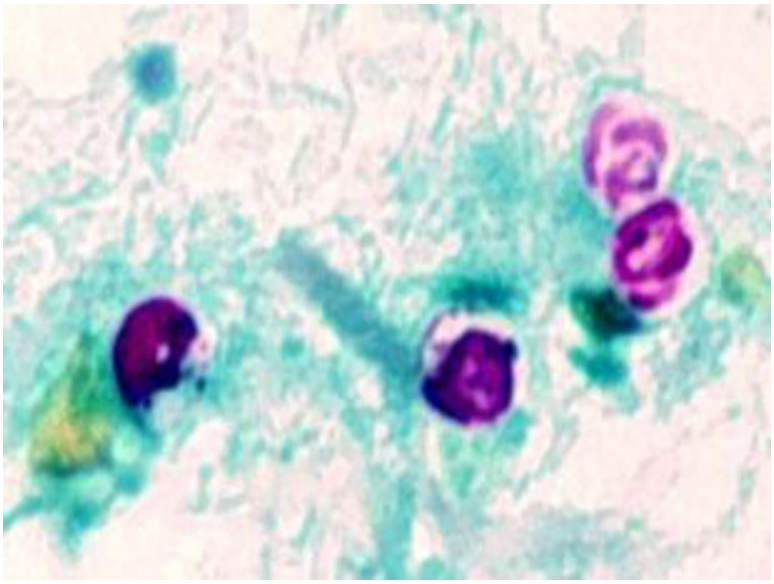
b) B

c) C

d) D

Question 6:

A patient who underwent a renal transplant 3 months ago comes with complaints of diarrhea for the last 9 days. The stool sample was subject to Kinyoun stain revealing 4-6µm structures shown below. Which of the following is true about the organism?



a) Pathogen does not shows autoinfection

b) Cryptosporidium parvum is the most common organism implicated worldwide

c) Oocysts are immediately infective after being excreted in stool

d) It is an obligate intracellular organism

Question 7:

GeneXpert detects mutations in which of the following genes?

a) inhA

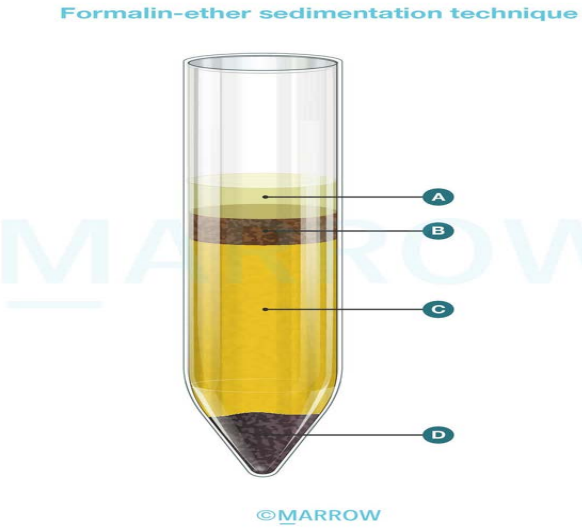
b) rpoB

c) KatG

d) pncA

Question 8:

A stool sample is collected. The specimen is processed for examination and is labeled at different levels as A, B, C, and D. Identify the level at which parasitic ova will be seen when viewed under a microscope.



a) A

b) B

c) C

d) D

Question 9:

Type IV hypersensitivity is due to?

a) Cell mediated response

b) Cell mediated and antibody mediated response

c) Antibody mediated response

d) Innate response

Question 10:

A child was brought to the OPD with a swollen, red knee joint that is tender to touch. 2 weeks prior, he had an episode of fever with bloody diarrhea. Which of the following could be the possible organism?

a) E. coli

b) Shigella

c) Giardia

d) Rotavirus

Question 11:

Specimen handling for molecular testing of SARS CoV 2 would require

a) BSL1

b) BSL2

c) BSL3

d) BSL4

Question 12:

Which of the following method is employed to measure the viral load?

a) ELISA

b) Western blot

c) Real time PCR

d) Immunoelectrophoresis

Question 13:

All of the following is true regarding scrub typhus except:

a) Transmitted by chiggers

b) Lymphadenopathy is a feature

c) Produces NLF producing colonies in MacConkey agar

d) Man is an accidental host

Question 14:

False about the Ebola virus is:

a) It is a filovirus

b) Transmitted by mosquito

c) Bats acts as reservoir

d) Nosocomial transmission seen

Question 15:

Identify the condenser _____

a) A

b) C

c) B

d) D

Question 16:

A young male presents to the STD clinic with painful lesions as shown in the image. What is the most likely microscopic finding of the lesion?

a) Tzank cells

b) Pund cells

c) Henderson-Patterson bodies

d) Guarnieri bodies

Question 17:

A patient has complains of fever with chills. A throat examination reveals swollen glands and a thick, whitish membrane over his tonsils. Albert staining is to be done. What are the constituents of Albert's stain?

a) Toluidine blue 'O' and malachite green

b) Carbol fuschin and methylene blue

c) Carbol fuschin and malachite green

d) Toluidine and methylene blue

Question 18:

Pneumonia due to a gram-negative pleomorphic bacillus growing on chocolate agar which is catalase and oxidase-positive is:

a) E.coli

b) Pseudomonas

c) Haemophilus influenzae

d) Actinomyces

Question 19:

A 30-year-old male presented to the OPD with painful genital ulcers. Which of the following can cause a painful ulcer on the glans penis?

a) Syphilis

b) Chlamydia

c) Chancroid

d) Lymphogranuloma venereum

Question 20:

Which protein is present in the HPV vaccine?

a) E6, E7

b) L1

c) E1, E2

d) L2

Question 21:

A patient presented with meningitis with a history of fever for 4 days and erythematous rashes on the chest. There was no history of travel and tick bite. His CSF findings showed increased protein, normal glucose, mild lymphocytosis and few RBCs. Which of the following is the most likely organism to cause this clinical picture?

a) West nile virus

b) Meningococci

c) Strep pneumoniae

d) Entero virus

Question 22:

A patient presents with seizures. His CT head reveals multiple parenchymal cysts. Which of the following is correct regarding management in this case?

a) Steroids followed by antiparasitic drugs

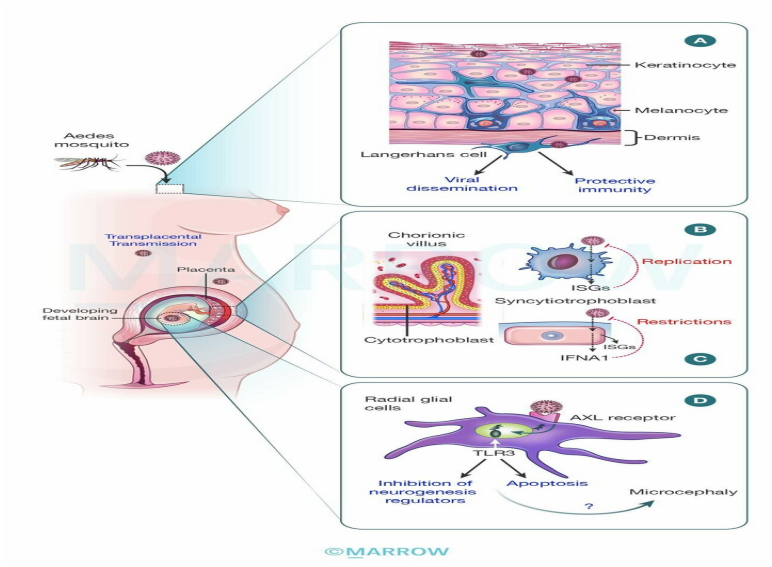
b) Antiparasitic drugs followed by steroids

c) Steroids before antiepileptics

d) Continue antiepileptics

Question 23:

The transplacental transmission of the organism given in the image which causes microcephaly is-



a) Nipah

b) Zika virus

c) CMV

d) Rubella

Question 24:

The disruption of which of the following is responsible for watery diarrhea in cholera caused by Vibrio?

a) Intercalated discs

b) Macula densa

c) Zonula occludens

d) Hemidesmosomes

Question 25:

Affinity maturation is due to:

a) Isotype switching

b) Somatic hypermutation

c) mRNA splicing

d) VDJ rearrangement

Question 26:

A farmer presents with a swollen foot and multiple sinuses as shown in the below image. What is the most likely diagnosis?

a) Mycetoma

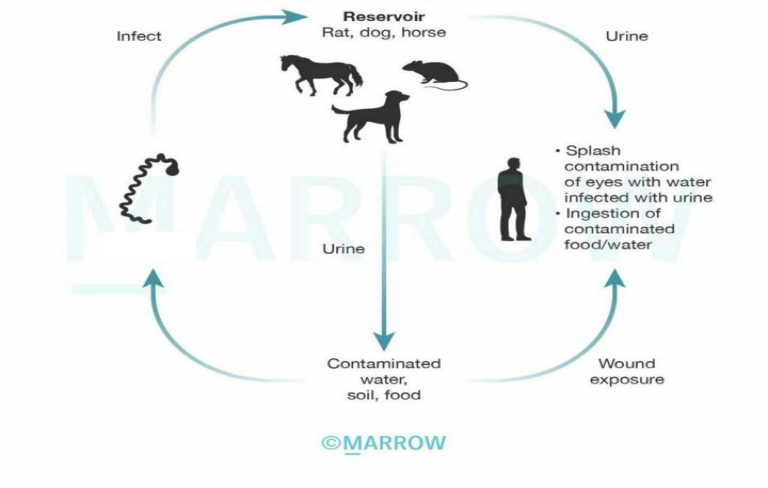
b) Squamous cell carcinoma

c) Nocardia

d) Sporotrichosis

Question 27:

The given life cycle belongs to which of the following organisms?



a) Leptospira

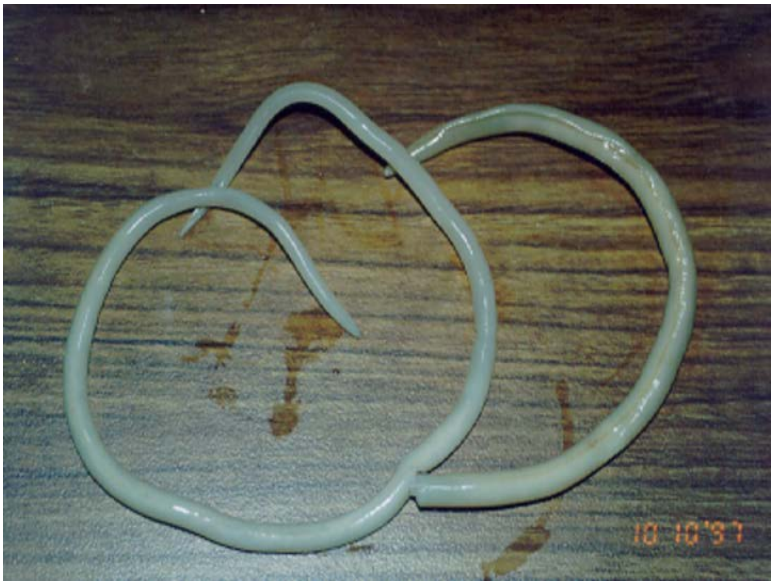
b) Hanta virus

c) Yersinia pestis

d) Salmonella typhi

Question 28:

Identify the organism shown in this image.



a) Strongyloides stercoralis

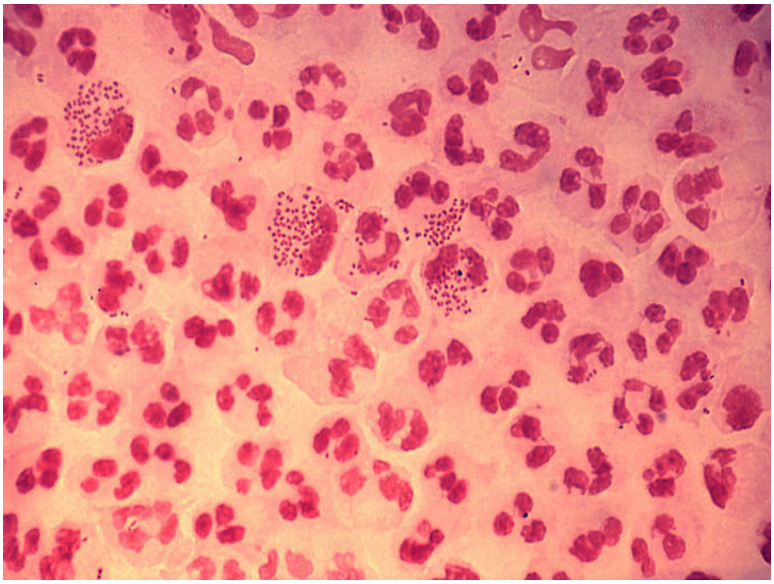
b) Enterobius vermicularis

c) Ancylostoma duodenale

d) Ascaris lumbricoides

Question 29:

A patient presents with urethral discharge. A gram stain smear is made from the discharge sample and the following microscopic image is seen. What is the most likely causative organism?



a) Trichomonas

b) Chlamydia trachomatis

c) Neisseria gonorrheae

d) Gardenella

Question 30:

Which of the following disease has the highest mortality once clinically manifested?

a) Nipah

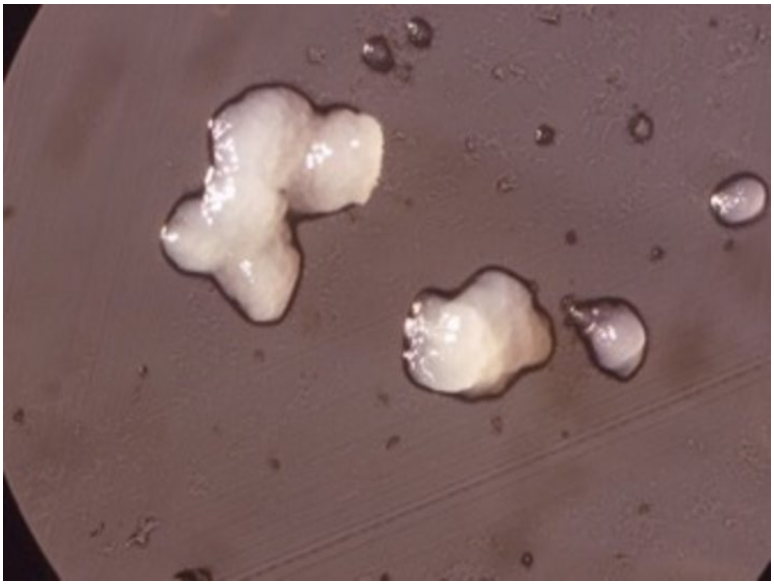
b) Rabies

c) Ebola

d) Zika

Question 31:

A patient presents with a mobile, warm to touch nodule in the neck. On the anaerobic culture of the biopsy material from this swelling, it showed colonies as shown in the image which had gram-positive branching rods on staining. Which of the following is the drug of choice in this condition?



a) Doxycycline

b) Cotrimoxazole

c) Penicillin

d) Surgical drainage

Question 32:

In which of the following situations will you use a sanitizer?

a) A, B & C only

b) A & B only

c) A, B C & D

d) C & D only

Question 33:

The following are true about chancroid:

a) C & D only

b) A, B,C & D

c) A B & C

d) A & B only

Question 34:

Match the following E.coli with their respective pathogenesis.

a) A-4,B-3,C-2,D-1

b) A-1,B-3,C-2,D-4

c) A-1,B-2,C-3,D-4

d) A-4,B-2,C-3.D-1

Question 35:

Match the following:

a) A-2, B-1, C-3, D-4

b) A-3, B-2, C-1, D-4

c) A-4, B-1, C-2, D-3

d) A-1, B-2, C-4, D-3

Question 36:

Galactomannan in serum is seen in:

a) 1 & 2 only

b) 1 & 3 only

c) 1 only

d) 1, 2 & 3 only

Question 37:

Match the following parasites with their respective hosts:

a) A-3, B-2, C-4, D-1

b) A-2, B-1 ,C-4 ,D-3

c) A-1, B-2, C-3, D-4

d) A-4, B-3, C-1, D-2

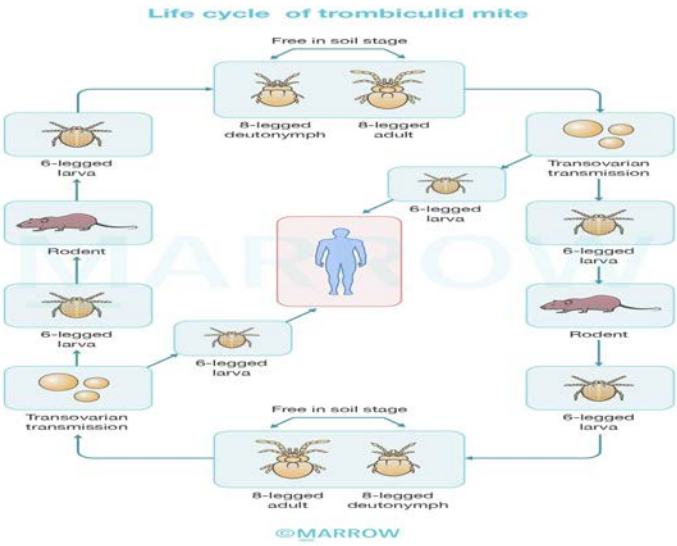
Detailed Explanations

Solution to Question 1:

The given clinical scenario of needle-stick injury shows that HBsAg is negative and the anti-HBs is >105 mIU/ml. This suggests that the resident has had routine vaccination for Hep B infection. Since the antibody titers are more than 10 mIU/ml, no treatment is required.

Solution to Question 2:

The given life cycle is of trombiculid mite which acts as a vector for scrub typhus. Humans are seen to be infected when they are bitten by the mite larvae (chiggers).



Solution to Question 3:

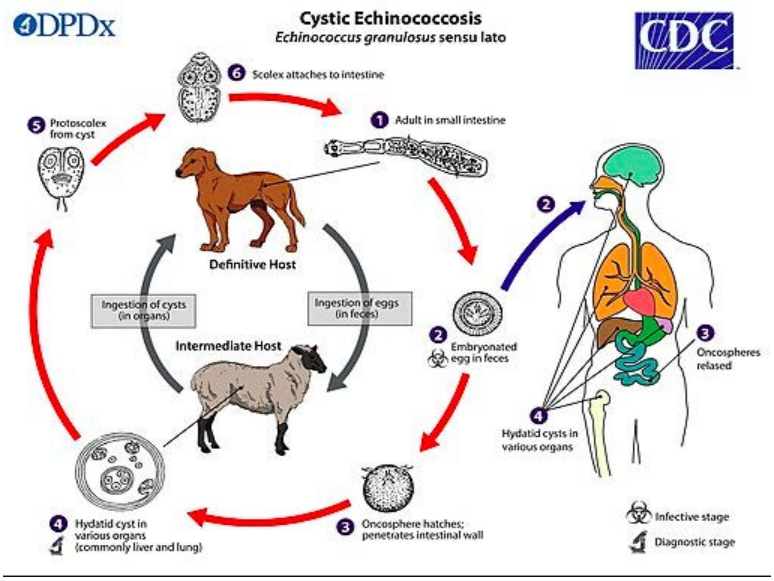
The given image shows a hydatid cyst in the liver. It is caused by Echinococcus granulosus.

Echinococcus granulosus is the most common causative agent in hydatid cysts, while Echinococcus multilocularis and Echinococcus ligartus account for a small number of cases.

Dogs are the definitive hosts of E. granulosus. Sheep are the usual intermediate hosts, but humans are accidental intermediate hosts. Humans are end-stage hosts of the parasite since there is no human to human transmission.

Approximately 75% of hydatid cysts are located in the right lobe of the liver and are solitary. The clinical presentation of a hydatid cyst is largely asymptomatic until complications occur. The most common presenting symptoms are abdominal pain, dyspepsia, and vomiting. The most frequent sign is hepatomegaly.

The life cycle of Echinococcus is depicted in the image below:



Solution to Question 4:

The presence of antibodies against SARS CoV 2 in the blood likely indicates a previous infection even if the patient has been asymptomatic.

Antibodies most commonly become detectable 1–3 weeks after symptom onset, at which time evidence suggests that infectiousness likely is greatly decreased and that some degree of immunity from future infection has developed. But it is imperative to note that the information on SARS CoV 2 is still emerging.

Solution to Question 5:

The enzyme conjugate in the given ELISA technique is 'B'.

Other options:

A- Substrate - it will be cleaved by the enzyme present on the conjugate antibody.

B - Conjugate - it is an antibody that binds to the detection antibody. It is labeled with an enzyme that cleaves the substrate to form a color product/dye.

C - Detection antibody-binds the antigen. We direct our conjugate against this.

D - Capture Antibody-forms the base, on which antigen (say rotavirus from feces) from the patient sample binds.

Solution to Question 6:

Oocysts are immediately infective after being excreted in the stool.

Cryptosporidium is a coccidian parasite and implicated in causing traveler's diarrhea in immunocompromised patients. The two cryptosporidium species responsible are C.hominis and C.parvum. As the patient has undergone a renal transplant, he/she would most likely be on immunosuppressive medications, making the infection likely. Cryptosporidium hominis is the most common organism implicated worldwide

The infective form is oocysts, excreted in the affected patient's feces, acquired through drinking or recreational water. The oocysts are immediately infectious (unlike Isospora oocysts, which require maturation), and may cause autoinfection or implicated in person to person transmission. Because of its small size (4-5micron), it is difficult to see in routine staining, hence is subjected to acid-fast/kinyoun's stain.

Once ingested, the 4 sporozoites come out of the cyst and attach to the small intestinal mucosa. It causes crampy abdominal pain and non-inflammatory watery diarrhea.

Treatment is mainly supportive, though nitazoxanide has been FDA approved for use in cryptosporidium.

Comparative features of coccidian parasites:

Property	Cryptosporidium	Cyclospora	Cystoisospora
Sporulated oocyst	4-6 µm, round, contains f our sporozoites	8-12 µm, round, contains 2 sporocysts each having t wo sporozoites	23-36 µm, oval, contain t wo sporocysts, each havin g four sporozoites.
Acid-fast detection	Uniformly acid-fast	Variable acid-fast	Uniformly acid-fast
Sporulation of the ooc yst	Occurs inside the host cell	Occurs in soil	Occurs in soil
Diagnostic form	Sporulated cyst	Unsporulated cyst	Unsporulated oocyst

Solution to Question 7:

Gene Xpert identifies mutations in the rpoB gene to detect rifampicin resistance (RR).

Other options:

inhA and KatG- involved in resistance against isoniazid

pncA- involved in resistance against pyrazinamide

Solution to Question 8:

The parasitic ova will be seen in a specimen taken from level D.

The image shows a formol-ether sedimentation technique to concentrate the ova in the bottom (D) part of the tube. It is used for samples in which the concentration of parasitic ova is scanty. It is useful for all helminth ova/eggs and parasitic cysts. The ether adsorbs the fecal debris and floats. Formalin fixes and preserves the specimen.

This method is useful for all helminth eggs and protozoan cysts.

Solution to Question 9:

Type IV hypersensitivity is due to the cell-mediated response.

Type IV or cell-mediated hypersensitivity reaction: These reactions are induced by sensitized T cells which on contact with the specific antigen releases cytokines that produce biological effects on leucocytes, macrophages, and tissue cells.

Solution to Question 10:

The given clinical scenario points towards a diagnosis of reactive arthritis after shigella infection.

Shigellosis is a spectrum of symptoms caused by shigella consisting of 4 phases:

Other options:

E.coli - it may cause diarrhea associated with fever or blood in stools, but reactive arthritis is not typically seen.

Giardia - it may cause persistent watery diarrhea with waxing and waning course. Fever, blood in stools should prompt alternate diagnosis. Also, reactive arthritis is not seen.

Rotavirus - it is a well known viral cause of fever with diarrhea in children. But not known to have reactive arthritis as a sequela.

Incubation period	1-4 days (up to 8 days)
Watery diarrhea	Fever, watery diarrhea, anore xia
Dysentry	Bloody mucopurulent stools

Incubation period	1-4 days (up to 8 days)
Post-infectious complication	Hemolytic-uremic syndrome Reactive arthritisToxic megac olon

Solution to Question 11:

Specimen handling for molecular testing of SARS CoV 2 would require BSL-2 or equivalent facilities. Attempts to culture the virus requires minimum BSL-3 facilities.

SARS CoV 2 virus can cause coronavirus disease 2019 (COVID-19)

Microbiology and pathology laboratories performing diagnostic tests on a stool or respiratory specimen should handle potential SARS-CoV specimens using standard biosafety level (BSL)-2.

Note: Biosafety levels include a specific combination of work practices, safety equipment, and facilities that are designed to minimize the exposure of workers and the environment to infectious agents. There are four biosafety levels.

BSL-1: Work can be done on an open bench or table and PPE needed. Eg: Non-pathogenic E.coli.

BSL-2: Work to be done in the biosafety cabinet with PPE. Eg: Staphylococcus aureus.

BSL-3 laboratory has appropriate PPE and respirators might be required. All work performed within BSC(biosafety cabinet). Entrance is through 2 sets of self-closing and locking doors. Eg: when dealing with Mycobacterium tuberculosis.

BSL-4: This is the highest level of biological safety, where containment of microbes is done, which are fatal without treatment and vaccines. Eg: Ebola and Marburg viruses.

Solution to Question 12:

Viral load can be measured by the real time-PCR technique.

Real time-PCR assays are commonly used for viral load quantification of HIV, hepatitis C virus, hepatitis B virus, and CMV.

Other options:

• Western blotting is used for the detection of protein.

• ELISA is an immunosorbent assay used to detect antigens of infectious agents present in clinical specimens.

• Immuno electrophoresis includes electrophoretic separation of antigens followed by an antigen-antibody reaction.

Solution to Question 13:

The organism causing scrub typhus i.e Orientia tsutsugamushi is non-cultivable on cell-free media like MacConkey agar.

Scrub Typhus is also known as chigger borne typhus. The vector is trombiculid mite. Humans are infected when they are bitten by the mite larvae known as chiggers.

The incubation period is 1- 3 weeks. The patient typically develops a characteristic eschar at the site of the mite bite, with regional lymphadenopathy and maculopapular rash.

Solution to Question 14:

Ebola virus is not transmitted by mosquito.

Ebola virus is the cause of an emerging disease called Ebola virus disease and is widespread in Africa. It belongs to the Filoviridae family.

Fruit bats act as reservoir hosts of the virus and it is transmitted to humans only accidentally. Human to human transmission is through direct contact with blood or body fluids of an infected symptomatic person.

The incubation period of the disease is 2 to 21 days. Symptoms include fever, intense weakness, vomiting, diarrhea, rashes, and, in extreme cases, internal and external bleeding. The current treatment is mainly supportive. Nosocomial transmission seen.

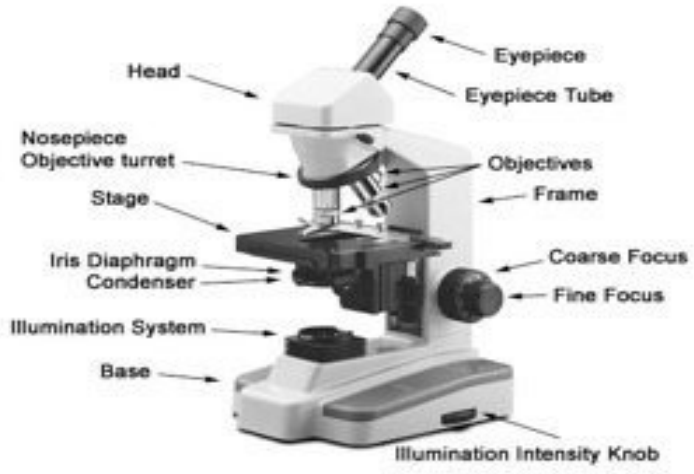
Solution to Question 15:

Condensor lens of microscope is marked as B in the image. The purpose of the condenser lens is to focus the light onto the specimen.

A is coarse focusing knob.

C is objective lens. There are usually 3 or 4 objective lenses on a microscope. They almost always consist of 4X, 10X, 40X and 100X powers.

D is Illuminator. It is a steady light source used in place of a mirror.



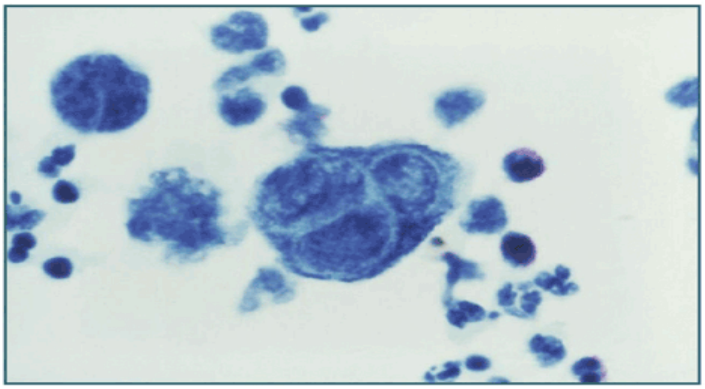
Solution to Question 16:

Clusters of vesicles are seen on an erythematous base in the image, suggesting a diagnosis of genital herpes. Tzanck cells or multinucleated giant cells are present on microscopy.

The Tzanck smear is a rapid, sensitive, and inexpensive diagnostic method for herpes simplex infections. Smears are prepared from the lesions, from the base of vesicles and stained with a 1% aqueous solution of O-toluidine blue for 15 seconds. Multinucleated giant cells with faceted nuclei and homogeneously stained ground glass chromatin (Tzanck cells) are seen.

Mucocutaneous herpetic lesions are thin-walled, umbilicated vesicles, the roof of which breaks down, leaving tiny superficial ulcers which heal without scarring. Painful and pruritic lymphadenopathy may be seen. The most common site of cutaneous lesions is the face - on the cheeks, chin, around the mouth, or on the forehead - and is caused by herpes simplex virus-1. Genital infections are more commonly caused by herpes simplex virus-2.

Tzanck smear



©MARROW

Solution to Question 17:

Albert's stain contains toluidine blue 'O' and malachite green which have an affinity for acidic cytoplasm, both being basic dyes.

Albert's stain, Neisser's and Ponder's stain are used to demonstrate the metachromatic granules (Volutin / Babes Ernst Granules) of Corynebacterium diphtheria.

Procedure for Albert's staining:

• A heavy smear of bacterial isolate was prepared on glass slide and allowed to dry without fixing.

• Albert's stain was applied for (3-4) minutes then it was washed with water and Albert's iodine was applied for one minute.

• Wash with water and let dry with blotting paper.

• Examine the slide under oil immersion, it was examined under microsope showed bacili with numerous metachromatic granules.

Results:

Metachromatic granules: Bluish- black

Bacillary body or protoplasm: Green

Uses:

• Albert staining is useful in the demonstration of metachromatic granules.

• Presence of metachromatic granules helps to distinguish C.diphtheriae from diphtheriods which lack them.

Solution to Question 18:

Pneumonia due to a gram-negative pleomorphic bacillus growing on chocolate agar which is catalase and oxidase-positive is most likely Haemophilus influenza.

Haemophilus pneumonia typically occurs in infants and is accompanied by empyema and sometimes meningitis as well. In older children and adults, the picture is of lobar pneumonia. Sputum is collected for the detection and isolation of Hemophilus. As the bacillus is very sensitive to low temperatures, specimens should never be refrigerated before inoculation. H.infiuenzae is a Gram-negative, non-motile, non-sporing bacillus, exhibiting considerable pleomorphism. In sputum, it usually occurs as clusters of coccobacillary forms.

The bacillus has fastidious growth requirements. The accessory growth factors, named X and V, present in the blood are essential for growth. Catalase and

oxidase reactions are positive. Nitrates are reduced to nitrites. Biotyping has been done on the basis of indole production.

Cultures may be preserved for about a month on chocolate agar slopes. Chocolate agar is made by heating blood agar to 80-90°C for 15-20 minutes. This causes the release of V factor from within the erythrocytes.

Treatment- Amoxycillin-clavulanate or clarithromycin is more effective in treating respiratory infections by Haemophilus influenzae.

Solution to Question 19:

Painful genital ulcers are caused by Haemophilus ducreyi, and are known as chancroid.

The regional lymph nodes are enlarged and painful. Microscopic appearance seen in H. ducreyi is called the school of fish appearance or railroad appearance. Chocolate agar with isovitaleX is a suitable culture medium for Haemophilus ducreyi.

The given image shows the microscopic appearance of H. ducreyi.

Solution to Question 20:

The HPV vaccines use virus-like particles (VLPs) that consist of the HPV L1 major capsid protein. The L1 protein self-assembles into VLPs when expressed in eukaryotic cells.

These VLPs contain the same epitopes as the HPV virion. But they do not contain genetic material and cannot transmit infection. The immunogenicity of the HPV vaccines relies on the development of conformational neutralizing antibodies to epitopes displayed on viral capsids.

The nonavalent HPV vaccine works against strains 6,11,16,18,31,33,45,52 and 58. It is usually commercialized in the name of Gardasil 9.

HPV VACCINE	HPV TYPES COVERED
Quadrivalent	6, 11,16, 18
Bivalent	16, 18
Nonavalent	6, 11, 16, 18, 31, 33, 45, 52, 58

Recent update: Gardasil 9 has received expanded indication which now includes the prevention of oropharyngeal and other head and neck cancers caused by HPV types 16,18,31,33,45,52,58.

Solution to Question 21:

Meningitis with normal glucose, increased protein, and mild lymphocytosis is suggestive of viral meningitis, most probably by an Enterovirus.

Coxsackieviruses are typical enteroviruses. Two groups of Coxsackie viruses A and B, are known. Aseptic meningitis may be caused by a majority of group A and all group B viruses. A maculopapular rash may be present. The disease can also occur as epidemics.

CSF findings in Viral meningitis:

• A mild increase in CSF protein/pressure

• Normal glucose

• Mild increase in lymphocytes in CSF.

Other options:

West Nile virus is endemic in certain regions in North America. But there is no history of travel mentioned in the clinical scenario above. Current hotspots in North America are the California Central Valley, southwestern Arizona, southern Texas, and Louisiana, which have both compatible climates and avian reservoirs for the disease.

	Normal	Bacterial Meningitis	Viral Meningitis	Fungal Meningitis	Parasitic Meningitis	Tuberculo Meningitis
WBC Count (per μL)	<5	>1000	25-500	40-600	150-2000	25-100
Differential of WBC	60-70% lymphocytes, ≤30% monocytes/ macrophages	↑↑PMNs (≥80 %)	Predominantly lymphocytes	Lymphocytes or PMNs, depending on the specific organism	↑↑ Eosinophils (≥50 %)	Predominantly lymphocytes
Gram,s stain	Negative	Positive (in > 60% of cases)	Negative	Rarely positive	Negative	Occasionally positive
Glucose (mg/dL)	40-85	<40	Normal	↓ to normal	Normal	<50 in 75% of cases

	Normal	Bacterial Meningitis	Viral Meningitis	Fungal Meningitis	Parasitic Meningitis	Tuberculo Meningitis
Protein (mg/dL)	15-45	>100	20-80	150-300	50-200	100-200
Opening pressure (mmH2O)	50-180	>300	100-350	160-340	Normal	150-280

Solution to Question 22:

The given clinical scenario is suggestive of neurocysticercosis caused by larvae of T. solium (cysticercosis cellulosae). Glucocorticoid therapy is usually begun before initiating albendazole (antiparasitic drug). This is continued for several days after the institution of therapy to reduce the incidence of side effects from inflammatory reactions to dead and dying cysticerci of Taenia solium.

Albendazole is the drug of choice for neurocysticercosis.

There are various types of cysticercosis based on the site affected such as:

• Subcutaneous nodules (asymptomatic)

• Neurocysticercosis

• Muscular cysticercosis

• Ocular cysticercosis.

Neurocysticercosis is considered the second most common cause of intracranial space-occupying lesion (ICSOL) in India following tuberculosis. Its clinical features include:

• Epilepsy

• Raised intracranial tension

• Hydrocephalus

• Psychiatric disturbances

• Meningoencephalitis

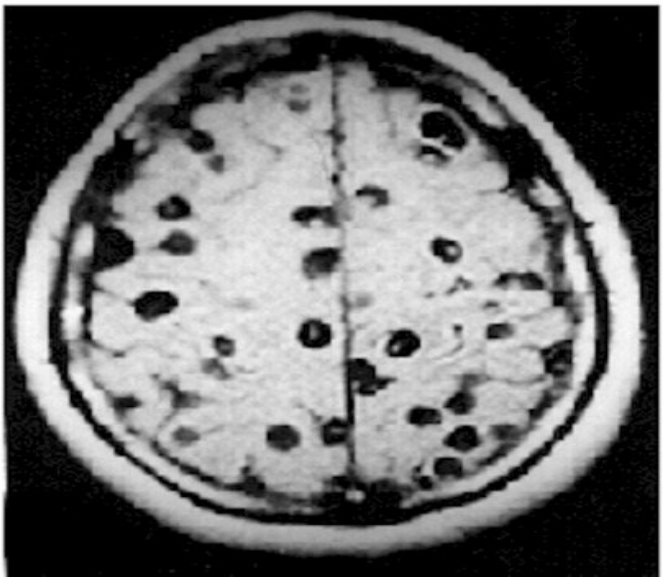
• Transient paresis

• Behavioral disorders

• Aphasia

• Visual disturbances.

The below MRI of the brain shows multiple cysts containing scolices in a patient with neurocysticercosis.



Solution to Question 23:

The image shows transplacental transmission of a virus, leading to microcephaly, with the Aedes mosquito as its vector. Among the given options, Zika virus has the above features.

Zika virus is a mosquito-borne Flavivirus mainly transmitted through Aedes aegypti. Zika virus infection presents with mild symptoms of fever, rash, conjunctivitis, malaise, headache and muscle and joint pain. These symptoms usually last for 2-7 days. Maternal infection during pregnancy leads to congenital Zika syndrome or microcephaly.

The complications of Zika virus infection include Guillain-Barré syndrome, neuropathy, and myelitis.

Note: NCDC Delhi and the National Institute of Virology Pune are the only institutes that have the capacity to provide the diagnosis in an acute febrile stage. RT-PCR is the standard test available for the diagnosis of Zika virus infection.

Solution to Question 24:

The disruption of zonula occludens is responsible for watery diarrhea in cholera caused by Vibrio cholerae.

Zonula occludens toxin (Zot) is an enterotoxin elaborated by Vibrio cholerae that increases intestinal permeability by interacting with a mammalian cell receptor with subsequent activation of intracellular signaling leading to the disassembly of the intercellular tight junctions.

Mechanism of action of cholera toxin:

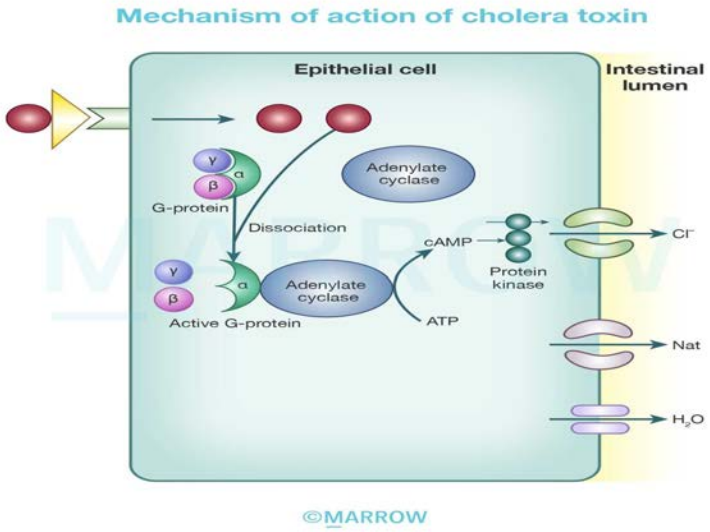
• The cholera toxin molecule consists of 1 A and 5 B subunits. The B (binding) units attach to the GM1 ganglioside receptors on the surface of jejunal epithelial cells. The A (active) subunit, on being transported into the enterocyte, dissociates into A1 and A2. A2 fragment only links

biologically active A1 to the B subunit.

• A1 causes prolonged activation of cellular adenylate cyclase and accumulation of cAMP, leading to outpouring into the small intestinal lumen, of large quantities of water and electrolytes. This leads to watery diarrhea which is isotonic with plasma but contains much more potassium and bicarbonate.

• The toxin also inhibits the intestinal absorption of sodium and chloride.

• All clinical manifestations and complications in cholera result from the massive water and electrolyte depletion thus caused.



Solution to Question 25:

Affinity maturation is due to somatic hypermutation.

Affinity maturation is the process by which antibodies gain increased affinity, avidity, and anti-pathogen activity. It is a result of somatic hypermutation (SHM) of immunoglobulin genes in B cells, coupled to selection for antigen binding.

This process occurs in the germinal centers and proceeds for weeks after acute infection or vaccination, or for many cycles during chronic infection. The resulting antibodies can be highly mutated from their germline-encoded counterparts, with increases of several orders of magnitude in affinity for antigen compared to the corresponding naïve B cell receptors (BCRs).

Other options:

Option A: Isotype switching, also known as class switch recombination, is a process where the constant region of the antibody heavy chain is changed, leading to a switch in the antibody isotype (e.g., from IgM to IgG). This process is crucial for the functional properties of antibodies but is not directly involved in affinity maturation.

Option C: mRNA splicing is a cellular process that involves the removal of introns and the joining of exons to generate mature mRNA. While this process is essential for the production of functional antibodies, it is not specifically associated with affinity maturation. Affinity maturation

primarily occurs through somatic hypermutation.

Option D: VDJ rearrangement is the process by which the variable regions of immunoglobulin genes are assembled from gene segments (V, D, and J segments). This process contributes to the diversity of antibodies but is distinct from affinity maturation. Affinity maturation occurs after VDJ rearrangement and is driven by somatic hypermutation in the variable regions.

Solution to Question 26:

The most likely diagnosis here is Mycetoma which is caused by Eumycetoma.

Mycetoma:-

• Mycetoma is a chronic, granulomatous infection of the skin, subcutaneous tissues, fascia and bone, which most often affects the foot or the hand. It is, therefore, commonly known as Maduramycosis or Madura foot. Mycetoma occurs worldwide.

• Etiology: It can be divided into three types, eumycetomas, actinomycetomas and botryomycosis.

Pathogenesis:-

• Triad of symptoms: Infection follows traumatic inoculation of the organism into the subcutaneous tissue from soil or vegetable sources, usually on thorns or splinters and results in tumefactions, deformities and draining sinuses discharging fungal colonies called grains or granules (triad of symptoms).

• Subcutaneous tissues of the feet, lower extremities, hands, and exposed areas are most often involved.

• Grains: Within host tissues the organisms develop to form compacted colonies (grains) 0.5–2 mm in diameter, the color of which depends on the organism responsible.

Laboratory Diagnosis

• A. Direct Examination: The presence of grains in pus collected from draining sinuses or in biopsy material is diagnostic.

• B. Culture Samples should also be cultured, at both 25–30°C and 37°C, on brain-heart infusion agar or blood agar for actinomycetes and on Sabouraud agar (without cycloheximide) for fungi.

Treatment:-

The management of eumycetoma is difficult, involving surgical debridement or excision and chemotherapy. Actinomycetoma responds well to rifampicin in combination with sulfonamides or cotrimoxazole.

Solution to Question 27:

The life cycle shown in the above image is suggestive of leptospirosis.

It is caused by contact with the urine or blood of an infected organism. It is a zoonotic disease, with rats being the most well-known reservoirs.

Illness is classically biphasic after an incubation period of up to 1 month. The stages are:

• Acute leptospiremic phase- organism can be cultured from blood.

• Resolving immune phase- organism can be cultured from urine.

The stages may not be clinically distinguishable.

Most cases are asymptomatic but a few may present with severe manifestations. Clinical features include:

• High-grade fever

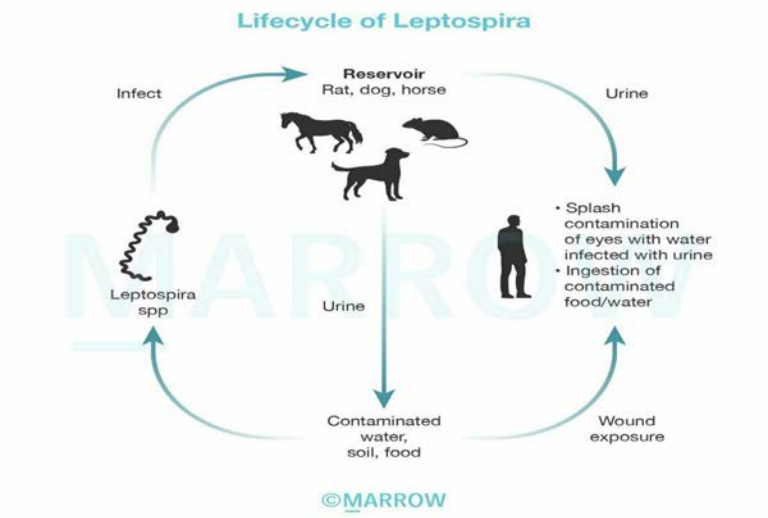
• Hepatic dysfunction

• Renal impairment

• Hemorrhages- gastrointestinal, pulmonary (most common), petechiae and purpura

The severe form is known as Weil's disease, with a triad of hemorrhage, jaundice, and acute kidney injury.

Treatment of choice is IV penicillin or IV ceftriaxone.



Solution to Question 28:

The given image shows large cylindrical worms with tapering ends, and thus represents Ascaris lumbricoides (roundworm).

Ascaris lumbricoides is the most common of human helminths and is distributed worldwide. It is the largest nematode parasite in the human intestine. The adult worms are large cylindrical worms, with tapering ends. The anterior end is more pointed than the posterior. It appears white outside the body.

Its natural host is humans. There is no intermediate host. Adult worms live in the small intestine - jejunum and ileum. Humans acquire infectionby consuming food or water contaminated with nightsoil or human feces containing eggs. The eggs contain the infective rhabditiform larva.

Solution to Question 29:

The above image shows gram■negative intracellular diplococci within phagocytes in a stained smear from the urethral discharge sample, which is seen in infection with Neisseria gonorrhoeae.

According to CDC recommendations 2021, the first line of treatment in uncomplicated gonococcal infections is a single dose of ceftriaxone 500 mg IM.

Note: BASHH (British Association for Sexual Health and HIV) in the United Kingdom also recommends higher doses of ceftriaxone of about 500 mg along with azithromycin because it would result in fewer failures.

Solution to Question 30:

Rabies has the highest mortality once clinically presented.

Rabies is a vaccine-preventable, zoonotic, viral disease of the central nervous system. Rabies virus is a bullet-shaped rhabdovirus containing ssRNA. It spreads to humans by bites or contact with the saliva of rabid animals (bats, dogs, cats). Once clinical symptoms appear, rabies is virtually 100% fatal. The disease can be divided into 3 phases:

• Prodromal phase: It lasts 2-10 days. Patients present with malaise, headache, photophobia, vomiting, and fever. They may also have parasthesias, pain or pruritus near the site of exposure.

• Acute neurologic phase: It lasts 2-7 days. In the more common encephalitic rabies, Hydrophobia (fear of water) or aerophobia (fear of breeze) can be seen. Swallowing liquids precipitates painful spasms of the throat muscles. Patients may also have nervousness, hallucinations, excessive lacrimation, salivation, perspiration and pupillary dilation. Convulsive seizures may occur

• Coma and death (due to cardiorespiratory arrest)

In about 20% of patients, paralytic rabies is seen. Flaccid muscle weakness is seen, which progresses to quadriparesis and facial palsy.

Note: In rabid animals, the virus depicts two modes of spread:

• Centripetal spread: The virus enters the peripheral neurons. It moves via retrograde fast axonal transport towards the spinal cord or brainstem a.k.a the central nervous system (CNS) at a speed of up to 250 mm/day. Once within the CNS, it spreads quickly to other regions in the CNS through fast axonal transport. It infects neurons primarily, but may rarely infect astrocytes.

• Centrifugal spread: After CNS infection is established, it spreads along the sensory and autonomic nerves to salivary glands, adrenal glands, skin

Rabies virus replicates in acinar cells of the salivary glands and is secreted in the saliva of rabid animals that serve as vectors.

Solution to Question 31:

The given image shows molar tooth colonies that are characteristic of Actinomyces species. The given clinical scenario of a mobile, warm to touch nodule in the neck describes cervicofacial actinomycosis also known as 'lumpy jaw syndrome'. Penicillin is the drug of choice for actinomyces infection.

Actinomyces are Gram-positive anaerobic bacilli that produce molar tooth colonies on incubation for 72 hours on brain-heart infusion agar. They cause a chronic suppurative and granulomatous infection called actinomycosis. It can present as one of the following clinical types:

• Cervicofacial type- Fluctuant mass in the jaw area producing draining fistulas.

• Thoracic type- Pulmonary infection with fever, cough, and purulent sputum.

• Abdominal type- Occurs following ruptured appendix or ulcer. It may spread throughout the peritoneum and involve multiple organs.

Actinomycosis can spread to bones and surrounding tissue and produce multiple discharging sinuses. Treatment requires prolonged administration of penicillin for 6–12 months. In penicillin-allergic patients, clindamycin or erythromycin is effective. Surgical excision and drainage may be required in some cases.

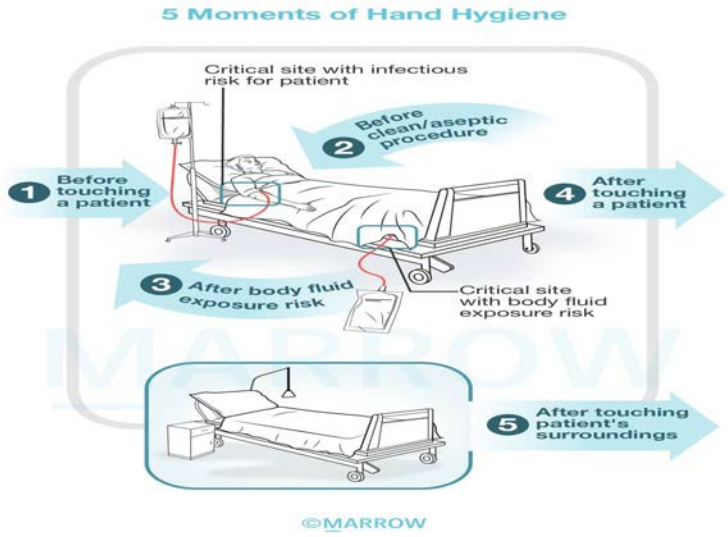
The given image shows cervicofacial actinomycosis.

The given image shows a patient with multiple cutaneous lesions caused by Actinomyces:

Solution to Question 32:

You should use a sanitiser before and after examining the patient and after touching the patients' surroundings. The hands should be washed with soap and water thoroughly in case they are visibly soiled.

Sanitization is the process through which pathogenic organisms are reduced to safe levels on inanimate objects to reduce the likelihood of cross-infections. It is a component of hand-hygiene, which is demonstrated by the image below.

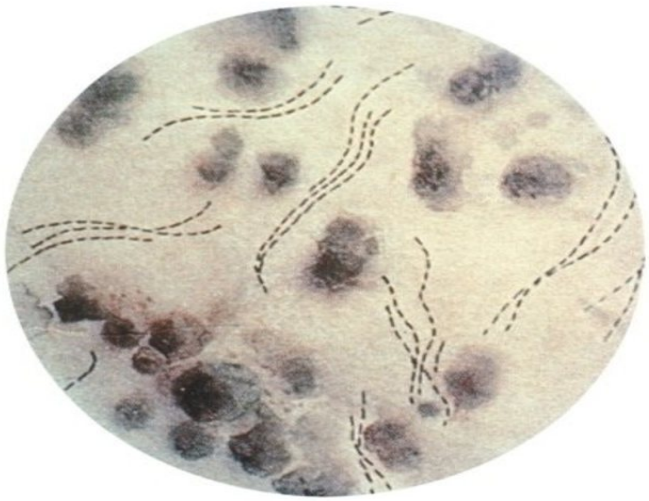


Note: Disinfectants like chlorhexidine and alexidine have a biguanide functional group. They are mostly used as oral disinfectants and hand products. They are bactericidal but not sporicidal. Mycobacteria are also resistant to these compounds.

Solution to Question 33:

Chancroid is a painful genital ulcer caused by Haemophilus ducreyi, which is a gram-negative coccobacillus. Microscopic appearance of H. ducreyi is called the school of fish appearance or railroad appearance. Chancroid ulcers have a soft base that bleeds easily to touch. They also cause painful lymphadenopathy.

The image below shows the 'school-of-fish' appearance characteristic of H. ducreyi.



Note: Groove sign is a characteristic sign seen in lymphogranuloma venereum. It refers to the depression created by the inguinal ligament as it passes between the groups of inflamed inguinal lymph nodes.

Solution to Question 34:

The correctly matched pairs are as follows:

The various strains of Escherichia coli are:

• Enterotoxigenic E. coli (ETEC) is the most common organism that causes diarrhea in travelers. It produces the following toxins:

• LT (heat-labile toxin)- acts by ↑cAMP

• ST (heat-stable toxin)- two types of ST are known, ST-A (ST-I) and ST-B (ST-II)

• ST-A is soluble in methanol and acts by ↑cGMP in the intestine.

• ST-B is insoluble in methanol, and the mode of action is not known.

• Enteroinvasive E. coli (EIEC) invade interstitial epithelial cells in the intestine and cause a condition resembling shigellosis. This ability is determined by a plasmid, detection of which can

also be a diagnostic test. Sereny's test was employed to diagnose EIEC but it is not in use anymore.

• Enterohemorrhagic E. coli (EHEC) produces verocytotoxin, which targets vascular endothelium. It causes hemorrhagic colitis and hemolytic uremic syndrome.

• Enteropathogenic E. coli (EPEC) causes infantile diarrhea in developing countries. It adheres to the mucosal surface of small intestine using EAF and LEE and causes effacement of microvilli. This leads to attachment and effacement lesions of intestinal cells.

• Enteroaggregative E. coli (EAEC) produces the stacked brick pattern of adherence on hep-2 cells. EAEC has been associated with persistent diarrhea. Intestinal colonization of EAEC is mediated by AAF (aggregative adherence fimbriae). EAEC produces EAST-1 toxin (enteroaggregative heat-stable toxin) which is considered to be a major virulence factor.

E. coli	Mechanism of action
1. ETEC	A. Produce a heat-stable toxin and cause activation of guanylyl cyclase
2. EIEC	B. Invades intestinal mucosal cells
3. EHEC	C. Produces a toxin against vascular endothelium cells
4. EPEC	D. Adhere to the mucosal surface and cause effacement of microvilli

Solution to Question 35:

Identification features of Trichomonas vaginalis:

• Pear-shaped or ovoid

• Short undulating membrane reaching upto the middle of the body

• It has four anterior flagella and fifth running along the outer margin of the undulating membrane, which is supported at its base by a flexible rod, costa

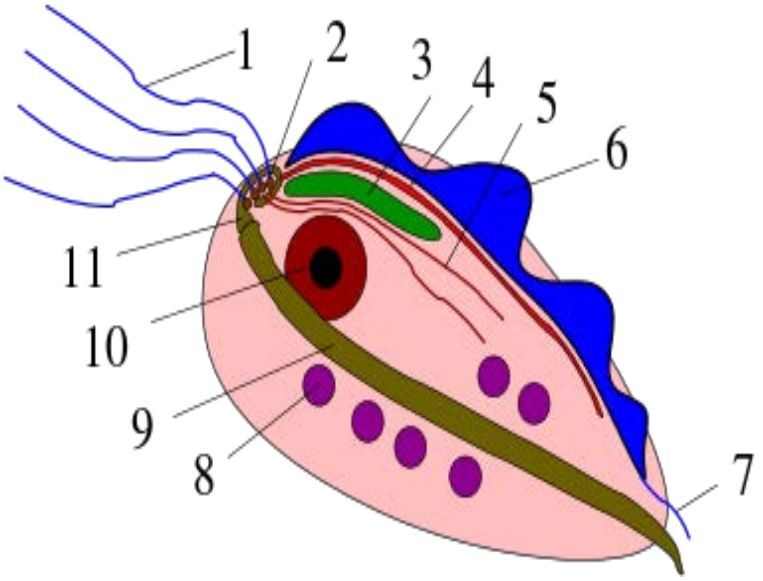
• A prominent axostyle runs throughout the length of the body and projects posteriorly like a tail

• The cytoplasm shows prominent siderophillic granules, which are most numerous alongside the axostyle and costa

• Jerky or twitching type of mobility

Parasite	Organ of locomotion
Balamuthia mandrillaris	Pseudopod

Parasite	Organ of locomotion
Balantidium coli	Cilia
Trichomonas vaginalis	Flagella
Toxoplasma gondi	No Particular organ



The above image shows Trichomonas vaginalis : 1-anterior flagella, 2-kinetosomes, 3-parabasal body, 4-costa, 5-parabasal fibers, 6-undulating membrane, 7-posterior flagellum, 8-hydrogenosomes, 9-axostyle, 10-nucleus, 11-pelta.

Obligate parasite - Organism cannot survive outside host

• No cystic stage. Trophozoites are infective forms

• Sexual transmission is the main route of infection. Other modes are fomites, babies during passage through infected birth canal

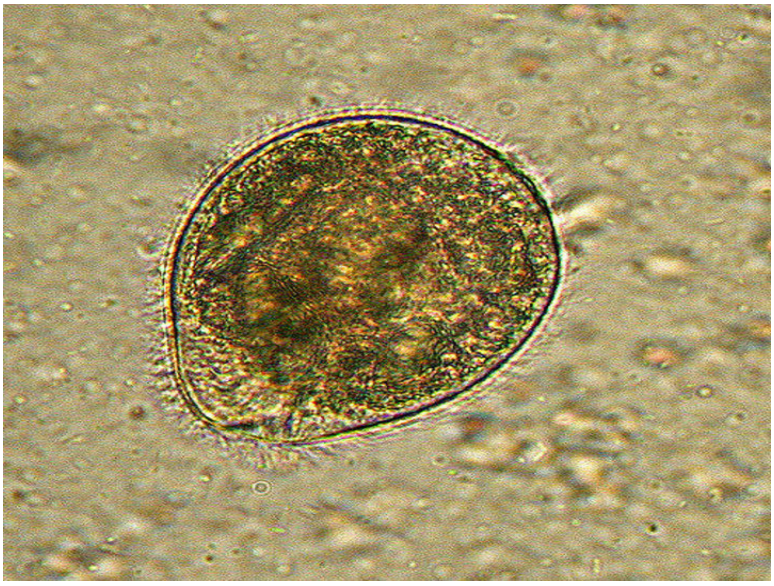
• Affects squamous epithelium - Intracellular edema and so called chicken-like epithelium, is the most characteristic feature of trichomoniasis

• Habitat: Vagina and cervix in female and urethra in males

• Clinical features: Often asymptomatic in males. In females, it leads to pruritic vaginitis with greenish yellow discharge, strawberry mucosa and dysuria

• Diagnosis: By wet mount microscopy of vaginal or urethral discharge, Culture (gold standard - Cysteine-peptone-liver-maltose (CPLM) medium and plastic envelope medium (PEM)), PCR, and by demonstration of antigen in vaginal smear by ELISA

• Treatment: Metronidazole is the drug of choice and simultaneous treatment of both partners is recommended



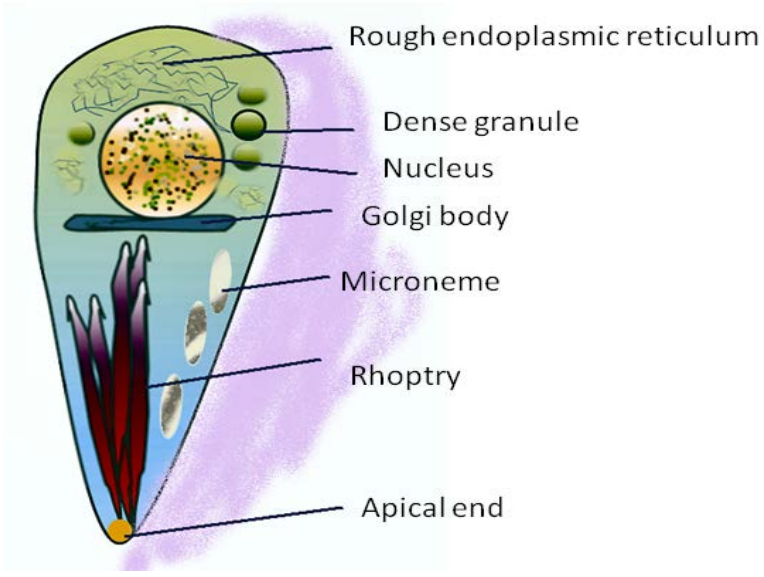
The given image is the trophozoite form of the Balantidium coli.

Balantidium coli occurs in two stages

• Trophozoites are oval in shape and contain two nuclei. There is the presence of cilia over the entire surface and are larger around the mouth. Its anterior end is narrow and the posterior end is broad. At the anterior end, there is a groove leading to the mouth (cytostome). Posteriorly, there is a small anal pore (cytopyge).

• Cysts are smaller, round with a micronucleus, a macronucleus and many contractile vacuoles.

Living trophozoites/cysts are yellowish or greenish in color on wet mount.



The image given above shows Toxoplasma gondii which has two types of life cycles:

• Enteric cycle

• Exoenteric cycle

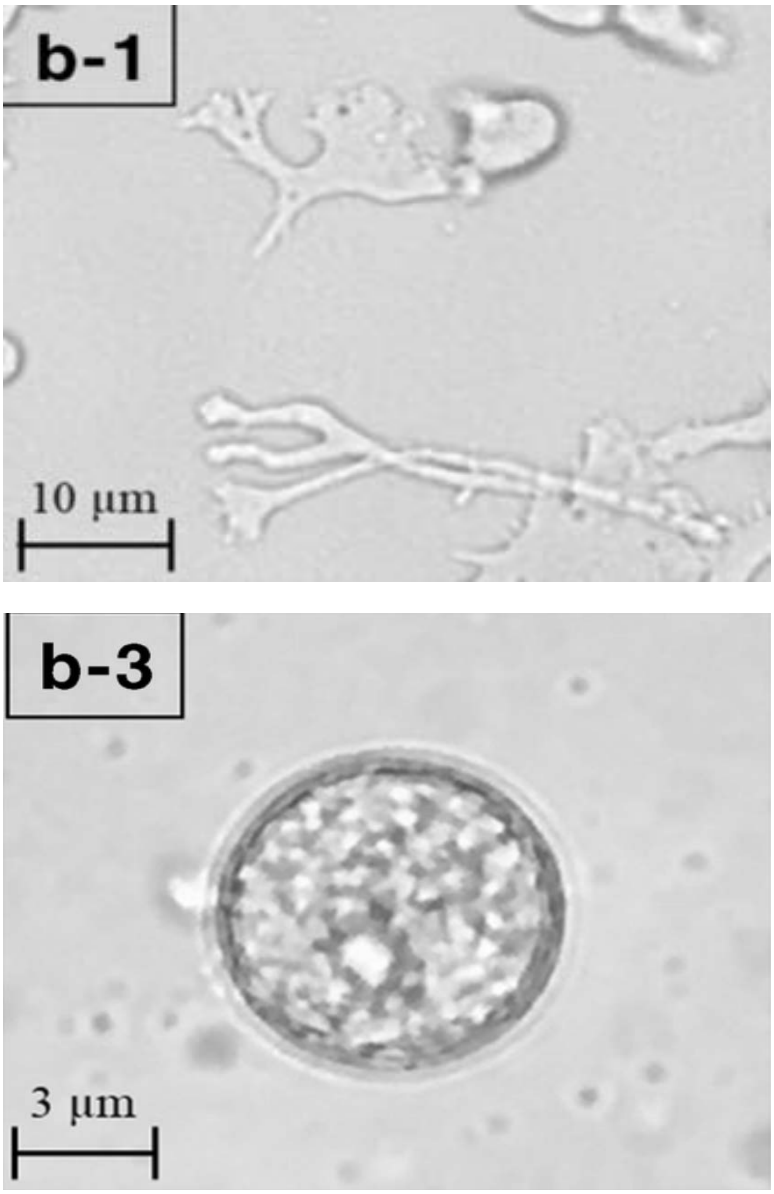
The enteric cycle occurs in definitive hosts such as cats. Exoenteric cycle occurs in intermediate hosts such as humans, mice, rats, etc.

Both sexual reproduction (gametogony) and asexual reproduction (schizogony) occur within the mucosal epithelial cells of the small intestine of the cat.

Sporozoites from the oocysts and bradyzoites from the tissue cysts enter the intestinal mucosa and multiply asexually. Tachyzoites are formed within the intermediate host.

Tachyzoites continue to multiply and spread locally by lymphatic system and blood, while the bradyzoites multiply slowly inside the tissue cyst.

The dormant bradyzoites inside the cyst may be reactivated in immune suppression causing renewed infection in the host.



Images b-1 and b-3 showing the Trophozoite and Cystic form of Balamuthia mandrillaris in Salmonella Shigella (SS) Agar respectively.

Balamuthia Mandrillaris

B. mandrillaris is a free-living ameba, which is a newly identified species reported to cause granulomatous amebic encephalitis (GAE).

Morphology

It exists in ameboid trophozoite stage. The flagellate stage is absent

• It is relatively large (12-60 μm), irregular in shape and actively motile by broad pseudopodia.

• Cyst of B. mandrillaris are usually spherical (6-20 μm), surrounded by a three-layered cyst wall: (1) outer irregular ectocyst, (2) a middle mesocyst and (3) an inner endocyst round wall. Under light microscopy, it appears to have two walls: (1) an outer irregular wall and (2) an inner smooth wall.

• Infection is transmitled through respiratory tract, skin lesions, or eyes.

Solution to Question 36:

The galactomannan assay is used for the diagnosis of invasive (deep-seated) mycoses caused by Aspergillus species.

Galactomannan is a component of the cell wall of Aspergillus. It can be detected in serum or bronchoalveolar lavage by ELISA for the diagnosis of invasive aspergillosis in adults and children. This test is especially useful in hematopoietic stem cell transplant recipients or patients with hematologic malignancies. Invasive aspergillosis affects the lungs and presents with fever, cough, dyspnea, and hemoptysis. The organism may spread to the eye, gastrointestinal tract, kidney, liver or brain, leading to abscesses and necrotic lesions.

Other diagnostic features of invasive aspergillosis are:

• Positive culture from the affected organ

• Microscopy showing narrow, septate hyphae with branching at 45o and conidiophores

• Halo sign on CT scan

Solution to Question 37:

The correct answer is A-3, B-2, C-4, D-1.

The hosts of the above parasites are given below:

A. Diphyllobothrium	3. Cyclops
B. Paragonimus	2. Crayfish
C. Brugia	4. Mansonia
D. Fasciola	1. Sheep

Parasite	Definitive host	First intermediate host	Second intermediate host
Diphyllobothrium	Humans	Cyclops	Cyclops and fish
Paragonimus	Humans	Snail	Crayfish and crab
Fasciola	Sheep and humans	Snail	Aquatic vegetations
Brugia	Humans	Mansonia mosquito	-

Microbiology NEET 2018

Question 1:

Nude mice are not resistant to xenograft due to the absence of _____

a) B cell

b) T cell

c) Both B and T cell

d) NK cell

Question 2:

Which of the following is Burkholderia cepacia resistant to?

a) Ceftazidime

b) Trimethoprim-sulfamethoxazole

c) Temocillin

d) Cefotetan

Question 3:

Which of the following organisms causes scombroid fish poisoning?

a) Salmonella

b) Staphylococcus

c) Pseudomonas aeruginosa

d) Peptostreptococcus

Question 4:

Which of the following is the predominant pathogen to infect renal transplant recipients one to four months following transplantation?

a) Cytomegalovirus

b) JC virus

c) BK virus

d) Epstein-Barr virus

Question 5:

Sabin-Feldman dye test is used for diagnosis of which of the following condition?

a) Paragonimiasis

b) Hydatid cyst

c) Toxoplasmosis

d) Cryptococcus

Question 6:

Which of the following is called as Australia antigen?

a) HBsAg

b) HBeAg

c) HBcAg

d) HBV-DNA

Question 7:

Bacterial transduction occurs by

a) Plasmids

b) Sex pili

c) Bacteriophage

d) Uptake of genetic material by other bacteria.

Question 8:

Which fungus is most commonly associated with orbital cellulitis in patients with diabetic ketoacidosis ?

a) Candida

b) Rhizopus

c) Aspergillus

d) Trichophyton

Question 9:

The adult form of echinococcus is seen in which of the following?

a) Dog

b) Cat

c) Swine

d) Sheep

Question 10:

Which of the following can grow in an acidic pH?

a) Vibrio

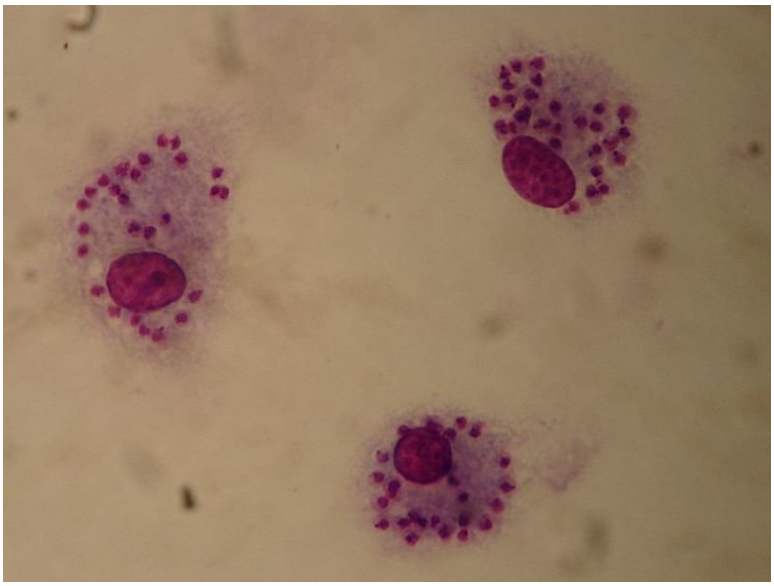
b) Lactobacilli

c) Salmonella

d) Shigella

Question 11:

What is the vector for the condition diagnosed by the image shown below?



a) Anopheles mosquito

b) Ixodes Tick

c) Sandfly

d) Tsetse fly

Question 12:

TB test done only on whole blood sample is _____.

a) TrueNat TB

b) Gene xpert

c) Interferon gamma release assay

d) All the above

Question 13:

Multiple abscesses with discharging sinuses, demonstrating sulphur granules in pus, are caused by

a) Actinomyces

b) Nocardia

c) Salmonella

d) Tularemia

Question 14:

Cutaneous larva migrans is most commonly caused by which organism?

a) Strongyloides stercoralis

b) Toxocara canis

c) Ancylostoma braziliense

d) Necator americanus

Question 15:

Which type of hypersensitivity reaction is involved in the hyperacute rejection of renal transplants?

a) Type IV

b) Type III

c) Type II

d) Type I

Question 16:

Which of the following organisms produce urease?

a) Helicobacter pylori

b) Salmonella

c) Escherichia coli

d) Shigella

Question 17:

Mycoplasma is inherently resistant to which of the following antibiotics?

a) Beta lactam antibiotics

b) Macrolides

c) Tetracyclines

d) Flouroquinolones

Question 18:

Pasteurization is done at _____.

a) 73 degree Celsius for 20 minutes

b) 63 degree Celsius for 30 minutes

c) 72 degree Celsius for 30 seconds

d) 63 degree Celsius for 30 seconds

Answer Key

Question No.	Correct Option
1	b
2	d
3	c
4	a
5	c
6	a
7	c
8	b
9	a
10	b
11	c
12	c
13	a
14	c
15	c
16	a
17	a
18	b

Detailed Explanations

Solution to Question 1:

Nude mice are not resistant to xenograft due to absence of T cell.

A xenograft is a tissue graft or organ transplant from a donor of a different species.

Nude mice lack body hair, hence the name. They lack a thymus and thus cannot generate mature T lymphocytes. The absence of T-lymphocytes makes them unable to mount adaptive immune responses requiring helper T cells and cytotoxic T cells. The absence of functioning T cells also prevents the rejection of allografts & xenografts.

Solution to Question 2:

Burkholderia cepacia is resistant to cefotetan.

B. cepacia complex strains are intrinsically resistant to aminoglycosides, polymixin, first and second-generation cephalosporins (e.g. cefotetan) and carboxypenicillins. This antimicrobial resistance is mediated by efflux pumps, antimicrobial degradation, modifying enzymes or altered

membrane functions.

B. cepacia is a Gram-negative bacillus which can cause severe necrotizing pneumonia in patients with chronic granulomatous disease. It can lead to fatal septicemia in patients with cystic fibrosis.

Antimicrobial agents that are effective against B. cepacia complex include meropenem, ceftazidime, trimethoprim-sulfamethoxazole, piperacillin and temocillin.

Solution to Question 3:

Scombroid fish poisoning is associated with Pseudomonas aeruginosa.

It follows the consumption of both scombroid (mackerel-like) fish and nonscombroid fish that have not been refrigerated properly. The musculature of these dark- or red-fleshed fish undergoes decomposition by Morganella morganii, Escherichia coli, Proteus species, Klebsiella species, and Pseudomonas aeruginosa. There is consequent decarboxylation of the amino acid L-histidine to form histamine.

A second compound is thought to play a causative role in this intoxication because large doses of oral histamine do not reproduce the affliction. The toxin or toxins involved are heat stable and are not destroyed by cooking or freezing.

Symptoms develop within 15–90 min of ingestion. Most cases are mild, with tingling of lips and mouth, mild abdominal discomfort, and nausea. The more severe and commonly described presentation includes flushing, conjunctival hyperemia, pruritus, urticaria, and angioedema. Without treatment, the symptoms generally resolve within 8–12 h.

Solution to Question 4:

The predominant pathogen to infect renal transplant recipients in the period around 1 to 4 months following the transplantation is cytomegalovirus (CMV).

CMV is the most common virus to affect recipients after organ transplantation (kidney, heart, lung etc). The maximal risk occurs between 1 and 4 months after transplantation (in the absence of prophylaxis). The most common CMV presentation in kidney transplant patients includes fever, leukopenia, hepatosplenomegaly, myalgia, and arthralgia. Antiviral prophylaxis with ganciclovir or valganciclovir is used in renal transplant recipients whenever indicated to prevent CMV disease.

Given below are the most common opportunistic infections in renal transplant recipients:

Peritransplant (less than 1 m onth)	Early (1-6 months)	Late (more than 6 months)
Wound infectionHerpes virus Oral candidiasisUrinary tract infection	Pneumocystis jiroveciCytome galovirusHepatitis BListeria	AspergillusNocardiaBK Virus (polyoma)Herpes Zoster

Solution to Question 5:

Sabin-Feldman dye test is used for the diagnosis of toxoplasmosis.

It is based on the principle that the presence of anti-toxoplasma antibodies in the patient's serum inhibits the staining of trophozoites by alkaline methylene blue dye. Toxoplasma trophozoites and complement are added to the patient's serum which is then incubated for an hour at 37°C. After incubation, methylene blue dye is added.

• If anti-toxoplasma antibodies are present in the serum, these are activated by complement and the parasite membrane is lysed. Thus, the trophozoites are not stained (positive result).

• If there are no antibodies, trophozoites will take up the stain and appear blue under the microscope (negative result).

The dilution of the test serum at which 50% of the tachyzoites are not stained is reported as the antibody titer of the test serum. The test is highly sensitive and specific. However, it cannot differentiate between recent or past infections as it detects only IgG antibodies.

Solution to Question 6:

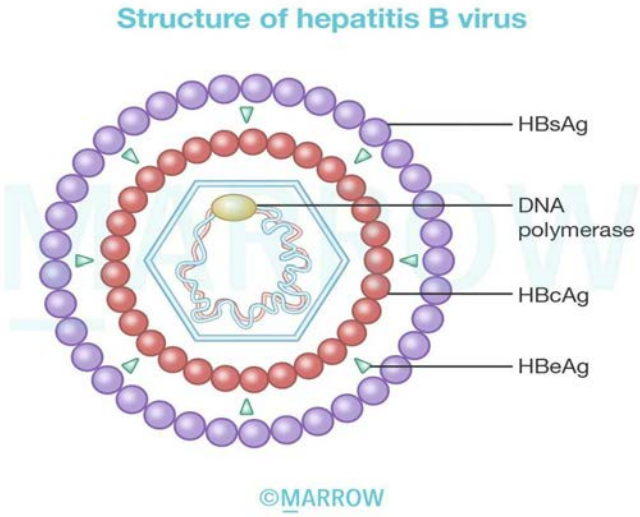
HBsAg (Hepatitis B surface antigen) is also known as the Australia antigen. It is called so because it was first isolated from the serum of an Australian person.

Sera from hepatitis B patients when observed under an electron microscope show three types of particles:

• A spherical particle: 22nm, most abundant, contains only HBsAg.

• Filamentous or tubular particle: 22nm, contains only HBsAg.

• A double-walled spherical structure: 42nm diameter, is the complete Hepatitis B virus. It was described by Dane and is called Dane particle.

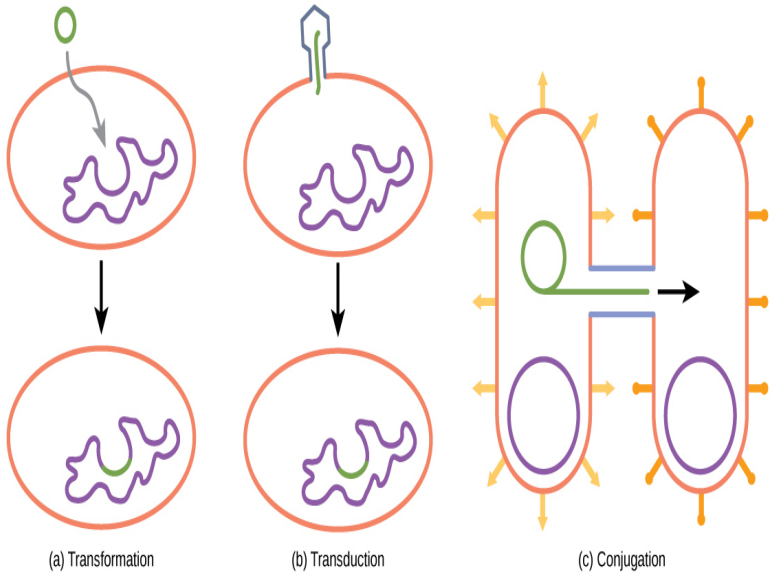


Solution to Question 7:

Bacterial transduction occurs by bacteriophages.

Transduction is a process of acquiring bacterial DNA from a bacteriophage (virus) that has incorporated bacterial DNA from previous host bacteria.

Other methods of exchange of genetic material are transformation and conjugation. Transformation involves the uptake of genetic material from the environment, which is released by other bacteria. Conjugation is the direct transfer of DNA from one bacterial cell to another bacterial cell through a sex pilus or bridge. The transferred DNA is a plasmid, a circle of DNA that is distinct from the main bacterial chromosome.



Solution to Question 8:

Rhizopus is the most common fungus associated with orbital cellulitis in patients with diabetic ketoacidosis.

Diabetic patients are immunocompromised and so prone to develop opportunistic infections like mucormycosis - caused by Rhizopus and Mucor spp. Rhino-orbital- cerebral disease is the most common form of mucormycosis. It mostly occurs in diabetics. Patients initially present with eye or facial pain, facial numbness, conjunctival suffusion and swelling, and blurry vision. Infection then spreads from the ethmoid sinus to the orbit, leading to proptosis and orbital cellulitis.

Rhizopus is angioinvasive, and thus the infection may spread to the frontal lobe and cavernous sinus, leading to septicemia and thromboses. The sinus tissue in such patients often develops into a black necrotic eschar.

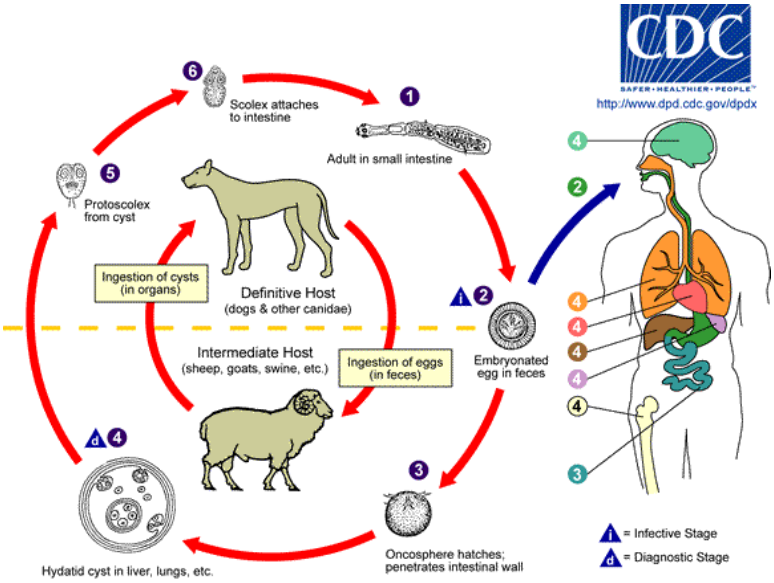
Solution to Question 9:

The adult form of echinococcus is seen in dogs and other canids, which are its definitive hosts.

The larval stage is passed in intermediate hosts such as sheep, cattle, goat, swine, horses, camels, and man. Man acts as an accidental intermediate host (dead end). Human infection follows the ingestion of eggs due to the intimate handling of dogs or by eating raw vegetables or other food contaminated with dog feces.

Note: Humans can become accidental definitive hosts, second intermediate hosts, or paratenic hosts for spirometra. These are cestodes belonging to the Diphyllobothriidae family. They cause a condition called sparagnosis.

The image below shows the life cycle of Echinococcus granulosus.



Solution to Question 10:

Among the given options, lactobacilli is the one that can grow in an acidic pH.

It is a gram-positive, facultatively anaerobic, non-motile, non–spore-forming bacterium. Lactobacillus derives lactic acid from glucose, creating an acidic environment, and can grow in an acidic medium. It is found in the vagina as part of its normal microbiota.

Solution to Question 11:

The image shown is of the Leishman-Donovan bodies whose presence are diagnostic of Kala Azar. The vector of Kala Azar is a sandfly.

Leishman-Donovan bodies are amastigotes with a double dot appearance containing a nucleus and small rod-like kinetoplast. They are present inside the macrophage.

Solution to Question 12:

TB test done on a whole blood sample is the interferon-gamma release assay. It has been used for the diagnosis of latent tuberculosis in patients with HIV(who frequently have a negative Mantoux test).

Interferon-gamma release assays include:

• QuantiFERON-TB Gold

• T-SPOT.TB

QuantiFERON-TB Gold quantitates the amount of IFN-γ produced by CD4+ T cells in response to the antigens from Mycobacterium tuberculosis. QuantiFERON-TB Gold Plus (QFT- Plus) is an improved version of the QuantiFERON-TB Gold test. QuantiFERON-TB Gold detects only TB-specific CD4+ responses. However, QuantiFeron-TB Gold Plus detects both CD8+ and CD4+ T-cell responses to TB-specific antigens.

T-SPOT.TB determines the total number of individual effector T cells expressing IFN-γ.

The TrueNat TB test is a new molecular test that can diagnose TB in one hour as well as test for rifampicin resistance. This test uses a sputum sample taken from the patient. Only about 0.5 ml of the sample is required. Gene Xpert is also a molecular method of testing that cannot use blood as a sample. (Option A and B)

Solution to Question 13:

Multiple abscesses with discharging sinuses, demonstrating sulfur granules in pus, are characteristic of actinomycosis caused by Actinomyces.

Actinomycosis is a chronic granulomatous infection characterized by indurated swellings in the connective tissue with suppuration and discharge of sulfur granules. The most common causative agent is Actinomyces israelli.

Various clinical forms of actinomycosis include cervicofacial, thoracic, abdominal, and pelvic actinomycosis. Among them, oral-cervicofacial actinomycosis is most common, presenting as a soft tissue swelling, abscess, or mass lesion involving the angle of the jaw.

Solution to Question 14:

Cutaneous larva migrans is most commonly caused by Ancylostoma braziliense.

Cutaneous larva migrans or ground itch or creeping eruption is caused by nematode larvae that infect by skin penetration.

The most common cause is non-human species of Hookworm Ancylostoma braziliense and A. caninum.

Necator americanus and Strongyloides sp also cause cutaneous larva migrans, and Toxocara canis usually causes viscreal and ocular larva migrans.

Differences between cutaneous larva migrans and visceral larva migrans:

	Cutaneous larva migrans	Visceral larva migrans
Tissue involved	Skin	Various organs of the body li ke the liver, lungs, and eyes
Infecting Organis m	Mostly by non-human nemat odes	Mostly by non-human nemat odes (mainly by dog and cat)
Portal of Entry	Penetration of skin	Ingestion of infected eggs
Eosinophilia	Mild	Persistent high
Serodiagnosis	Not developed	Well developed
Treatment	Thiabendazole	Diethylcarbamazine and pred nisolone

Solution to Question 15:

Hyperacute graft rejection is an example of type II hypersensitivity reaction.

It is mediated by preformed antibodies. It is a rare event that occurs in kidney transplantation.

Graft rejectio n	Time taken for rejection	Immune mechanisms involve d	Type of hypersensitivity
Hyperacute	Minutes to hours	Preformed antibodies	II
Acute	Weeks to months	Cytotoxic T-cell mediated	IV
Chronic	Months to years	Chronic DTH mediated and Ab mediated	IV

Solution to Question 16:

Helicobacter pylori produces urease.

Urease-producing organisms: (Mnemonic-PUNCH)

• Proteus

• Ureaplasma urealyticum

• Nocardia

• Cryptococcus, Corynebacterium urealyticum

• H. pylori

Solution to Question 17:

Mycoplasma are inherently resistant to beta-lactam antibiotics.

Mycoplasma lack cell wall, and are therefore inherently resistant to antibiotics acting on the bacterial cell wall e.g. beta-lactams (penicillins, cephalosporins).

Solution to Question 18:

Pasteurization: Milk is heated at either

• 63°C for 30 minutes: the Holder method or

• 72°C for 15–20 seconds: the flash process

followed by cooling quickly to 13°C or lower.

All the non-sporing pathogens are killed except Coxiella burnetti, which may survive in Holder method.

Microbiology NEET 2019

Question 1:

BCYE medium is used to culture:

a) Leptospira

b) Bacillus cereus

c) Campylobacter

d) Legionella

Question 2:

A 16-year-old boy is admitted with fever, icterus, conjunctival suffusion, and hematuria for 15 days. Which serological test should be done for diagnosis?

a) Widal test

b) Microscopic agglutination test

c) Weil felix reaction

d) Paul Bunnell test

Question 3:

A patient presents with gastrointestinal problems including abdominal pain and distension, bloody and mucus-filled diarrhea, and tenesmus, with rectal prolapse. A stool examination reveals the presence of typical barrel-shaped eggs. What is the possible causative agent?

a) Giardia lamblia

b) Trichuris trichiura

c) Ascaris lumbricoides

d) Ancylostoma duodenale

Question 4:

Viral infection mimicking erythroblastosis fetalis is:

a) HSV

b) Epstein-Barr virus

c) Picornavirus

d) Parvovirus B19

Question 5:

An 11-year-old boy was brought to the pediatric OPD with multiple abscesses over his face, chest, and back. The child has a history of recurrent■ respiratory infections. On examination, he has atopic excoriating skin and multiple cold abscesses on his back. What is the most probable diagnosis?

a) Hyper IgM syndrome

b) Wiskott-Aldrich syndrome

c) Hyper IgE syndrome

d) Carcinoid syndrome

Question 6:

Cowdry type A inclusions are seen in:

a) Herpes simplex

b) Rabies

c) Molluscum contagiosum

d) Adenovirus

Question 7:

Which of the following statements is false regarding MHC molecules?

a) MHC class II presents peptide antigen to CD4 T cells

b) The action of MHC II occurs via endocytic pathway

c) MHC Class II presents endogenous antigens

d) MHC II is present on antigen presenting cells

Question 8:

Which of the following investigations does not use antibody marking?

a) ELISA

b) Radioimmunoassay

c) Immunofluorescence

d) Hemagglutination

Question 9:

A 3-year-old child presents with a history of repeated sinopulmonary infections caused by encapsulated organisms. Which of the following is most likely to be deficient in this case?

a) IgG1

b) IgG2

c) IgG3

d) IgG4

Question 10:

A veterinarian developed an ulcer with central black eschar over the forearm as shown in the image. Which of the following is the most probable causative organism?

a) Pseudomonas aeruginosa

b) Yersinia pestis

c) Bacillus anthracis

d) Francisella tularensis

Question 11:

Which of the following is not used as an immediate test in the screening of urinary tract infections (UTI)?

a) Pour plate culture

b) Griess Nitrite test

c) Leukocyte esterase test

d) Wet mount examination

Question 12:

In which of the following is the disc diffusion method for antibiotic susceptibility testing applied?

a) Agar dilution method

b) Kirby-Bauer method

c) Broth dilution method

d) PCR based assay

Question 13:

What is the investigation of choice for neurosyphilis?

a) Venereal disease research laboratory (VDRL) test

b) FTA-ABS- Fluorescent Treponemal Antibody Absorption test

c) RPR- Rapid Plasma Reagin test

d) TPI-Treponema pallidum immobilization test

Question 14:

Contact based isolation is employed for which of the following diseases?

a) Diphtheria

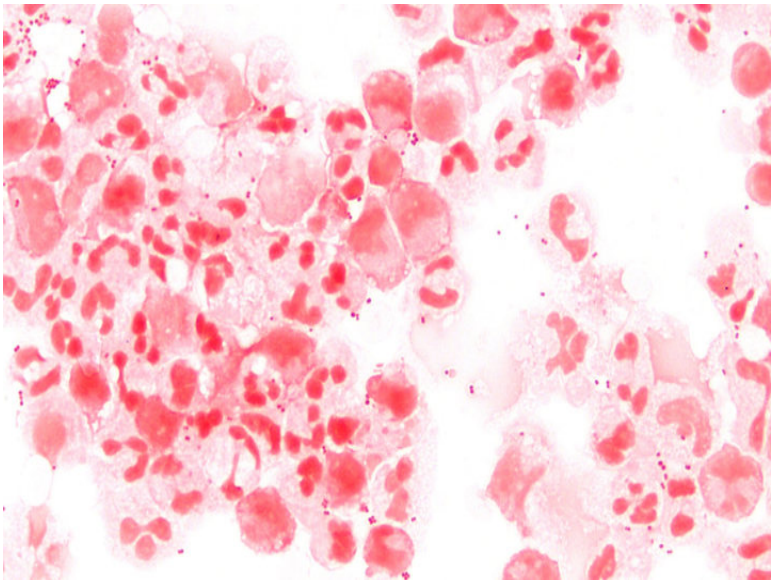
b) MRSA

c) Mumps

d) Asthma

Question 15:

An 18 year old female presents with severe headache and high fever of 101°F. On examination, papilloedema and nuchal rigidity was present. Gram staining of the CSF is shown below. Causative organism is



a) Haemophilus influenza type B

b) Neisseria meningitidis

c) Streptococcus pneumoniae

d) Listeria monocytogenes

Question 16:

What is the stain used for identifying cryptococcus?

a) Giemsa stain

b) Ziehl-Nielsen stain

c) Gram staining

d) Mucicarmine

Question 17:

Which of the following organisms follow a bird-arthropod-human transmission route?

a) Malaria

b) Japanese encephalitis

c) Plague

d) Paragonimiasis

Question 18:

A 23-year-old patient has a history of travel to China and the consumption of pickled crab. He now complains of rusty sputum and cough. What is the most likely causative organism?

a) Fasciola buski

b) Fasciola hepatica

c) Paragonimus westermani

d) Schistosoma japonicum

Question 19:

Which type of virus is rubella?

a) Flavivirus

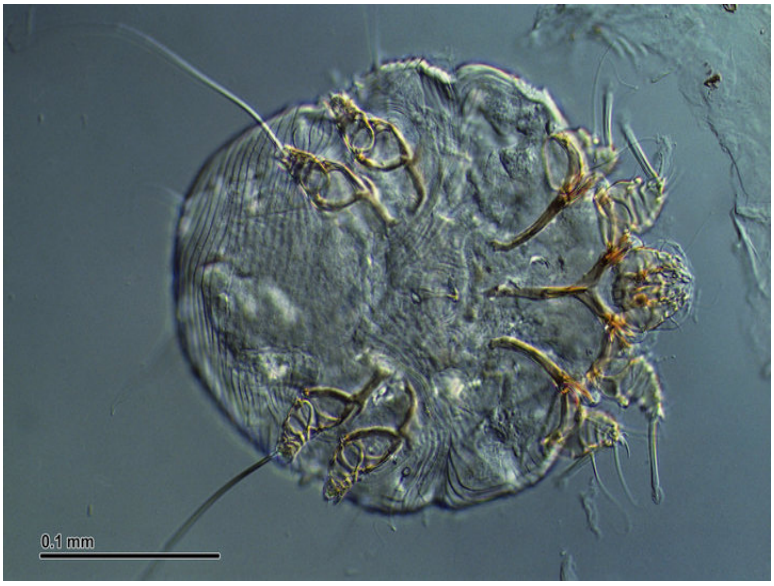
b) Togavirus

c) Paramyxovirus

d) Orthomyxovirus

Question 20:

A 30 year old female developed pruritic papules with excoriated plaques in the interdigital web spaces. Later the lesion spread to the groin and under-surface of the breasts. The lady gives a history of intense pruritus which is more severe at night. Given below is the organism responsible for this condition. Identify the wrong statement about the same.



a) Life history has 4 stages

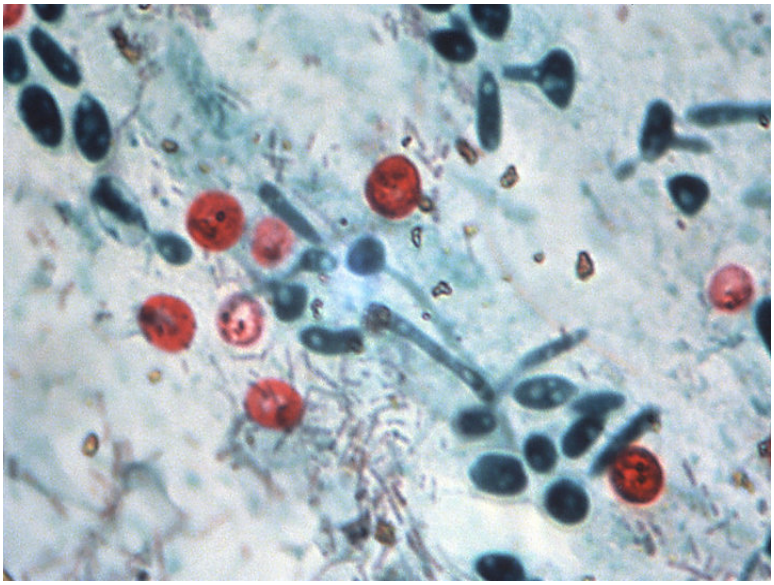
b) Larvae have 3 pairs of legs

c) The entire life cycle takes about 15 days

d) Male parasite burrows into the epidermis

Question 21:

A HIV patient presents with persistent diarrhea. Microscopic examination of the stool is given below. Identify the causative organism:



a) Cryptosporidium

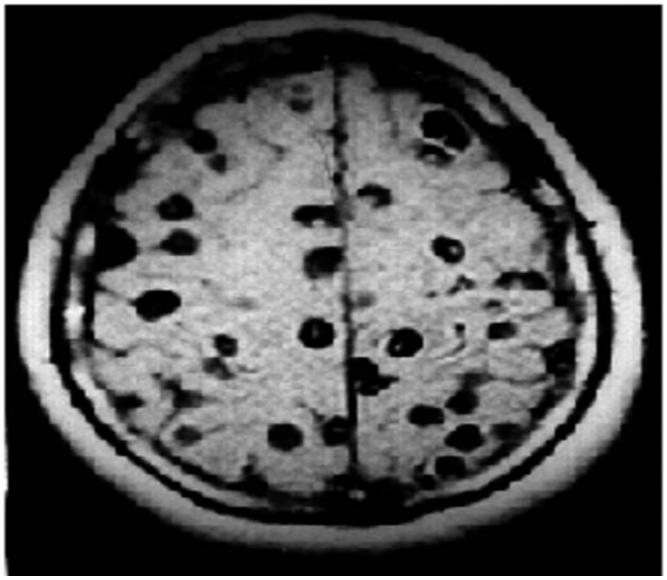
b) Cyclospora

c) Microspora

d) Cystoisospora

Question 22:

A patient is brought to the hospital, with complaints of seizures and the MRI image of the brain is given below. The disease is most probably caused by?



a) Cysticercosis cellulosae

b) T. saginata

c) Cysticerocosis bovis

d) T. asiatica

Question 23:

Vaccine that requires strain change due to evolving organism is?

a) Influenza

b) Diphtheria

c) Polio

d) Typhoid

Answer Key

Detailed Explanations

Solution to Question 1:

BCYE medium (buffered charcoal yeast extract agar) is used to culture Legionella pneumophila.

Legionella pneumophila has fastidious growth requirements and grows on complex media such as BCYE medium with L-cysteine and antibiotic supplements (e.g., polymyxin B, cefazolin, vancomycin). The charcoal acts as a detoxifying agent. It grows slowly, and the colonies may take 3–6 days to appear.

Other options:

Option A: Leptospira is cultured on EMJH (Ellinghausen, McCullough, Johnson and Harris) medium

Option B: Bacillus cereus is cultured on PEMBA (Polymyxin pyruvate egg-yolk mannitol–bromothymol blue) agar

Option C: Campylobacter is cultured on Skirrow's, Campy BAP or Butzler's agar.

Solution to Question 2:

A history of fever with liver and kidney involvement should arouse suspicion of leptospirosis (Weil's disease). A microscopic agglutination test is used for the diagnosis of leptospirosis.

Antibodies against leptospirosis appear in the blood 5-7 days after infection. Serotype-specific tests for leptospirosis includes:

• Microscopic agglutination test

• Macroscopic agglutination test

Other options:

Option A: Widal test is used to screen for typhoid fever

Option C: Weil-Felix reaction is used to diagnose rickettsial fevers

Option D: Paul-Bunnell test is the investigation of choice for infectious mononucleosis.

Solution to Question 3:

The given clinical picture and the barrel-shaped eggs are suggestive of infection with Trichuris trichiura (whipworm).

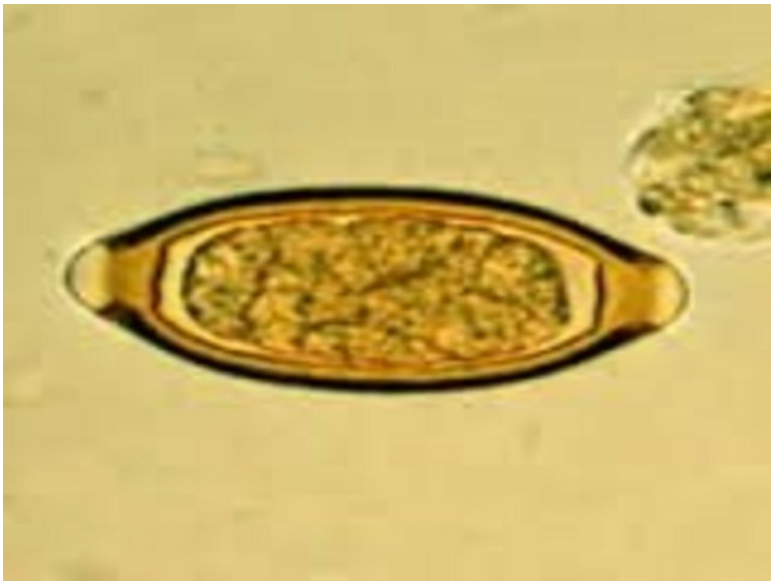
The characteristic features of whipworm eggs are:

• Eggs are barrel-shaped in the middle with a projecting mucus plug at each pole containing an unsegmented ovum. The plugs are colorless.

• They float in the saturated salt solution.

• It has a triple shell, the outermost layer of which is stained brown.

The below image shows the egg of Trichuris trichiura.



In moderate infections of 20 adult worms or less, the worms are confined to the caecum and ascending colon. The symptoms include epigastric and lower abdominal pain, diarrhea (rarely bloody), vomiting, flatulence and distention, weight loss, and increased blood and iron loss.

In heavy infections of 200 adults worms or more (trichuris dysentery syndrome), the worms are in the distal colon and rectum. The symptoms include bloody diarrhea with profuse mucus, abdominal pain, tenesmus, weight loss leading to cachexia, severe anemia, and rectal prolapse. On examination, clubbing may be present. Blood investigations may show moderate eosinophilia.

Chronic infection leads to growth retardation and nutritional deficiencies. Around 0.005 ml of blood is lost per day per worm. In heavy infections, as much as 4 to 5 ml can be lost per day per worm.

Treatment is mebendazole or albendazole.

Solution to Question 4:

Parvovirus B19 infection mimics erythroblastosis fetalis.

Parvovirus B19, belonging to the parvovirus group consisting of the smallest animal DNA viruses, primarily infect immature cells of the erythroid lineage. It is associated with erythema infectiosum (fifth disease), transient aplastic crisis, pure red cell aplasia and hydrops fetalis.

During pregnancy, infection with parvovirus B19 can lead to severe anemia, non-immune hydrops fetalis and fetal death. This is because parvovirus preferentially infects RBC progenitor cells. This mimics erythroblastosis fetalis, in which maternal antibodies against fetal RBCs cause varying degrees of anemia and immune-mediated hydrops fetalis in sever cases.

Picornavirus, Epstein-Barr virus and HSV infections do not mimic erythroblastosis fetalis.

Solution to Question 5:

From the above clinical history and examination, the most probable diagnosis is hyper IgE syndrome (Job's syndrome).

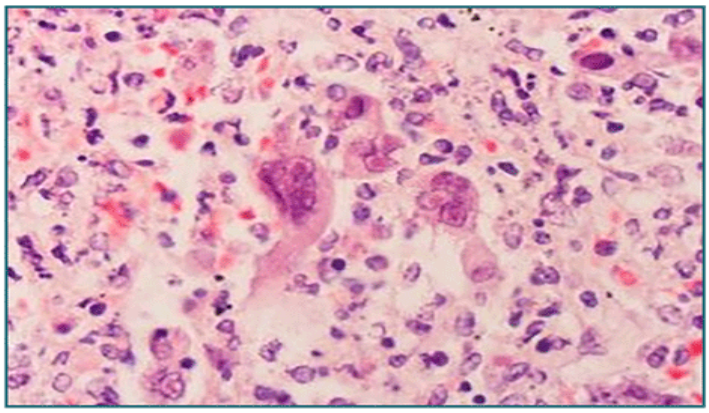
It is an autosomal dominant primary immunodeficiency disease caused by a mutation of STAT3 gene. Neutrophils do not generate an immune response, probably due to a defect in chemotaxis. Patients present with recurrent staphylococcal skin abscesses, recurrent lung infections (pneumatoceles), eczema, eosinophilia and high serum levels of lgE.

Solution to Question 6:

Cowdry type A inclusions are seen in herpes simplex infection.

The classic Cowdry type A (Lipshutz) inclusion appears as a light purple, homogeneous intranuclear structure surrounded by a clear halo. The inclusions stain with antibodies to HSV, permitting a rapid, specific diagnosis of HSV infection.

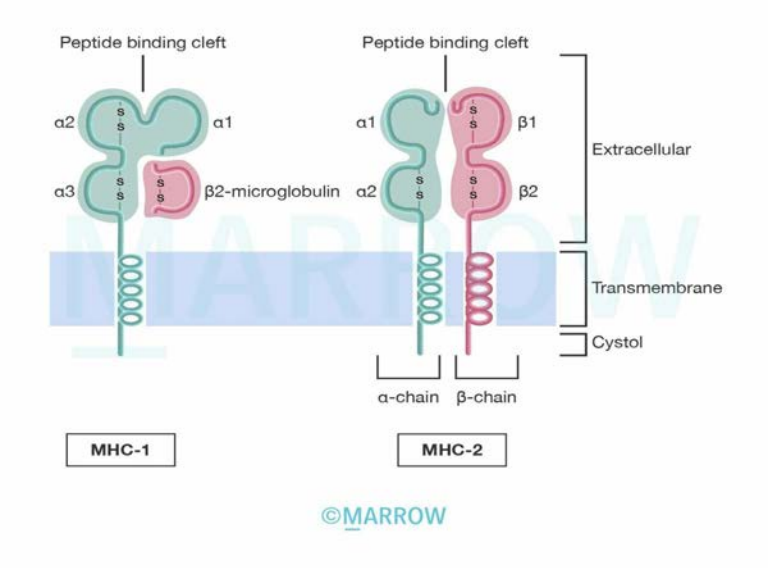
HSV inclusion bodies



©MARROW

Solution to Question 7:

MHC class II presents exogenous antigens while MHC class I presents endogenous antigens.

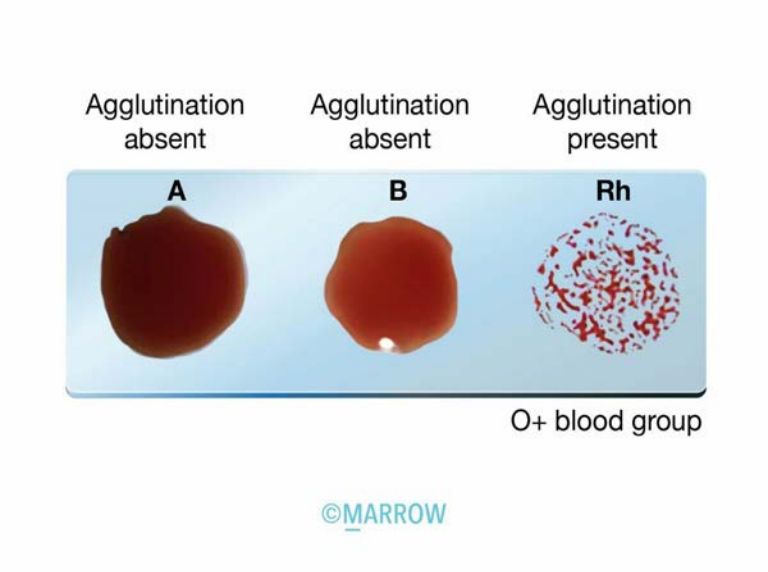


Solution to Question 8:

The hemagglutination test is not based on the principle of antibody marking.

In tests based on the principle of antibody marking, the antigens or antibodies are labelled or marked with enzymes, fluorescent dyes, radioisotopes etc. In radioimmunoassay, fixed amounts of antibody and radiolabelled antigen react in the presence of unlabelled antigen. The labelled and unlabelled antigens compete for binding sites on the antibody. Thus, the concentration of the test antigen can be calculated from the ratio of the bound and total antigen counts using a standard dose-response curve. In immunofluorescence, fluorescent dyes are conjugated to antibodies or antigens. The labelled antibodies or antigens can then be used to identify antigens and antibodies, respectively. In ELISA, an adsorbing material - cellulose, agarose, polystyrene, polyvinvyl etc - is used to bind to either antigens or antibodies.

When antibodies bind to antigens on the surface of red blood cells, the resultant clumping reaction is referred to as hemagglutination. It is routinely performed to type red blood cells in ABO blood-typing. The image below shows hemagglutination.



Note: If no hemagglutination occurs it means the patient's serum has anti-haemagglutinin antibodies that bind to hemagglutinin and prevent the clumping reaction. This hemagglutination inhibition reaction is a method of detection of viruses and antiviral-antibodies and is used to make a diagnosis of influenza.

Solution to Question 9:

Deficiency of IgG2 results in recurrent sinopulmonary infections with encapsulated organisms.

IgG is the only maternal immunoglobulin that is normally transported across the placenta and provides natural passive immunity to the newborn. IgG1 is the antibody maximally transported across the placenta, whereas IgG2 has the least transplacental movement.

Deficiencies of other IgG:

• IgG1- bacterial infections (diphtheria, tetanus)(Option A)

• IgG3- viral infections (Option C)

• IgG4- parasitic infections (Option D)

Solution to Question 10:

The given clinical scenario is suggestive of cutaneous anthrax which is caused by Bacillus anthracis.

Human anthrax presents in one of three ways:

• Cutaneous Anthrax(hide porter's disease)- Black eschar at the base, with a very prominent inflammatory ring around the eschar, is referred to as a malignant pustule.

• Pulmonary Anthrax(Wool sorter's disease)- Hemorrhagic pneumonia.

• Intestinal Anthrax- Hemorrhagic diarrhoea. It occurs mainly in primitive communities that eat the carcasses of animals dying of anthrax.

Robert Koch validated the germ theory of disease after discovering the anthrax bacillus as the cause of anthrax. He also discovered the causative agents of tuberculosis and cholera. Hence, he is known as the Father of Bacteriology.

Koch's postulates, which link specific microorganisms to specific diseases, state that the microorganism must be:

• Found in abundance in diseased organisms, but not in healthy organisms.

• Isolated from a diseased organism and grown in pure culture

• Able to cause disease when inoculated into a healthy organism

• Re-isolated from the diseased experimental host and identical to the original specific causative agent

Solution to Question 11:

Pour plate culture (quantitative test) is not used as an immediate test for screening of UTI. However it is considered the best diagnostic test for confirmation of UTI due it's high sensitivity and specificity.

The screening tests for UTI are as follows:

• Wet mount examination: It is done to demonstrate pus cells in urine.

• Leukocyte esterase test: It is a rapid and cheaper method, and detects leukocyte esterases secreted by pus cells present in urine.

• Nitrate reduction test (Griess test): Nitrate reducing bacteria like E. coli give a positive result.

• Catalase test: E. coli and other bacteria that produce the enzyme catalase give a positive result.

Quantitative Culture:

• Standardized loop technique

• Pour plate method

Solution to Question 12:

The disc diffusion method for antibiotic susceptibility testing is applied in the Kirby-Bauer method.

In Kirby-Bauer's disc diffusion method, a suitable standard dilution of a broth culture of the test bacterium is inoculated on the surface of a solid medium (Cation-adjusted Mueller-Hinton agar) as a lawn culture. After drying, various antibiotic discs are placed on its surface. Zones of inhibition around the disc are recorded and interpreted according to the zone diameters available in the tables of the Clinical and Laboratory Standards Institute (CLSI) guidelines. The results obtained are qualitative (resistant, sensitive, or partially sensitive).

The image below shows Kirby-Bauer disc diffusion method.

Laboratory testing for antibiotic sensitivity can be done by:

• Diffusion methods: The drug diffuses through a solid medium so that a gradient is established. The concentration is highest near the site of drug application and decreases with distance. The test bacterium is cultured on the medium and its sensitivity to the antibiotic is determined by the zone of growth inhibition. Examples include Kirby–Bauer method and Stokes method.

• Dilution methods: Serial dilutions of the drug are prepared and inoculated with bacteria. Examples include tube dilution method and agar dilution method

• Diffusion and dilution method: E–test (Epsilometer)

Solution to Question 13:

The investigation of choice for neurosyphilis is VDRL.

The CSF-VDRL test is highly specific and, when reactive, is considered diagnostic of neurosyphilis.

Involvement of the CNS in syphilis is detected by examination of CSF for:

• Mononuclear pleocytosis (>5 white blood cells/µL).

• Increased protein concentration (>45 mg/dL).

• CSF VDRL reactivity.

Solution to Question 14:

Contact based isolation is employed for patients who are infected with MRSA (methicillin-resistant Staphylococcus aureus).

The three categories of transmission-based precautions include:

• Contact-based isolation is used for infections, diseases, or germs that are spread by touching the patient or items in the room. Examples include MRSA, vancomycin-resistant enterococci (VRE), diarrheal illnesses, open wounds, and respiratory syncytial virus (RSV).

• Droplet-based isolation is employed for diphtheria and mumps.

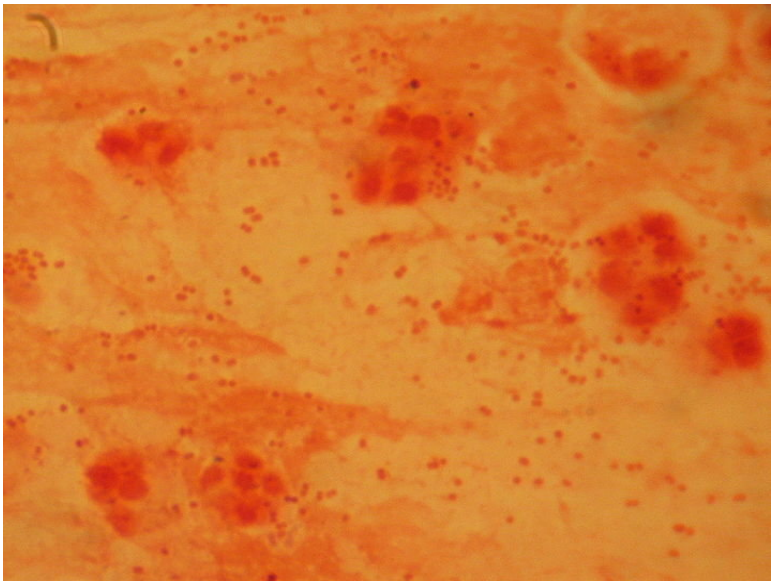
• Airborne precautions are required to protect against conditions like measles, severe acute respiratory syndrome (SARS), varicella (chickenpox), and Mycobacterium tuberculosis.

Solution to Question 15:

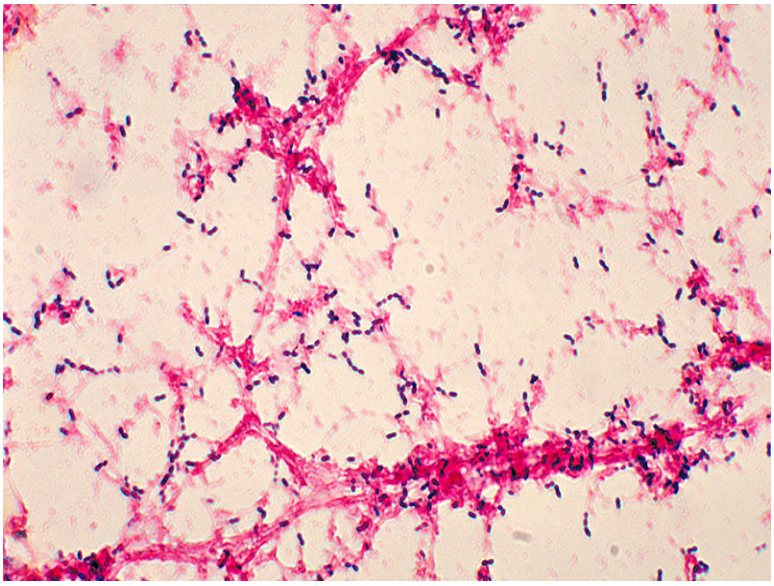
History and physical examination findings are suggestive of meningitis.

The given image shows intracellular gram negative diplococci i.e. Neisseria meningitidis.

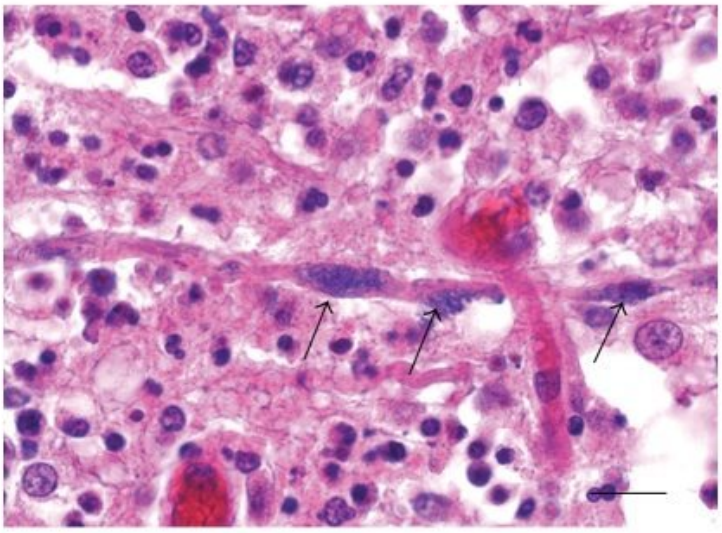
Option a:Haemophilus influenzae type B is a gram negative bacillus. In CSF, long bacillary filamentous forms predominate.



Option c: Streptococcus pneumoniae is a gram positive, capsulated, flame shaped or lanceolate shaped diplococci.



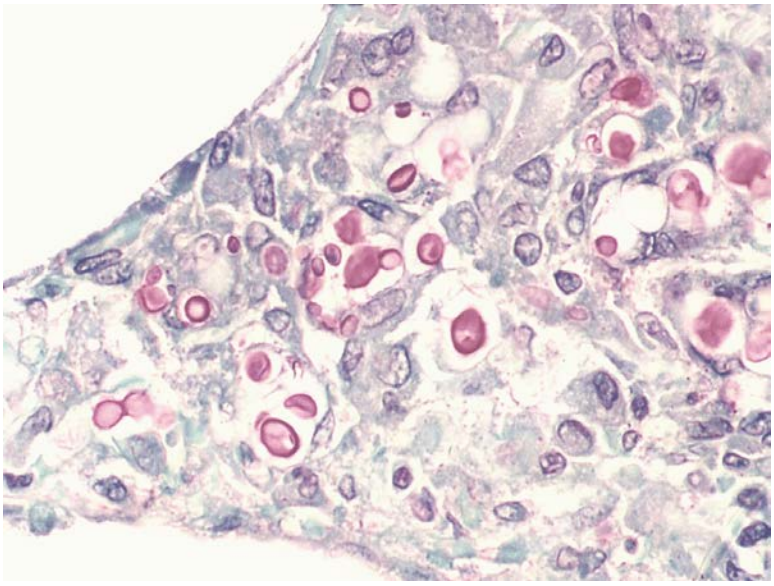
Option d: Listeria monocytogenes is a gram positive bacillus.



Solution to Question 16:

Mucicarmine stain is used in the identification of cryptococcus.

Mucicarmine stain helps in the detection of the cryptococcal capsule, as it stains mucins of epithelial origin (PAS, alcian blue). Given below is an image of Mucicarmine stained specimen of lung tissue containing cryptococci:



Solution to Question 17:

Japanese encephalitis follows bird-arthropod-human transmission.

JE virus infects several extra-human hosts, e.g., pigs and birds (like pond herons). The basic cycles of transmission are:

(a)Pig → Mosquito → Pig

(b) Bird → Mosquito → Bird

Humans are incidental "dead-end" hosts and are infected by the bite of infected Culex mosquitoes.

Solution to Question 18:

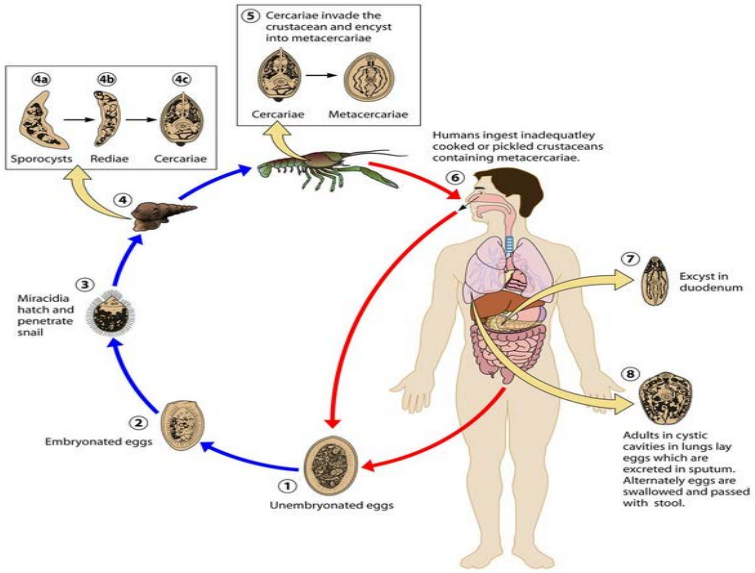
The given clinical scenario is suggestive of infection with Paragonimus westermani.

Paragonimus westermani is a trematode. The transmission to humans occurs by eating raw or undercooked crab or crayfish containing metacercariae. The metacercariae excyst in the human gut and young worms migrate to the lungs, where they become encapsulated in lung tissue.

The patient complains of cough, chest pain, and hemoptysis. The viscous sputum is speckled with golden-brown eggs.

Praziquantel (25 mg/ kg TDS for 1-2 days) is the drug of choice.

The image below shows the life cycle of Paragonimus westermani.



Solution to Question 19:

Rubella belongs to the Togaviridae family.

Rubella (German measles)

• Causative organism belongs to family Togaviridae

• Period of infectivity is -5 to +6 days after the onset of the rash

• Incubation period: 2-3 weeks

• Rash appears on day 1

• Forchheimer spots are seen, which are tiny, rose-colored lesions in the oropharynx

• Associated with post infectious thrombocytopenia

• Most serious complication: Encephalitis

• Vaccination: 27/3 live attenuated

Congenital rubella syndrome:

• When a woman in the 1st trimester gets infected with rubella, the resulting complications may include miscarriage, fetal death, premature delivery, or live birth with congenital defects.

• The commonest malformations caused by rubella are cardiac defects, cataract, and deafness, which constitute the classical congenital rubella syndrome.

• Thrombocytopenic purpura present in the babies gave rise to the term “blueberry muffin syndrome.”

Expanded rubella syndrome:

• Some babies present with several other features like hepatosplenomegaly, thrombocytopenic purpura, myocarditis, and bone lesions constituting the expanded rubella syndrome.

• This term also refers to a baby with metastatic neuroblastoma.

Note: Rubella has been reclassified into the family of Matonaviridae in 2020. This is an MCQ from NEET 2019, hence the best answer out of the given options would be Togaviridae.

Solution to Question 20:

The clinical background is probably suggestive Scabies. The given image depicts Itch mite also called Sarcoptes scabiei. The female parasite burrows into the stratum corneum layer of the epidermis and lays eggs in the burrow.

A single female may lay about 30 eggs at a rate of 2 to 3 per day, and ultimately dies at the end of the burrow.

The life cycle has 4 stages: Egg, Larva, Nymph, and Adult. The adult mites live for 1 to 2 months.

Itching is a hypersensitivity reaction to the eggs and dead parasite in the epidermis.

Permethrin cream - 5% is the treatment of choice.

Solution to Question 21:

Diarrhea in an HIV patient is suggestive of a coccidean parasitic infestation. Kinyoun stain - positive oocysts as seen in the given image is suggestive of Cryptosporidium.

Points in favor:

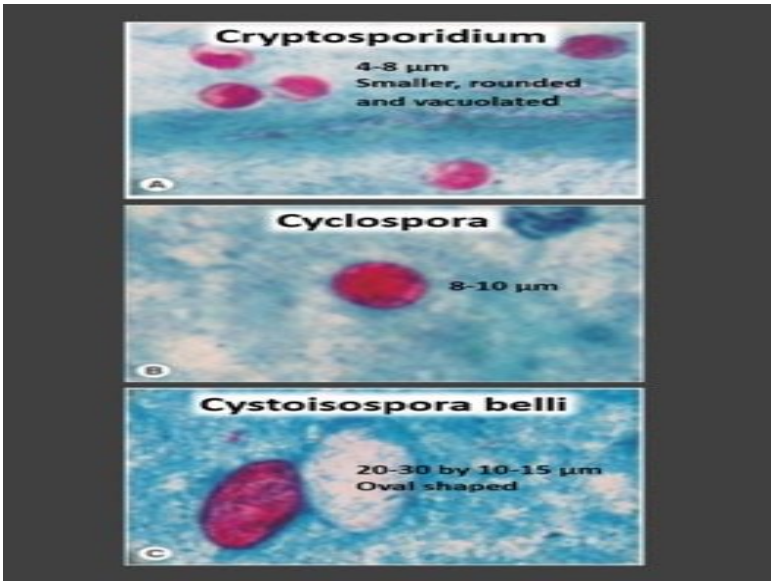
• HIV patient with diarrhea

• Oocysts are round, contains four sporozites which is uniformly acid fast on staining.

Comparison of coccidian parasites causing diarrhea in an immunocompromised host:

Treatment is fluid replacement and cotrimoxazole.

Property	Cryptosporidium	Cyclospora	Isospora
Sporulated oocyst	4-6 µm, round contains fo ur sporozoites	8-12 µm, round contains 2 sporocyst each having tw o sporozoites	23-36 µm, oval contain tw o sporocyst, each having f our sporozoites.
Acid-fast detection	Uniformly acid fast	Variable acid fast	Uniformly acid fast
Sporulation of the ooc yst	Occurs inside host cell	Occurs in soil	Occurs in soil
Diagnostic form	Sporulated cyst	Unsporulated cyst	Unsporulated oocyst



- ***Cryptosporidium parvum***

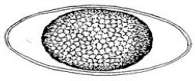
Oocyst with 4 sporozoites
Size: 4 -5 um
Staining : Ziehl-Neelsen or Auramin

- ***Cyclospora cayetanensis***

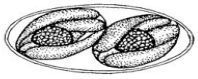
Young oocyst

Mature oocyst with 2 sporocysts containing
2 sporozoites each
Size: 8 - 10 um
Staining : Ziehl-Neelsen or Auramin

- ***Isospora belli***



Young oocyst



Mature oocyst with 2 sporocysts containing
4 sporozoites each
Size: up to 20 x 30 um

Solution to Question 22:

The given clinical scenario and MRI brain showing scolex within multiple cystic lesions are suggestive of neurocysticercosis caused by the larval form of T. solium called Cysticercosis cellulosae.

Neurocysticercosis is the most common central nervous system parasitic infection.

The clinical features of neurocysticercosis include epilepsy, features of raised intracranial tension, and evident hydrocephalus. Patients can also have psychiatric disturbances, transient paresis, and visual disturbances.

The CT and MRI findings seen in neurocysticercosis are:

• Scolex within a cyst

• Cystic lesions with or without ring enhancement

• Nodular calcifications

• Focal enhancing lesions

• Multilobulated cystic lesions in the subarachnoid space.

Note: About 70% of adult-onset epilepsy is due to neurocysticercosis.

Albendazole is the drug of choice for neurocysticercosis. Glucocorticoid therapy is usually begun before initiating albendazole (an antiparasitic drug). This is continued for several days after the institution of therapy to reduce the incidence of side effects from inflammatory reactions to dead and dying cysticerci of Taenia solium.

Solution to Question 23:

Influenza vaccine requires periodic strain change due to antigenic change in the surface glycoprotein of the virus.

The change may be gradual (antigenic drift) or drastic (antigenic shift).

Microbiology NEET 2020

Question 1:

A 35-year-old HIV positive■ patient presents with mucosal lesions in the mouth as shown in the image below. On microscopy, budding yeasts and pseudohyphae are seen. What is the likely diagnosis?

a) Oral candidiasis

b) Hairy leukoplakia

c) Lichen planus

d) Diphtheria

Question 2:

Zika virus is transmitted by:

a) Aedes aegypti

b) Culex

c) Anopheles

d) Phlebotomus papatasii

Question 3:

Which of the following organisms causes disease following traumatic inoculation into the skin?

a) Sporothrix schenckii

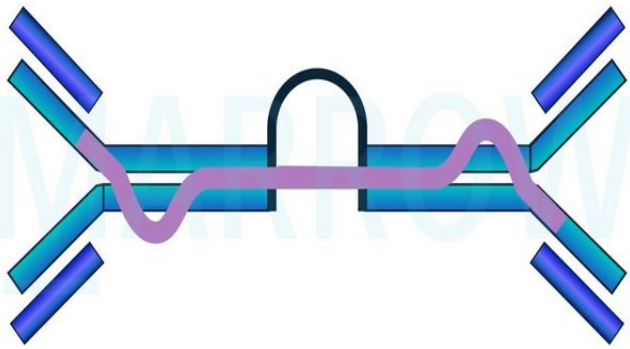
b) Blastomyces dermatitidis

c) Coccidioides immitis

d) Paracoccidioides brasiliensis

Question 4:

Identify the class of immunoglobulin■ shown in the image below.



a) Ig A

b) Ig G

c) Ig M

d) Ig E

Question 5:

A 14-year-old boy presents with a history of vomiting within 3 hours of consumption of food at a party. Which of the following organism is most likely to cause these symptoms?

a) Staphylococcus aureus

b) Clostridium botulinum

c) Clostridium perfringes

d) Salmonella typhi

Question 6:

Which of the following organisms produces superantigen?

a) Staphylococcus epidermidis

b) Streptococcus pyogenes

c) Clostridium perfringens

d) Vibrio cholera

Question 7:

A female patient who is from the north-eastern part of the country came to the hospital with complaints of progressive swelling of the upper limbs. She has a history of coronary artery disease for which she underwent percutaneous coronary intervention. On examination, the upper limbs are more swollen proximally than distally. What is the next best step in the management of this patient?

a) Echocardiography

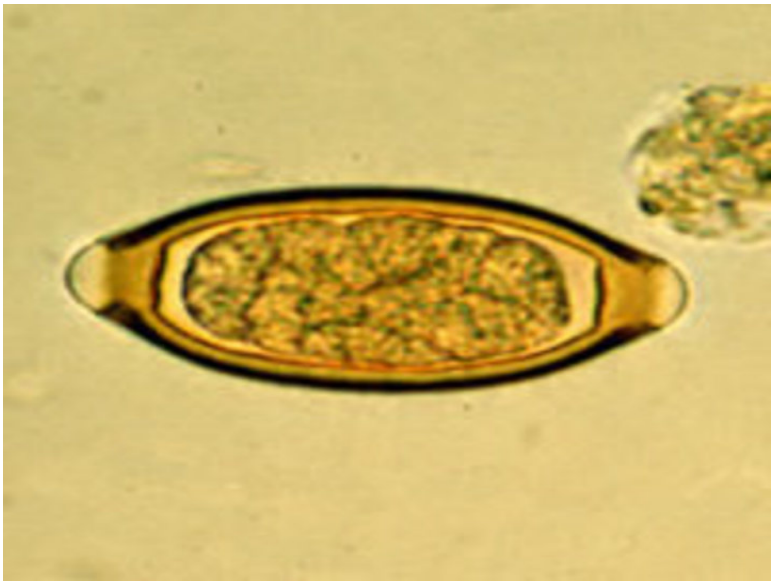
b) Night blood test for worms

c) Duplex venous scan of limbs

d) ECG

Question 8:

Which of the following helminthic infections, that is commonly transmitted by soil, is characterized by■ the egg in stool as shown in the image below?



a) Trichuris trichiura

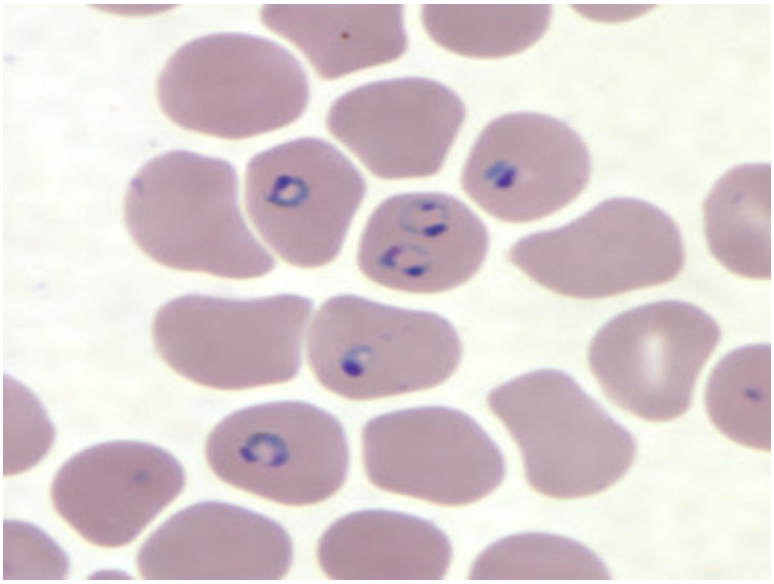
b) Ancyclostoma duodenale

c) Necator americanus

d) Ascaris lumbricoides

Question 9:

A 30-year-old female from tribal area presented with fever for the last 3 days. On examination of the peripheral smear, a diagnosis of malaria was made. Which of the following is most likely to be the causative agent?



a) P. falciparum

b) P. malariae

c) P. ovale

d) P. vivax

Question 10:

The test kit shown in the image below works on the principle of:

©MARROW

a) ELISA

b) Immunochromatography

c) Immunofluroscence

d) Chemiluminiscence

Question 11:

A 22-year-old student presented with high-grade fever, and purpuric rash as shown in the image below. CSF sample showed gram-negative diplococci. Which of the following is the most likely aetiology?

a) Neisseria meningitidis

b) Pseudomonas aeruginosa

c) Streptococcus pneumoniae

d) E.coli

Question 12:

Which of the following is the predominant pathogen to infect renal transplant recipients one to four months following transplantation?

a) Cytomegalovirus

b) JC virus

c) BK virus

d) Epstein-Barr virus

Question 13:

Which of the following is not true about Japanese encephalitis?

a) Transmitted by Culex vishnui

b) Pig is the amplifier host

c) Man acts as the reservoir

d) Vaccinating pigs is helpful in disease control

Question 14:

Which of the following helps in bacterial adhesion?

a) Cytoplasmic membrane

b) Mesosomes

c) Fimbriae

d) Lipopolysaccharides

Question 15:

Which of the following is not involved in urethritis?

a) Trichomonas

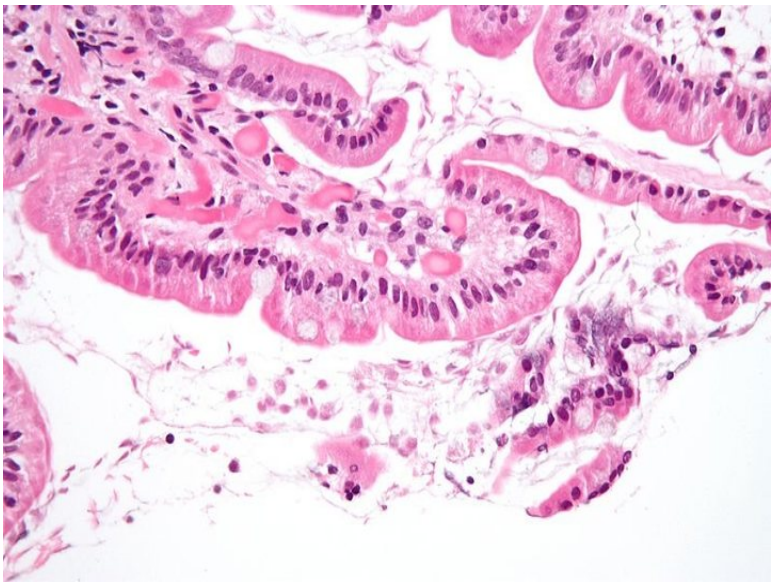
b) Chlamydia

c) Gonococcus

d) H.ducreyi

Question 16:

A 30-year-old HIV-positive patient presented with a chronic history of watery diarrhea. Histopathology of the ■duodenum is shown in the image below. Which of the following is the causative organism?



a) Giardia lamblia

b) Entamoeba histolytica

c) Microsporidia

d) Cryptosopridia

Question 17:

What is the drug of choice for invasive pulmonary aspergillosis?

a) Itraconazole

b) Voriconazole

c) Lyophylised Amphotericin B

d) Posaconazole

Question 18:

Which of the following culture media is used to differentiate other E.coli species from E.coli O157: H7?

a) Mannitol salt agar

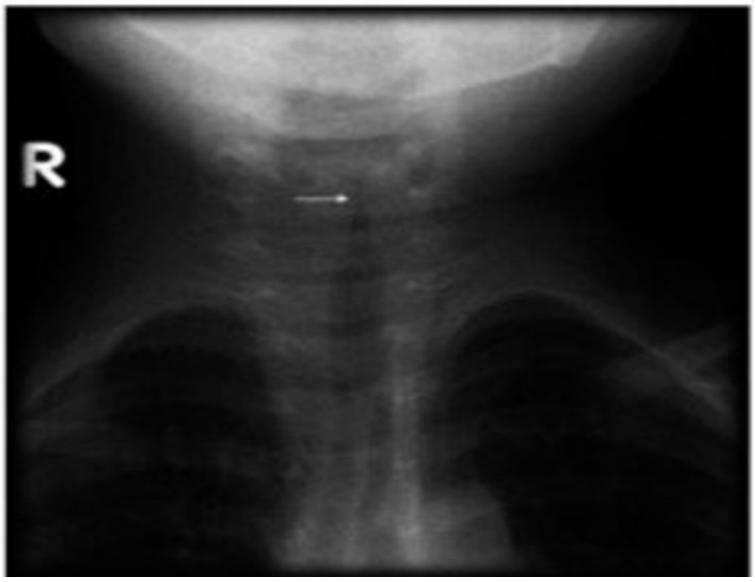
b) Xylose lysine deoxycholate agar

c) Sorbitol MacConkey agar

d) CLED medium

Question 19:

A 5 year old boy was suffering from low grade fever, inspiratory stridor and barking cough for past 5 days. His chest X-ray is given below. What is the cause of this condition?



a) Moraxella

b) Parainfluenza

c) Hemophilus influenza

d) Staphylococcus aureus

Question 20:

Which of the following is a bioterrorism category A agent?

a) Nipah virus

b) Anthrax

c) Coxiella

d) Brucella

Detailed Explanations

Solution to Question 1:

An HIV patient with white patches over the tonsils and posterior pharynx showing budding yeasts and pseudohyphae on microscopy suggests a diagnosis of oral candidiasis.

Oral candidiasis or thrush is a patchy, pseudomembranous lesion that develops over the tongue, lips, gum or palate. It is composed of epithelial cells, yeasts, and pseudohyphae and can be scraped off. The causative agent is usually Candida albicans. It occurs in almost all individuals with AIDS. Other risk factors include hyperglycemia, cellular immunodeficiency, corticosteroids or antibiotics. It is treated with topical nystatin, oral ketoconazole or fluconazole.

Option B: Hairy leukoplakia is a wart-like growth on the tongue, caused by Epstein-Barr virus. It is commonly seen as a white lesion on the lateral side of the tongue.

Option C: Lichen planus is a pruritic disease characterized by papules commonly seen over the flexor surfaces and trunk. Oral and vulvovaginal lesions may also occur. Oral lesions appear as lacy, white, and raised lesions.

Option D: Diphtheria is characterized by the presence of a grey pseudomembrane covering the tonsils and pharynx. It is caused by Corynebacterium diphtheriae.

Solution to Question 2:

Zika virus is transmitted by the bite of infected Aedes aegypti and Aedes albopictus.

Zika virus is an RNA virus belonging to the Flaviviridae group. The symptoms of Zika virus disease include fever, maculopapular rash, conjunctivitis, muscle and joint pain, malaise and headache. These symptoms are mild and usually last for 2-7 days. It can be misdiagnosed as dengue or influenza. In severe cases, it can lead to complications like Guillain-Barré syndrome, neuropathy, and myelitis.

Zika virus infection during pregnancy may lead to microcephaly or congenital Zika syndrome.

Solution to Question 3:

Sporothrix schenckii causes infection followed by traumatic inoculation into the skin.

It is a dimorphic fungus that lives on vegetation such as grasses, trees, rose bushes, etc. Following traumatic inoculation into the skin as in thorn prick, S schenckii causes sporotrichosis, a chronic granulomatous infection. This is usually further followed by spread along the draining lymphatics and lymph nodes as shown in the image below.
